To Ruth and Daniel, with all my love and gratitude.
MSS

To Ralph, Eric, Samantha, and Lindsay:
you bring me much joy.
PGA

BRIEF CONTENTS

Preface xx
Acknowledgments xxxi

1 *Keys to the Study of Chemistry* 2
2 *The Components of Matter* 40
3 *Stoichiometry of Formulas and Equations* 90
4 *Three Major Classes of Chemical Reactions* 138
5 *Gases and the Kinetic-Molecular Theory* 198
6 *Thermochemistry: Energy Flow and Chemical Change* 250
7 *Quantum Theory and Atomic Structure* 286
8 *Electron Configuration and Chemical Periodicity* 322
9 *Models of Chemical Bonding* 358
10 *The Shapes of Molecules* 394
11 *Theories of Covalent Bonding* 428
12 *Intermolecular Forces: Liquids, Solids, and Phase Changes* 454
13 *The Properties of Mixtures: Solutions and Colloids* 516
14 *Periodic Patterns in the Main-Group Elements* 568
15 *Organic Compounds and the Atomic Properties of Carbon* 616
16 *Kinetics: Rates and Mechanisms of Chemical Reactions* 674
17 *Equilibrium: The Extent of Chemical Reactions* 730
18 *Acid-Base Equilibria* 776
19 *Ionic Equilibria in Aqueous Systems* 826
20 *Thermodynamics: Entropy, Free Energy, and the Direction of Chemical Reactions* 876
21 *Electrochemistry: Chemical Change and Electrical Work* 918
22 *The Elements in Nature and Industry* 976
23 *Transition Elements and Their Coordination Compounds* 1016
24 *Nuclear Reactions and Their Applications* 1052

Appendix A Common Mathematical Operations in Chemistry A-1
Appendix B Standard Thermodynamic Values for Selected Substances A-5
Appendix C Equilibrium Constants for Selected Substances A-8
Appendix D Standard Electrode (Half-Cell) Potentials A-14
Appendix E Answers to Selected Problems A-15
Glossary G-1
Credits C-1
Index I-1

DETAILED CONTENTS

CHAPTER 1 Keys to the Study of Chemistry 2

1.1 Some Fundamental Definitions 4
The States of Matter 4
The Properties of Matter and Its Changes 5
The Central Theme in Chemistry 8
The Importance of Energy in the Study of Matter 8

1.2 Chemical Arts and the Origins of Modern Chemistry 10
Prechemical Traditions 10
The Phlogiston Fiasco and the Impact of Lavoisier 11

1.3 The Scientific Approach: Developing a Model 12

1.4 Measurement and Chemical Problem Solving 13
General Features of SI Units 13
Some Important SI Units in Chemistry 14
Units and Conversion Factors in Calculations 17
A Systematic Approach to Solving Chemistry Problems 19
Temperature Scales 24
Extensive and Intensive Properties 26

1.5 Uncertainty in Measurement: Significant Figures 27
Determining Which Digits Are Significant 28
Significant Figures: Calculations and Rounding Off 29
Precision, Accuracy, and Instrument Calibration 31

CHAPTER REVIEW GUIDE 32

PROBLEMS 35

CHAPTER 2 The Components of Matter 40

2.1 Elements, Compounds, and Mixtures: An Atomic Overview 42

2.2 The Observations That Led to an Atomic View of Matter 44
Mass Conservation 44
Definite Composition 45
Multiple Proportions 46

2.3 Dalton's Atomic Theory 47
Postulates of the Atomic Theory 47
How the Theory Explains the Mass Laws 48

2.4 The Observations That Led to the Nuclear Atom Model 49
Discovery of the Electron and Its Properties 49
Discovery of the Atomic Nucleus 51

2.5 The Atomic Theory Today 52
Structure of the Atom 53
Atomic Number, Mass Number, and Atomic Symbol 53
Isotopes 54
Atomic Masses of the Elements 55

TOOLS OF THE LABORATORY:
MASS SPECTROMETRY 57

2.6 Elements: A First Look at the Periodic Table 58

2.7 Compounds: Introduction to Bonding 61
The Formation of Ionic Compounds 61
The Formation of Covalent Substances 63

2.8 Compounds: Formulas, Names, and Masses 65
Binary Ionic Compounds 65
Compounds That Contain Polyatomic Ions 68
Acid Names from Anion Names 70
Binary Covalent Compounds 71
The Simplest Organic Compounds: Straight-Chain Alkanes 72
Molecular Masses from Chemical Formulas 72
Representing Molecules with Formulas and Models 75

2.9 Mixtures: Classification and Separation 77
An Overview of the Components of Matter 77

TOOLS OF THE LABORATORY:
BASIC SEPARATION TECHNIQUES 79

CHAPTER REVIEW GUIDE 80

PROBLEMS 82

CHAPTER 3 Stoichiometry of Formulas and Equations 90

3.1 The Mole 91
Defining the Mole 92
Determining Molar Mass 92
Converting Between Amount, Mass, and Number of Chemical Entities 93
The Importance of Mass Percent 98

3.2 Determining the Formula of an Unknown Compound 100
Empirical Formulas 101
Molecular Formulas 102
Chemical Formulas and Molecular Structures; Isomers 105

3.3 Writing and Balancing Chemical Equations 107

3.4 Calculating Quantities of Reactant and Product 112
Stoichiometrically Equivalent Molar Ratios from the Balanced Equation 112
Reactions That Occur in a Sequence 116
Reactions That Involve a Limiting Reactant 117
Theoretical, Actual, and Percent Reaction Yields 123

CHAPTER REVIEW GUIDE 125

PROBLEMS 130

CHAPTER 4 Three Major Classes of Chemical Reactions 138

4.1 Solution Concentration and the Role of Water as a Solvent 139
The Polar Nature of Water 140
Ionic Compounds in Water 140
Covalent Compounds in Water 143
Expressing Concentration in Terms of Molarity 144
Amount-Mass-Number Conversions Involving Solutions 144
Preparing and Diluting Molar Solutions 146

4.2 Writing Equations for Aqueous Ionic Reactions 149

4.3 Precipitation Reactions 151
The Key Event: Formation of a Solid from Dissolved Ions 151
Predicting Whether a Precipitate Will Form 151
Stoichiometry of Precipitation Reactions 155

4.4 Acid-Base Reactions 158
The Key Event: Formation of H_2O from H^+ and OH^- 161
Proton Transfer in Acid-Base Reactions 162
Stoichiometry of Acid-Base Reactions: Acid-Base Titrations 165

4.5 Oxidation-Reduction (Redox) Reactions 168
The Key Event: Movement of Electrons Between Reactants 168
Some Essential Redox Terminology 169
Using Oxidation Numbers to Monitor Electron Charge 170
Stoichiometry of Redox Reactions: Redox Titrations 172

4.6 Elements in Redox Reactions 174
Combination Redox Reactions 174
Decomposition Redox Reactions 176
Displacement Redox Reactions and Activity Series 177
Combustion Reactions 180

4.7 The Reversibility of Reactions and the Equilibrium State 181

CHAPTER REVIEW GUIDE 184

PROBLEMS 189

CHAPTER 5 Gases and the Kinetic-Molecular Theory 198

5.1 An Overview of the Physical States of Matter 199

5.2 Gas Pressure and Its Measurement 201
Measuring Gas Pressure: Barometers and Manometers 202
Units of Pressure 202

5.3 The Gas Laws and Their Experimental Foundations 204
The Relationship Between Volume and Pressure: Boyle's Law 205
The Relationship Between Volume and Temperature: Charles's Law 206
The Relationship Between Volume and Amount: Avogadro's Law 208
Gas Behavior at Standard Conditions 209
The Ideal Gas Law 209
Solving Gas Law Problems 210

5.4 Rearrangements of the Ideal Gas Law 216
The Density of a Gas 216
The Molar Mass of a Gas 218
The Partial Pressure of Each Gas in a Mixture of Gases 219
The Ideal Gas Law and Reaction Stoichiometry 222

5.5 The Kinetic-Molecular Theory: A Model for Gas Behavior 224
How the Kinetic-Molecular Theory Explains the Gas Laws 224
Effusion and Diffusion 229
The Chaotic World of Gases: Mean Free Path and Collision Frequency 232

CHEMICAL CONNECTIONS TO ATMOSPHERIC SCIENCE:
HOW THE GAS LAWS APPLY TO EARTH'S ATMOSPHERE 233

5.6 Real Gases: Deviations from Ideal Behavior 235
Effects of Extreme Conditions on Gas Behavior 235
The van der Waals Equation: Adjusting the Ideal Gas Law 237

CHAPTER REVIEW GUIDE 238

PROBLEMS 241

CHAPTER 6 Thermochemistry: Energy Flow and Chemical Change 250

6.1 Forms of Energy and Their Interconversion 251
Defining the System and Its Surroundings 252
Energy Change (ΔE): Energy Transfer to or from a System 252
Heat and Work: Two Forms of Energy Transfer 252
The Law of Energy Conservation 255
Units of Energy 255
State Functions and the Path Independence of the Energy Change 256

6.2 Enthalpy: Changes at Constant Pressure 257
The Meaning of Enthalpy 258
Comparing ΔE and ΔH 259
Exothermic and Endothermic Processes 259

6.3 Calorimetry: Measuring the Heat of a Chemical or Physical Change 261
Specific Heat Capacity 261
The Two Major Types of Calorimetry 262

6.4 Stoichiometry of Thermochemical Equations 266

6.5 Hess's Law: Finding ΔH of Any Reaction 267

6.6 Standard Enthalpies of Reaction (ΔH°_{rxn}) 270
Formation Equations and Their Standard Enthalpy Changes 270
Determining ΔH°_{rxn} from ΔH°_f Values for Reactants and Products 271

CHEMICAL CONNECTIONS TO ENVIRONMENTAL SCIENCE:
THE FUTURE OF ENERGY USE 273

CHAPTER REVIEW GUIDE 277

PROBLEMS 280

CHAPTER 7 Quantum Theory and Atomic Structure 286

7.1 The Nature of Light 287
The Wave Nature of Light 288
The Particle Nature of Light 291

7.2 Atomic Spectra 294
Line Spectra and the Rydberg Equation 294
The Bohr Model of the Hydrogen Atom 295
The Energy Levels of the Hydrogen Atom 297

TOOLS OF THE LABORATORY:
SPECTROMETRY IN CHEMICAL ANALYSIS 300

7.3 The Wave-Particle Duality of Matter and Energy 302
The Wave Nature of Electrons and the Particle Nature of Photons 302
Heisenberg's Uncertainty Principle 305

7.4 The Quantum-Mechanical Model of the Atom 306
The Atomic Orbital and the Probable Location of the Electron 306
Quantum Numbers of an Atomic Orbital 308
Quantum Numbers and Energy Levels 309
Shapes of Atomic Orbitals 311
The Special Case of Energy Levels in the Hydrogen Atom 313

CHAPTER REVIEW GUIDE 314

PROBLEMS 316

CHAPTER 8 Electron Configuration and Chemical Periodicity 322

8.1 Characteristics of Many-Electron Atoms 324
The Electron-Spin Quantum Number 324
The Exclusion Principle 325
Electrostatic Effects and Energy-Level Splitting 325

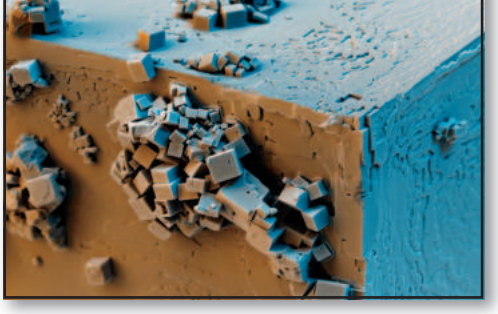
8.2 The Quantum-Mechanical Model and the Periodic Table 327
Building Up Period 1 327
Building Up Period 2 328
Building Up Period 3 330
Similar Electron Configurations Within Groups 331
Building Up Period 4: The First Transition Series 332
General Principles of Electron Configurations 333
Intervening Series: Transition and Inner Transition Elements 334

8.3 Trends in Three Atomic Properties 336
Trends in Atomic Size 336
Trends in Ionization Energy 339
Trends in Electron Affinity 343

8.4 Atomic Properties and Chemical Reactivity 344
Trends in Metallic Behavior 344
Properties of Monatomic Ions 346

CHAPTER REVIEW GUIDE 352

PROBLEMS 354



CHAPTER 9 Models of Chemical Bonding 358

9.1 Atomic Properties and Chemical Bonds 359
The Three Ways Elements Combine 359
Lewis Symbols and the Octet Rule 361

9.2 The Ionic Bonding Model 362
Why Ionic Compounds Form: The Importance of Lattice Energy 363
Periodic Trends in Lattice Energy 365
How the Model Explains the Properties of Ionic Compounds 367

9.3 The Covalent Bonding Model 369
The Formation of a Covalent Bond 369
Bonding Pairs and Lone Pairs 370
Properties of a Covalent Bond: Order, Energy, and Length 370
How the Model Explains the Properties of Covalent Substances 373

TOOLS OF THE LABORATORY: **INFRARED SPECTROSCOPY 374**

9.4 Bond Energy and Chemical Change 376
Changes in Bond Energy: Where Does ΔH°_{rxn} Come From? 376
Using Bond Energies to Calculate ΔH°_{rxn} 376
Bond Strengths and the Heat Released from Fuels and Foods 379

9.5 Between the Extremes: Electronegativity and Bond Polarity 380
Electronegativity 380
Bond Polarity and Partial Ionic Character 382
The Gradation in Bonding Across a Period 384

9.6 An Introduction to Metallic Bonding 385
The Electron-Sea Model 385
How the Model Explains the Properties of Metals 386

CHAPTER REVIEW GUIDE 387

PROBLEMS 389

CHAPTER 10 The Shapes of Molecules 394

10.1 Depicting Molecules and Ions with Lewis Structures 395
Applying the Octet Rule to Write Lewis Structures 395
Resonance: Delocalized Electron-Pair Bonding 399
Formal Charge: Selecting the More Important Resonance Structure 401
Lewis Structures for Exceptions to the Octet Rule 402

10.2 Valence-Shell Electron-Pair Repulsion (VSEPR) Theory 406
Electron-Group Arrangements and Molecular Shapes 407
The Molecular Shape with Two Electron Groups (Linear Arrangement) 407
Molecular Shapes with Three Electron Groups (Trigonal Planar Arrangement) 408
Molecular Shapes with Four Electron Groups (Tetrahedral Arrangement) 409
Molecular Shapes with Five Electron Groups (Trigonal Bipyramidal Arrangement) 410
Molecular Shapes with Six Electron Groups (Octahedral Arrangement) 411
Using VSEPR Theory to Determine Molecular Shape 412
Molecular Shapes with More Than One Central Atom 415

10.3 Molecular Shape and Molecular Polarity 416
Bond Polarity, Bond Angle, and Dipole Moment 417
The Effect of Molecular Polarity on Behavior 419

CHEMICAL CONNECTIONS TO SENSORY PHYSIOLOGY: **MOLECULAR SHAPE, BIOLOGICAL RECEPTORS, AND THE SENSE OF SMELL 420**

CHAPTER REVIEW GUIDE 421

PROBLEMS 424

CHAPTER 11 Theories of Covalent Bonding 428

11.1 Valence Bond (VB) Theory and Orbital Hybridization 429
The Central Themes of VB Theory 429
Types of Hybrid Orbitals 430

11.2 Modes of Orbital Overlap and the Types of Covalent Bonds 436
Orbital Overlap in Single and Multiple Bonds 436
Orbital Overlap and Rotation Within a Molecule 439

11.3 Molecular Orbital (MO) Theory and Electron Delocalization 440
The Central Themes of MO Theory 440
Homonuclear Diatomic Molecules of Period 2 Elements 442
Two Heteronuclear Diatomic Molecules: HF and NO 446
Two Polyatomic Molecules: Benzene and Ozone 447

CHAPTER REVIEW GUIDE 448

PROBLEMS 450

CHAPTER 12 Intermolecular Forces: Liquids, Solids, and Phase Changes 454

12.1 An Overview of Physical States and Phase Changes 455

12.2 Quantitative Aspects of Phase Changes 458
Heat Involved in Phase Changes 459
The Equilibrium Nature of Phase Changes 462
Phase Diagrams: Effect of Pressure and Temperature on Physical State 466

12.3 Types of Intermolecular Forces 468
How Close Can Molecules Approach Each Other? 468
Ion-Dipole Forces 469
Dipole-Dipole Forces 469
The Hydrogen Bond 470
Polarizability and Induced Dipole Forces 471
Dispersion (London) Forces 472

12.4 Properties of the Liquid State 474
Surface Tension 475
Capillarity 475
Viscosity 476

12.5 The Uniqueness of Water 477
Solvent Properties of Water 477
Thermal Properties of Water 477
Surface Properties of Water 478
The Unusual Density of Solid Water 478

12.6 The Solid State: Structure, Properties, and Bonding 479
Structural Features of Solids 479

***TOOLS OF THE LABORATORY:* X-RAY DIFFRACTION ANALYSIS AND SCANNING TUNNELING MICROSCOPY 486**
Types and Properties of Crystalline Solids 487
Amorphous Solids 490
Bonding in Solids: Molecular Orbital Band Theory 490

12.7 Advanced Materials 493
Electronic Materials 493
Liquid Crystals 495
Ceramic Materials 498
Polymeric Materials 500
Nanotechnology: Designing Materials Atom by Atom 505

CHAPTER REVIEW GUIDE 507

PROBLEMS 509

CHAPTER 13 The Properties of Mixtures: Solutions and Colloids 516

13.1 Types of Solutions: Intermolecular Forces and Solubility 518
Intermolecular Forces in Solution 518
Liquid Solutions and the Role of Molecular Polarity 519
Gas Solutions and Solid Solutions 521

13.2 Intermolecular Forces and Biological Macromolecules 523
The Structures of Proteins 523
Dual Polarity in Soaps, Membranes, and Antibiotics 525
The Structure of DNA 527

13.3 Why Substances Dissolve: Breaking Down the Solution Process 528
The Heat of Solution and Its Components 528
The Heat of Hydration: Dissolving Ionic Solids in Water 529
The Solution Process and the Change in Entropy 531

13.4 Solubility as an Equilibrium Process 533
Effect of Temperature on Solubility 534
Effect of Pressure on Solubility 535

13.5 Concentration Terms 536
Molarity and Molality 537
Parts of Solute by Parts of Solution 538
Interconverting Concentration Terms 540

13.6 Colligative Properties of Solutions 541
Nonvolatile Nonelectrolyte Solutions 542
Using Colligative Properties to Find Solute Molar Mass 547
Volatile Nonelectrolyte Solutions 548
Strong Electrolyte Solutions 548
Applications of Colligative Properties 550

13.7 The Structure and Properties of Colloids 552

CHEMICAL CONNECTIONS TO ENVIRONMENTAL ENGINEERING: **SOLUTIONS AND COLLOIDS IN WATER PURIFICATION 554**

CHAPTER REVIEW GUIDE 556

PROBLEMS 559

CHAPTER 14 Periodic Patterns in the Main-Group Elements 568

14.1 Hydrogen, the Simplest Atom 569
Where Hydrogen Fits in the Periodic Table 569
Highlights of Hydrogen Chemistry 570

14.2 Trends Across the Periodic Table: The Period 2 Elements 571

14.3 Group 1A(1): The Alkali Metals 574
Why the Alkali Metals Are Unusual Physically 574
Why the Alkali Metals Are So Reactive 576

14.4 Group 2A(2): The Alkaline Earth Metals 576
How the Alkaline Earth and Alkali Metals Compare Physically 577
How the Alkaline Earth and Alkali Metals Compare Chemically 577
Diagonal Relationships: Lithium and Magnesium 577

14.5 Group 3A(13): The Boron Family 579
How the Transition Elements Influence This Group's Properties 579
Features That First Appear in This Group's Chemical Properties 579
Highlights of Boron Chemistry 581
Diagonal Relationships: Beryllium and Aluminum 582

14.6 Group 4A(14): The Carbon Family 582
How Type of Bonding Affects Physical Properties 582
How Bonding Changes in This Group's Compounds 585
Highlights of Carbon Chemistry 585
Highlights of Silicon Chemistry 587
Diagonal Relationships: Boron and Silicon 588

14.7 Group 5A(15): The Nitrogen Family 588
The Wide Range of Physical Behavior 590
Patterns in Chemical Behavior 590
Highlights of Nitrogen Chemistry 591
Highlights of Phosphorus Chemistry 594

14.8 Group 6A(16): The Oxygen Family 596
How the Oxygen and Nitrogen Families Compare Physically 596
How the Oxygen and Nitrogen Families Compare Chemically 598
Highlights of Oxygen Chemistry: Range of Oxide Properties 599
Highlights of Sulfur Chemistry 599

14.9 Group 7A(17): The Halogens 601
Physical Behavior of the Halogens 601
Why the Halogens Are So Reactive 601
Highlights of Halogen Chemistry 603

14.10 Group 8A(18): The Noble Gases 606
How the Noble Gases and Alkali Metals Contrast Physically 608
How Noble Gases Can Form Compounds 608

CHAPTER REVIEW GUIDE 608

PROBLEMS 609

CHAPTER 15 Organic Compounds and the Atomic Properties of Carbon 616

15.1 The Special Nature of Carbon and the Characteristics of Organic Molecules 617
The Structural Complexity of Organic Molecules 618
The Chemical Diversity of Organic Molecules 618

15.2 The Structures and Classes of Hydrocarbons 620
Carbon Skeletons and Hydrogen Skins 620
Alkanes: Hydrocarbons with Only Single Bonds 622
Dispersion Forces and the Physical Properties of Alkanes 625
Constitutional Isomerism 625
Chiral Molecules and Optical Isomerism 626
Alkenes: Hydrocarbons with Double Bonds 628
Restricted Rotation and Geometric (*Cis-Trans*) Isomerism 628
Alkynes: Hydrocarbons with Triple Bonds 630
Aromatic Hydrocarbons: Cyclic Molecules with Delocalized π Electrons 631
Variations on a Theme: Catenated Inorganic Hydrides 632

TOOLS OF THE LABORATORY: **NUCLEAR MAGNETIC RESONANCE (NMR) SPECTROSCOPY 633**

15.3 Some Important Classes of Organic Reactions 635
Types of Organic Reactions 635
The Redox Process in Organic Reactions 637

15.4 Properties and Reactivities of Common Functional Groups 638
Functional Groups with Only Single Bonds 638
Functional Groups with Double Bonds 643
Functional Groups with Both Single and Double Bonds 646
Functional Groups with Triple Bonds 650

15.5 The Monomer-Polymer Theme I: Synthetic Macromolecules 652
Addition Polymers 652
Condensation Polymers 653

15.6 The Monomer-Polymer Theme II: Biological Macromolecules 654
Sugars and Polysaccharides 654
Amino Acids and Proteins 656
Nucleotides and Nucleic Acids 658

CHEMICAL CONNECTIONS TO GENETICS AND FORENSICS: **DNA SEQUENCING AND FINGERPRINTING 663**

CHAPTER REVIEW GUIDE 665

PROBLEMS 667

CHAPTER 16 Kinetics: Rates and Mechanisms of Chemical Reactions 674

16.1 Focusing on Reaction Rate 675

16.2 Expressing the Reaction Rate 678
Average, Instantaneous, and Initial Reaction Rates 678
Expressing Rate in Terms of Reactant and Product Concentrations 680

16.3 The Rate Law and Its Components 682
Some Laboratory Methods for Determining the Initial Rate 683
Determining Reaction Orders 683
Determining the Rate Constant 688

16.4 Integrated Rate Laws: Concentration Changes over Time 691
Integrated Rate Laws for First-, Second-, and Zero-Order Reactions 692
Determining Reaction Orders from an Integrated Rate Law 693
Reaction Half-Life 695

16.5 Theories of Chemical Kinetics 699
Collision Theory: Basis of the Rate Law 699
Transition State Theory: What the Activation Energy Is Used For 703

16.6 Reaction Mechanisms: The Steps from Reactant to Product 706
Elementary Reactions and Molecularity 706
The Rate-Determining Step of a Reaction Mechanism 708
Correlating the Mechanism with the Rate Law 708

16.7 Catalysis: Speeding Up a Reaction 712
The Basis of Catalytic Action 712
Homogeneous Catalysis 713
Heterogeneous Catalysis 714
Kinetics and Function of Biological Catalysts 714

CHEMICAL CONNECTIONS TO ATMOSPHERIC SCIENCE: **DEPLETION OF EARTH'S OZONE LAYER 716**

CHAPTER REVIEW GUIDE 718

PROBLEMS 721

CHAPTER 17 Equilibrium: The Extent of Chemical Reactions 730

17.1 The Equilibrium State and the Equilibrium Constant 731

17.2 The Reaction Quotient and the Equilibrium Constant 734
The Changing Value of the Reaction Quotient 734
Writing the Reaction Quotient in Its Various Forms 735

17.3 Expressing Equilibria with Pressure Terms: Relation Between K_c and K_p 740

17.4 Comparing *Q* and *K* to Determine Reaction Direction 742

17.5 How to Solve Equilibrium Problems 744
Using Quantities to Find the Equilibrium Constant 745
Using the Equilibrium Constant to Find Quantities 747
Problems Involving Mixtures of Reactants and Products 752

17.6 Reaction Conditions and Equilibrium: Le Châtelier's Principle 754
The Effect of a Change in Concentration 754
The Effect of a Change in Pressure (Volume) 757
The Effect of a Change in Temperature 759
The Lack of Effect of a Catalyst 761
Applying Le Châtelier's Principle to the Synthesis of Ammonia 763

***CHEMICAL CONNECTIONS TO CELLULAR METABOLISM:* DESIGN AND CONTROL OF A METABOLIC PATHWAY 765**

CHAPTER REVIEW GUIDE 766

PROBLEMS 768

CHAPTER 18 Acid-Base Equilibria 776

18.1 Acids and Bases in Water 778
Release of H^+ or OH^- and the Arrhenius Acid-Base Definition 778
Variation in Acid Strength: The Acid-Dissociation Constant (K_a) 779
Classifying the Relative Strengths of Acids and Bases 781

18.2 Autoionization of Water and the pH Scale 782
The Equilibrium Nature of Autoionization: The Ion-Product Constant for Water (K_w) 783
Expressing the Hydronium Ion Concentration: The pH Scale 784

18.3 Proton Transfer and the Brønsted-Lowry Acid-Base Definition 787
Conjugate Acid-Base Pairs 788
Relative Acid-Base Strength and the Net Direction of Reaction 789

18.4 Solving Problems Involving Weak-Acid Equilibria 792
Finding K_a Given Concentrations 793
Finding Concentrations Given K_a 794
The Effect of Concentration on the Extent of Acid Dissociation 795
The Behavior of Polyprotic Acids 797

18.5 Molecular Properties and Acid Strength 799
Acid Strength of Nonmetal Hydrides 799
Acid Strength of Oxoacids 800
Acidity of Hydrated Metal Ions 801

18.6 Weak Bases and Their Relation to Weak Acids 802
Molecules as Weak Bases: Ammonia and the Amines 802
Anions of Weak Acids as Weak Bases 804
The Relation Between K_a and K_b of a Conjugate Acid-Base Pair 805

18.7 Acid-Base Properties of Salt Solutions 807
Salts That Yield Neutral Solutions 807
Salts That Yield Acidic Solutions 807
Salts That Yield Basic Solutions 807
Salts of Weakly Acidic Cations and Weakly Basic Anions 808
Salts of Amphiprotic Anions 809

18.8 Generalizing the Brønsted-Lowry Concept: The Leveling Effect 810

18.9 Electron-Pair Donation and the Lewis Acid-Base Definition 811
Molecules as Lewis Acids 812
Metal Cations as Lewis Acids 813
An Overview of Acid-Base Definitions 814

CHAPTER REVIEW GUIDE 814

PROBLEMS 817

CHAPTER 19 Ionic Equilibria in Aqueous Systems 826

19.1 Equilibria of Acid-Base Buffers 827
What a Buffer Is and How It Works: The Common-Ion Effect 827
The Henderson-Hasselbalch Equation 832
Buffer Capacity and Buffer Range 833
Preparing a Buffer 835

19.2 Acid-Base Titration Curves 837
Monitoring pH with Acid-Base Indicators 837
Strong Acid–Strong Base Titration Curves 838
Weak Acid–Strong Base Titration Curves 840
Weak Base–Strong Acid Titration Curves 843
Titration Curves for Polyprotic Acids 844
Amino Acids as Biological Polyprotic Acids 845

19.3 Equilibria of Slightly Soluble Ionic Compounds 846
The Ion-Product Expression (Q_{sp}) and the Solubility-Product Constant (K_{sp}) 846
Calculations Involving the Solubility-Product Constant 848
Effect of a Common Ion on Solubility 850
Effect of pH on Solubility 852
Applying Ionic Equilibria to the Formation of a Limestone Cave 853
Predicting the Formation of a Precipitate: Q_{sp} vs. K_{sp} 853
Separating Ions by Selective Precipitation and Simultaneous Equilibria 856

CHEMICAL CONNECTIONS TO ENVIRONMENTAL SCIENCE: **THE ACID-RAIN PROBLEM 857**

19.4 Equilibria Involving Complex Ions 859
Formation of Complex Ions 859
Complex Ions and the Solubility of Precipitates 861
Complex Ions of Amphoteric Hydroxides 863

CHAPTER REVIEW GUIDE 865

PROBLEMS 868

CHAPTER 20 Thermodynamics: Entropy, Free Energy, and the Direction of Chemical Reactions 876

20.1 The Second Law of Thermodynamics: Predicting Spontaneous Change 877
The First Law of Thermodynamics Does Not Predict Spontaneous Change 878
The Sign of ΔH Does Not Predict Spontaneous Change 878
Freedom of Particle Motion and Dispersal of Kinetic Energy 879
Entropy and the Number of Microstates 880
Entropy and the Second Law of Thermodynamics 883
Standard Molar Entropies and the Third Law 883
Predicting Relative S° of a System 883

20.2 Calculating the Change in Entropy of a Reaction 888
Entropy Changes in the System: Standard Entropy of Reaction (ΔS°_{rxn}) 888
Entropy Changes in the Surroundings: The Other Part of the Total 889
The Entropy Change and the Equilibrium State 891
Spontaneous Exothermic and Endothermic Changes 892

20.3 Entropy, Free Energy, and Work 893
Free Energy Change and Reaction Spontaneity 893
Calculating Standard Free Energy Changes 894
The Free Energy Change and the Work a System Can Do 896
The Effect of Temperature on Reaction Spontaneity 897
Coupling of Reactions to Drive a Nonspontaneous Change 901

CHEMICAL CONNECTIONS TO BIOLOGICAL ENERGETICS: **THE UNIVERSAL ROLE OF ATP 902**

20.4 Free Energy, Equilibrium, and Reaction Direction 903

CHAPTER REVIEW GUIDE 909

PROBLEMS 912

CHAPTER 21 Electrochemistry: Chemical Change and Electrical Work 918

21.1 Redox Reactions and Electrochemical Cells 919
A Quick Review of Oxidation-Reduction Concepts 919
Half-Reaction Method for Balancing Redox Reactions 920
An Overview of Electrochemical Cells 924

21.2 Voltaic Cells: Using Spontaneous Reactions to Generate Electrical Energy 925
Construction and Operation of a Voltaic Cell 926
Notation for a Voltaic Cell 928
Why Does a Voltaic Cell Work? 929

21.3 Cell Potential: Output of a Voltaic Cell 930
Standard Cell Potential (E°_{cell}) 930
Relative Strengths of Oxidizing and Reducing Agents 933
Using $E^\circ_{half\text{-}cell}$ Values to Write Spontaneous Redox Reactions 934
Explaining the Activity Series of the Metals 937

21.4 Free Energy and Electrical Work 939
Standard Cell Potential and the Equilibrium Constant 939
The Effect of Concentration on Cell Potential 941
Following Changes in Potential During Cell Operation 943
Concentration Cells 944

21.5 Electrochemical Processes in Batteries 947
Primary (Nonrechargeable) Batteries 947
Secondary (Rechargeable) Batteries 949
Fuel Cells 950

21.6 Corrosion: An Environmental Voltaic Cell 951
The Corrosion of Iron 951
Protecting Against the Corrosion of Iron 953

21.7 Electrolytic Cells: Using Electrical Energy to Drive Nonspontaneous Reactions 954
Construction and Operation of an Electrolytic Cell 954
Predicting the Products of Electrolysis 955
Stoichiometry of Electrolysis: The Relation Between Amounts of Charge and Products 959

CHEMICAL CONNECTIONS TO BIOLOGICAL ENERGETICS: **CELLULAR ELECTROCHEMISTRY AND THE PRODUCTION OF ATP 962**

CHAPTER REVIEW GUIDE 964

PROBLEMS 967

CHAPTER 22 The Elements in Nature and Industry 976

22.1 How the Elements Occur in Nature 977
Earth's Structure and the Abundance of the Elements 977
Sources of the Elements 981

22.2 The Cycling of Elements Through the Environment 982
The Carbon Cycle 982
The Nitrogen Cycle 984
The Phosphorus Cycle 986

22.3 Metallurgy: Extracting a Metal from Its Ore 988
Pretreating the Ore 989
Converting Mineral to Element 990
Refining and Alloying the Element 992

22.4 Tapping the Crust: Isolation and Uses of Selected Elements 994
Producing the Alkali Metals: Sodium and Potassium 994
The Indispensable Three: Iron, Copper, and Aluminum 996
Mining the Sea for Magnesium 1002
The Sources and Uses of Hydrogen 1003

22.5 Chemical Manufacturing: Two Case Studies 1006
Sulfuric Acid, the Most Important Chemical 1006
The Chlor-Alkali Process 1008

CHAPTER REVIEW GUIDE 1009

PROBLEMS 1010

CHAPTER 23 Transition Elements and Their Coordination Compounds 1016

23.1 Properties of the Transition Elements 1017
Electron Configurations of the Transition Metals and Their Ions 1018
Atomic and Physical Properties of the Transition Elements 1020
Chemical Properties of the Transition Elements 1022

23.2 The Inner Transition Elements 1024
The Lanthanides 1024
The Actinides 1025

23.3 Coordination Compounds 1026
Complex Ions: Coordination Numbers, Geometries, and Ligands 1026
Formulas and Names of Coordination Compounds 1028
Isomerism in Coordination Compounds 1031

23.4 Theoretical Basis for the Bonding and Properties of Complexes 1034
Applying Valence Bond Theory to Complex Ions 1034
Crystal Field Theory 1036

CHEMICAL CONNECTIONS TO NUTRITIONAL SCIENCE: **TRANSITION METALS AS ESSENTIAL DIETARY TRACE ELEMENTS 1043**

CHAPTER REVIEW GUIDE 1045

PROBLEMS 1046

CHAPTER 24 Nuclear Reactions and Their Applications 1052

24.1 Radioactive Decay and Nuclear Stability 1053
Comparing Chemical and Nuclear Change 1054
The Components of the Nucleus: Terms and Notation 1054
The Discovery of Radioactivity and the Types of Emissions 1055
Modes of Radioactive Decay; Balancing Nuclear Equations 1055
Nuclear Stability and the Mode of Decay 1058

24.2 The Kinetics of Radioactive Decay 1062
Detection and Measurement of Radioactivity 1063
The Rate of Radioactive Decay 1064
Radioisotopic Dating 1067

24.3 Nuclear Transmutation: Induced Changes in Nuclei 1069
Early Transmutation Experiments; Nuclear Shorthand Notation 1070
Particle Accelerators and the Transuranium Elements 1070

24.4 Effects of Nuclear Radiation on Matter 1072
Effects of Ionizing Radiation on Living Tissue 1073
Background Sources of Ionizing Radiation 1075
Assessing the Risk from Ionizing Radiation 1076

24.5 Applications of Radioisotopes 1077
Radioactive Tracers 1077
Additional Applications of Ionizing Radiation 1080

24.6 The Interconversion of Mass and Energy 1081
The Mass Difference Between a Nucleus and Its Nucleons 1081
Nuclear Binding Energy and Binding Energy per Nucleon 1082

24.7 Applications of Fission and Fusion 1084
The Process of Nuclear Fission 1084
The Promise of Nuclear Fusion 1088

CHEMICAL CONNECTIONS TO COSMOLOGY: **ORIGIN OF THE ELEMENTS IN THE STARS 1090**

CHAPTER REVIEW GUIDE 1092

PROBLEMS 1094

Appendix A Common Mathematical Operations in Chemistry A-1
Appendix B Standard Thermodynamic Values for Selected Substances A-5
Appendix C Equilibrium Constants for Selected Substances A-8
Appendix D Standard Electrode (Half-Cell) Potentials A-14
Appendix E Answers to Selected Problems A-15

Glossary G-1
Credits C-1
Index I-1

LIST OF SAMPLE PROBLEMS *(Molecular-scene problems are shown in color.)*

Chapter 1

1.1 Visualizing Change on the Atomic Scale 6
1.2 Distinguishing Between Physical and Chemical Change 7
1.3 Converting Units of Length 20
1.4 Converting Units of Volume 21
1.5 Converting Units of Mass 21
1.6 Converting Units Raised to a Power 22
1.7 Calculating Density from Mass and Volume 24
1.8 Converting Units of Temperature 26
1.9 Determining the Number of Significant Figures 28
1.10 Significant Figures and Rounding 30

Chapter 2

2.1 Distinguishing Elements, Compounds, and Mixtures at the Atomic Scale 43
2.2 Calculating the Mass of an Element in a Compound 46
2.3 Visualizing the Mass Laws 48
2.4 Determining the Number of Subatomic Particles in the Isotopes of an Element 54
2.5 Calculating the Atomic Mass of an Element 55
2.6 Identifying an Element from Its *Z* Value 60
2.7 Predicting the Ion an Element Forms 63
2.8 Naming Binary Ionic Compounds 66
2.9 Determining Formulas of Binary Ionic Compounds 67
2.10 Determining Names and Formulas of Ionic Compounds of Metals That Form More Than One Ion 68
2.11 Determining Names and Formulas of Ionic Compounds Containing Polyatomic Ions 69
2.12 Recognizing Incorrect Names and Formulas of Ionic Compounds 69
2.13 Determining Names and Formulas of Anions and Acids 70
2.14 Determining Names and Formulas of Binary Covalent Compounds 71
2.15 Recognizing Incorrect Names and Formulas of Binary Covalent Compounds 72
2.16 Calculating the Molecular Mass of a Compound 73
2.17 Using Molecular Depictions to Determine Formula, Name, and Mass 74

Chapter 3

3.1 Converting Between Mass and Amount of an Element 94
3.2 Converting Between Number of Entities and Amount of an Element 95
3.3 Converting Between Number of Entities and Mass of an Element 95
3.4 Converting Between Number of Entities and Mass of a Compound I 96
3.5 Converting Between Number of Entities and Mass of a Compound II 97
3.6 Calculating the Mass Percent of Each Element in a Compound from the Formula 98
3.7 Calculating the Mass of an Element in a Compound 100
3.8 Determining an Empirical Formula from Amounts of Elements 101
3.9 Determining an Empirical Formula from Masses of Elements 102
3.10 Determining a Molecular Formula from Elemental Analysis and Molar Mass 103
3.11 Determining a Molecular Formula from Combustion Analysis 104
3.12 Balancing Chemical Equations 110
3.13 Balancing an Equation from a Molecular Scene 111
3.14 Calculating Quantities of Reactants and Products: Amount (mol) to Amount (mol) 114
3.15 Calculating Quantities of Reactants and Products: Amount (mol) to Mass (g) 114
3.16 Calculating Quantities of Reactants and Products: Mass to Mass 115
3.17 Writing an Overall Equation for a Reaction Sequence 116
3.18 Using Molecular Depictions in a Limiting-Reactant Problem 119
3.19 Calculating Quantities in a Limiting-Reactant Problem: Amount to Amount 120
3.20 Calculating Quantities in a Limiting-Reactant Problem: Mass to Mass 121
3.21 Calculating Percent Yield 123

Chapter 4

4.1 Using Molecular Scenes to Depict an Ionic Compound in Aqueous Solution 142
4.2 Determining Amount (mol) of Ions in Solution 143
4.3 Calculating the Molarity of a Solution 144
4.4 Calculating Mass of Solute in a Given Volume of Solution 145
4.5 Determining Amount (mol) of Ions in a Solution 145
4.6 Preparing a Dilute Solution from a Concentrated Solution 147
4.7 Visualizing Changes in Concentration 148
4.8 Predicting Whether a Precipitation Reaction Occurs: Writing Ionic Equations 153
4.9 Using Molecular Depictions in Precipitation Reactions 154
4.10 Calculating Amounts of Reactants and Products in a Precipitation Reaction 156
4.11 Solving a Limiting-Reactant Problem for a Precipitation Reaction 157
4.12 Determining the Number of H^+ (or OH^-) Ions in Solution 160
4.13 Writing Ionic Equations for Acid-Base Reactions 161
4.14 Writing Proton-Transfer Equations for Acid-Base Reactions 165
4.15 Calculating the Amounts of Reactants and Products in an Acid-Base Reaction 165
4.16 Finding the Concentration of an Acid from a Titration 167
4.17 Determining the Oxidation Number of Each Element in a Compound (or Ion) 170
4.18 Identifying Redox Reactions and Oxidizing and Reducing Agents 171
4.19 Finding the Amount of Reducing Agent by Titration 173
4.20 Identifying the Type of Redox Reaction 180

Chapter 5

5.1 Converting Units of Pressure 203
5.2 Applying the Volume-Pressure Relationship 211
5.3 Applying the Volume-Temperature and Pressure-Temperature Relationships 211
5.4 Applying the Volume-Amount and Pressure-Amount Relationships 212
5.5 Applying the Volume-Pressure-Temperature Relationship 213
5.6 Solving for an Unknown Gas Variable at Fixed Conditions 214
5.7 Using Gas Laws to Determine a Balanced Equation 214
5.8 Calculating Gas Density 216
5.9 Finding the Molar Mass of a Volatile Liquid 218
5.10 Applying Dalton's Law of Partial Pressures 220
5.11 Calculating the Amount of Gas Collected over Water 221
5.12 Using Gas Variables to Find Amounts of Reactants or Products I 222
5.13 Using Gas Variables to Find Amounts of Reactants or Products II 223
5.14 Applying Graham's Law of Effusion 230

Chapter 6
6.1 Determining the Change in Internal Energy of a System 256
6.2 Calculating Pressure-Volume Work Done by or on a System 258
6.3 Drawing Enthalpy Diagrams and Determining the Sign of ΔH 260
6.4 Finding the Quantity of Heat from a Temperature Change 262
6.5 Determining the Specific Heat Capacity of a Solid 263
6.6 Determining the Enthalpy Change of an Aqueous Reaction 263
6.7 Calculating the Heat of a Combustion Reaction 265
6.8 Using the Enthalpy Change of a Reaction (ΔH) to Find the Amount of a Substance 267
6.9 Using Hess's Law to Calculate an Unknown ΔH 269
6.10 Writing Formation Equations 270
6.11 Calculating ΔH°_{rxn} from ΔH°_f Values 272

Chapter 7
7.1 Interconverting Wavelength and Frequency 289
7.2 Interconverting Energy, Wavelength, and Frequency 293
7.3 Determining ΔE and λ of an Electron Transition 298
7.4 Calculating the de Broglie Wavelength of an Electron 303
7.5 Applying the Uncertainty Principle 305
7.6 Determining Quantum Numbers for an Energy Level 309
7.7 Determining Sublevel Names and Orbital Quantum Numbers 310
7.8 Identifying Incorrect Quantum Numbers 310

Chapter 8
8.1 Correlating Quantum Numbers and Orbital Diagrams 329
8.2 Determining Electron Configurations 335
8.3 Ranking Elements by Atomic Size 338
8.4 Ranking Elements by First Ionization Energy 341
8.5 Identifying an Element from Its Ionization Energies 342
8.6 Writing Electron Configurations of Main-Group Ions 347
8.7 Writing Electron Configurations and Predicting Magnetic Behavior of Transition Metal Ions 350
8.8 Ranking Ions by Size 351

Chapter 9
9.1 Depicting Ion Formation 362
9.2 Predicting Relative Lattice Energy from Ionic Properties 366
9.3 Comparing Bond Length and Bond Strength 372
9.4 Using Bond Energies to Calculate ΔH°_{rxn} 378
9.5 Determining Bond Polarity from EN Values 383

Chapter 10
10.1 Writing Lewis Structures for Species with One Central Atom 397
10.2 Writing Lewis Structures for Molecules with More Than One Central Atom 398
10.3 Writing Lewis Structures for Molecules with Multiple Bonds 398
10.4 Writing Resonance Structures 400
10.5 Writing Lewis Structures for Octet-Rule Exceptions 405
10.6 Examining Shapes with Two, Three, or Four Electron Groups 414
10.7 Examining Shapes with Five or Six Electron Groups 414
10.8 Predicting Molecular Shapes with More Than One Central Atom 416
10.9 Predicting the Polarity of Molecules 418

Chapter 11
11.1 Postulating Hybrid Orbitals in a Molecule 435
11.2 Describing the Types of Bonds in Molecules 438
11.3 Predicting Stability of Species Using MO Diagrams 442
11.4 Using MO Theory to Explain Bond Properties 446

Chapter 12
12.1 Finding the Heat of a Phase Change Depicted by Molecular Scenes 461
12.2 Applying the Clausius-Clapeyron Equation 464
12.3 Using a Phase Diagram to Predict Phase Changes 467
12.4 Drawing Hydrogen Bonds Between Molecules of a Substance 471
12.5 Identifying the Types of Intermolecular Forces 473
12.6 Determining the Number of Particles per Unit Cell and the Coordination Number 480
12.7 Determining Atomic Radius 484
12.8 Determining Atomic Radius from the Unit Cell 485

Chapter 13
13.1 Predicting Relative Solubilities 521
13.2 Calculating an Aqueous Ionic Heat of Solution 531
13.3 Using Henry's Law to Calculate Gas Solubility 536
13.4 Calculating Molality 537
13.5 Expressing Concentrations in Parts by Mass, Parts by Volume, and Mole Fraction 539
13.6 Interconverting Concentration Terms 540
13.7 Using Raoult's Law to Find ΔP 543
13.8 Determining Boiling and Freezing Points of a Solution 545
13.9 Determining Molar Mass from Osmotic Pressure 547
13.10 Depicting Strong Electrolyte Solutions 549

Chapter 15
15.1 Drawing Hydrocarbons 621
15.2 Naming Alkanes, Alkenes, and Alkynes 630
15.3 Recognizing the Type of Organic Reaction 636
15.4 Predicting the Reactions of Alcohols, Alkyl Halides, and Amines 642
15.5 Predicting the Steps in a Reaction Sequence 645
15.6 Predicting Reactions of the Carboxylic Acid Family 649
15.7 Recognizing Functional Groups 651

Chapter 16
16.1 Expressing Rate in Terms of Changes in Concentration with Time 681
16.2 Determining Reaction Orders from Rate Laws 685
16.3 Determining Reaction Orders and Rate Constants from Rate Data 689
16.4 Determining Reaction Orders from Molecular Scenes 690
16.5 Determining the Reactant Concentration after a Given Time 692
16.6 Using Molecular Scenes to Find Quantities at Various Times 696
16.7 Determining the Half-Life of a First-Order Reaction 697
16.8 Determining the Energy of Activation 702
16.9 Drawing Reaction Energy Diagrams and Transition States 705
16.10 Determining Molecularities and Rate Laws for Elementary Steps 707
16.11 Identifying Intermediates and Correlating Rate Laws and Reaction Mechanisms 710

Chapter 17
17.1 Writing the Reaction Quotient from the Balanced Equation 736
17.2 Writing the Reaction Quotient and Finding K for an Overall Reaction 737
17.3 Finding the Equilibrium Constant for an Equation Multiplied by a Common Factor 739
17.4 Converting Between K_c and K_p 741
17.5 Using Molecular Scenes to Determine Reaction Direction 743
17.6 Using Concentrations to Determine Reaction Direction 744

17.7 Calculating K_c from Concentration Data 746
17.8 Determining Equilibrium Concentrations from K_c 747
17.9 Determining Equilibrium Concentrations from Initial Concentrations and K_c 748
17.10 Making a Simplifying Assumption to Calculate Equilibrium Concentrations 750
17.11 Predicting Reaction Direction and Calculating Equilibrium Concentrations 752
17.12 Predicting the Effect of a Change in Concentration on the Equilibrium Position 756
17.13 Predicting the Effect of a Change in Volume (Pressure) on the Equilibrium Position 758
17.14 Predicting the Effect of a Change in Temperature on the Equilibrium Position 760
17.15 Determining Equilibrium Parameters from Molecular Scenes 762

Chapter 18
18.1 Classifying Acid and Base Strength from the Chemical Formula 782
18.2 Calculating $[H_3O^+]$ or $[OH^-]$ in Aqueous Solution 784
18.3 Calculating $[H_3O^+]$, pH, $[OH^-]$, and pOH for Strong Acids and Bases 786
18.4 Identifying Conjugate Acid-Base Pairs 789
18.5 Predicting the Net Direction of an Acid-Base Reaction 790
18.6 Using Molecular Scenes to Predict the Net Direction of an Acid-Base Reaction 791
18.7 Finding K_a of a Weak Acid from the Solution pH 793
18.8 Determining Concentration and pH from K_a and Initial [HA] 794
18.9 Finding the Percent Dissociation of a Weak Acid 796
18.10 Calculating Equilibrium Concentrations for a Polyprotic Acid 798
18.11 Determining pH from K_b and Initial [B] 803
18.12 Determining the pH of a Solution of A^- 805
18.13 Predicting Relative Acidity of Salt Solutions from Reactions of the Ions with Water 808
18.14 Predicting the Relative Acidity of a Salt Solution from K_a and K_b of the Ions 810
18.15 Identifying Lewis Acids and Bases 813

Chapter 19
19.1 Calculating the Effect of Added H_3O^+ or OH^- on Buffer pH 830
19.2 Using Molecular Scenes to Examine Buffers 834
19.3 Preparing a Buffer 835
19.4 Finding the pH During a Weak Acid–Strong Base Titration 842
19.5 Writing Ion-Product Expressions 847
19.6 Determining K_{sp} from Solubility 848
19.7 Determining Solubility from K_{sp} 849
19.8 Calculating the Effect of a Common Ion on Solubility 851
19.9 Predicting the Effect on Solubility of Adding Strong Acid 852
19.10 Predicting Whether a Precipitate Will Form 854
19.11 Using Molecular Scenes to Predict Whether a Precipitate Will Form 854
19.12 Separating Ions by Selective Precipitation 856
19.13 Calculating the Concentration of a Complex Ion 860
19.14 Calculating the Effect of Complex-Ion Formation on Solubility 862

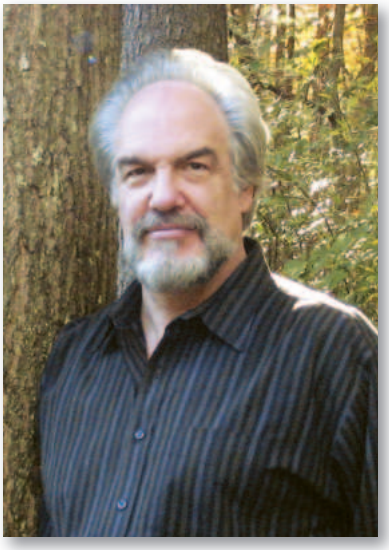
Chapter 20
20.1 Predicting Relative Entropy Values 887
20.2 Calculating the Standard Entropy of Reaction, ΔS°_{rxn} 889
20.3 Determining Reaction Spontaneity 890
20.4 Calculating ΔG°_{rxn} from Enthalpy and Entropy Values 894
20.5 Calculating ΔG°_{rxn} from ΔG°_f Values 896
20.6 Using Molecular Scenes to Determine the Signs of ΔH, ΔS, and ΔG 898
20.7 Determining the Effect of Temperature on ΔG 899
20.8 Finding the Temperature at Which a Reaction Becomes Spontaneous 900
20.9 Exploring the Relationship Between ΔG° and K 904
20.10 Using Molecular Scenes to Find ΔG for a Reaction at Nonstandard Conditions 905
20.11 Calculating ΔG at Nonstandard Conditions 907

Chapter 21
21.1 Balancing a Redox Reaction in Basic Solution 922
21.2 Describing a Voltaic Cell with Diagram and Notation 928
21.3 Using $E^\circ_{half\text{-}cell}$ to Find E°_{cell} 931
21.4 Calculating an Unknown $E^\circ_{half\text{-}cell}$ from E°_{cell} 933
21.5 Writing Spontaneous Redox Reactions and Ranking Oxidizing and Reducing Agents by Strength 936
21.6 Calculating K and ΔG° from E°_{cell} 940
21.7 Using the Nernst Equation to Calculate E_{cell} 942
21.8 Calculating the Potential of a Concentration Cell 945
21.9 Predicting the Electrolysis Products of a Molten Salt Mixture 956
21.10 Predicting the Electrolysis Products of Aqueous Salt Solutions 958
21.11 Applying the Relationship Among Current, Time, and Amount of Substance 960

Chapter 23
23.1 Writing Electron Configurations of Transition Metal Atoms and Ions 1020
23.2 Finding the Number of Unpaired Electrons 1025
23.3 Finding the Coordination Number and Charge of the Central Metal Ion in a Coordination Compound 1029
23.4 Writing Names and Formulas of Coordination Compounds 1030
23.5 Determining the Type of Stereoisomerism 1034
23.6 Ranking Crystal Field Splitting Energies (Δ) for Complex Ions of a Metal 1040
23.7 Identifying High-Spin and Low-Spin Complex Ions 1041

Chapter 24
24.1 Writing Equations for Nuclear Reactions 1058
24.2 Predicting Nuclear Stability 1060
24.3 Predicting the Mode of Nuclear Decay 1061
24.4 Calculating the Specific Activity and the Decay Constant of a Radionuclide 1064
24.5 Finding the Number of Radioactive Nuclei 1066
24.6 Applying Radiocarbon Dating 1069
24.7 Calculating the Binding Energy per Nucleon 1083

ABOUT THE AUTHORS



Martin S. Silberberg received a B.S. in Chemistry from the City University of New York and a Ph.D. in Chemistry from the University of Oklahoma. He then accepted a position as research associate in analytical biochemistry at the Albert Einstein College of Medicine in New York City, where he developed methods to study neurotransmitter metabolism in Parkinson's disease and other neurological disorders. Following six years in neurochemical research, Dr. Silberberg joined the faculty of Bard College at Simon's Rock, a liberal arts college known for its excellence in teaching small classes of highly motivated students. As head of the Natural Sciences Major and Director of Premedical Studies, he taught courses in general chemistry, organic chemistry, biochemistry, and liberal-arts chemistry. The small class size and close student contact afforded him insights into how students learn chemistry, where they have difficulties, and what strategies can help them succeed. Dr. Silberberg decided to apply these insights in a broader context and established a textbook writing, editing, and consulting company. Before writing his own texts, he worked as a consulting and development editor on chemistry, biochemistry, and physics texts for several major college publishers. He resides with his wife Ruth in the Pioneer Valley near Amherst, Massachusetts, where he enjoys the rich cultural and academic life of the area and relaxes by cooking, gardening, and singing.

Patricia G. Amateis graduated with a B.S. in Chemistry Education from Concord University in West Virginia and a Ph.D. in Analytical Chemistry from Virginia Tech. She has been on the faculty of the Chemistry Department at Virginia Tech for 28 years, teaching General Chemistry and Analytical Chemistry. For the past 13 years, she has served as Director of General Chemistry, responsible for the oversight of both the lecture and lab portions of the large General Chemistry program. She has taught thousands of students during her career and has been awarded the University Sporn Award for Introductory Teaching, the Alumni Teaching Award, and the William E. Wine Award for a history of university teaching excellence. She and her husband live in Blacksburg, Virginia and are the parents of three adult children. In her free time, she enjoys biking, hiking, competing in the occasional sprint triathlon, and playing the double second in Panjammers, Blacksburg's steel drum band.

PREFACE

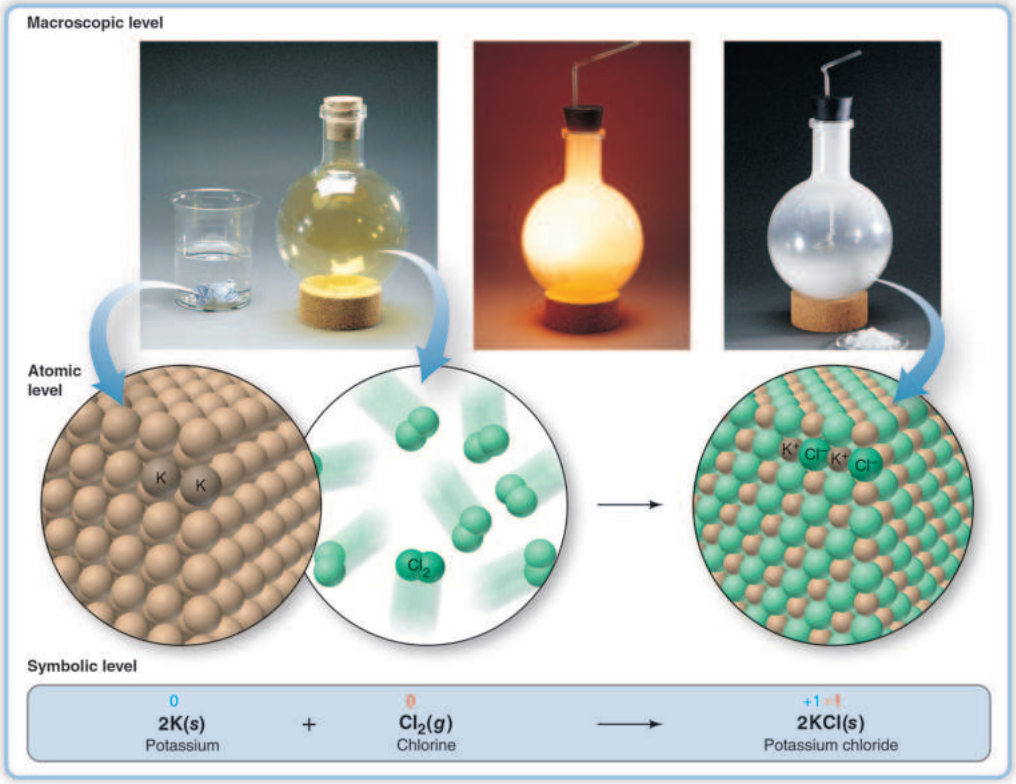
Chemistry is so crucial to an understanding of medicine and biology, environmental science, and many areas of engineering and industrial processing that it has become a requirement for an increasing number of academic majors. Furthermore, chemical principles lie at the core of some of the key societal issues we face in the 21st century—dealing with climate change, finding new energy options, and supplying nutrition and curing disease on an ever more populated planet.

SETTING THE STANDARD FOR A CHEMISTRY TEXT

The seventh edition of *Chemistry: The Molecular Nature of Matter and Change* maintains its standard-setting position among general chemistry textbooks by evolving further to meet the needs of professor and student. The text still contains the most accurate molecular illustrations, consistent step-by-step worked problems, and an extensive collection of end-of-chapter problems. And changes throughout this edition make the text more readable and succinct, the artwork more teachable and modern, and the design more focused and inviting. The three hallmarks that have made this text a market leader are now demonstrated in its pages more clearly than ever.

Visualizing Chemical Models—Macroscopic to Molecular

Chemistry deals with observable changes caused by unobservable atomic-scale events, requiring an appreciation of a size gap of mind-boggling proportions. One of the text's goals coincides with that of so many instructors: to help students visualize chemical events on the molecular scale. Thus, concepts are explained first at the macroscopic level and then from a molecular point of view, with pedagogic illustrations always placed next to the discussions to bring the point home for today's visually oriented students.



Thinking Logically to Solve Problems

The problem-solving approach, based on the four-step method widely accepted by experts in chemical education, is introduced in Chapter 1 and employed *consistently* throughout the text. It encourages students to *plan* a logical approach to a problem, and only then proceed to *solve* it. Each sample problem includes a *check,* which fosters the habit of "thinking through" both the chemical and the quantitative reasonableness of the answer. Finally, for *practice* and reinforcement, each sample problem is now followed immediately by *two* similar follow-up problems. And, *Chemistry* marries problem solving to visualizing models with molecular-scene problems, which appear not only in homework sets, as in other texts, but also in the running text, where they are worked out stepwise.

SAMPLE PROBLEM 3.9 Determining an Empirical Formula from Masses of Elements

Problem Analysis of a sample of an ionic compound yields 2.82 g of Na, 4.35 g of Cl, and 7.83 g of O. What are the empirical formula and the name of the compound?

Plan This problem is similar to Sample Problem 3.8, except that we are given element *masses* that we must convert into integer subscripts. We first divide each mass by the element's molar mass to find the amount (mol). Then we construct a preliminary formula and convert the amounts (mol) to integers.

Solution Finding amount (mol) of each element:

$$\text{Amount (mol) of Na} = 2.82\ \text{g Na} \times \frac{1\ \text{mol Na}}{22.99\ \text{g Na}} = 0.123\ \text{mol Na}$$

$$\text{Amount (mol) of Cl} = 4.35\ \text{g Cl} \times \frac{1\ \text{mol Cl}}{35.45\ \text{g Cl}} = 0.123\ \text{mol Cl}$$

$$\text{Amount (mol) of O} = 7.83\ \text{g O} \times \frac{1\ \text{mol O}}{16.00\ \text{g O}} = 0.489\ \text{mol O}$$

Constructing a preliminary formula: $Na_{0.123}Cl_{0.123}O_{0.489}$

Converting to integer subscripts (dividing all by the smallest subscript):

$$Na_{\frac{0.123}{0.123}}Cl_{\frac{0.123}{0.123}}O_{\frac{0.489}{0.123}} \longrightarrow Na_{1.00}Cl_{1.00}O_{3.98} \approx Na_1Cl_1O_4, \quad \text{or} \quad NaClO_4$$

The empirical formula is $NaClO_4$; the name is sodium perchlorate.

Check The numbers of moles seem correct because the masses of Na and Cl are slightly more than 0.1 of their molar masses. The mass of O is greatest and its molar mass is smallest, so it should have the greatest number of moles. The ratio of subscripts, 1/1/4, is the same as the ratio of moles, 0.123/0.123/0.489 (within rounding).

FOLLOW-UP PROBLEMS

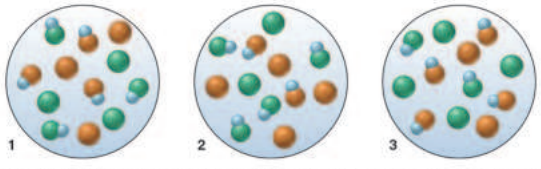
3.9A A sample of an unknown compound is found to contain 1.23 g of H, 12.64 g of P, and 26.12 g of O. What is the empirical formula?

3.9B An unknown metal M reacts with sulfur to form a compound with the formula M_2S_3. If 3.12 g of M reacts with 2.88 g of S, what are the names of M and M_2S_3? [*Hint:* Determine the amount (mol) of S, and use the formula to find the amount (mol) of M.]

SOME SIMILAR PROBLEMS 3.42(b), 3.43(b), 3.46(b), and 3.47(b)

SAMPLE PROBLEM 18.6 Using Molecular Scenes to Predict the Net Direction of an Acid-Base Reaction

Problem Given that 0.10 *M* HX *(blue and green)* has a pH of 2.88, and 0.10 *M* HY *(blue and orange)* has a pH of 3.52, which scene best represents the final mixture after equimolar solutions of HX and Y^- are mixed?



Plan A stronger acid and base yield a weaker acid and base, so we have to determine the relative acid strengths of HX and HY in order to choose the correct molecular scene. The concentrations of the acid solutions are equal, so we can pick the stronger acid directly from the pH values of the two acid solutions. Because the stronger acid reacts to a greater extent, fewer molecules of it will be in the scene than molecules of the weaker acid.

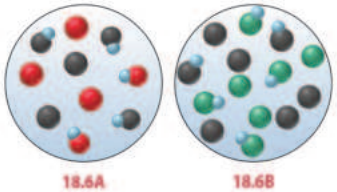
Solution The HX solution has a lower pH (2.88) than the HY solution (3.52), so we know right away that HX is the stronger acid and Y^- is the stronger base. Therefore, the reaction of HX and Y^- has a $K_c > 1$, which means the equilibrium mixture will have more HY than HX. Scene 1 has equal numbers of HX and HY, which would occur if the acids were of equal strength, and scene 2 shows fewer HY than HX, which would occur if HY were stronger. Therefore, only scene 3 is consistent with the relative acid strengths.

FOLLOW-UP PROBLEMS

18.6A The left-hand scene in the margin represents the equilibrium mixture after 0.10 *M* solutions of HA *(blue and red)* and B^- *(black)* react: Does this reaction have a K_c greater or less than 1? Which acid is stronger, HA or HB?

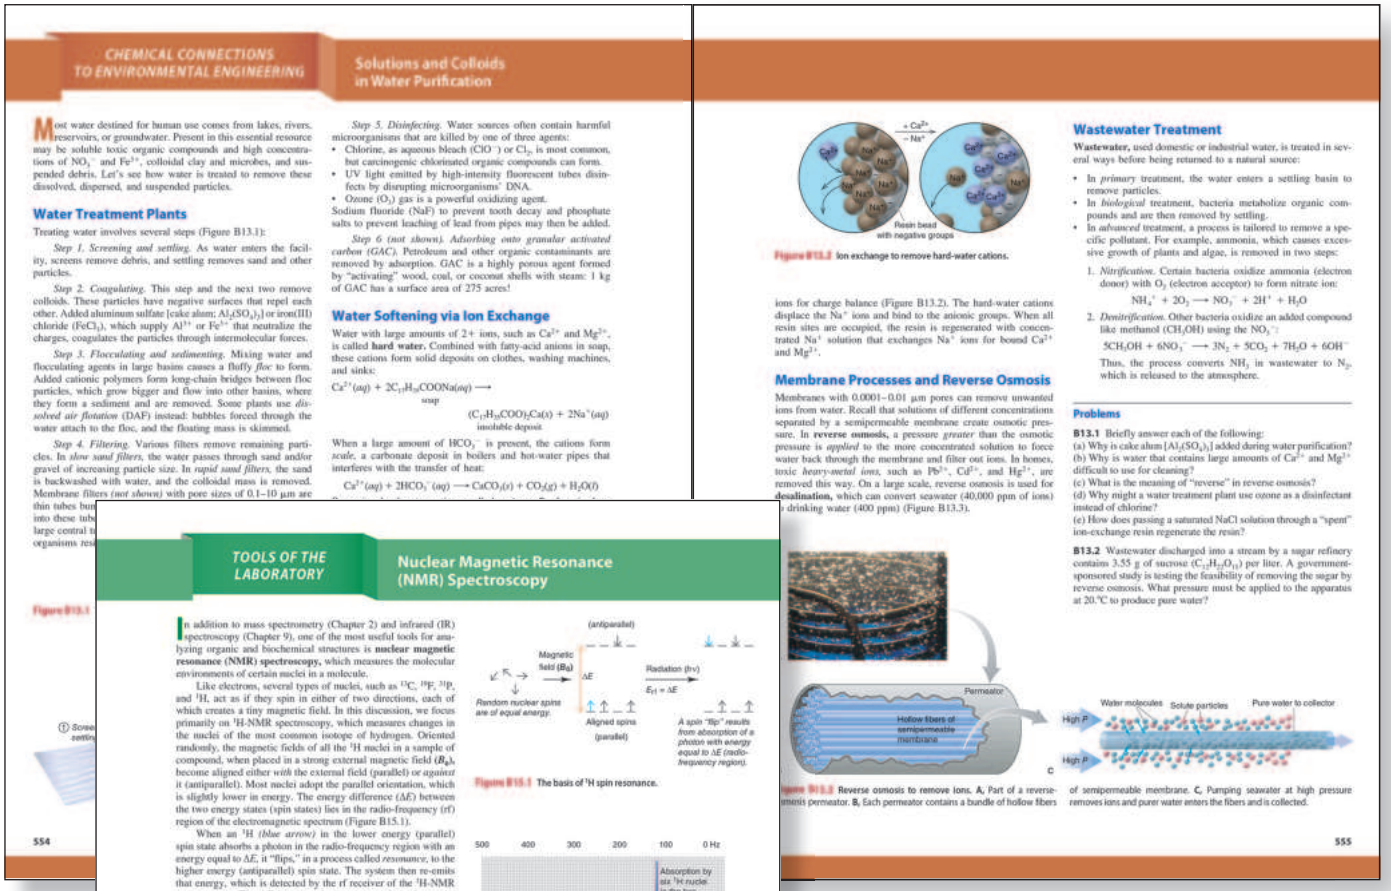
18.6B The right-hand scene depicts an aqueous solution of two conjugate acid-base pairs: HC/C^- and HD/D^-. HD is a stronger acid than HC. What colors represent the base C^- and the base D^-? Does the reaction between HC and D^- have a K_c greater or less than 1?

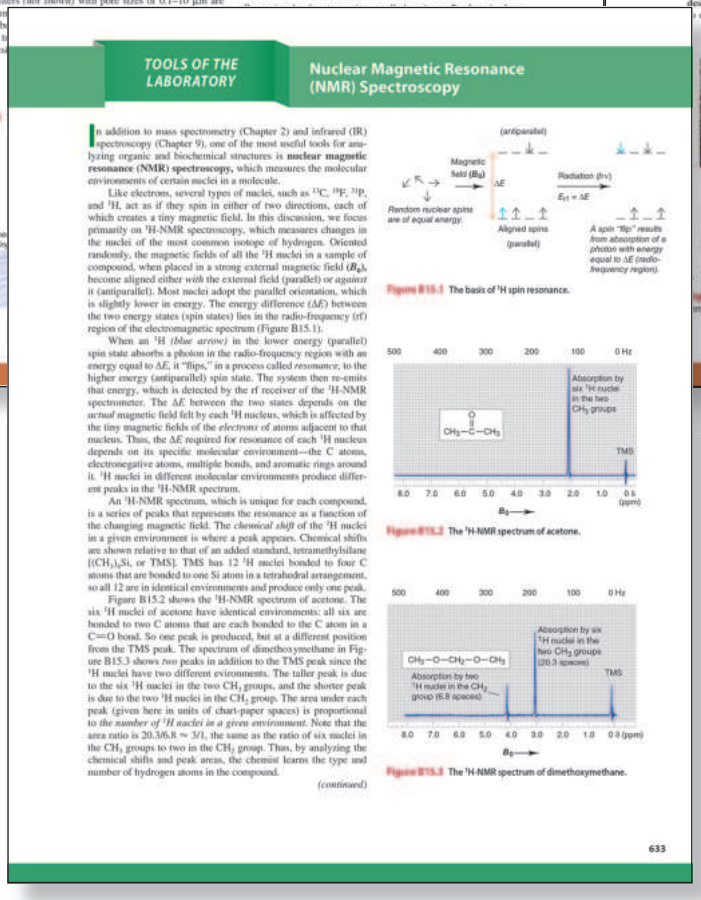
A SIMILAR PROBLEM 18.39



Applying Ideas to the Real World

As the most practical science, chemistry should have a textbook that highlights its countless applications. Moreover, today's students may enter emerging chemistry-related hybrid fields, like biomaterials science or planetary geochemistry, and the text they use should point out the relevance of chemical concepts to such related sciences. The *Chemical Connections* and *Tools of the Laboratory* boxed essays (which include problems for added relevance), the more pedagogic margin notes, and the many applications woven into the chapter content are up-to-date, student-friendly features that are directly related to the neighboring content.





Reinforcing through Review and Practice

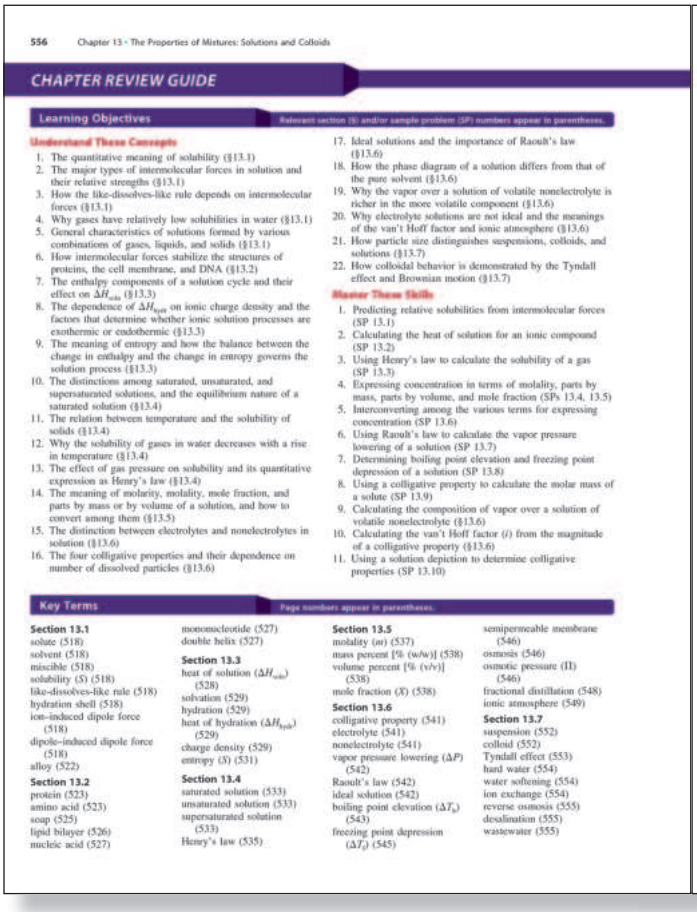
A favorite feature, the section summaries that conclude every section restate the major ideas concisely and immediately (rather than postponing such review until the end of the chapter).

A rich catalog of study aids ends each chapter to help students review the content:

- **Learning Objectives,** with section and/or sample problem numbers, focus on the concepts to understand and the skills to master.
- **Key Terms,** boldfaced and defined within the chapter, are listed here by section (with page numbers), as well as being defined in the *Glossary.*
- **Key Equations and Relationships** are highlighted and numbered within the chapter and listed here with page numbers.
- **Brief Solutions to Follow-up Problems** triple the number of worked problems by providing multistep calculations at the end of the chapter, rather than just numerical answers at the back of the book.

Summary of Section 9.1

- Nearly all naturally occurring substances consist of atoms or ions bonded to others. Chemical bonding allows atoms to lower their energy.
- Ionic bonding occurs when metal atoms transfer electrons to nonmetal atoms, and the resulting ions attract each other and form an ionic solid.
- Covalent bonding is most common between nonmetal atoms and usually results in individual molecules. Bonded atoms share one or more pairs of electrons that are localized between them.
- Metallic bonding occurs when many metal atoms pool their valence electrons into a delocalized electron "sea" that holds all the atoms in the sample together.
- The Lewis electron-dot symbol of a main-group atom shows valence electrons as dots surrounding the element symbol.
- The octet rule says that, when bonding, many atoms lose, gain, or share electrons to attain a filled outer level of eight (or two) electrons.



556 Chapter 13 • The Properties of Mixtures: Solutions and Colloids

CHAPTER REVIEW GUIDE

Learning Objectives — Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The quantitative meaning of solubility (§13.1)
2. The major types of intermolecular forces in solution and their relative strengths (§13.1)
3. How the like-dissolves-like rule depends on intermolecular forces (§13.1)
4. Why gases have relatively low solubilities in water (§13.1)
5. General characteristics of solutions formed by various combinations of gases, liquids, and solids (§13.1)
6. How intermolecular forces stabilize the structures of proteins, the cell membrane, and DNA (§13.2)
7. The enthalpy components of a solution cycle and their effect on ΔH_{soln} (§13.3)
8. The dependence of ΔH_{hyd} on ionic charge density and the factors that determine whether ionic solution processes are exothermic or endothermic (§13.3)
9. The meaning of entropy and how the balance between the change in enthalpy and the change in entropy governs the solution process (§13.3)
10. The distinctions among saturated, unsaturated, and supersaturated solutions, and the equilibrium nature of a saturated solution (§13.4)
11. The relation between temperature and the solubility of solids (§13.4)
12. Why the solubility of gases in water decreases with a rise in temperature (§13.4)
13. The effect of gas pressure on solubility and its quantitative expression as Henry's law (§13.4)
14. The meaning of molarity, molality, mole fraction, and parts by mass or by volume of a solution, and how to convert among them (§13.5)
15. The distinction between electrolytes and nonelectrolytes in solution (§13.6)
16. The four colligative properties and their dependence on number of dissolved particles (§13.6)
17. Ideal solutions and the importance of Raoult's law (§13.6)
18. How the phase diagram of a solution differs from that of the pure solvent (§13.6)
19. Why the vapor over a solution of volatile nonelectrolyte is richer in the more volatile component (§13.6)
20. Why electrolyte solutions are not ideal and the meanings of the van't Hoff factor and ionic atmosphere (§13.6)
21. How particle size distinguishes suspensions, colloids, and solutions (§13.7)
22. How colloidal behavior is demonstrated by the Tyndall effect and Brownian motion (§13.7)

Master These Skills

1. Predicting relative solubilities from intermolecular forces (SP 13.1)
2. Calculating the heat of solution for an ionic compound (SP 13.2)
3. Using Henry's law to calculate the solubility of a gas (SP 13.3)
4. Expressing concentration in terms of molality, parts by mass, parts by volume, and mole fraction (SPs 13.4, 13.5)
5. Interconverting among the various terms for expressing concentration (SP 13.6)
6. Using Raoult's law to calculate the vapor pressure lowering of a solution (SP 13.7)
7. Determining boiling point elevation and freezing point depression of a solution (SP 13.8)
8. Using a colligative property to calculate the molar mass of a solute (SP 13.9)
9. Calculating the composition of vapor over a solution of volatile nonelectrolyte (§13.6)
10. Calculating the van't Hoff factor (i) from the magnitude of a colligative property (§13.6)
11. Using a solution depiction to determine colligative properties (SP 13.10)

Chapter 13 • Chapter Review Guide 557

Key Equations and Relationships — Page numbers appear in parentheses.

13.1 Dividing the general heat of solution into component enthalpies (528):

$$\Delta H_{soln} = \Delta H_{solute} + \Delta H_{solvent} + \Delta H_{mix}$$

13.2 Dividing the heat of solution of an ionic compound in water into component enthalpies (530):

$$\Delta H_{soln} = \Delta H_{lattice} + \Delta H_{hyd\ of\ the\ ions}$$

13.3 Relating gas solubility to its partial pressure (Henry's law) (535):

$$S_{gas} = k_H \times P_{gas}$$

13.4 Defining concentration in terms of molarity (537):

$$\text{Molarity } (M) = \frac{\text{amount (mol) of solute}}{\text{volume (L) of solution}}$$

13.5 Defining concentration in terms of molality (537):

$$\text{Molality } (m) = \frac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}}$$

13.6 Defining concentration in terms of mass percent (538):

$$\text{Mass percent [\% (w/w)]} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100$$

13.7 Defining concentration in terms of volume percent (538):

$$\text{Volume percent [\% (v/v)]} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100$$

13.8 Defining concentration in terms of mole fraction (538):

Mole fraction (X)

$$= \frac{\text{amount (mol) of solute}}{\text{amount (mol) of solute + amount (mol) of solvent}}$$

13.9 Expressing the relationship between the vapor pressure of solvent above a solution and its mole fraction in the solution (Raoult's law) (542):

$$P_{solvent} = X_{solvent} \times P^{\circ}_{solvent}$$

13.10 Calculating the vapor pressure lowering due to solute (542):

$$\Delta P = X_{solute} \times P^{\circ}_{solvent}$$

13.11 Calculating the boiling point elevation of a solution (544):

$$\Delta T_b = K_b m$$

13.12 Calculating the freezing point depression of a solution (545):

$$\Delta T_f = K_f m$$

13.13 Calculating the osmotic pressure of a solution (546):

$$\Pi = \frac{n_{solute}}{V_{solu}} RT = MRT$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

13.1A (a) 1,4-Butanediol is more soluble in water because it can form more H bonds.
(b) Chloroform is more soluble in water because of dipole-dipole forces.

13.1B (a) Chloroform dissolves more chloromethane due to similar dipole-dipole forces.
(b) Hexane dissolves more pentanol due to dispersion forces.

13.2A From Equation 13.2, we have

$$\Delta H_{soln} \text{ of } KNO_3 = \Delta H_{lattice} \text{ of } KNO_3 + (\Delta H_{hyd} \text{ of } K^+ + \Delta H_{hyd} \text{ of } NO_3^-)$$

$$34.89 \text{ kJ/mol} = 685 \text{ kJ/mol} + (\Delta H_{hyd} \text{ of } K^+ + \Delta H_{hyd} \text{ of } NO_3^-)$$

$$\Delta H_{hyd} \text{ of } K^+ + \Delta H_{hyd} \text{ of } NO_3^- = 34.89 \text{ kJ/mol} - 685 \text{ kJ/mol} = -650. \text{ kJ/mol}$$

13.2B From Equation 13.2, we have

$$\Delta H_{soln} \text{ of NaCN} = \Delta H_{lattice} \text{ of NaCN} + (\Delta H_{hyd} \text{ of } Na^+ + \Delta H_{hyd} \text{ of } CN^-)$$

$$1.21 \text{ kJ/mol} = 766 \text{ kJ/mol} - 410 \text{ kJ/mol} + \Delta H_{hyd} \text{ of } CN^-$$

$$\Delta H_{hyd} \text{ of } CN^- = 1.21 \text{ kJ/mol} - 766 \text{ kJ/mol} + 410. \text{ kJ/mol} = -355 \text{ kJ/mol}$$

13.3A $S_{N_2} = (7\times10^{-4} \text{ mol/L-atm})(0.78 \text{ atm}) = 5\times10^{-4} \text{ mol/L}$

13.3B In a mixture of gases, the volume percent of each gas times the total pressure equals its partial pressure (Dalton's law, Section 5.4). From Equation 13.3, we have

$$S_{gas} = k_H \times P_{gas} = (2.5\times10^{-2} \text{ mol/L-atm})(0.40 \times 1.2 \text{ atm}) = 1.2\times10^{-2} \text{ mol/L}$$

13.4A Mass (g) of glucose $= 563 \text{ g ethanol} \times \frac{1 \text{ kg}}{10^3 \text{ g}} \times \frac{2.40\times10^{-1} \text{ mol glucose}}{1 \text{ kg ethanol}} \times \frac{180.16 \text{ g glucose}}{1 \text{ mol glucose}} = 2.43 \text{ g glucose}$

13.4B Convert mass (g) of I_2 to amount (mol) and amount (mol) of $(CH_3CH_2)_2O$ to mass (kg). Then divide moles of I_2 by kg of $(CH_3CH_2)_2O$.

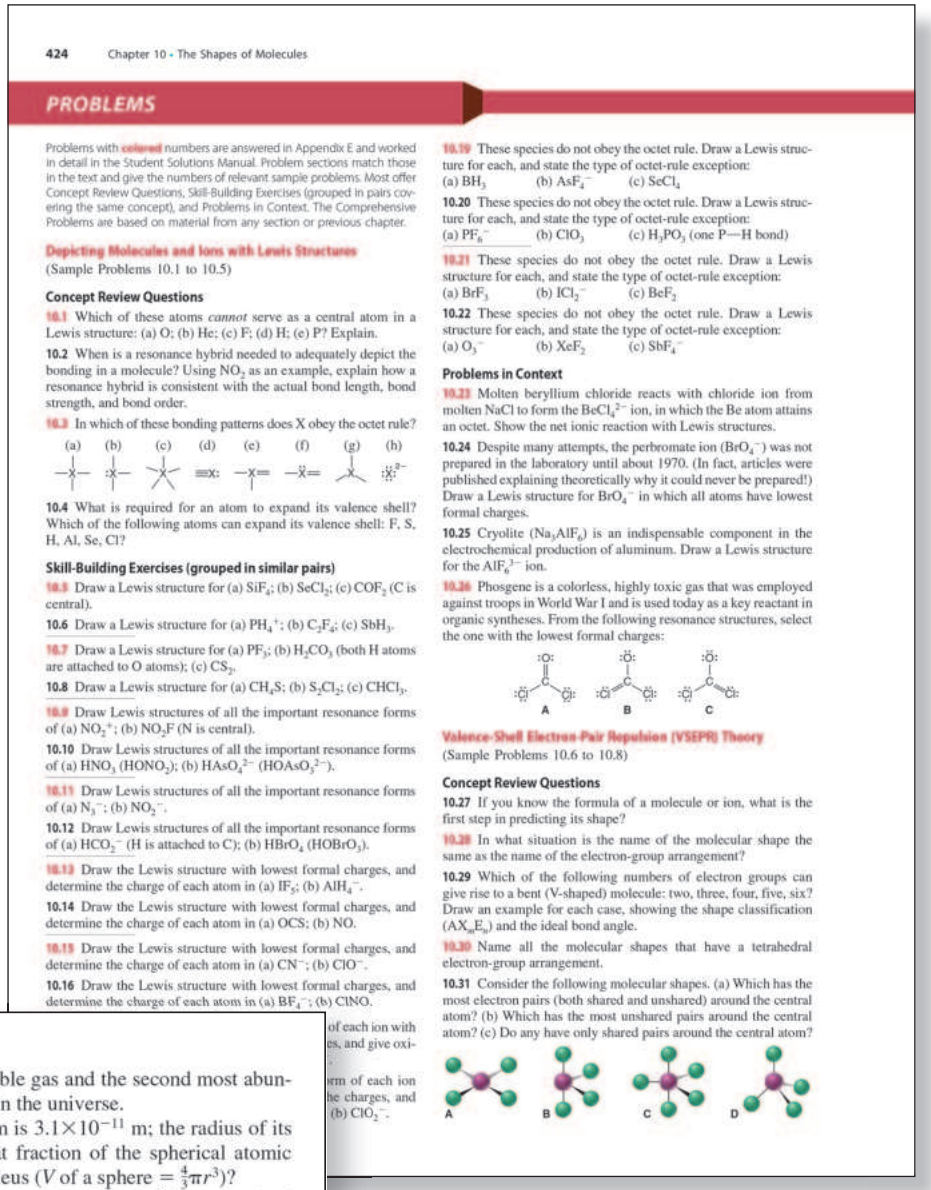
$$\text{Amount (mol) of } I_2 = 15.20 \text{ g } I_2 \times \frac{1 \text{ mol } I_2}{253.8 \text{ g } I_2} = 5.989\times10^{-2} \text{ mol } I_2$$

$$\text{Mass (kg) of } (CH_3CH_2)_2O = 1.33 \text{ mol } (CH_3CH_2)_2O \times \frac{74.12 \text{ g } (CH_3CH_2)_2O}{1 \text{ mol } (CH_3CH_2)_2O} \times \frac{1 \text{ kg}}{10^3 \text{ g}} = 9.86\times10^{-2} \text{ kg } (CH_3CH_2)_2O$$

$$\text{Molality } (m) = \frac{5.989\times10^{-2} \text{ mol}}{9.86\times10^{-2} \text{ kg}} = 0.607 \, m$$

Finally, an exceptionally large number of qualitative, quantitative, and molecular-scene problems end each chapter. Four types of problems are presented—three by chapter section, with comprehensive problems following:

- **Concept Review Questions** test qualitative understanding of key ideas.
- **Skill-Building Exercises** are grouped in similar pairs, with one of each pair answered in the back of the book. A group of similar exercises may begin with explicit steps and increase in difficulty, gradually weaning the student from the need for multistep directions.
- **Problems in Context** apply the skills learned in the skill-building exercises to interesting scenarios, including realistic examples dealing with industry, medicine, and the environment.
- **Comprehensive Problems,** mostly based on realistic applications, are more challenging and rely on material from any section of the current chapter or any previous chapter.



424 Chapter 10 • The Shapes of Molecules

PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Depicting Molecules and Ions with Lewis Structures
(Sample Problems 10.1 to 10.5)

Concept Review Questions

10.1 Which of these atoms *cannot* serve as a central atom in a Lewis structure: (a) O; (b) He; (c) F; (d) H; (e) P? Explain.

10.2 When is a resonance hybrid needed to adequately depict the bonding in a molecule? Using NO_2 as an example, explain how a resonance hybrid is consistent with the actual bond length, bond strength, and bond order.

10.3 In which of these bonding patterns does X obey the octet rule?

(a) (b) (c) (d) (e) (f) (g) (h)

10.4 What is required for an atom to expand its valence shell? Which of the following atoms can expand its valence shell: F, S, H, Al, Se, Cl?

Skill-Building Exercises (grouped in similar pairs)

10.5 Draw a Lewis structure for (a) SiF_4; (b) $SeCl_2$; (c) COF_2 (C is central).

10.6 Draw a Lewis structure for (a) PH_4^+; (b) C_2F_4; (c) SbH_3.

10.7 Draw a Lewis structure for (a) PF_3; (b) H_2CO_3 (both H atoms are attached to O atoms); (c) CS_2.

10.8 Draw a Lewis structure for (a) CH_4S; (b) S_2Cl_2; (c) $CHCl_3$.

10.9 Draw Lewis structures of all the important resonance forms of (a) NO_2^+; (b) NO_2F (N is central).

10.10 Draw Lewis structures of all the important resonance forms of (a) HNO_3 ($HONO_2$); (b) $HAsO_4^{2-}$ ($HOAsO_3^{2-}$).

10.11 Draw Lewis structures of all the important resonance forms of (a) N_3^-; (b) NO_2^-.

10.12 Draw Lewis structures of all the important resonance forms of (a) HCO_2^- (H is attached to C); (b) $HBrO_4$ ($HOBrO_3$).

10.13 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) IF_5; (b) AlH_4^-.

10.14 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) OCS; (b) NO.

10.15 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) CN^-; (b) ClO^-.

10.16 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) BF_4^-; (b) ClNO.

10.19 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) BH_3 (b) AsF_4^- (c) $SeCl_4$

10.20 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) PF_6^- (b) ClO_3 (c) H_3PO_3 (one P—H bond)

10.21 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) BrF_3 (b) ICl_2^- (c) BeF_2

10.22 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) O_3 (b) XeF_2 (c) SbF_4^-

Problems in Context

10.23 Molten beryllium chloride reacts with chloride ion from molten NaCl to form the $BeCl_4^{2-}$ ion, in which the Be atom attains an octet. Show the net ionic reaction with Lewis structures.

10.24 Despite many attempts, the perbromate ion (BrO_4^-) was not prepared in the laboratory until about 1970. (In fact, articles were published explaining theoretically why it could never be prepared!) Draw a Lewis structure for BrO_4^- in which all atoms have lowest formal charges.

10.25 Cryolite (Na_3AlF_6) is an indispensable component in the electrochemical production of aluminum. Draw a Lewis structure for the AlF_6^{3-} ion.

10.26 Phosgene is a colorless, highly toxic gas that was employed against troops in World War I and is used today as a key reactant in organic syntheses. From the following resonance structures, select the one with the lowest formal charges:

A B C

Valence-Shell Electron-Pair Repulsion (VSEPR) Theory
(Sample Problems 10.6 to 10.8)

Concept Review Questions

10.27 If you know the formula of a molecule or ion, what is the first step in predicting its shape?

10.28 In what situation is the name of the molecular shape the same as the name of the electron-group arrangement?

10.29 Which of the following numbers of electron groups can give rise to a bent (V-shaped) molecule: two, three, four, five, six? Draw an example for each case, showing the shape classification (AX_mE_n) and the ideal bond angle.

10.30 Name all the molecular shapes that have a tetrahedral electron-group arrangement.

10.31 Consider the following molecular shapes. (a) Which has the most electron pairs (both shared and unshared) around the central atom? (b) Which has the most unshared pairs around the central atom? (c) Do any have only shared pairs around the central atom?

A B C D

Comprehensive Problems

2.119 Helium is the lightest noble gas and the second most abundant element (after hydrogen) in the universe.
(a) The radius of a helium atom is 3.1×10^{-11} m; the radius of its nucleus is 2.5×10^{-15} m. What fraction of the spherical atomic volume is occupied by the nucleus (V of a sphere $=\frac{4}{3}\pi r^3$)?
(b) The mass of a helium-4 atom is 6.64648×10^{-24} g, and each of its two electrons has a mass of 9.10939×10^{-28} g. What fraction of this atom's mass is contributed by its nucleus?

2.120 From the following ions (with their radii in pm), choose the pair that forms the strongest ionic bond and the pair that forms the weakest:

Ion:	Mg^{2+}	K^+	Rb^+	Ba^{2+}	Cl^-	O^{2-}	I^-
Radius:	72	138	152	135	181	140	220

2.121 Give the molecular mass of each compound depicted below, and provide a correct name for any that are named incorrectly.

(a) boron fluoride (b) monosulfur dichloride
(c) phosphorus trichloride (d) dinitride pentoxide

OPTIMIZING THE TEXT

The modern chemistry student's learning experience is changing dramatically. To address the changes that students face, a modern text partnered with a suite of robust electronic tools must continue to evolve. With each edition, students and instructors alike have been involved in refining this text. From one-on-one interviews, focus groups, and symposia, as well as extensive chapter reviews and class tests of the previous edition, we learned that everyone praises the pioneering molecular art, the stepwise problem-solving approach, the abundant mix of qualitative, quantitative, and applied end-of-chapter problems, and the rigorous *and* student-friendly coverage of mainstream topics.

Global Changes to Every Chapter

Our revision for this edition has gone further than ever to optimize the text. We completed the distillation of the text and the annotation of the illustrations so appreciated in the previous edition, and created an inviting, easy-to-follow page design. But, when professors *and* students were asked what they wanted most in a new edition, the answer inevitably cited more good problems, so that became a major focus. We are delighted to introduce the seventh edition of *Chemistry: The Molecular Nature of Matter and Change,* which takes several major steps closer to perfecting its content and approach.

Learning ideas through focused writing and content presentation. Once again, every discussion has been revised to optimize clarity, readability, and the conciseness and directness of the presentation. The use of additional subheads, numbered (and titled) paragraphs, and bulleted (and titled) lists that was introduced in the sixth edition has been completed in the seventh.

Applying ideas with an enhanced problem-solving approach. The much admired—and copied—four-part problem-solving format (plan, solution, check, follow-up) is still used throughout, in both data-based *and* molecular-scene *Sample Problems*. But, many changes make the seventh edition a problem-solving "powerhouse." Each sample problem now includes ***two*** *Follow-up Problems:* as professors requested, the first closely matches the worked-out problem, so the student gains confidence, while the second varies a bit to test comprehension. As always, a thoroughly worked-out *Brief Solution* for each follow-up problem appears at the end of the chapter (rather than providing just a numerical answer in a distant end-of-book appendix, as is typical). As students requested, for more practice, each sample problem now lists *Some Similar Problems* within the end-of-chapter problem set. Moreover, some remaining pedagogic gaps have been filled with 22 *new* sample problems: thus, the seventh edition has over 250 sample problems and over 500 follow-up problems.

Re-learning ideas with annotated illustrations. The innovative three-level figures and other art that raised the bar for molecular visualization in chemistry textbooks is still present. Many existing figures have been revised and several new ones added to create an even better teaching tool. And, continuing the innovation of last edition, wherever appropriate, figure legends have been turned into simple captions and their content into clarifying annotations within the figures themselves.

Easier studying with attractive and functional page design and layout. A more open layout with three-dimensional accents engages students by focusing attention on section heads, sample problems, tables, and other important features, while maintaining clean margins. The orderly presentation fosters easier viewing and studying and allows the intimate placement of figures and tables in relation to the discussion.

Mastering the content with abundant end-of-chapter problem sets. With the more open design for improved readability, traditional and molecular-scene problems updated and revised, and many new problems added, these problem sets are more extensive than in most other texts. They provide students and teachers with abundant choices in a wide range of difficulty and real-life scenarios.

Content Changes to Individual Chapters

The major revision that created this seventh edition of *Chemistry* included key improvements to nearly every chapter:

- **Chapter 1** has been rearranged so that units are now discussed *before* the problem-solving approach and unit conversions are introduced. The chapter includes a *new sample problem* on converting units raised to a power.
- **Chapter 2** now clarifies the meaning of mass fraction and introduces IUPAC's new recommendations on atomic-mass ranges. It presents the periodic table updated with the latest atomic masses and includes a *new sample problem* on identifying an element from its Z value.
- **Chapter 3** includes more information in its road maps, and road maps in later chapters also have these enhancements. Sample problems on calculating mass percent of an element and the mass of an element have been carefully revised. The section on calculations for reactions in solution has been moved to Chapter 4.
- **Chapter 4** introduces many types of reactions in solution, so it was thoroughly revised to, more logically, include the

material on molarity and solution stoichiometry previously in Chapter 3. The table on solubility rules was revised, and a new table focuses on the reactions of strong versus weak acids in strong base. *Two new sample problems* show how to determine the amount of ions in solution and the amounts of reactants and products in a precipitation reaction. And two sample problems from the last edition were combined to show the logical relation of their material. Balancing redox reactions by the oxidation-number method was deleted, but balancing them by the half-reaction method is covered in the electrochemistry chapter (Chapter 21).

- **Chapter 5** includes *two new sample problems* that apply various combinations of the individual gas laws, and it provides a derivation of Graham's law.
- **Chapter 6** includes *a new sample problem* on calculating *PV* work.
- **Chapter 7** incorporates carefully revised atomic and continuous spectra throughout.
- **Chapter 8** contains a new table on changes in Z_{eff} within the sublevels of an atom.
- **Chapter 9** includes *a new sample problem* on predicting relative lattice energy and a revised figure on the properties of the covalent bond.
- **Chapter 10** has pedagogic improvements to several figures and expanded coverage in two sample problems.
- **Chapter 12** includes *two new sample problems,* one on the use of phase diagrams to predict phase changes and the other on determining the number of particles in a unit cell and the coordination number.
- **Chapter 13** presents *a new sample problem* on calculating an aqueous ionic heat of solution.
- **Chapter 14** incorporates in its unique Family Portraits all the updated atomic masses and newly synthesized elements that fill out the periodic table.
- **Chapter 16** includes revisions to two important figures and *two new sample problems,* one on rate laws and the molecularity of elementary steps and the other on intermediates and the correlation of rate laws and mechanism.
- **Chapter 17** contains *a new sample problem* on writing a reaction quotient from the balanced equation, and two important figures have been revised.
- **Chapter 18** has undergone major improvements. It has *two new sample problems,* one on calculating hydronium and hydroxide ion concentrations in strong acids and bases and the other on finding the percent dissociation of a weak acid. Several summarizing tables were revised to display reactions, and a key figure was revised. Also, the discussion was rearranged to present the material on acids in a clearer sequence.
- **Chapter 19** incorporates improvements to several key figures, as well as a new figure that summarizes the effects of added acid or base to buffer-component concentration and pH.
- **Chapter 20** has clearer discussions of measuring the change in entropy and of free energy and work, as well as *a new sample problem* on the relationship between ΔG° and K.
- **Chapter 21** includes *a new sample problem* on using $E^\circ_{\text{half-cell}}$ to find E°_{cell}, as well as much clearer discussions of the activity series of the metals, the electrolysis of aqueous salts, and the stoichiometry of electrolysis.
- **Chapter 23** has improvements to many figures as well as *a new sample problem* on finding the coordination number and ion charge in a coordination compound.
- **Chapter 24** provides *a new sample problem* on calculating the specific activity and decay constant of a radionuclide.

Innovative Topic and Chapter Presentation

While the topic sequence coincides with that used in most mainstream courses, built-in flexibility allows a wide range of differing course structures:

For courses that follow their own topic sequence, the general presentation, with its many section and subsection breaks and bulleted lists, allows topics to be rearranged, or even deleted, with minimal loss of continuity.

For courses that present several chapters, or topics within chapters, in different orders:

- Redox balancing by the oxidation-number method (formerly covered in Chapter 4) has been removed from the text, and the half-reaction method is covered with electrochemistry in Chapter 21, but it can easily be taught with Chapter 4.
- Gases (Chapter 5) can be covered in sequence to explore the mathematical modeling of physical behavior or, with no loss of continuity, just before liquids and solids (Chapter 12) to show the effects of intermolecular forces on the three states of matter.

For courses that want an atoms-first approach for some of the material, Chapters 7 through 13 move smoothly from quantum theory (7) through electron configuration (8), bonding models (9), molecular shape (10), VB and MO bonding theories (11), intermolecular forces in liquids and solids (12), and solutions (13). Immediate applications of these concepts appear in the discussions of periodic patterns in main-group chemistry (Chapter 14) and in the survey of organic chemistry (Chapter 15). Some instructors have also brought forward the coverage of transition elements and coordination compounds (23) as further applications of bonding concepts. (Of course, Chapters 14, 15, and 23 can just as easily remain in their more traditional placement later in the course.)

For courses that want biological/medical applications, many chapters highlight these topics, including the role of intermolecular forces in biomolecular structure (12), the

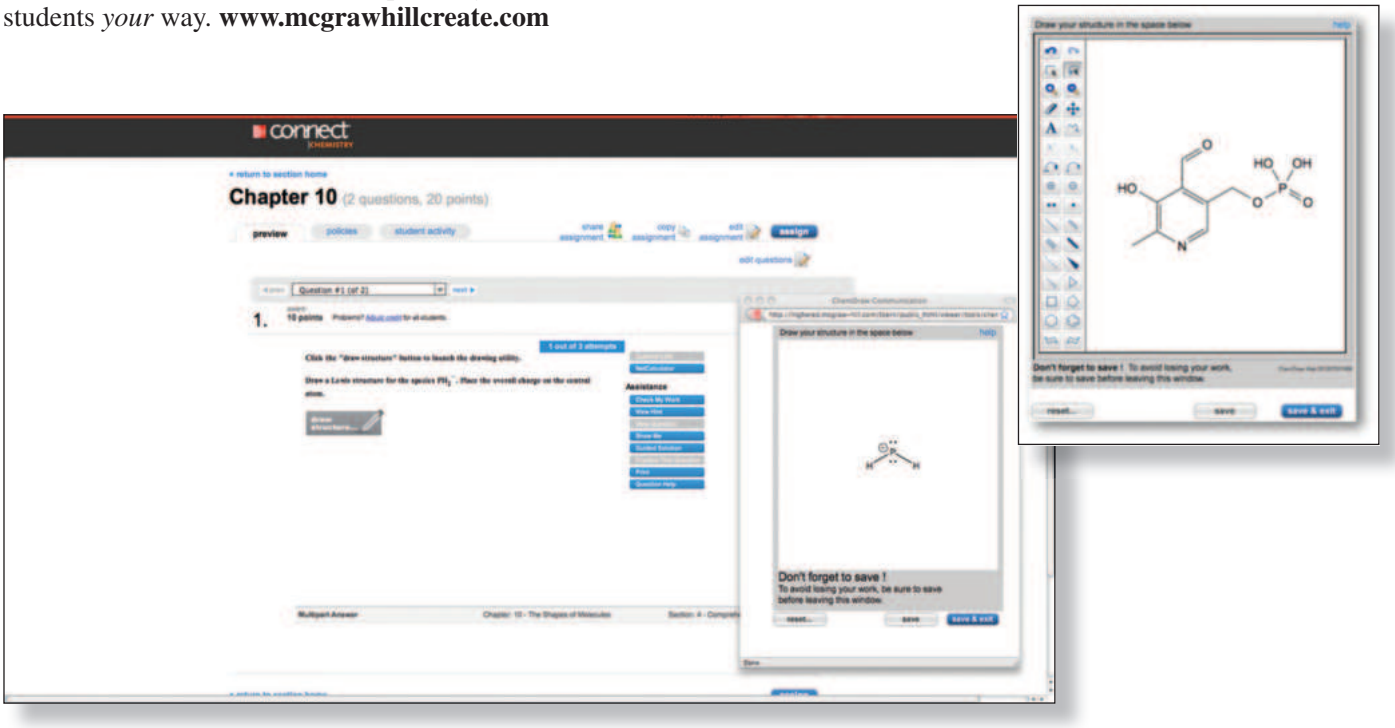
chemistry of polysaccharides, proteins, and nucleic acids (including protein synthesis, DNA replication, and DNA sequencing) (15), as well as introductions to enzyme catalysis (16), biochemical pathways (17), and trace elements in protein function (23).

For courses that want engineering applications of physical chemistry topics, Chapters 16 through 21 cover kinetics (16), equilibrium in gases (17), acids and bases (18), and aqueous ionic systems (19) and entropy and free energy (20) as they apply to electrochemical systems (21), all in preparation for coverage of the elements in geochemical cycles, metallurgy, and industry in Chapter 22.

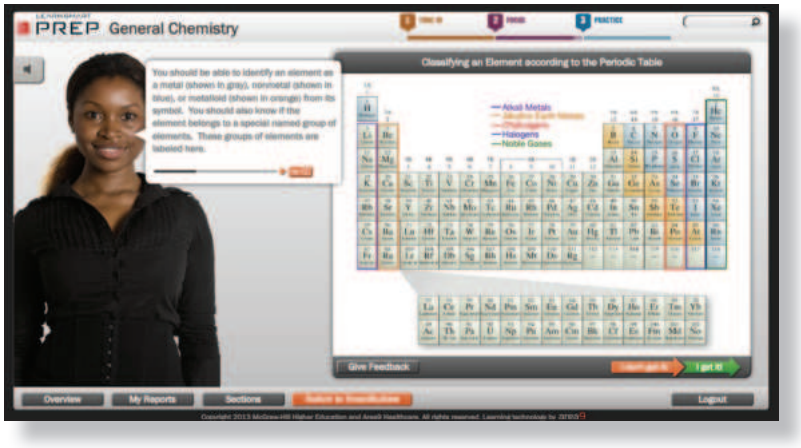
McGraw-Hill Create™ is another way to implement innovative chapter presentation. With Create, you can easily rearrange chapters, combine material from other content sources, and quickly upload content you have written, such as your course syllabus or teaching notes. Find the content you need in Create by searching through thousands of leading McGraw-Hill textbooks. Create even allows you to personalize your book's appearance by selecting the cover and adding your name, school, and course information. Order a Create book, and you'll receive a complimentary print review copy in 3–5 business days or a complimentary electronic review copy (eComp) via e-mail in minutes. Go to www.mcgrawhillcreate.com today and register to experience how McGraw-Hill Create empowers you to teach *your* students *your* way. **www.mcgrawhillcreate.com**

LEARNING RESOURCES

McGraw-Hill Connect® Chemistry provides online presentation, assignment, and assessment solutions. It connects your students with the tools and resources they'll need to achieve success. With Connect Chemistry, you can deliver assignments, quizzes, and tests online. A robust set of questions, problems, and interactive figures are presented and aligned with the textbook's learning goals. The integration of **ChemDraw by PerkinElmer,** the industry standard in chemical drawing software, allows students to create accurate chemical structures in their online homework assignments. As an instructor, you can edit existing questions and write entirely new problems. Track individual student performance—by question, assignment, or in relation to the class overall—with detailed grade reports. Integrate grade reports easily with Learning Management Systems (LMS), such as WebCT and Blackboard—and much more. **ConnectPlus Chemistry** provides students with all the advantages of Connect Chemistry, plus 24/7 online access to an eBook. This media-rich version of the book is available through the McGraw-Hill Connect platform and allows seamless integration of text, media, and assessments. To learn more, visit **www.mcgrawhillconnect.com.**



LEARNSMART PREP™



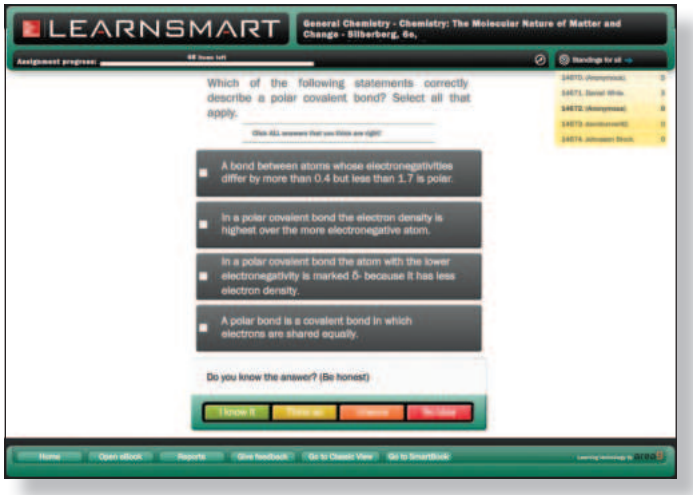
Fueled by LearnSmart—the most widely used and intelligent adaptive learning resource—**LearnSmart Prep** is designed to get students ready for a forthcoming course by quickly and effectively addressing prerequisite knowledge gaps that may cause problems down the road.

By distinguishing what students know from what they don't, and honing in on concepts they are most likely to forget, LearnSmart Prep maintains a continuously adapting learning path individualized for each student, and tailors content to focus on what the student needs to master in order to have a successful start in the new class.

This revolutionary technology is available only from McGraw-Hill Education and for hundreds of course areas, including general and organic chemistry, as part of the LearnSmart Advantage series.

LEARNSMART®

McGraw-Hill LearnSmart™ is available as a stand-alone product or as an integrated feature of McGraw-Hill Connect® Chemistry. It is an adaptive learning system designed to help students learn faster, study more efficiently, and retain more knowledge for greater success. LearnSmart assesses a student's knowledge of course content through a series of adaptive questions. It pinpoints concepts the student does not understand and maps out a personalized study plan for success. This innovative study tool also has features that allow instructors to see exactly what students have accomplished and a built-in assessment tool for graded assignments. Visit the following site for a demonstration: **www.mhlearnsmart.com.**



SMARTBOOK™

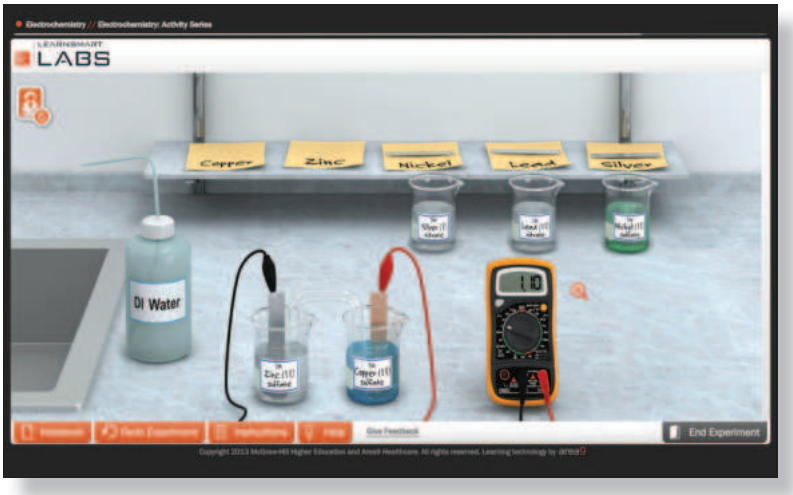
Powered by the intelligent and adaptive LearnSmart engine, **SmartBook** is the first and only continuously adaptive reading experience available. Distinguishing what students know from what they don't, and honing in on concepts they are most likely to forget, SmartBook personalizes content for each of them. Reading is no longer a passive and linear experience but an engaging and dynamic one, in which students are more likely to master and retain important concepts, coming to class better prepared.

SmartBook includes powerful reports that identify specific topics and learning objectives students need to study. These valuable reports also provide instructors with insight into how students are progressing through textbook content and are useful for identifying class trends, focusing precious class time, providing personalized feedback to students, and tailoring assessment.

How does SmartBook work? Each SmartBook contains four components: Preview, Read, Practice, and Recharge. Starting with a preview of each chapter and key learning objectives, students read the material and are guided to topics on which they need the most practice based on their responses to a continuously adapting diagnostic. Reading and practice continue until SmartBook directs students to review—or recharge—important material they are most likely to forget to ensure concept mastery and retention.

LEARNSMART LABS™

THE Virtual Lab Experience



Based on the same world-class, superbly adaptive technology as LearnSmart, **McGraw-Hill LearnSmart Labs** is a must-see, outcomes-based lab simulation. It assesses a student's knowledge and adaptively corrects deficiencies, allowing the student to learn faster and retain more knowledge with greater success.

First, a student's knowledge is adaptively leveled on core learning outcomes: Questioning reveals knowledge deficiencies that are corrected by the delivery of content that is conditional on a student's response. Then, a simulated lab experience requires the student to think and act like a scientist: Recording, interpreting, and analyzing data using simulated equipment found in labs and clinics. The student is allowed to make mistakes—a powerful part of the learning experience! A virtual coach provides subtle hints when needed, asks questions about the student's choices, and allows the student to reflect on and correct those mistakes. Whether your need is to overcome the logistical challenges of a traditional lab, provide better lab prep, improve student performance, or make your online experience one that rivals the real world, LearnSmart Labs accomplishes it all. Learn more at **www.mhlearnsmart.com.**

McGraw-Hill Tegrity® records and distributes your class lecture with just a click of a button. Students can view it anytime and anywhere via computer, iPod, or mobile device. Tegrity indexes as it records your PowerPoint® presentations and anything shown on your computer, so students can use key words to find exactly what they want to study. Tegrity is available as an integrated feature of McGraw-Hill Connect® Chemistry and as a stand-alone product.

Presentation Tools

Accessed from your textbook's Connect website, the presentation tools include McGraw-Hill–owned photos, artwork, animations, and other types of media that can be used to create customized lectures, visually enhanced tests and quizzes, compelling course websites, or attractive printed support materials for classroom purposes. The visual resources in this collection include the following:

- **Art** Full-color digital files of all illustrations in the book can be readily incorporated into lecture presentations, exams, or custom-made classroom materials. In addition, all files have been inserted into PowerPoint slides for ease of lecture preparation.
- **Photos** The photo collection contains digital files of photographs from the text, which can be reproduced for multiple classroom uses.
- **Tables** Every table that appears in the text has been saved in electronic form for use in classroom presentations and/or materials.
- **Animations** Numerous full-color animations illustrating important processes are also provided. Harness the visual impact of concepts in motion by importing these files into classroom presentations or online course materials.

PowerPoint materials can also be accessed through your textbook's Connect website:

- **PowerPoint Lecture Outlines** Ready-made presentations that combine art and lecture notes are provided for each chapter of the text.
- **PowerPoint Slides** For instructors who prefer to create their lectures from scratch, all illustrations, photos, sample problems, and tables have been inserted into blank PowerPoint slides, arranged by chapter.

Computerized Test Bank

Prepared by Walter Orchard, Professor Emeritus of Tacoma Community College, over 2300 test questions that accompany *Chemistry: The Molecular Nature of Matter and Change* are available utilizing Brownstone's *Diploma* testing software. *Diploma's* software allows you to quickly create a customized test using McGraw-Hill's supplied questions or by writing your own. *Diploma* allows you to create your tests without an Internet connection—just download the software and question files directly to your computer.

Instructor's Solutions Manual

This supplement, prepared by MaryKay Orgill of the University of Nevada, Las Vegas, contains complete, worked-out solutions for *all* the end-of-chapter problems in the text. It can be found within the Instructors' Resources, on the Connect website.

Cooperative Chemistry Laboratory Manual

Prepared by Melanie Cooper of Clemson University, this innovative manual features open-ended problems designed to simulate experience in a research lab. Working in groups, students investigate one problem over a period of several weeks, so they might complete three or four projects during the semester, rather than one preprogrammed experiment per class. The emphasis is on experimental design, analytic problem solving, and communication.

Student Study Guide

This valuable study guide, prepared by Libby Bent Weberg, is designed to help students recognize learning style; understand how to read, classify, and create a plan for solving a problem; and practice problem-solving skills. For each section of each chapter, the guide provides study objectives and a summary of the corresponding text. Following the summary are sample problems with detailed solutions. Each chapter has true-false questions and a self-test, with all answers provided at the end of the chapter.

Student Solutions Manual

This supplement, prepared by MaryKay Orgill of the University of Nevada, Las Vegas, contains detailed solutions and explanations for all problems in the main text that have colored numbers.

Animations for MP3/iPod

A number of animations are available for downloading to an MP3 player or iPod through the textbook's Connect website.

ACKNOWLEDGMENTS

Beginning with the 7th edition, I am delighted to welcome Professor Patricia Amateis of Virginia Tech, who shared equally all the responsibilities for creating the text. Patricia's experience teaching large classes in a research university is the perfect complement to my teaching small classes in a liberal-arts college. She is thorough in her understanding of chemistry, meticulous in her execution of the text, and, as her numerous teaching awards attest, insightful in her appreciation of student learning and devoted to their comprehension of chemistry. I am very fortunate to have her as my co-author.

It would be nearly impossible to put together a more professional, talented, supportive publishing team than my colleagues at McGraw-Hill Education: Managing Director Thomas Timp, Executive Editor David Spurgeon, Developmental Editor Lora Neyens, Project Manager Peggy Selle, Designer David Hash, Marketing Manager Tami Hodge, and Director of Digital Content Shirley Hino. I feel especially grateful that, over the years, we have also become friends.

MaryKay Orgill of the University of Nevada, Las Vegas, provided a thorough accuracy check of all the new sample problems and follow-up problems as part of her superb preparation of both the Student and Instructor's Solutions Manuals.

The seventh edition and its robust learning system are the culmination of numerous chapter reviews, insightful suggestions, brainstorming sessions, symposia, focus groups, interviews, and class tests. Therefore, our deepest gratitude is extended to the following individuals, who participated in preparation of the seventh edition and its associated learning system:

Jeff Allison, *Austin Community College*
Rebecca Barlag, *Ohio University*
David Bateman, *Henderson State University*
James Beil, *Lorain County Community College*
Stacy Benson, *Oklahoma State University at Stillwater*
Michael Brelle, *Sierra College*
Ron Briggs, *Arizona State University*
Gary Buckley, *Cameron University*
Tara Carpenter, *University of Maryland, Baltimore County*
William Case, *University of Richmond*
Paul Charlesworth, *Michigan Technological University*
Tabitha Chigwada, *West Virginia University*
Claire Cohen-Schmidt, *The University of Toledo*
Gregg Dieckman, *The University of Texas at Dallas*
Lambert Doezema, *Loyola Marymount University*
David Esjornson, *Southwestern Oklahoma State University*
Deborah Exton, *University of Oregon*
Brandon Fetterly, *University of Wisconsin–Richland*
Andrew Frazer, *University of Central Florida*
Kenneth Friedrich, *Portland Community College*
Simon Garrett, *California State University, Northridge*
John Gelder, *Oklahoma State University at Stillwater*
Alan Gengenbach, *University of Wisconsin–Eau Claire*
Eric Goll, *Brookdale Community College*
Donna Gosnell, *Valdosta State University*
Brian Gute, *University of Minnesota Duluth*
Nathan Hammer, *University of Mississippi*
Mandë Holford, *City University of New York, York College*
Jason Holland, *University of Central Missouri*
Burt Hollandsworth, *Harding University*
Byron Howell, *Tyler Junior College*
Lenore Hoyt, *University of Louisville*
Timothy Hughbanks, *Texas A&M University*
Tara Hurt, *East Mississippi Community College*
Jason Jadin, *Rochester Community and Technical College*
Jason Jones, *Francis Marion University*
Mary Elizabeth Kramer, *University of Delaware*
Gerald Korenowski, *Rensselaer Polytechnic Institute*
Mirela Krichten, *The College of New Jersey*
Stephen Lawrence, *Saginaw Valley State University*
Ronald Marks, *North Greenville University*
Reza Mohseni, *East Tennessee State University*
Patricia Muisener, *University of South Florida*
Edith Osborne, *Angelo State University*
Greg Oswald, *North Dakota State University*
Shadrick Paris, *Ohio University*
Manoj Patil, *Western Iowa Tech Community College*
Scott Pegan, *University of Denver*
Joanna Petridou-Fischer, *Spokane Falls Community College*
Jay Pike, *Providence College*
Dawn Rickey, *Colorado State University*
Linda Schultz, *Tarleton State University*
Jacob Schroeder, *Clemson University*
John Sibert, *The University of Texas at Dallas*
Heather Sklenicka, *Rochester Community and Technical College*
Joshua Telser, *Roosevelt University*
Michael Webb, *Central Piedmont Community College*
Lorelei Wood, *Chandler-Gilbert Community College*
Christine Yerkes, *University of Illinois at Urbana-Champaign*
Curtis Zaleski, *Shippensburg University*

The following individuals helped write and review learning goal-oriented content for **LearnSmart for General Chemistry:** Peter de Lijser, California State University–Fullerton; Adam I. Keller, Columbus State Community College; and Erin L. Whitteck.

Several expert freelancers contributed as well. Jane Hoover did her usual excellent job in copyediting the text, and Janelle Pregler and Judy Bantebein followed with meticulous proofreading. And many thanks to Jerry Marshall, who patiently researched new stock and studio photos, and to Charles Winters, who shot the new lab photos.

In this edition, perhaps more than in any other after the first, my wife Ruth's dedication and expertise shaped the quality of the text. She checked the style, revised the layout, and monitored changes in the pages, among countless other details—all while she kept smiling and supporting me.

Determining Significant Digits
Calculations and Rounding Off
Precision, Accuracy, and Instrument Calibration

Concepts and Skills to Review Before You Study This Chapter

- exponential (scientific) notation (Appendix A)

Maybe you're taking this course because chemistry is fundamental to understanding other natural sciences. Maybe it's required for your medical or engineering major. Or maybe you just want to learn more about the impact of chemistry on society or even on a personal, everyday level. For example, were you awakened today by your alarm clock? In chemical terms, the sound of the alarm was created when molecules aligned in the liquid-crystal display of your clock and electrons flowed to create a noise. You might have thrown off a thermal insulator of manufactured polymer (blanket) and jumped in the shower to emulsify fatty substances on your skin and hair with purified water and formulated detergents. Perhaps you next adorned yourself in an array of pleasant-smelling pigmented gels, dyed polymeric fibers, synthetic footwear, and metal-alloy jewelry. After a breakfast of nutrient-enriched, spoilage-retarded carbohydrates (cereal) in a white emulsion of fats, proteins, and monosaccharides (milk) and a cup of hot aqueous extract containing a stimulating alkaloid (coffee), you probably abraded your teeth with a colloidal dispersion of artificially flavored, dental-hardening agents (toothpaste), grabbed your portable electronic device containing ultrathin, microetched semiconductor layers powered by a series of voltaic cells (laptop), collected some objects made from processed cellulose and plastic, electronically printed with light- and oxygen-resistant inks (books), hopped in your hydrocarbon-fueled, metal-vinyl-ceramic vehicle, electrically ignited a synchronized series of controlled gaseous explosions (started your car), and took off for class!

But the true impact of chemistry extends much farther than the commercial products of daily life. The truth is that the most profound biological and environmental questions ultimately have chemical answers: How does an organism reproduce, grow, and age? What are the underlying explanations for health and disease? How can we sustain a planetary ecosystem in which plant, animal, and human populations thrive? Is there life on other worlds?

So, no matter what your reason for studying chemistry, you're going to learn some amazing ideas. And, this course comes with a bonus for developing two mental skills. The first, common to all science courses, is the ability to solve problems systematically. The second is specific to chemistry, for as you comprehend its ideas, you begin to view a hidden reality, one filled with incredibly minute particles moving at fantastic speeds, colliding billions of times a second, and interacting in ways that allow your brain to translate fluxes of electric charge into thoughts and that determine how all the matter inside and outside of you behaves. This chapter holds the keys to unlock and enter this new world.

IN THIS CHAPTER . . . *We discuss some central ideas about matter and energy, the process of science, units of measurement, and how scientists handle data.*

- We begin with fundamental concepts about matter and energy and their changes.
- A brief discussion of chemistry's origins, including some major missteps, leads to an overview of how scientists build models to study nature.
- We examine modern units for mass, length, volume, density, and temperature and apply systematic chemical problem solving to unit conversions.
- We see that data collection always includes some uncertainty and examine the distinction between accuracy and precision.

1.1 SOME FUNDAMENTAL DEFINITIONS

A good place to begin our exploration of chemistry is to define it and a few central concepts. **Chemistry** is *the study of matter and its properties, the changes that matter undergoes, and the energy associated with those changes.* **Matter** is the "stuff" of the universe: air, glass, planets, students—*anything that has mass and volume.* (In Section 1.4, we discuss the meanings of mass and volume in terms of how they are measured.) Chemists want to know the **composition** of matter, *the types and amounts of simpler substances that make it up.* A *substance* is a type of matter that has a defined, fixed composition.

The States of Matter

Matter occurs commonly in *three physical forms* called **states:** solid, liquid, and gas. On the macroscopic scale, each state of matter is defined by the way the sample fills a container (Figure 1.1, *flasks at top*):

- A **solid** has a fixed shape that does not conform to the container shape. Solids are *not* defined by rigidity or hardness: solid iron is rigid and hard, but solid lead is flexible, and solid wax is soft.
- A **liquid** has a varying shape that conforms to the container shape, but only to the extent of the liquid's volume; that is, a liquid has *an upper surface.*
- A **gas** also has a varying shape that conforms to the container shape, but it fills the entire container and, thus, does *not* have a surface.

On the atomic scale, each state is defined by the relative positions of its particles (Figure 1.1, *circles at bottom*):

- In a *solid,* the particles lie next to each other in a regular, three-dimensional *array.*
- In a *liquid,* the particles also lie close together but move randomly around each other.
- In a *gas,* the particles have large distances between them and move randomly throughout the container.

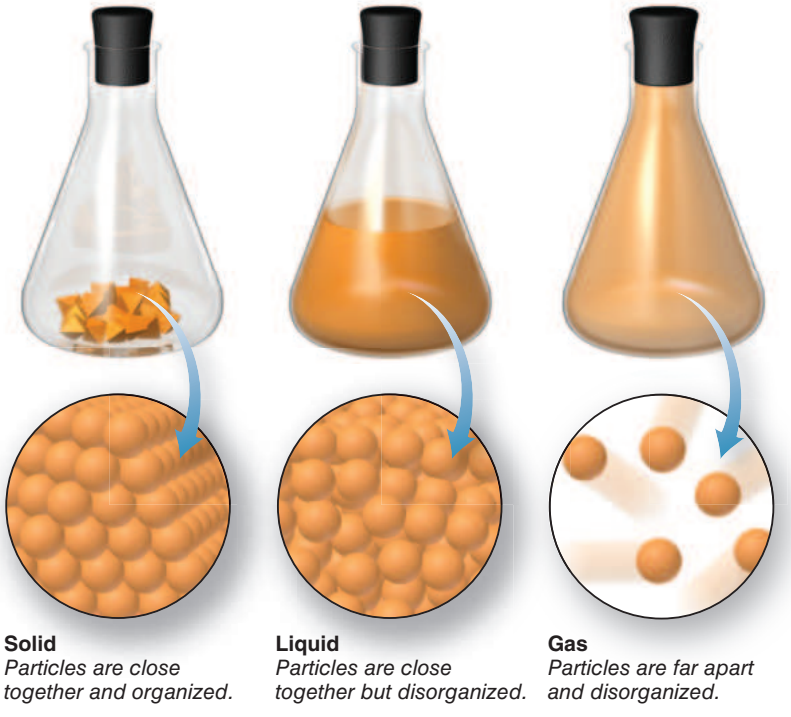

Figure 1.1 The physical states of matter.

The Properties of Matter and Its Changes

We learn about matter by observing its **properties,** *the characteristics that give each substance its unique identity.* To identify a person, we might observe height, weight, hair and eye color, fingerprints, and, now, even DNA pattern, until we arrive at a unique identification. To identify a substance, we observe two types of properties, physical and chemical, which are closely related to two types of change that matter undergoes.

Physical Change: No Change in Composition

Physical properties are characteristics a substance shows *by itself, without changing into or interacting with another substance*. These properties include melting point, electrical conductivity, and density. A **physical change** occurs when a substance *alters its physical properties,* ***not*** *its composition*. For example, when ice melts, several physical properties change, such as hardness, density, and ability to flow. But the composition of the sample does *not* change: it is still water. The photograph in Figure 1.2A shows what this change looks like in everyday life. The "blow-up" circles depict a magnified view of the particles making up the sample. In the icicle, the particles lie in the repeating pattern characteristic of a solid, whereas they are jumbled in the liquid droplet, but *the particles are the same* in both states of water.

Physical change (same substance before and after):

$$\text{Water (solid state)} \longrightarrow \text{water (liquid state)}$$

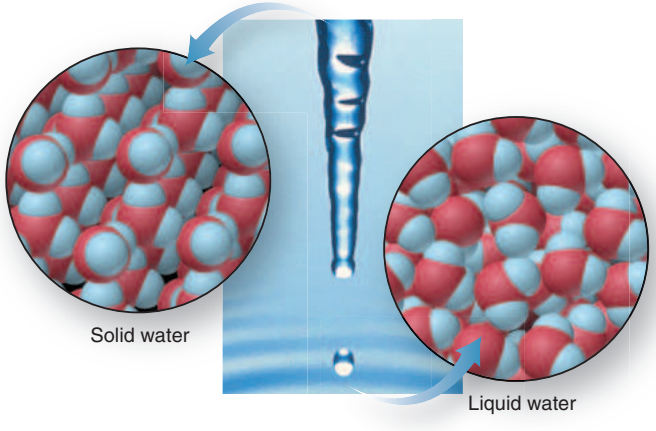
Chemical Change: A Change in Composition

Chemical properties are characteristics a substance shows *as it changes into or interacts with another substance (or substances)*. Chemical properties include flammability, corrosiveness, and reactivity with acids. A **chemical change,** also called a **chemical reaction,** occurs when *a substance (or substances) is converted into a different substance (or substances)*. Figure 1.2B shows the chemical change (reaction) that occurs when you pass an electric current through water: the water decomposes (breaks down) into two other substances, hydrogen and oxygen, that bubble into the tubes. The composition *has* changed: the final sample is no longer water.

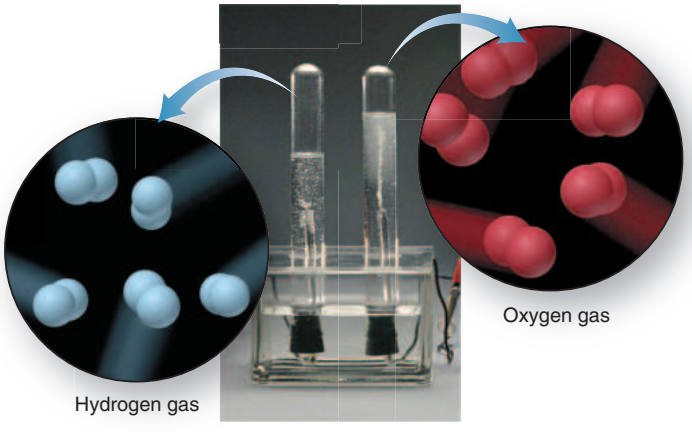
Chemical change (different substances before and after):

$$\text{Water} \xrightarrow{\text{electric current}} \text{hydrogen} + \text{oxygen}$$

Let's work through a sample problem that uses atomic-scale scenes to distinguish between physical and chemical change.



A Physical change:
Solid state of water becomes liquid state. Particles before and after remain the same, which means composition did ***not*** *change.*

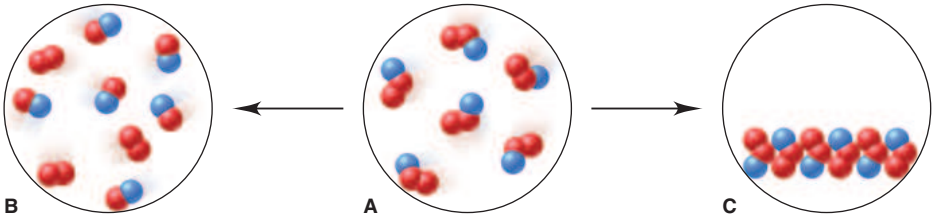


B Chemical change:
Electric current decomposes water into different substances (hydrogen and oxygen). Particles before and after are different, which means composition ***did*** *change.*

Figure 1.2 **The distinction between physical and chemical change.**

SAMPLE PROBLEM 1.1 Visualizing Change on the Atomic Scale

Problem The scenes below represent an atomic-scale view of a sample of matter, A, undergoing two different changes, left to B and right to C:



Decide whether each depiction shows a physical or a chemical change.

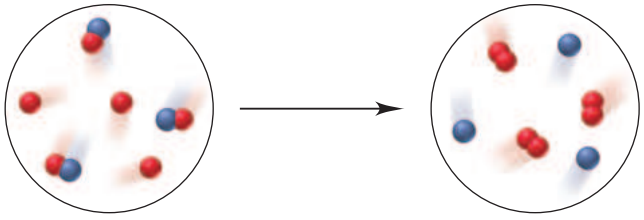
Plan Given depictions of the changes, we have to determine whether each represents a physical or a chemical change. The number and colors of the little spheres that make up each particle tell its "composition." Samples with particles of the *same* composition but in a different arrangement depict a *physical* change, whereas samples with particles of a *different* composition depict a *chemical* change.

Solution In A, each particle consists of one blue and two red spheres. The particles in A change into two types in B, one made of red and blue spheres and the other made of two red spheres; therefore, they have undergone a chemical change to form different particles. The particles in C are the same as those in A, but they are closer together and arranged in a different state of matter; therefore, they have undergone a physical change.

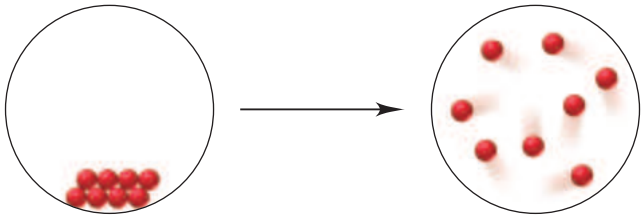
FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

1.1A Is the following change chemical or physical?



1.1B Is the following change chemical or physical?



A SIMILAR PROBLEM 1.1

Like water, hydrogen, oxygen, or any other real substance, copper is also identified by *its own set* of physical and chemical properties (Table 1.1).

Temperature and Changes in Matter Depending on the temperature and pressure of the surroundings, many substances can exist in each of the three physical states and undergo changes in state as well. For example, as the temperature increases, solid water melts to liquid water, which boils to gaseous water (also called *water vapor*). Similarly, as the temperature drops, water vapor condenses to liquid water, and with further cooling, the liquid freezes to ice. In a steel plant, solid iron melts to liquid

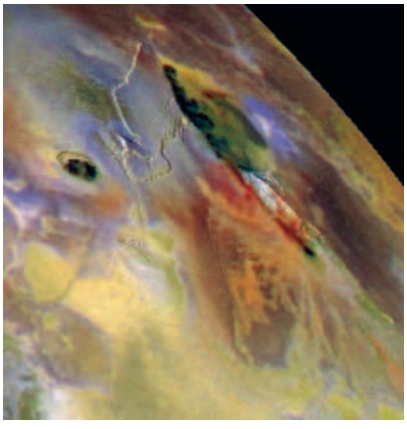
Table 1.1 Some Characteristic Properties of Copper

Physical Properties		Chemical Properties	
Easily shaped into sheets (malleable) and wires (ductile)		Slowly forms a blue-green carbonate in moist air	
Can be melted and mixed with zinc to form brass		Reacts with nitric or sulfuric acid	
Density = 8.95 g/cm^3 Melting point = 1083°C Boiling point = 2570°C		Slowly forms deep-blue solution in aqueous ammonia	

(molten) iron and then cools to the solid again. And, far beyond the confines of a laboratory or steel plant, lakes of molten sulfur lie on Jupiter's moon Io *(see photo),* which is capped by poles of frozen hydrogen sulfide, a gas on Earth.

The main point is that *a physical change caused by heating can generally be reversed by cooling*. This is *not* generally true for a chemical change. For example, heating iron in moist air causes a chemical reaction that yields the brown, crumbly substance known as rust. Cooling does not reverse this change; rather, another chemical change (or series of them) is required.

The following sample problem provides practice in distinguishing some familiar examples of physical and chemical change.



Many common substances occur in unusual states on other worlds.

SAMPLE PROBLEM 1.2 Distinguishing Between Physical and Chemical Change

Problem Decide whether each of the following processes is primarily a physical or a chemical change, and explain briefly:
(a) Frost forms as the temperature drops on a humid winter night.
(b) A cornstalk grows from a seed that is watered and fertilized.
(c) A match ignites to form ash and a mixture of gases.
(d) Perspiration evaporates when you relax after jogging.
(e) A silver fork tarnishes slowly in air.

Plan The basic question we ask to decide whether a change is chemical or physical is, "Does the substance change composition or just change form?"

Solution **(a)** Frost forming is a physical change: the drop in temperature changes water vapor (gaseous water) in humid air to ice crystals (solid water).
(b) A seed growing involves chemical change: the seed uses water, substances from air, fertilizer, and soil, and energy from sunlight to make complex changes in composition.
(c) The match burning is a chemical change: the combustible substances in the match head are converted into other substances.
(d) Perspiration evaporating is a physical change: the water in sweat changes its state, from liquid to gas, but not its composition.
(e) Tarnishing is a chemical change: silver changes to silver sulfide by reacting with sulfur-containing substances in the air.

FOLLOW-UP PROBLEMS

1.2A Decide whether each of the following processes is primarily a physical or a chemical change, and explain briefly:

(a) Purple iodine vapor appears when solid iodine is warmed.

(b) Gasoline fumes are ignited by a spark in an automobile engine's cylinder.

(c) A scab forms over an open cut.

1.2B Decide whether each of the following processes is primarily a physical or a chemical change, and explain briefly:

(a) Clouds form in the sky.

(b) Old milk turns sour.

(c) Butter is melted to use on popcorn.

Methane and oxygen form carbon dioxide and water in the flame of a lab burner. (Carbon is black, oxygen red, and hydrogen blue.)

The Central Theme in Chemistry

Understanding the properties of a substance and the changes it undergoes leads to the central theme in chemistry: *macroscopic-scale* properties and behavior, those we can see, are the results of *atomic-scale* properties and behavior that we cannot see. The distinction between chemical and physical change is defined by composition, which we study macroscopically. But composition ultimately depends on the makeup of substances at the atomic scale. Similarly, macroscopic properties of substances in any of the three states arise from atomic-scale behavior of their particles. Picturing a chemical event on the molecular scale, even one as common as the flame of a laboratory burner *(see margin),* helps clarify what is taking place. What is happening when water boils or copper melts? What events occur in the invisible world of minute particles that cause a seed to grow, a neon light to glow, or a nail to rust? Throughout the text, we return to this central idea:

*We study **observable** changes in matter to understand their **unobservable** causes.*

The Importance of Energy in the Study of Matter

Physical and chemical changes are accompanied by energy changes. **Energy** is often defined as *the ability to do work.* Essentially, all work involves moving something. Work is done when your arm lifts a book, when a car's engine moves the wheels, or when a falling rock moves the ground as it lands. The object doing the work (arm, engine, rock) transfers some of the energy it possesses to the object on which the work is done (book, wheels, ground).

The total energy an object possesses is the sum of its potential energy and its kinetic energy.

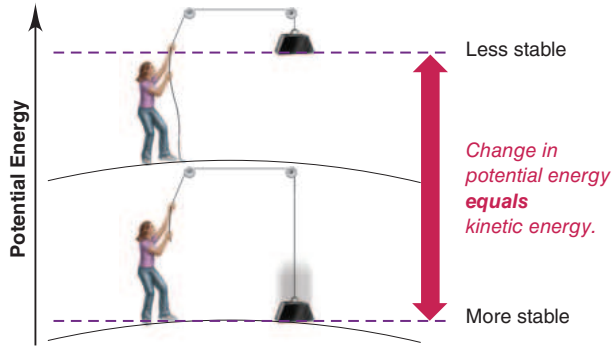
- **Potential energy** is *the energy due to the **position** of the object relative to other objects.*
- **Kinetic energy** is *the energy due to the **motion** of the object.*

Let's examine four systems that illustrate the relationship between these two forms of energy: a weight raised above the ground, two balls attached by a spring, two electrically charged particles, and a fuel and its waste products. Two concepts central to all these cases are

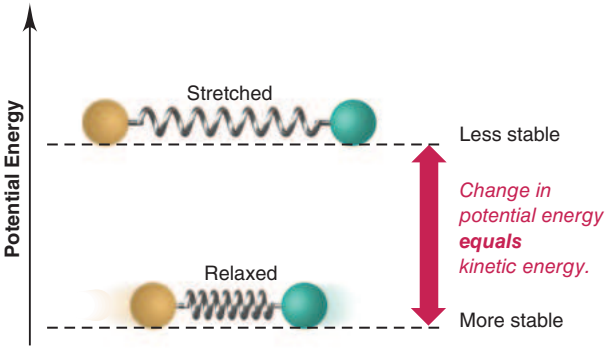
1. *When energy is converted from one form to the other, it is conserved, not destroyed.*
2. *Situations of lower energy (more stable) are favored over situations of higher energy (less stable).*

The four cases are

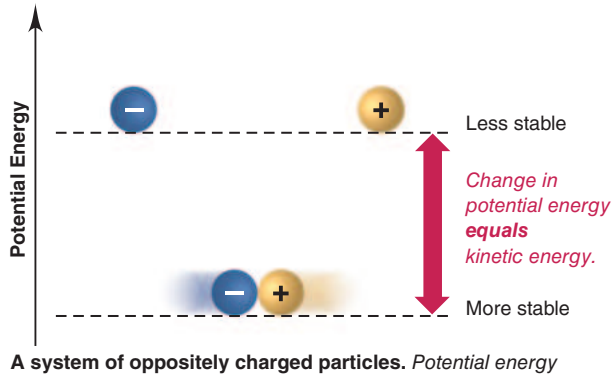
- *A weight raised above the ground* (Figure 1.3A). The energy you exert to lift a weight against gravity increases the weight's potential energy (energy due to its position). When you drop the weight, that additional potential energy is converted to kinetic energy (energy due to motion). The situation with the weight elevated and higher in potential energy is *less stable,* so the weight will fall when released, resulting in a situation that is lower in potential energy and *more stable.*
- *Two balls attached by a spring* (Figure 1.3B). When you pull the balls apart, the energy you exert to stretch the relaxed spring increases the system's potential energy. This change in potential energy is converted to kinetic energy when you release the balls. The system of balls and spring is less stable (has more potential energy) when the spring is stretched than when it is relaxed.
- *Two electrically charged particles* (Figure 1.3C). Due to interactions known as *electrostatic forces, opposite charges attract each other, and like charges repel each other.* When energy is exerted to move a positive particle away from a negative one, the potential energy of the system increases, and that increase is converted to kinetic energy when the particles are pulled together by the electrostatic attraction. Similarly, when energy is used to move two positive (or two negative) particles together, their potential energy increases and changes to kinetic energy when they are pushed apart by the electrostatic repulsion. Charged particles move naturally to a more stable situation (lower energy).
- *A fuel and its waste products* (Figure 1.3D). Matter is composed of positively and negatively charged particles. *The chemical potential energy of a substance results*



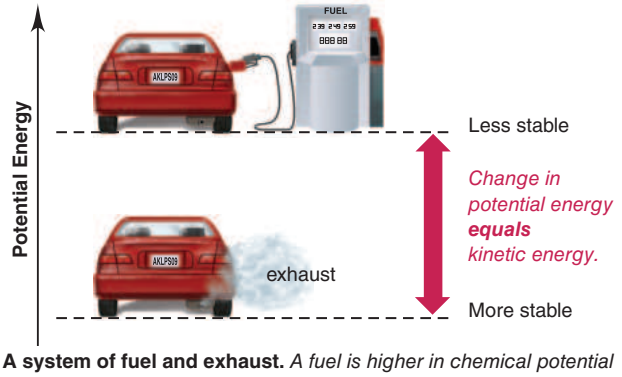
A A gravitational system. *Potential energy is gained when a weight is lifted. It is converted to kinetic energy as the weight falls.*



B A system of two balls attached by a spring. *Potential energy is gained when the spring is stretched. It is converted to the kinetic energy of the moving balls as the spring relaxes.*



C A system of oppositely charged particles. *Potential energy is gained when the charges are separated. It is converted to kinetic energy as the attraction pulls the charges together.*



D A system of fuel and exhaust. *A fuel is higher in chemical potential energy than the exhaust. As the fuel burns, some of its potential energy is converted to the kinetic energy of the moving car.*

Figure 1.3 Potential energy is converted to kinetic energy. The dashed horizontal lines indicate the potential energy of each system before and after the change.

from the relative positions of and the attractions and repulsions among its particles. Some substances are higher in potential energy than others. For example, gasoline and oxygen have more chemical potential energy than the exhaust gases they form. This difference is converted into kinetic energy, which moves the car, heats the interior, makes the lights shine, and so on. Similarly, the difference in potential energy between the food and air we take in and the wastes we excrete enables us to move, grow, keep warm, study chemistry, and so on.

Summary of Section 1.1

- Chemists study the composition and properties of matter and how they change.
- Matter exists in three physical states—solid, liquid, and gas. The behavior of each state is due to the arrangement of the particles.
- Each substance has a unique set of *physical* properties (attributes of the substance itself) and *chemical* properties (attributes of the substance as it interacts with or changes to other substances). Changes in matter can be *physical* (different form of the same substance) or *chemical* (different substance).
- A physical change caused by heating may be reversed by cooling. But a chemical change caused by heating can be reversed only by other chemical changes.
- Macroscopic changes result from submicroscopic changes.
- Changes in matter are accompanied by changes in energy.
- An object's potential energy is due to its position; an object's kinetic energy is due to its motion. Energy used to lift a weight, stretch a spring, or separate opposite charges increases the system's potential energy, which is converted to kinetic energy as the system returns to its original condition. Energy changes form but is conserved.
- Chemical potential energy arises from the positions and interactions of a substance's particles. When a higher energy (less stable) substance is converted into a more stable (lower energy) substance, some potential energy is converted into kinetic energy.

1.2 CHEMICAL ARTS AND THE ORIGINS OF MODERN CHEMISTRY

This brief overview of early breakthroughs, and a few false directions, describes how the modern science of chemistry arose and progressed.

Figure 1.4 Alchemical apparatus.

Prechemical Traditions

Chemistry had its origin in a prescientific past that incorporated three overlapping traditions—alchemy, medicine, and technology:

1. *The alchemical tradition. Alchemy* was an occult study of nature that began in the 1st century AD and dominated thinking for over 1500 years. Originally influenced by the Greek idea that matter strives for "perfection," alchemists later became obsessed with converting "baser" metals, such as lead, into "purer" ones, such as gold. The alchemists' names for substances and their belief that matter could be altered magically were very difficult to correct over the centuries. Their legacy to chemistry was in technical methods. They invented distillation, percolation, and extraction and devised apparatus still used routinely today (Figure 1.4). But perhaps even more important was that alchemists encouraged observation and experimentation, which replaced the Greek approach of explaining nature solely through reason.

2. *The medical tradition.* Alchemists also influenced medical practice in medieval Europe. And ever since the 13th century, distillates and extracts of roots, herbs, and other plant matter have been used as sources of medicines. The alchemist and physician Paracelsus (1493–1541) considered the body to be a chemical system and illness an imbalance that could be restored by treatment with drugs. Although many early prescriptions were useless, later ones had increasing success. Thus began the alliance between medicine and chemistry that thrives today.

3. *The technological tradition.* For thousands of years, pottery making, dyeing, and especially metallurgy contributed greatly to people's experience with materials. During the Middle Ages and the Renaissance, books were published that described how to purify, assay, and coin silver and gold, how to use balances, furnaces, and crucibles, and how to make glass and gunpowder. Some introduced quantitative measurement, which was lacking in alchemical writings. Many creations from those times are still marveled at throughout the world. Nevertheless, the skilled artisans showed little interest in *why* a substance changes or *how to predict* its behavior.

The Phlogiston Fiasco and the Impact of Lavoisier

Chemical investigation in the modern sense—inquiry into the causes of changes in matter—began in the late 17th century. At that time, most scientists explained **combustion,** the process of burning, with the *phlogiston theory*. It proposed that combustible materials contain *phlogiston,* an undetectable substance released when the material burns. Highly combustible materials like charcoal were thought to contain a lot of phlogiston, and slightly combustible materials like metals only a little. But inconsistencies continuously arose.

> **Phlogiston critics:** Why is air needed for combustion, and why does charcoal stop burning in a closed vessel?
> **Phlogiston supporters:** Air "attracts" phlogiston out of the charcoal, and burning stops when the air in the vessel is "saturated" with phlogiston.

Critics also noted that when a metal burns, it forms its *calx,* which weighs more than the metal, leading them to ask,

> **Critics:** How can the *loss* of phlogiston cause a *gain* in mass?
> **Supporters:** Phlogiston has negative mass.

As ridiculous as these responses seem now, it's important to remember that, even today, scientists may dismiss conflicting evidence rather than abandon an accepted idea.

The conflict over phlogiston was resolved when the young French chemist Antoine Lavoisier (1743–1794) performed several experiments:

1. Heating mercury calx decomposed it into two products—mercury and a gas—whose *total mass equaled the starting mass of the calx.*
2. Heating mercury with the gas reformed the calx, and, again, *the total mass remained constant.*
3. Heating mercury in a measured volume of air yielded mercury calx and left four-fifths of the air remaining.
4. A burning candle placed in the remaining air was extinguished.

Lavoisier named the gas *oxygen* and gave metal calxes the name *metal oxides.* His explanation of his results made the phlogiston theory irrelevant:

- Oxygen, a normal component of air, combines with a substance when it burns.
- In a closed container, a combustible substance stops burning when it has combined with all the available oxygen.
- A metal calx (metal oxide) weighs more than the metal because its mass includes the mass of the oxygen.

This new theory triumphed because it relied on *quantitative, reproducible measurements,* not on strange properties of undetectable substances. Because this approach is at the heart of science, many propose that the *science* of chemistry began with Lavoisier.

Summary of Section 1.2

- Alchemy, medicine, and technology placed little emphasis on objective experimentation, focusing instead on mystical explanations or practical experience, but these traditions contributed some apparatus and methods that are still important.
- Lavoisier overthrew the phlogiston theory by showing quantitatively that oxygen, a component of air, is required for combustion and combines with a burning substance.

1.3 THE SCIENTIFIC APPROACH: DEVELOPING A MODEL

Our prehistoric ancestors survived through *trial and error,* gradually learning which types of stone were hard enough to shape others, which plants were edible and which poisonous, and so forth. Unlike them, we employ the *quantitative theories* of chemistry to understand materials, make better use of them, and create new ones: specialized drugs, advanced composites, synthetic polymers, and countless others (Figure 1.5).

To understand nature, scientists use an approach called the **scientific method.** It is not a stepwise checklist, but rather a process involving creative propositions and tests aimed at objective, verifiable discoveries. There is no single procedure, and luck often plays a key role in discovery. In general terms, the scientific approach includes the following parts (Figure 1.6):

- ***Observations.*** These are the facts our ideas must explain. The most useful observations are quantitative because they can be analyzed to reveal *trends*. Pieces of quantitative information are **data.** When the same observation is made by many investigators in many situations with no clear exceptions, it is summarized, often in mathematical terms, as a **natural law.** The observation that mass remains constant during chemical change—made by Lavoisier and numerous experimenters since—is known as the law of mass conservation (Chapter 2).
- ***Hypothesis.*** Whether derived from observation or from a "spark of intuition," a hypothesis is a proposal made to explain an observation. A sound hypothesis need not be correct, but it must be *testable by experiment.* Indeed, a hypothesis is often the reason for performing an experiment: if the results do not support it, the hypothesis must be revised or discarded. *Hypotheses can be altered, but experimental results cannot*.
- ***Experiment.*** A set of procedural steps that tests a hypothesis, an experiment often leads to a revised hypothesis and new experiments to test it. An experiment typically contains at least two **variables,** quantities that can have more than one value. A well-designed experiment is **controlled** in that it measures the effect of one variable on another while keeping all other variables constant. Experimental results must be *reproducible* by others. Both skill and creativity play a part in experimental design.
- ***Model.*** Formulating conceptual models, or **theories,** based on *experiments* that test *hypotheses* about *observations* distinguishes scientific thinking from speculation. As hypotheses are revised according to experimental results, a model emerges to explain how the phenomenon occurs. A model is a *simplified,* not an exact, representation of some aspect of nature that we use to *predict* related phenomena. Ongoing experimentation refines the model to account for new facts.

Lavoisier's overthrow of the phlogiston theory demonstrates the scientific method of thinking. *Observations* of burning and smelting led to the *hypothesis* that combustion involved the loss of phlogiston. *Experiments* showing that air is required for

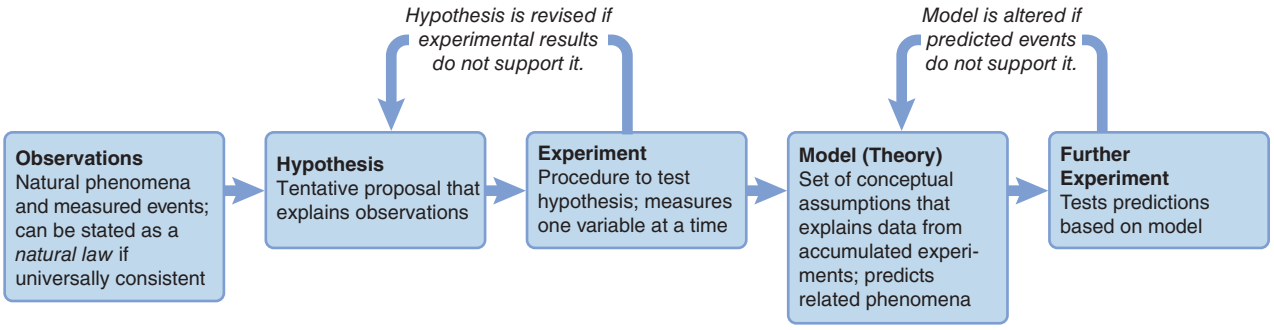

Figure 1.6 The scientific approach to understanding nature. Hypotheses and models are mental pictures that are revised to match observations and experimental results, *not* the other way around.

burning and that a metal gains mass during combustion led Lavoisier to propose a new *hypothesis,* which he tested repeatedly with quantitative *experiments.* Accumulating evidence supported his developing *model (theory)* that combustion involves combination with a component of air (oxygen). Innumerable *predictions* based on this theory have supported its validity, and Lavoisier himself extended the theory to account for animal respiration and metabolism.

Summary of Section 1.3

- The scientific method is a process designed to explain and predict phenomena.
- Observations lead to hypotheses about how or why a phenomenon occurs. When repeated with no exceptions, observations may be expressed as a natural law.
- Hypotheses are tested by controlled experiments and revised when necessary.
- If reproducible data support a hypothesis, a model (theory) can be developed to explain the observed phenomenon. A good model predicts related phenomena but must be refined whenever conflicting data appear.

1.4 MEASUREMENT AND CHEMICAL PROBLEM SOLVING

Measurement has a rich history characterized by the search for *exact, invariable standards.* Measuring for purposes of trade, building, and surveying began thousands of years ago, but for most of that time, it was based on standards that could vary: a yard was the distance from the king's nose to the tip of his outstretched arm, and an acre was the area tilled in one day by a man with a pair of oxen. Our current system of measurement began in 1790 in France, when a committee, of which Lavoisier was a member, developed the *metric system.* Then, in 1960, another committee in France revised the metric system and established the universally accepted **SI units** (from the French **S**ystème **I**nternational d'Unités).

General Features of SI Units

The SI system is based on seven **fundamental units,** or **base units,** each identified with a physical quantity (Table 1.2). All other units are **derived units,** combinations

Table 1.2 SI Base Units

Physical Quantity (Dimension)	Unit Name	Unit Abbreviation
Mass	kilogram	kg
Length	meter	m
Time	second	s
Temperature	kelvin	K
Electric current	ampere	A
Amount of substance	mole	mol
Luminous intensity	candela	cd

Table 1.3 Common Decimal Prefixes Used with SI Units

Prefix*	Prefix Symbol	Word	Conventional Notation	Exponential Notation
tera	T	trillion	1,000,000,000,000	1×10^{12}
giga	G	billion	1,000,000,000	1×10^{9}
mega	M	million	1,000,000	1×10^{6}
kilo	k	thousand	1000	1×10^{3}
hecto	h	hundred	100	1×10^{2}
deka	da	ten	10	1×10^{1}
—	—	one	1	1×10^{0}
deci	d	tenth	0.1	1×10^{-1}
centi	c	hundredth	0.01	1×10^{-2}
milli	m	thousandth	0.001	1×10^{-3}
micro	μ	millionth	0.000001	1×10^{-6}
nano	n	billionth	0.000000001	1×10^{-9}
pico	p	trillionth	0.000000000001	1×10^{-12}
femto	f	quadrillionth	0.000000000000001	1×10^{-15}

*The prefixes most frequently used by chemists appear in bold type.

of the seven base units. For example, the derived unit for speed, meters per second (m/s), is the base unit for length (m) divided by the base unit for time (s). For quantities much smaller or larger than the base unit, we use decimal prefixes and exponential (scientific) notation (Table 1.3). (If you need a review of exponential notation, see Appendix A.) Because the prefixes are based on powers of 10, SI units are easier to use in calculations than English units.

Some Important SI Units in Chemistry

In this chapter, we discuss units for length, volume, mass, time, density, and temperature; other units are presented in later chapters. Table 1.4 shows some SI quantities for length, volume, and mass, along with their English-system equivalents.

Length The SI base unit of length is the **meter (m).** In the metric system, it was originally defined as 1/10,000,000 of the distance from the equator to the North Pole, and later as the distance between two fine lines engraved on a corrosion-resistant metal bar. More recently, the first exact, unchanging standard was adopted:

Table 1.4 Common SI-English Equivalent Quantities

Quantity	SI	SI Equivalents	English Equivalents	English to SI Equivalent
Length	1 kilometer (km)	1000 (10^3) meters	0.6214 mile (mi)	1 mile = 1.609 km
	1 meter (m)	100 (10^2) centimeters	1.094 yards (yd)	1 yard = 0.9144 m
		1000 millimeters (mm)	39.37 inches (in)	1 foot (ft) = 0.3048 m
	1 centimeter (cm)	0.10 (10^{-2}) meter	0.3937 inch	1 inch = 2.54 cm (exactly)
Volume	1 cubic meter (m^3)	1,000,000 (10^6) cubic centimeters	35.31 cubic feet (ft^3)	1 cubic foot = 0.02832 m^3
	1 cubic decimeter (dm^3)	1000 cubic centimeters	0.2642 gallon (gal)	1 gallon = 3.785 dm^3
			1.057 quarts (qt)	1 quart = 0.9464 dm^3
				1 quart = 946.4 cm^3
	1 cubic centimeter (cm^3)	0.001 dm^3	0.03381 fluid ounce	1 fluid ounce = 29.57 cm^3
Mass	1 kilogram (kg)	1000 grams (g)	2.205 pounds (lb)	1 pound = 0.4536 kg

1,650,763.73 wavelengths of orange-red light from electrically excited krypton atoms. The current standard is exact and invariant: 1 meter is the distance light travels in a vacuum in 1/299,792,458 of a second.

A meter is a little longer than a yard (1 m = 1.094 yd); a centimeter (10^{-2} m) is about two-fifths of an inch (1 cm = 0.3937 in; 1 in = 2.54 cm). Biological cells are often measured in micrometers (1 μm = 10^{-6} m). On the atomic scale, nanometers (10^{-9} m) and picometers (10^{-12} m) are used. Many proteins have diameters of about 2 nm; atomic diameters are about 200 pm (0.2 nm). An older unit still in use is the angstrom (1 Å = 10^{-10} m = 0.1 nm = 100 pm).

Volume Any sample of matter has a certain **volume (*V*),** the amount of space it occupies. The SI unit of volume is the **cubic meter (m^3).** In chemistry, we often use non-SI units, the **liter (L)** and the **milliliter (mL)** (note the uppercase L). Physicians and other medical practitioners measure body fluids in cubic decimeters (dm^3), which are equivalent to liters:

$$1\ L = 1\ dm^3 = 10^{-3}\ m^3$$

And 1 mL, or $\frac{1}{1000}$ of a liter, is equivalent to 1 cubic centimeter (cm^3):

$$1\ mL = 1\ cm^3 = 10^{-3}\ dm^3 = 10^{-3}\ L = 10^{-6}\ m^3$$

A liter is slightly larger than a quart (qt) (1 L = 1.057 qt; 1 qt = 946.4 mL); 1 fluid ounce ($\frac{1}{32}$ of a quart) equals 29.57 mL (29.57 cm^3).

Figure 1.7 is a life-size depiction of the two 1000-fold decreases in volume from 1 dm^3 to 1 cm^3 and then to 1 mm^3. The edge of a 1-m^3 cube would be about 2.5 times the width of this text opened flat.

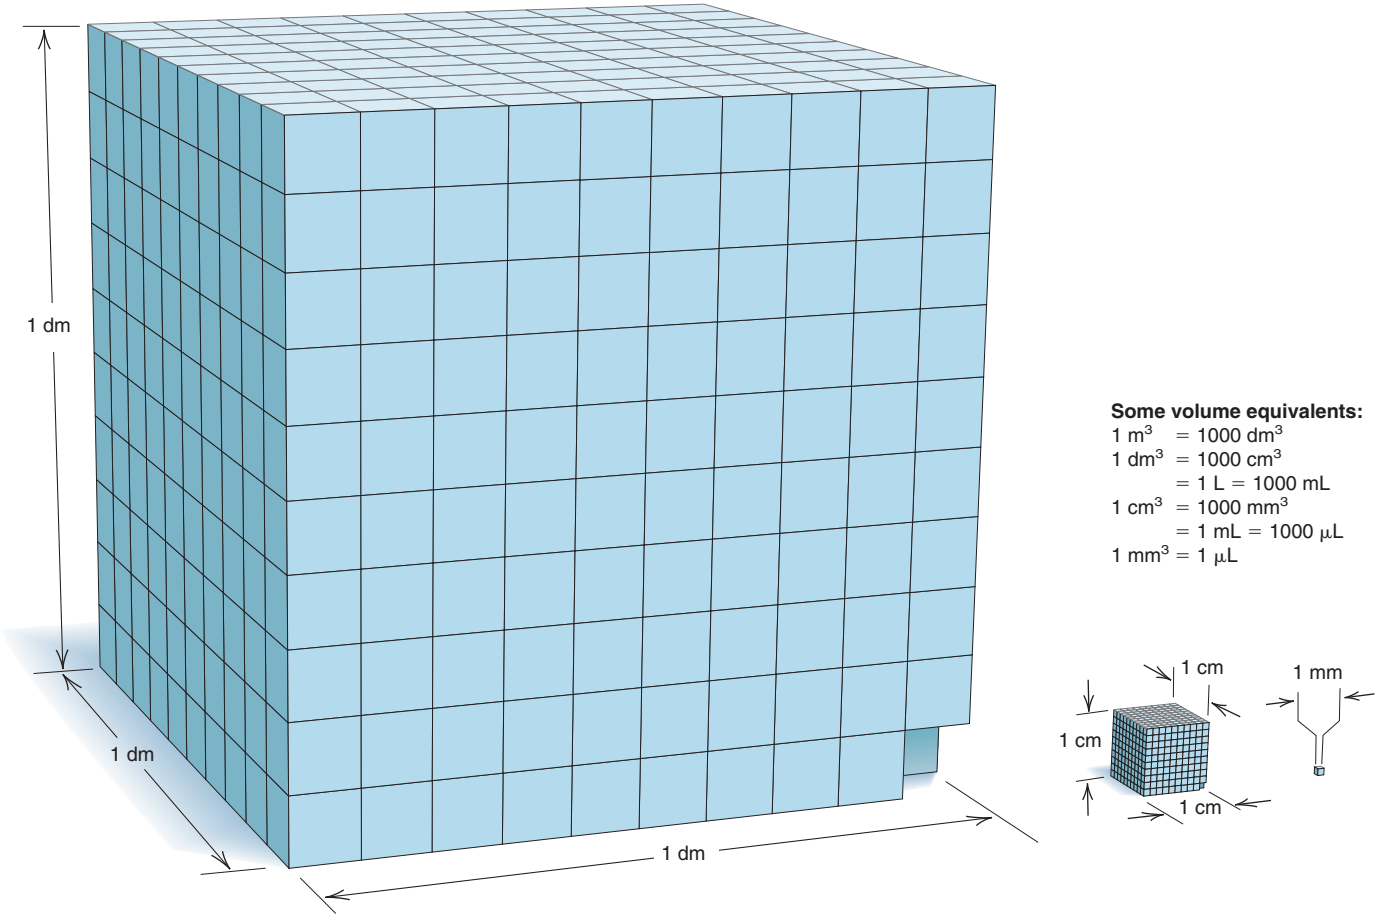

Figure 1.7 Some volume relationships in SI: From cubic decimeter (dm^3) to cubic centimeter (cm^3) to cubic millimeter (mm^3).

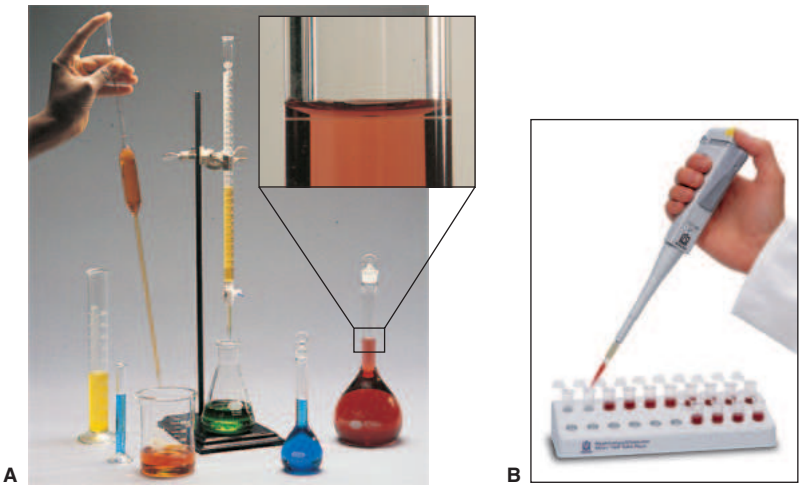

Figure 1.8 Common laboratory volumetric glassware. A, From left to right are two graduated cylinders, a pipet being emptied into a beaker, a buret delivering liquid to an Erlenmeyer flask, and two volumetric flasks. **Inset,** In contact with the glass neck of the flask, the liquid forms a concave meniscus (curved surface). **B,** An automatic pipet delivers a given volume of liquid to each test tube.

Figure 1.8A shows some laboratory glassware for working with volumes. Erlenmeyer flasks and beakers are used to contain liquids. Graduated cylinders, pipets, and burets are used to measure and transfer them. Volumetric flasks and pipets have a fixed volume indicated by a mark on the neck. Solutions are prepared quantitatively in volumetric flasks, and specific amounts are put into cylinders, pipets, or burets to transfer to beakers or flasks for further steps. In Figure 1.8B, an automatic pipet transfers liquid accurately *and* quickly.

Mass The quantity of matter an object contains is its **mass.** The SI unit of mass is the **kilogram (kg),** the only base unit whose standard is an object—a platinum-iridium cylinder kept in France—and the only one whose name has a prefix.*

The terms *mass* and *weight* have distinct meanings:

- *Mass is constant* because an object's quantity of matter cannot change.
- ***Weight** is variable* because it depends on the local gravitational field acting on the object.

Because the strength of the gravitational field varies with altitude, you (and other objects) weigh slightly less on a high mountain than at sea level.

Does this mean that a sample weighed on laboratory balances in Miami (sea level) and in Denver (about 1.7 km above sea level) give different results? No, because these balances measure mass, not weight. (We actually "mass" an object when we weigh it on a balance, but we don't use that term.) Mechanical balances compare the object's mass with masses built into the balance, so the local gravitational field pulls on them equally. Electronic (analytical) balances generate an electric field that counteracts the local field, and the current needed to restore the pan to zero is converted to the equivalent mass and displayed.

Figure 1.9 shows the ranges of some common lengths, volumes, and masses.

Time The SI base unit of time is the **second (s),** which is now based on an atomic standard. The best pendulum clock is accurate to within 3 seconds per year, and the best quartz clock is 1000 times more accurate. The most recent version of the atomic clock is over 6000 times more accurate than that—within 1 second in 20 million years! Rather than the oscillations of a pendulum, the atomic clock measures the oscillations of microwave radiation absorbed by gaseous cesium atoms cooled to around 10^{-6} K:

*The names of the other base units are used as the root words, but for units of mass we attach prefixes to the word "gram," as in "microgram" and "kilogram"; thus, we say "milligram," never "microkilogram."

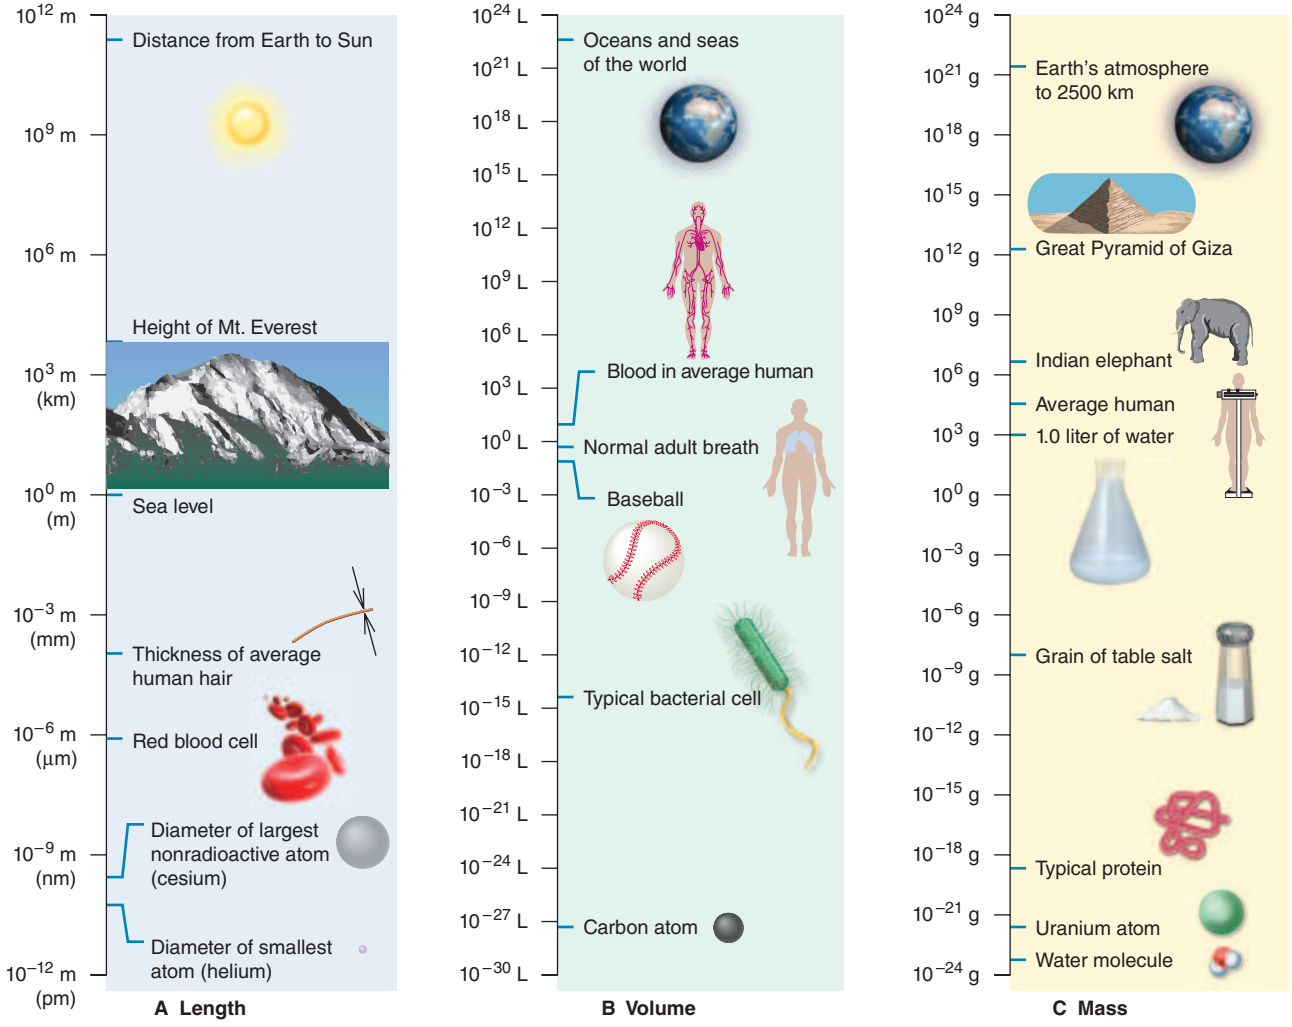

Figure 1.9 Some interesting quantities of length (A), volume (B), and mass (C). The vertical scales are exponential.

1 second is defined as 9,192,631,770 of these oscillations. Chemists now use lasers to measure the speed of extremely fast reactions that occur in a few picoseconds (10^{-12} s) or femtoseconds (10^{-15} s).

Units and Conversion Factors in Calculations

All measured quantities consist of a number *and* a unit: a person's height is "5 feet, 10 inches," not "5, 10." Ratios of quantities have ratios of units, such as miles/hour. To minimize errors, make it a habit to *include units in all calculations*.

The arithmetic operations used with quantities are the same as those used with pure numbers; that is, units can be multiplied, divided, and canceled:

- A carpet measuring 3 feet by 4 feet (ft) has an area of

$$\text{Area} = 3\ \text{ft} \times 4\ \text{ft} = (3 \times 4)\ (\text{ft} \times \text{ft}) = 12\ \text{ft}^2$$

- A car traveling 350 miles (mi) in 7 hours (h) has a speed of

$$\text{Speed} = \frac{350\ \text{mi}}{7\ \text{h}} = \frac{50\ \text{mi}}{1\ \text{h}}\ (\text{often written } 50\ \text{mi}\cdot\text{h}^{-1})$$

- In 3 hours, the car travels a distance of

$$\text{Distance} = 3\ \cancel{\text{h}} \times \frac{50\ \text{mi}}{1\ \cancel{\text{h}}} = 150\ \text{mi}$$

Constructing a Conversion Factor **Conversion factors** are *ratios used to express a quantity in different units.* Suppose we want to know the distance of that 150-mile car trip in feet. To convert miles to feet, we use *equivalent quantities,*

$$1 \text{ mi} = 5280 \text{ ft}$$

from which we can construct two conversion factors. Dividing both sides by 5280 ft gives one conversion factor (shown in blue):

$$\frac{1 \text{ mi}}{5280 \text{ ft}} = \frac{5280 \text{ ft}}{5280 \text{ ft}} = 1$$

And, dividing both sides by 1 mi gives the other conversion factor (the inverse):

$$\frac{1 \text{ mi}}{1 \text{ mi}} = \frac{5280 \text{ ft}}{1 \text{ mi}} = 1$$

Since the numerator and denominator of a conversion factor are equal, multiplying a quantity by a conversion factor is the same as multiplying by 1. Thus, *even though the number and unit change, the size of the quantity remains the same.*

To convert the distance from miles to feet, we choose the conversion factor with miles in the denominator, because it cancels miles and gives the answer in feet:

$$\underset{\text{mi}}{\text{Distance (ft)}} = 150 \text{ mi} \times \frac{5280 \text{ ft}}{1 \text{ mi}} \underset{\Rightarrow}{} = \underset{\text{ft}}{792{,}000 \text{ ft}}$$

Choosing the Correct Conversion Factor It is easier to convert if you first decide whether the answer expressed in the new units should have a larger or smaller number. In the previous case, we know that a foot is *smaller* than a mile, so the distance in feet should have a *larger* number (792,000) than the distance in miles (150). The conversion factor has the larger number (5280) in the numerator, so it gave a larger number in the answer.

Most importantly, the *conversion factor you choose must cancel all units except those you want in the answer.* Therefore, set the unit you are converting *from* (beginning unit) in the *opposite position in the conversion factor* (numerator or denominator) so that it cancels and you are left with the unit you are converting *to* (final unit):

$$\text{beginning unit} \times \frac{\text{final unit}}{\text{beginning unit}} = \text{final unit} \qquad \text{as in} \qquad \text{mi} \times \frac{\text{ft}}{\text{mi}} = \text{ft}$$

Or, in cases that involve units raised to a power:

$$(\text{beginning unit} \times \text{beginning unit}) \times \frac{\text{final unit}^2}{\text{beginning unit}^2} = \text{final unit}^2$$

$$\text{as in} \qquad (\text{ft} \times \text{ft}) \times \frac{\text{mi}^2}{\text{ft}^2} = \text{mi}^2$$

Or, in cases that involve a ratio of units:

$$\frac{\text{beginning unit}}{\text{final unit}_1} \times \frac{\text{final unit}_2}{\text{beginning unit}} = \frac{\text{final unit}_2}{\text{final unit}_1} \qquad \text{as in} \qquad \frac{\text{mi}}{\text{h}} \times \frac{\text{ft}}{\text{mi}} = \frac{\text{ft}}{\text{h}}$$

Converting Between Unit Systems We use the same procedure to convert between one system of units and another, for example, between the English (or American) unit system and the International System. Suppose we know that the height of Angel Falls in Venezuela (the world's highest) is 3212 ft, and we find its height in miles as

$$\underset{\text{ft}}{\text{Height (mi)}} = 3212 \text{ ft} \times \frac{1 \text{ mi}}{5280 \text{ ft}} \underset{\Rightarrow}{} = \underset{\text{mi}}{0.6083 \text{ mi}}$$

Now, we want its height in kilometers (km). The equivalent quantities (see Table 1.4) are

$$1.609 \text{ km} = 1 \text{ mi}$$

Because we are converting *from* miles *to* kilometers, we use the conversion factor with miles in the denominator in order to cancel miles:

$$\text{Height (km)} = 0.6083 \text{ mi} \times \frac{1.609 \text{ km}}{1 \text{ mi}} = 0.9788 \text{ km}$$

mi ⇒ km

Notice that kilometers are *smaller* than miles, so this conversion factor gave us an answer with a *larger* number (0.9788 is larger than 0.6083).

If we want the height of Angel Falls in meters (m), we use the equivalent quantities 1 km = 1000 m to construct the conversion factor:

$$\text{Height (m)} = 0.9788 \text{ km} \times \frac{1000 \text{ m}}{1 \text{ km}} = 978.8 \text{ m}$$

km ⇒ m

In longer calculations, we often string together several conversion steps:

$$\text{Height (m)} = 3212 \text{ ft} \times \frac{1 \text{ mi}}{5280 \text{ ft}} \times \frac{1.609 \text{ km}}{1 \text{ mi}} \times \frac{1000 \text{ m}}{1 \text{ km}} = 978.8 \text{ m}$$

ft ⇒ mi ⇒ km ⇒ m

The use of conversion factors in calculations is also referred to as the factor-label method or **dimensional analysis** (because units represent physical dimensions). We use this approach throughout the text.

A Systematic Approach to Solving Chemistry Problems

The approach used in this book to solve problems emphasizes reasoning, not memorizing, and is based on a simple idea: plan how to solve the problem *before* you try to solve it, then check your answer, and practice with similar follow-up problems. In general, the sample problems consist of several parts:

1. **Problem.** This part states all the information you need to solve the problem, usually framed in some interesting context.
2. **Plan.** This part helps you *think* about the solution *before* juggling numbers and pressing calculator buttons. There is often more than one way to solve a problem, and the given plan is one possibility. The plan will
   - Clarify the known and unknown: what information do you have, and what are you trying to find?
   - Suggest the steps from known to unknown: what ideas, conversions, or equations are needed?
   - Present a road map (especially in early chapters), a flow diagram of the plan. The road map has a box for each intermediate result and an arrow showing the step (conversion factor or operation) used to get to the next box.
3. **Solution.** This part shows the calculation steps in the same order as in the plan (and the road map).
4. **Check.** This part helps you check that your final answer makes sense: Are the units correct? Did the change occur in the expected direction? Is it reasonable chemically? To avoid a large math error, we also often do a rough calculation and see if we get an answer "in the same ballpark" as the actual result. Here's a typical "ballpark" calculation from everyday life. You are in a clothing store and buy three shirts at \$14.97 each. With a 5% sales tax, the bill comes to \$47.16. In your mind, you know that \$14.97 is about \$15, and 3 times \$15 is \$45; with the sales tax, the cost should be a bit more. So, your quick mental calculation *is* in the same ballpark as the actual cost.
5. **Comment.** This part appears occasionally to provide an application, an alternative approach, a common mistake to avoid, or an overview.
6. **Follow-up Problems.** This part presents similar problems that require you to apply concepts and/or methods used in solving the sample problem.
7. **Some Similar Problems.** This part lists a few more problems for practice.

Of course, you can't learn to solve chemistry problems, any more than you can learn to swim, by reading about it, so here are a few suggestions:

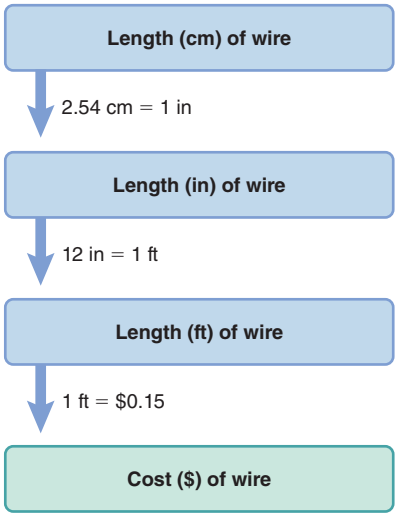
- Follow along in the sample problem with pencil, paper, and calculator.
- Try the follow-up problems as soon as you finish the sample problem. A very useful feature called Brief Solutions to Follow-up Problems appears at the end of each chapter, allowing you to compare your solution steps and answers.
- Read the sample problem and text again if you have trouble.
- Try the practice quizzes in the Online Learning Center at www.mhhe.com/silberberg. For each chapter, two interactive quizzes provide conceptual and problem-solving practice and offer feedback for review.
- The end-of-chapter problems review and extend the concepts and skills in the chapter, so work as many as you can. (Answers are given in the back of the book for problems with a colored number.)

Let's apply this systematic approach in some unit-conversion problems. Refer to Tables 1.3 and 1.4 as you work through these problems.

SAMPLE PROBLEM 1.3 Converting Units of Length

Problem To wire your stereo equipment, you need 325 centimeters (cm) of speaker wire that sells for \$0.15/ft. How much does the wire cost?

Road Map



Plan We know the length of wire in centimeters (325 cm) and the price in dollars per foot (\$0.15/ft). We can find the unknown cost of the wire by converting the length from centimeters to inches (in) and from inches to feet. The price gives us the equivalent quantities (1 ft = \$0.15) to convert feet of wire to cost in dollars. The road map starts with the known and moves through the calculation steps to the unknown.

Solution Converting the known length from centimeters to inches: The equivalent quantities alongside the road map arrow are needed to construct the conversion factor. We choose 1 in/2.54 cm, rather than the inverse, because it gives an answer in inches:

$$\text{Length (in)} = \text{length (cm)} \times \text{conversion factor}$$

$$= 325 \text{ cm} \times \frac{1 \text{ in}}{2.54 \text{ cm}} = 128 \text{ in}$$

Converting the length from inches to feet:

$$\text{Length (ft)} = \text{length (in)} \times \text{conversion factor}$$

$$= 128 \text{ in} \times \frac{1 \text{ ft}}{12 \text{ in}} = 10.7 \text{ ft}$$

Converting the length in feet to cost in dollars:

$$\text{Cost (\$)} = \text{length (ft)} \times \text{conversion factor}$$

$$= 10.7 \text{ ft} \times \frac{\$0.15}{1 \text{ ft}} = \$1.60$$

Check The units are correct for each step. The conversion factors make sense in terms of the relative unit sizes: the number of inches is *smaller* than the number of centimeters (an inch is *larger* than a centimeter), and the number of feet is *smaller* than the number of inches. The total cost seems reasonable: a little more than 10 ft of wire at \$0.15/ft should cost a little more than \$1.50.

Comment **1.** We could also have strung the three steps together:

$$\text{Cost (\$)} = 325 \text{ cm} \times \frac{1 \text{ in}}{2.54 \text{ cm}} \times \frac{1 \text{ ft}}{12 \text{ in}} \times \frac{\$0.15}{1 \text{ ft}} = \$1.60$$

2. There are usually alternative sequences in unit-conversion problems. Here, for example, we would get the same answer if we first converted the cost of wire from \$/ft to \$/cm and kept the wire length in cm. Try it yourself.

FOLLOW-UP PROBLEMS

1.3A A chemistry professor can walk a mile in 15 minutes. How many minutes will it take the professor to walk 10,500 meters (m)? Draw a road map to show how you planned the solution.

1.3B The rhinovirus, one cause of the common cold, has a diameter of 30 nm. How many of these virus particles could line up side by side on a line that is 1.0 inch long? Draw a road map to show how you planned the solution.

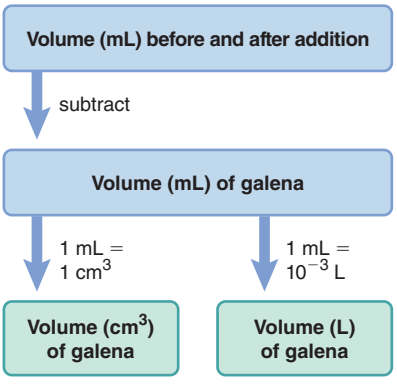
SOME SIMILAR PROBLEMS 1.26–1.29

SAMPLE PROBLEM 1.4 Converting Units of Volume

Problem The volume of an irregularly shaped solid can be determined from the volume of water it displaces. A graduated cylinder contains 19.9 mL of water. When a small piece of galena, an ore of lead, is added, it sinks and the volume increases to 24.5 mL. What is the volume of the piece of galena in cm^3 and in L?

Plan We have to find the volume of the galena from the change in volume of the cylinder contents. The volume of galena in mL is the difference before (19.9 mL) and after (24.5 mL) adding it. Since mL and cm^3 represent identical volumes, the volume in mL equals the volume in cm^3. We then use equivalent quantities ($1\ mL = 10^{-3}\ L$) to convert mL to L. The road map shows these steps.

Road Map



Solution Finding the volume of galena:

$$\text{Volume (mL)} = \text{volume after} - \text{volume before} = 24.5\ \text{mL} - 19.9\ \text{mL} = 4.6\ \text{mL}$$

Converting the volume from mL to cm^3:

$$\text{Volume } (cm^3) = \text{volume (mL)} \times \text{conversion factor} = 4.6\ \cancel{mL} \times \frac{1\ cm^3}{1\ \cancel{mL}} = 4.6\ cm^3$$

Converting the volume from mL to L:

$$\text{Volume (L)} = \text{volume (mL)} \times \text{conversion factor} = 4.6\ \cancel{mL} \times \frac{10^{-3}\ L}{1\ \cancel{mL}} = 4.6 \times 10^{-3}\ L$$

Check The units and magnitudes of the answers seem correct, and it makes sense that the volume in mL would have a number 1000 times larger than the same volume in L.

FOLLOW-UP PROBLEMS

1.4A Within a cell, proteins are synthesized on particles called ribosomes. Assuming ribosomes are spherical, what is the volume (in dm^3 and μL) of a ribosome whose average diameter is 21.4 nm (V of a sphere $= \frac{4}{3}\pi r^3$)? Draw a road map to show how you planned the solution.

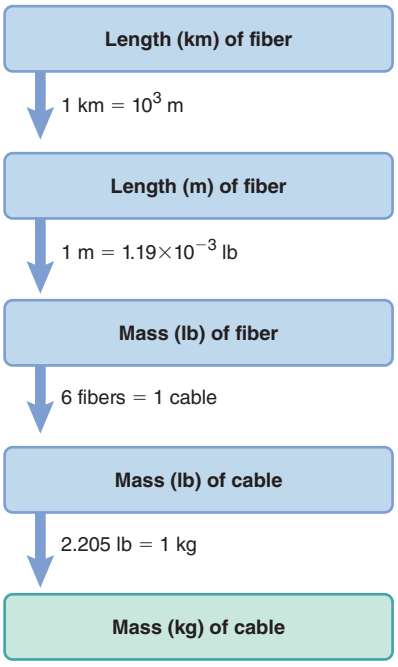
1.4B During an eruption, the famous geyser Old Faithful in Yellowstone National Park can expel as much as 8400 gal of water. What is this volume in L? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.36 and 1.37

SAMPLE PROBLEM 1.5 Converting Units of Mass

Problem Many international computer communications are carried by optical fibers in cables laid along the ocean floor. If one strand of optical fiber weighs 1.19×10^{-3} lb/m, what is the mass (in kg) of a cable made of six strands of optical fiber, each long enough to link New York and Paris (8.84×10^3 km)?

Road Map



Plan We have to find the mass of cable (in kg) from the given mass/length of fiber (1.19×10^{-3} lb/m), number of fibers/cable (6), and length of cable (8.84×10^{3} km). Let's first find the mass of one fiber and then the mass of cable. As shown in the road map, we convert the length of one fiber from km to m and then find its mass (in lb) by converting m to lb. Then we multiply the fiber mass by 6 to get the cable mass, and finally convert lb to kg.

Solution Converting the fiber length from km to m:

$$\text{Length (m) of fiber} = 8.84\times10^{3}\ \cancel{\text{km}} \times \frac{10^{3}\ \text{m}}{1\ \cancel{\text{km}}} = 8.84\times10^{6}\ \text{m}$$

Converting the length of one fiber to mass (lb):

$$\text{Mass (lb) of fiber} = 8.84\times10^{6}\ \cancel{\text{m}} \times \frac{1.19\times10^{-3}\ \text{lb}}{1\ \cancel{\text{m}}} = 1.05\times10^{4}\ \text{lb}$$

Finding the mass of the cable (lb):

$$\text{Mass (lb) of cable} = \frac{1.05\times10^{4}\ \text{lb}}{1\ \cancel{\text{fiber}}} \times \frac{6\ \cancel{\text{fibers}}}{1\ \text{cable}} = 6.30\times10^{4}\ \text{lb/cable}$$

Converting the mass of cable from lb to kg:

$$\text{Mass (kg) of cable} = \frac{6.30\times10^{4}\ \cancel{\text{lb}}}{1\ \text{cable}} \times \frac{1\ \text{kg}}{2.205\ \cancel{\text{lb}}} = 2.86\times10^{4}\ \text{kg/cable}$$

Check The units are correct. Let's think through the relative sizes of the answers to see if they make sense: The number of m should be 10^3 larger than the number of km. If 1 m of fiber weighs about 10^{-3} lb, about 10^7 m should weigh about 10^4 lb. The cable mass should be six times as much, or about 6×10^4 lb. Since 1 lb is about $\frac{1}{2}$ kg, the number of kg should be about half the number of lb.

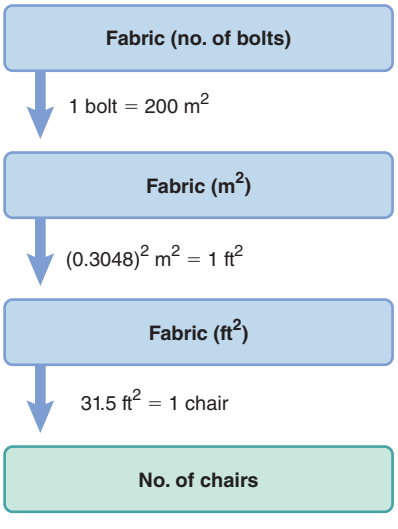
FOLLOW-UP PROBLEMS

1.5A An intravenous nutrient solution is delivered to a hospital patient at a rate of 1.5 drops per second. If a drop of solution weighs 65 mg on average, how many kilograms are delivered in 8.0 h? Draw a road map to show how you planned the solution.

1.5B Nutritional tables give the potassium content of a standard apple (about 3 apples per pound) as 159 mg. How many grams of potassium are in 3.25 kg of apples? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.32 and 1.33

Road Map



SAMPLE PROBLEM 1.6 Converting Units Raised to a Power

Problem A furniture factory needs 31.5 ft^2 of fabric to upholster one chair. Its Dutch supplier sends the fabric in bolts that hold exactly 200 m^2. How many chairs can be upholstered with 3 bolts of fabric?

Plan We know the amount of fabric in one bolt in m^2; multiplying the m^2 of fabric by the number of bolts gives the total amount of fabric available in m^2. We convert the amount of fabric from m^2 to ft^2 and use the conversion factor 31.5 ft^2 of fabric = 1 chair to find the number of chairs (see the road map).

Solution Converting from number of bolts to amount of fabric in m^2:

$$\text{Amount (m}^2\text{) of fabric} = 3\ \cancel{\text{bolts}} \times \frac{200\ \text{m}^2}{1\ \cancel{\text{bolt}}} = 600\ \text{m}^2$$

Converting the amount of fabric from m^2 to ft^2:

Since 0.3048 m = 1 ft, we have $(0.3048)^2\ m^2 = (1)^2\ ft^2$, so

$$\text{Amount (ft}^2\text{) of fabric} = 600\ \cancel{\text{m}^2} \times \frac{1\ \text{ft}^2}{(0.3048)^2\ \cancel{\text{m}^2}} = 6460\ \text{ft}^2$$

Finding the number of chairs:

$$\text{Number of chairs} = 6460\ \cancel{\text{ft}^2} \times \frac{1\ \text{chair}}{31.5\ \cancel{\text{ft}^2}} = 205\ \text{chairs}$$

Check Since 1 ft = 0.3048 m, 1 ft is a little less than $\frac{1}{3}$ of a meter, which means that 3.3 ft is about the same as 1 m. We are using squared length units, and $(3.3\ \text{ft})^2$, or 11 ft^2, is about the same as 1 m^2. Multiplying the amount of fabric in m^2 by 11 gives 6600 ft^2 of fabric. Each chair requires about 30 ft^2 of fabric, so 6600 ft^2 will upholster 220 chairs, a number close to our answer.

FOLLOW-UP PROBLEMS

1.6A A landowner wants to spray herbicide on a field that has an area of 2050 m^2. The herbicide comes in bottles that hold 16 fluid ounces (fl oz), and 1.5 fl oz mixed with 1 gal of water will treat 300 ft^2. How many bottles of herbicide will the landowner need? Draw a road map to show how you planned the solution.

1.6B From 1946 to 1970, 75,000 kg of mercury was discharged into a lake in New York. The lake has a surface area of 4.5 mi^2 and an average depth of 35 ft. What mass (in g) of mercury is contained in each mL of lake water? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.30, 1.31, and 1.34

Density: A Combination of Units as a Conversion Factor Derived units, combinations of two or more units, can serve as conversion factors (previously we mentioned that speed is length/time). In chemistry, a very important example is **density (*d*),** the mass of an object divided by its volume:

$$\text{Density} = \frac{\text{mass}}{\text{volume}} \qquad (1.1)$$

We isolate each of these variables by treating density as a conversion factor:

$$\text{Mass} = \text{volume} \times \text{density} = \cancel{\text{volume}} \times \frac{\text{mass}}{\cancel{\text{volume}}}$$

or,

$$\text{Volume} = \text{mass} \times \frac{1}{\text{density}} = \cancel{\text{mass}} \times \frac{\text{volume}}{\cancel{\text{mass}}}$$

Because volume can change with temperature, so can density. But, at a given temperature and pressure, the *density of a substance is a characteristic physical property and, thus, has a specific value*.

The SI unit of density is kilograms per cubic meter (kg/m^3), but in chemistry, density has units of g/L (g/dm^3) or g/mL (g/cm^3) (Table 1.5). The densities of gases are much lower than the densities of liquids or solids (see Figure 1.1).

Table 1.5 Densities of Some Common Substances*

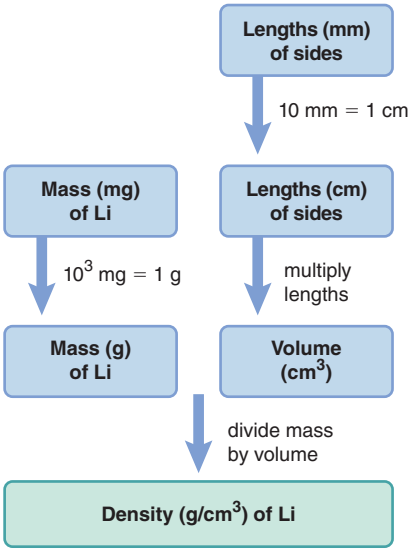
Substance	Physical State	Density (g/cm^3)
Hydrogen	gas	0.0000899
Oxygen	gas	0.00133
Grain alcohol	liquid	0.789
Water	liquid	0.998
Table salt	solid	2.16
Aluminum	solid	2.70
Lead	solid	11.3
Gold	solid	19.3

*At room temperature (20°C) and normal atmospheric pressure (1 atm).

SAMPLE PROBLEM 1.7 **Calculating Density from Mass and Volume**

Problem Lithium, a soft, gray solid with the lowest density of any metal, is a key component of advanced batteries, such as the one in your laptop. A slab of lithium weighs 1.49×10^3 mg and has sides that are 20.9 mm by 11.1 mm by 11.9 mm. Find the density of lithium in g/cm^3.

Road Map



Plan To find the density in g/cm^3, we need the mass of lithium in g and the volume in cm^3. The mass is 1.49×10^3 mg, so we convert mg to g. We convert the lengths of the three sides from mm to cm, and then multiply them to find the volume in cm^3. Dividing the mass by the volume gives the density (see the road map).

Solution Converting the mass from mg to g:

$$\text{Mass (g) of lithium} = 1.49\times10^3\ \cancel{\text{mg}}\left(\frac{10^{-3}\ \text{g}}{1\ \cancel{\text{mg}}}\right) = 1.49\ \text{g}$$

Converting side lengths from mm to cm:

$$\text{Length (cm) of one side} = 20.9\ \cancel{\text{mm}} \times \frac{1\ \text{cm}}{10\ \cancel{\text{mm}}} = 2.09\ \text{cm}$$

Similarly, the other side lengths are 1.11 cm and 1.19 cm.
Multiplying the sides to get the volume:

$$\text{Volume (cm}^3\text{)} = 2.09\ \text{cm} \times 1.11\ \text{cm} \times 1.19\ \text{cm} = 2.76\ \text{cm}^3$$

Calculating the density:

$$\text{Density of lithium} = \frac{\text{mass}}{\text{volume}} = \frac{1.49\ \text{g}}{2.76\ \text{cm}^3} = 0.540\ \text{g/cm}^3$$

Check Since 1 cm = 10 mm, the number of cm in each length should be $\frac{1}{10}$ the number of mm. The units for density are correct, and the size of the answer (~0.5 g/cm^3) seems correct since the number of g (1.49) is about half the number of cm^3 (2.76). Also, the problem states that lithium has a very low density, so this answer makes sense.

FOLLOW-UP PROBLEMS

1.7A The density of Venus is similar to that of Earth. The mass of Venus is 4.9×10^{24} kg, and its diameter is 12,100 km. Find the density of Venus in g/cm^3. The volume of a sphere is given by $\frac{4}{3}\pi r^3$. Draw a road map to show how you planned the solution.

1.7B The piece of galena in Sample Problem 1.4 has a volume of 4.6 cm^3. If the density of galena is 7.5 g/cm^3, what is the mass (in kg) of that piece of galena? Draw a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 1.38–1.41

Temperature Scales

Temperature is a frequently measured quantity in chemistry; there is a noteworthy distinction between temperature and heat:

- **Temperature (*T*)** is *a measure* of how hot or cold one object is relative to another.
- **Heat** is *the energy* that flows from the object with the higher temperature to the object with the lower temperature. When you hold an ice cube, it feels like the "cold" flows into your hand, but actually, heat flows from your hand to the ice.

In the laboratory, we measure temperature with a **thermometer,** a narrow tube containing a fluid that expands when heated. When the thermometer is immersed in a substance hotter than itself, heat flows from the substance through the glass into the fluid, which expands and rises in the thermometer tube. If a substance is colder than the thermometer, heat flows to the substance from the fluid, which contracts and falls within the tube.

We'll consider three temperature scales: the Celsius (°C, formerly called centigrade), the Kelvin (K), and the Fahrenheit (°F) scales. The SI base unit of temperature is the **kelvin** (**K,** with no degree sign, °). Figure 1.10 shows some interesting

temperatures in the Kelvin scale, which is preferred in scientific work (although the Celsius scale is still used frequently). In the United States, the Fahrenheit scale is used for weather reporting, body temperature, and so forth.

The three scales differ in the size of the unit and/or the temperature of the zero point. Figure 1.11 shows the freezing and boiling points of water on the three scales.

- The **Celsius scale** sets water's freezing point at 0°C and its boiling point (at normal atmospheric pressure) at 100°C. Thus, the size of a Celsius degree is $\frac{1}{100}$ of the difference between the freezing and boiling points of water.
- The **Kelvin (absolute) scale** uses the *same size degree* as the Celsius scale; the difference between the freezing point (+273.15 K) and the boiling point (+373.15 K) of water is again 100 degrees, but these temperatures are 273.15 degrees higher on the Kelvin scale because it has a *different zero point*. *Absolute zero,* 0 K, equals −273.15°C. Thus, on the Kelvin scale, *all temperatures are positive*.

  We convert between the Celsius and Kelvin scales by remembering the different zero points: 0°C = 273.15 K, so

$$T\,(\text{in K}) = T\,(\text{in °C}) + 273.15 \qquad \textbf{(1.2)}$$

  And, therefore,

$$T\,(\text{in °C}) = T\,(\text{in K}) - 273.15 \qquad \textbf{(1.3)}$$

- The Fahrenheit scale differs from the other scales in its zero point *and* in the size of its degree. Water freezes at 32°F and boils at 212°F. Therefore, 180 Fahrenheit degrees (212°F − 32°F) represents the same temperature change as 100 Celsius degrees (or 100 kelvins). Because 100 Celsius degrees equal 180 Fahrenheit degrees,

$$1 \text{ Celsius degree} = \tfrac{180}{100} \text{ Fahrenheit degrees} = \tfrac{9}{5} \text{ Fahrenheit degrees}$$

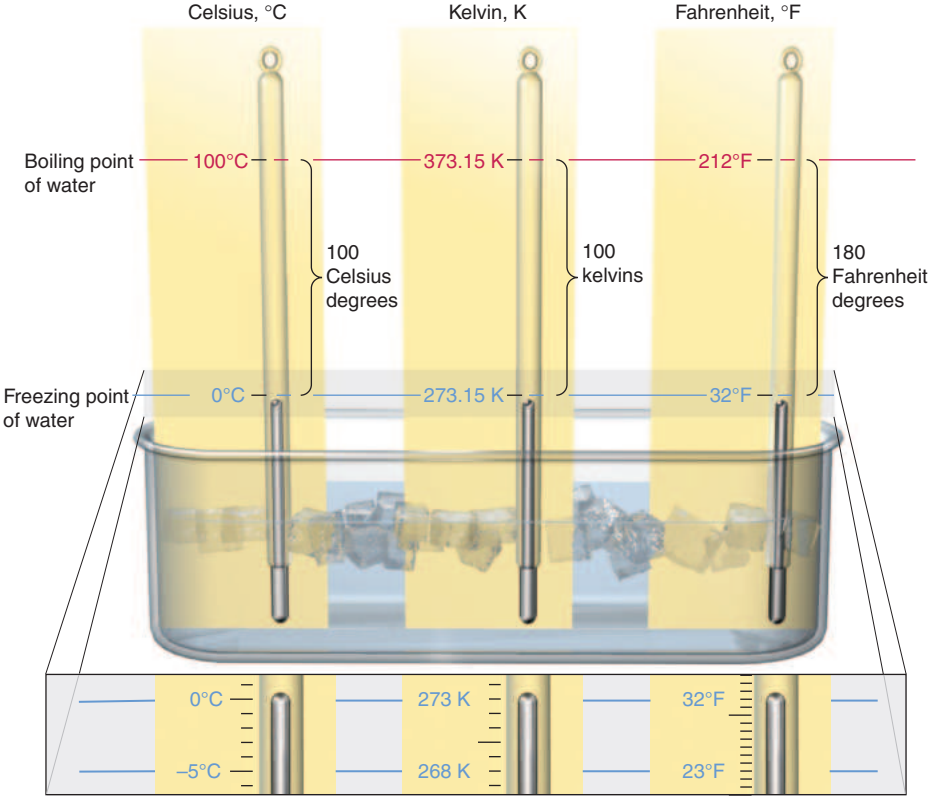


Figure 1.11 **Freezing and boiling points of water in the Celsius, Kelvin (absolute), and Fahrenheit scales.** At the bottom of the figure, a portion of each of the three thermometer scales is expanded to show the sizes of the units.

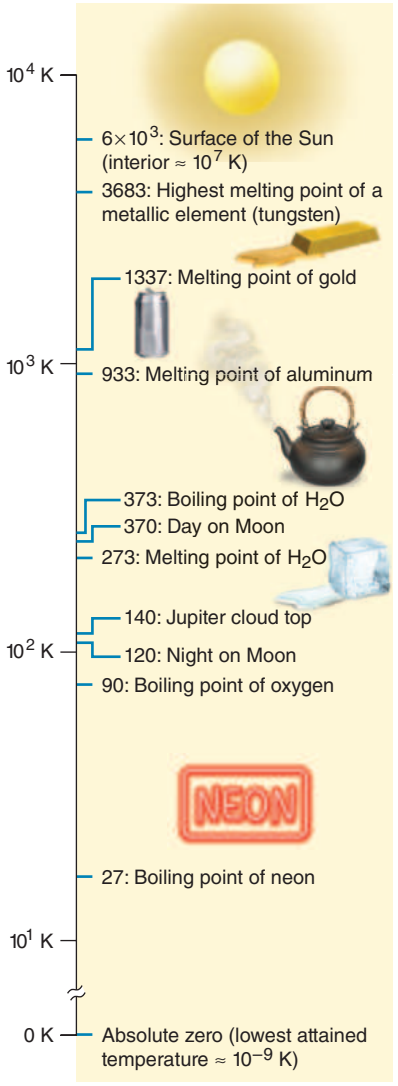

Figure 1.10 **Some interesting temperatures.**

Table 1.6 The Three Temperature Scales

Scale	Unit	Size of Degree (Relative to K)	Freezing Point of H_2O	Boiling Point of H_2O	*T* at Absolute Zero	Conversion
Kelvin (absolute)	kelvin (K)	—	273.15 K	373.15 K	0 K	to °C (Equation 1.2)
Celsius	Celsius degree (°C)	1	0°C	100°C	−273.15°C	to K (Equation 1.3) to °F (Equation 1.4)
Fahrenheit	Fahrenheit degree (°F)	$\frac{5}{9}$	32°F	212°F	−459.67°F	to °C (Equation 1.5)

To convert a temperature from °C to °F, first change the degree size and then adjust the zero point:

$$T\,(\text{in °F}) = \tfrac{9}{5}T\,(\text{in °C}) + 32 \qquad \textbf{(1.4)}$$

To convert a temperature from °F to °C, do the two steps in the opposite order: adjust the zero point and then change the degree size. In other words, solve Equation 1.4 for T (in °C):

$$T\,(\text{in °C}) = [T\,(\text{in °F}) - 32]\tfrac{5}{9} \qquad \textbf{(1.5)}$$

Table 1.6 compares the three temperature scales.

SAMPLE PROBLEM 1.8 Converting Units of Temperature

Problem A child has a body temperature of 38.7°C, and normal body temperature is 98.6°F. Does the child have a fever? What is the child's temperature in kelvins?

Plan To see if the child has a fever, we convert from °C to °F (Equation 1.4) and compare it with 98.6°F. Then, to convert the child's temperature in °C to K, we use Equation 1.2.

Solution Converting the temperature from °C to °F:

$$T\,(\text{in °F}) = \tfrac{9}{5}T\,(\text{in °C}) + 32 = \tfrac{9}{5}(38.7\text{°C}) + 32 = 101.7\text{°F};$$ yes, the child has a fever.

Converting the temperature from °C to K:

$$T\,(\text{in K}) = T\,(\text{in °C}) + 273.15 = 38.7\text{°C} + 273.15 = 311.8\ \text{K}$$

Check From everyday experience, you know that 101.7°F is a reasonable temperature for someone with a fever. In the second step, we can check for a large error as follows: 38.7°C is almost 40°C, and 40 + 273 = 313, which is close to our answer.

FOLLOW-UP PROBLEMS

1.8A Mercury melts at 234 K, lower than any other pure metal. What is its melting point in °C and °F?

1.8B The temperature in a blast furnace used for iron production is 2325°F. What is this temperature in °C and K?

SOME SIMILAR PROBLEMS 1.42 and 1.43

Extensive and Intensive Properties

Some variables are *dependent* on the amount of substance present; these are called **extensive properties.** On the other hand, **intensive properties** are *independent* of the amount of substance. Mass and volume, for example, are extensive properties, but

density is an intensive property. Thus, a gallon of water has four times the mass of a quart of water, but it also has four times the volume, so the density, the *ratio* of mass to volume, is the same for both samples.

Another important example concerns heat, an extensive property, and temperature, an intensive property: a vat of boiling water has more heat, that is, more energy, than a cup of boiling water, but both samples have the same temperature.

Summary of Section 1.4

- The SI unit system consists of seven base units and numerous derived units.
- Exponential notation and prefixes based on powers of 10 are used to express very small and very large numbers.
- The SI base unit of length is the meter (m); on the atomic scale, the nanometer (nm) and picometer (pm) are used commonly.
- Volume (V) units are derived from length units, and the most important volume units are the cubic meter (m^3) and the liter (L).
- The *mass* of an object—the quantity of matter in it—is constant. The SI unit of mass is the kilogram (kg). The *weight* of an object varies with the gravitational field.
- A measured quantity consists of a number and a unit.
- A conversion factor is a ratio of equivalent quantities (and, thus, equal to 1) that is used to express a quantity in different units.
- The problem-solving approach used in this book has four parts: (1) plan the steps to the solution, which often includes a flow diagram (road map) of the steps, (2) perform the calculations according to the plan, (3) check to see if the answer makes sense, and (4) practice with similar, follow-up problems and compare your solutions with the ones at the end of the chapter.
- Density (d) is a characteristic physical property of a substance and is the ratio of its mass to its volume.
- Temperature (T) is a measure of the relative hotness of an object. Heat is energy that flows from an object at higher T to one at lower T.
- Temperature scales differ in the size of the degree unit and/or the zero point. For scientific uses, temperature is measured in kelvins (K) or degrees Celsius (°C).
- Extensive properties, such as mass, volume, and energy, depend on the amount of a substance. Intensive properties, such as density and temperature, do not.

1.5 UNCERTAINTY IN MEASUREMENT: SIGNIFICANT FIGURES

All measuring devices—balances, pipets, thermometers, and so forth—are made to limited specifications, and we use our imperfect senses and skills to read them. Therefore, we can *never* measure a quantity exactly; put another way, every measurement includes some **uncertainty.** The device we choose depends on how much uncertainty is acceptable. When you buy potatoes, a supermarket scale that measures in 0.1-kg increments is acceptable; it tells you that the mass is, for example, 2.0 ± 0.1 kg. The "± 0.1 kg" term expresses the uncertainty: the potatoes weigh between 1.9 and 2.1 kg. Needing more certainty than that to weigh a substance, a chemist uses a balance that measures in 0.001-kg increments and finds the substance weighs 2.036 ± 0.001 kg, that is, between 2.035 and 2.037 kg. The greater number of digits in this measurement means we know the mass of the substance with *more certainty* than we know the mass of potatoes.

We *always estimate the rightmost digit* of a measurement. The uncertainty can be expressed with the ± sign, but generally we drop the sign and *assume an uncertainty of one unit in the rightmost digit.* The digits we record, both the certain and the uncertain ones, are called **significant figures.** There are four significant figures in

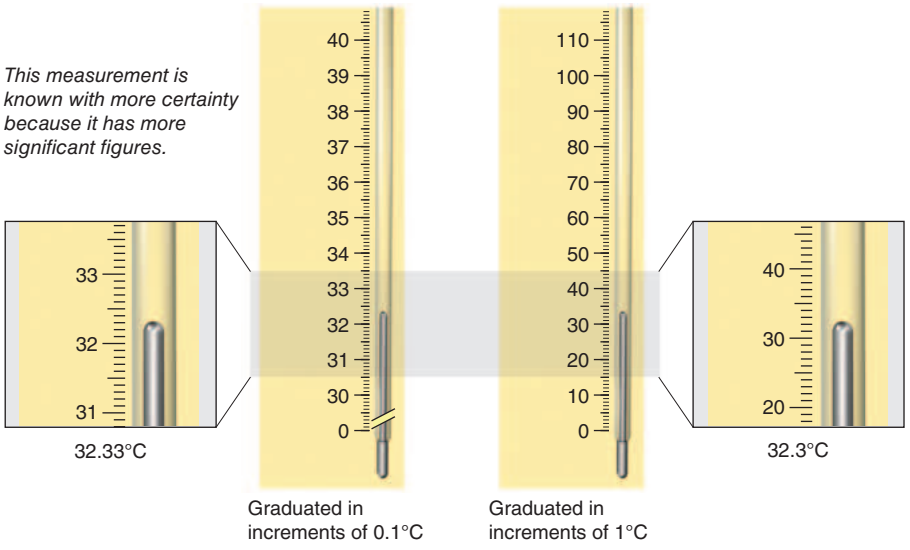

Figure 1.12 The number of significant figures in a measurement.

2.036 kg and two in 2.0 kg. *The greater the number of significant figures, the greater is the certainty of a measurement.* Figure 1.12 shows this point for two thermometers.

Determining Which Digits Are Significant

When you take a measurement or use one in a calculation, you must know the number of digits that are significant: *all digits are significant, except zeros used only to position the decimal point.* The following procedure applies this point:

1. Make sure the measurement has a decimal point.
2. Start at the left, and move right until you reach the first nonzero digit.
3. Count that digit and every digit to its right as significant.

A complication can arise when zeros end a number:

- If there *is* a decimal point and the zeros lie either after or before it, they *are* significant: 1.1300 g has five significant figures and 6500. has four.
- If there is *no* decimal point, we assume that the zeros are *not* significant, unless exponential notation clarifies the quantity: 5300 L is *assumed* to have two significant figures, but 5.300×10^3 L has four, 5.30×10^3 L has three, and 5.3×10^3 L has two.
- A terminal decimal point indicates that zeros are significant: 500 mL has one significant figure, but 500. mL has three (as do 5.00×10^2 mL and 0.500 L).

SAMPLE PROBLEM 1.9 Determining the Number of Significant Figures

Problem For each of the following quantities, underline the zeros that are significant figures (sf) and determine the total number of significant figures. For (d) to (f), express each quantity in exponential notation first.

(a) 0.0030 L **(b)** 0.1044 g **(c)** 53,069 mL
(d) 0.00004715 m **(e)** 57,600. s **(f)** 0.0000007160 cm^3

Plan We determine the number of significant figures by counting digits, as just presented, paying particular attention to the position of zeros in relation to the decimal point, and underline the zeros that are significant.

Solution **(a)** 0.003$\underline{0}$ L has 2 sf
(b) 0.1$\underline{0}$44 g has 4 sf
(c) 53,$\underline{0}$69 mL has 5 sf
(d) 0.00004715 m, or 4.715×10^{-5} m, has 4 sf

(e) 57,600. s, or 5.7600×10^{4} s, has 5 sf
(f) 0.00000071600 cm^3, or 7.1600×10^{-7} cm^3, has 4 sf

Check Be sure that every zero counted as significant comes after nonzero digit(s) in the number.

FOLLOW-UP PROBLEMS

1.9A For each of the following quantities, underline the zeros that are significant figures and determine the total number of significant figures (sf).
(a) 31.070 mg **(b)** 0.06060 g **(c)** 850.°C

1.9B For each of the following quantities, underline the zeros that are significant figures and determine the total number of significant figures (sf). Express each quantity in exponential notation first.
(a) 200.0 mL **(b)** 0.0000039 m **(c)** 0.000401 L

SOME SIMILAR PROBLEMS 1.52 and 1.53

Significant Figures: Calculations and Rounding Off

Measuring several quantities typically results in data with differing numbers of significant figures. In a calculation, we keep track of the number in each quantity so that we don't have more significant figures (more certainty) in the answer than in the data. If we do have too many significant figures, we must **round off** the answer.

The general rule for rounding is that *the least certain measurement sets the limit on certainty for the entire calculation and determines the number of significant figures in the final answer.* Suppose you want to find the density of a new ceramic. You measure the mass of a piece of it on a precise laboratory balance and obtain 3.8056 g; you measure the volume as 2.5 mL by displacement of water in a graduated cylinder. The mass has five significant figures, but the volume has only two. Should you report the density as 3.8056 g/2.5 mL = 1.5222 g/mL or as 1.5 g/mL? The answer with five significant figures implies more certainty than the answer with two. But you didn't measure the volume to five significant figures, so you can't possibly know the density with that much certainty. Therefore, you report 1.5 g/mL, the answer with two significant figures.

Rules for Arithmetic Operations The two rules in arithmetic calculations are

1. *For multiplication and division.* The answer contains the same number of significant figures as there are in the measurement with the *fewest significant figures*. Suppose you want to find the volume of a sheet of a new graphite composite. The length (9.2 cm) and width (6.8 cm) are obtained with a ruler, and the thickness (0.3744 cm) with a set of calipers. The calculation is

$$\text{Volume (cm}^3\text{)} = 9.2\text{ cm} \times 6.8\text{ cm} \times 0.3744\text{ cm} = 23.4225\text{ cm}^3 = 23\text{ cm}^3$$

Even though your calculator may show 23.4225 cm^3, you report 23 cm^3, the answer with two significant figures, the same as in the measurements with the lower number of significant figures. After all, if the length and width have two significant figures, you can't possibly know the volume with more certainty.

2. *For addition and subtraction.* The answer has the same number of decimal places as there are in the measurement with the *fewest decimal places*. Suppose you want the total volume after adding water to a protein solution: you have 83.5 mL of solution in a graduated cylinder and add 23.28 mL of water from a buret. The calculation is shown in the margin. Here the calculator shows 106.78 mL, but you report the volume as 106.8 mL, because the measurement with fewer decimal places (83.5 mL) has one decimal place *(see margin)*.

```
   83.5 mL
+ 23.28 mL
---------
  106.78 mL
```
Answer: Volume = 106.8 mL

Rules for Rounding Off You usually need to round off the final answer to the proper number of significant figures or decimal places. Notice that in calculating the volume

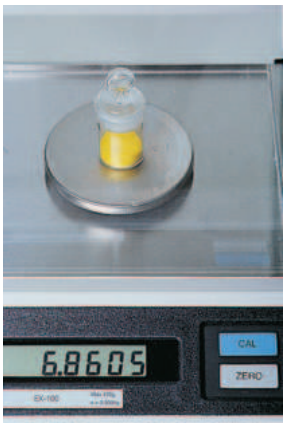

Figure 1.13 Significant figures and measuring devices. The mass measurement (6.8605 g) has more significant figures than the volume measurement (68.2 mL).

of the graphite composite, we removed the extra digits, but in calculating the total volume of the protein solution, we removed the extra digit and increased the last digit by one. The general rule for rounding is that *the least certain measurement sets the limit on the certainty of the final answer.* Here are detailed rules for rounding off:

1. If the digit removed is *more than 5,* the preceding number increases by 1: 5.379 rounds to 5.38 if you need three significant figures and to 5.4 if you need two.
2. If the digit removed is *less than 5,* the preceding number remains the same: 0.2413 rounds to 0.241 if you need three significant figures and to 0.24 if you need two.
3. If the digit removed *is 5,* the preceding number increases by 1 if it is odd and remains the same if it is even: 17.75 rounds to 17.8, but 17.65 rounds to 17.6. If the 5 is followed only by zeros, rule 3 is followed; if the 5 is followed by nonzeros, rule 1 is followed: 17.6500 rounds to 17.6, but 17.6513 rounds to 17.7.
4. *Always carry one or two additional significant figures through a multistep calculation and round off the final answer* ***only.*** Don't be concerned if you string together a calculation to check a sample or follow-up problem and find that your answer differs in the last decimal place from the one in the book. To show you the correct number of significant figures in text calculations, *we round off intermediate steps,* and that process may sometimes change the last digit.

Note that, unless you set a limit on your calculator, it gives answers with too many figures and you must round the displayed result.

Significant Figures in the Lab The measuring device you choose determines the number of significant figures you can obtain. Suppose an experiment requires a solution made by dissolving a solid in a liquid. You weigh the solid on an analytical balance and obtain a mass with five significant figures. It would make sense to measure the liquid with a buret or a pipet, which measures volumes to more significant figures than a graduated cylinder. If you do choose the cylinder, you would have to round off more digits, and some certainty in the mass value would be wasted (Figure 1.13). With experience, you'll choose a measuring device based on the number of significant figures you need in the final answer.

Exact Numbers **Exact numbers** have no uncertainty associated with them. Some are part of a unit conversion: by definition, there are exactly 60 minutes in 1 hour, 1000 micrograms in 1 milligram, and 2.54 centimeters in 1 inch. Other exact numbers result from actually counting items: there are exactly 3 coins in my hand, 26 letters in the English alphabet, and so forth. Therefore, unlike a measured quantity, *exact numbers do not limit the number of significant figures in a calculation.*

SAMPLE PROBLEM 1.10 Significant Figures and Rounding

Problem Perform the following calculations and round the answers to the correct number of significant figures:

(a) $\dfrac{16.3521\ \text{cm}^2 - 1.448\ \text{cm}^2}{7.085\ \text{cm}}$ **(b)** $\dfrac{(4.80\times10^4\ \text{mg})\left(\dfrac{1\ \text{g}}{1000\ \text{mg}}\right)}{11.55\ \text{cm}^3}$

Plan We use the rules just presented in the text: **(a)** We subtract before we divide. **(b)** We note that the unit conversion involves an exact number.

Solution **(a)** $\dfrac{16.3521\ \text{cm}^2 - 1.448\ \text{cm}^2}{7.085\ \text{cm}} = \dfrac{14.904\ \text{cm}^2}{7.085\ \text{cm}} = 2.104\ \text{cm}$

(b) $\dfrac{(4.80\times10^4\ \text{mg})\left(\dfrac{1\ \text{g}}{1000\ \text{mg}}\right)}{11.55\ \text{cm}^3} = \dfrac{48.0\ \text{g}}{11.55\ \text{cm}^3} = 4.16\ \text{g/cm}^3$

Check Note that in (a) we lose a decimal place in the numerator, and in (b) we retain 3 sf in the answer because there are 3 sf in 4.80. Rounding to the nearest whole number is always a good way to check: **(a)** $(16 - 1)/7 \approx 2$; **(b)** $(5\times10^4/1\times10^3)/12 \approx 4$.

FOLLOW-UP PROBLEMS

1.10A Perform the following calculation and round the answer to the correct number of significant figures: $$\frac{25.65\ \text{mL} + 37.4\ \text{mL}}{73.55\ \text{s}\left(\frac{1\ \text{min}}{60\ \text{s}}\right)}$$

1.10B Perform the following calculation and round the answer to the correct number of significant figures: $$\frac{154.64\ \text{g} - 35.26\ \text{g}}{4.20\ \text{cm} \times 5.12\ \text{cm} \times 6.752\ \text{cm}}$$

SOME SIMILAR PROBLEMS 1.56–1.59, 1.66, and 1.67

Precision, Accuracy, and Instrument Calibration

We may use the words "precision" and "accuracy" interchangeably in everyday speech, but for scientific measurements they have distinct meanings. **Precision,** or *reproducibility,* refers to how close the measurements in a series are to each other, and **accuracy** refers to how close each measurement is to the actual value. These terms are related to two widespread types of error:

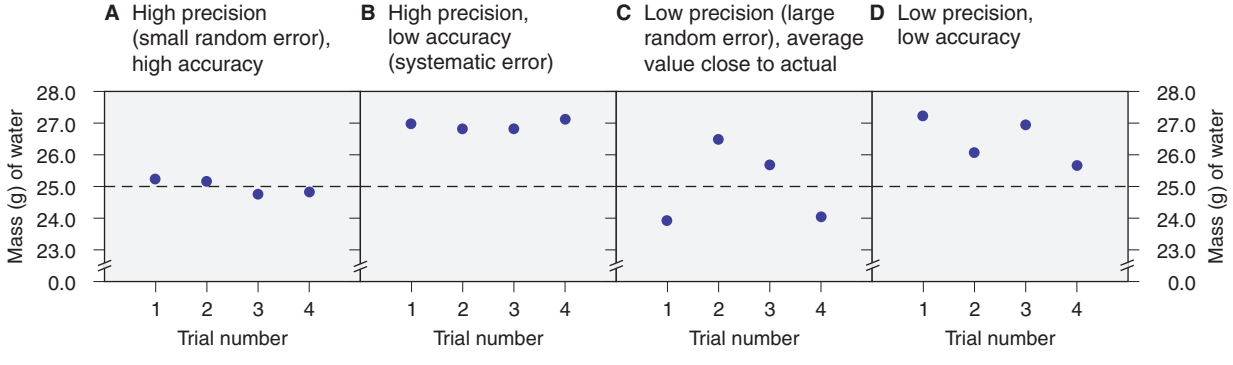
1. **Systematic error** produces values that are *either* all higher or all lower than the actual value. This type of error is part of the experimental system, often caused by a faulty device or by a consistent mistake in taking a reading.
2. **Random error,** in the absence of systematic error, produces values that are higher *and* lower than the actual value. Random error *always* occurs, but its size depends on the measurer's skill and the instrument's precision.

Precise measurements have low random error, that is, small deviations from the average. *Accurate measurements have low systematic error and, generally, low random error.* In some cases, when many measurements have a high random error, the *average* may still be accurate.

Suppose each of four students measures 25.0 mL of water in a preweighed graduated cylinder and then weighs the water *plus* cylinder on a balance. If the density of water is 1.00 g/mL at the temperature of the experiment, the *actual* mass of 25.0 mL of water is 25.0 g. Each student performs the operation four times, subtracts the mass of the empty cylinder, and obtains one of four graphs (Figure 1.14):

- In Graph A, random error is small; that is, precision is high (the weighings are reproducible). Accuracy is high as well, as all of the values are close to 25.0 g.
- Random error is also small and precision high in Graph B, but accuracy is low; there is systematic error, with all of the weighings above 25.0 g.
- In Graph C, random error is large and precision is low. But since the average of the scattered values is close to the actual value, systematic error is low.
- Graph D also exhibits large random error, but note that there is also significant systematic error in this case, resulting in low accuracy (all the values are high).

Figure 1.14 **Precision and accuracy in a laboratory calibration.**



Systematic error can be taken into account through **calibration,** comparing the measuring device with a known standard. The systematic error in Graph B, for example, might be caused by a poorly manufactured cylinder that reads "25.0" when it actually contains about 27 mL. If that cylinder had been calibrated, the student could have adjusted all volumes measured with it. The students also should calibrate the balance with standardized masses.

Summary of Section 1.5

- The final digit of a measurement is always estimated. Thus, all measurements have some uncertainty, which is expressed by the number of significant figures.
- The certainty of a calculated result depends on the certainty of the data, so the answer has as many significant figures as in the least certain measurement.
- Excess digits are rounded off in the final answer with a set of rules.
- The choice of laboratory device depends on the certainty needed.
- Exact numbers have as many significant figures as the calculation requires.
- Precision refers to how close values are to each other, and accuracy refers to how close values are to the actual value.
- Systematic errors give values that are either all higher or all lower than the actual value. Random errors give some values that are higher and some that are lower than the actual value.
- Precise measurements have low random error; accurate measurements have low systematic error and low random error.
- A systematic error is often caused by faulty equipment and can be compensated for by calibration.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The defining features of the states of matter (§1.1)
2. The distinction between physical and chemical properties and changes (§1.1; SPs 1.1, 1.2)
3. The nature of potential and kinetic energy and their interconversion (§1.1)
4. The process of approaching a phenomenon scientifically and the distinctions between observation, hypothesis, experiment, and model (§1.3)
5. The common units of length, volume, mass, and temperature and their numerical prefixes (§1.4)
6. The distinctions between mass and weight, heat and temperature, and intensive and extensive properties (§1.4)
7. The meaning of uncertainty in measurements and the use of significant figures and rounding (§1.5)
8. The distinctions between accuracy and precision and between systematic and random error (§1.5)

Master These Skills

1. Using conversion factors in calculations and a systematic approach of plan, solution, check, and follow-up for solving problems (§1.4; SPs 1.3–1.6)
2. Finding density from mass and volume (SP 1.7)
3. Converting among the Kelvin, Celsius, and Fahrenheit scales (SP 1.8)
4. Determining the number of significant figures (SP 1.9) and rounding to the correct number of digits (SP 1.10)

Key Equations and Relationships

Page numbers appear in parentheses.

1.1 Calculating density from mass and volume (23):

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$

1.2 Converting temperature from °C to K (25):

$$T\,(\text{in K}) = T\,(\text{in °C}) + 273.15$$

1.3 Converting temperature from K to °C (25):

$$T\,(\text{in °C}) = T\,(\text{in K}) - 273.15$$

1.4 Converting temperature from °C to °F (26):

$$T\,(\text{in °F}) = \tfrac{9}{5}T\,(\text{in °C}) + 32$$

1.5 Converting temperature from °F to °C (26):

$$T\,(\text{in °C}) = [T\,(\text{in °F}) - 32]\tfrac{5}{9}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

1.1A Chemical. The red-and-blue and separate red particles on the left become paired red and separate blue particles on the right.

1.1B Physical. The red particles are the same on the right and on the left, but they have changed from being close together in the solid state to being far apart in the gaseous state.

1.2A (a) Physical. Solid iodine changes to gaseous iodine.
(b) Chemical. Gasoline burns in air to form different substances.
(c) Chemical. In contact with air, substances in torn skin and blood react to form different substances.

1.2B (a) Physical. Gaseous water (water vapor) changes to droplets of liquid water.
(b) Chemical. Different substances are formed in the milk that give it a sour taste.
(c) Physical. Solid butter changes to a liquid.

1.3A Time (min)

$$= 10{,}500\ \cancel{\text{in}} \times \frac{1\ \cancel{\text{km}}}{1000\ \cancel{\text{in}}} \times \frac{1\ \cancel{\text{mi}}}{1.609\ \cancel{\text{km}}} \times \frac{15\ \text{min}}{1\ \cancel{\text{mi}}} = 98\ \text{min}$$

See Road Map 1.3A.

1.3B No. of virus particles

$$= 1.0\ \cancel{\text{in}} \times \frac{2.54\ \cancel{\text{cm}}}{1\ \cancel{\text{in}}} \times \frac{1\times10^{7}\ \cancel{\text{nm}}}{1\ \cancel{\text{cm}}} \times \frac{1\ \text{virus particle}}{30\ \cancel{\text{nm}}}$$

1.10B $$\frac{154.64\text{ g} - 35.26\text{ g}}{4.20\text{ cm} \times 5.12\text{ cm} \times 6.752\text{ cm}} = 0.823\text{ g/cm}$$

PROBLEMS

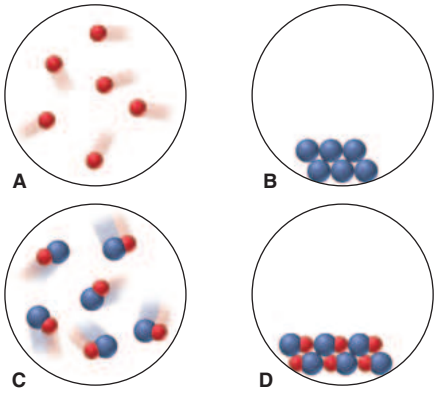
Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section.

Some Fundamental Definitions

(Sample Problems 1.1 and 1.2)

Concept Review Question

1.1 Scenes A–D represent atomic-scale views of different samples of substances:



(a) Under one set of conditions, the substances in A and B mix, and the result is depicted in C. Does this represent a chemical or a physical change?
(b) Under a second set of conditions, the same substances mix, and the result is depicted in D. Does this represent a chemical or a physical change?
(c) Under a third set of conditions, the sample depicted in C changes to that in D. Does this represent a chemical or a physical change?
(d) After the change in part (c) has occurred, does the sample have different chemical properties? Physical properties?

Skill-Building Exercises (grouped in similar pairs)

1.2 Describe solids, liquids, and gases in terms of how they fill a container. Use your descriptions to identify the physical state (at room temperature) of the following: (a) helium in a toy balloon; (b) mercury in a thermometer; (c) soup in a bowl.

1.3 Use your descriptions from Problem 1.2 to identify the physical state (at room temperature) of the following: (a) the air in your room; (b) tablets in a bottle of vitamins; (c) sugar in a packet.

1.4 Define *physical property* and *chemical property*. Identify each type of property in the following statements:
(a) Yellow-green chlorine gas attacks silvery sodium metal to form white crystals of sodium chloride (table salt).
(b) A magnet separates a mixture of black iron shavings and white sand.

1.5 Define *physical change* and *chemical change*. State which type of change occurs in each of the following statements:
(a) Passing an electric current through molten magnesium chloride yields molten magnesium and gaseous chlorine.
(b) The iron in discarded automobiles slowly forms reddish brown, crumbly rust.

1.6 Which of the following is a chemical change? Explain your reasoning: (a) boiling canned soup; (b) toasting a slice of bread; (c) chopping a log; (d) burning a log.

1.7 Which of the following changes can be reversed by changing the temperature: (a) dew condensing on a leaf; (b) an egg turning

hard when it is boiled; (c) ice cream melting; (d) a spoonful of batter cooking on a hot griddle?

1.8 For each pair, which has higher potential energy?
(a) The fuel in your car or the gaseous products in its exhaust
(b) Wood in a fire or the ashes after the wood burns

1.9 For each pair, which has higher kinetic energy?
(a) A sled resting at the top of a hill or a sled sliding down the hill
(b) Water above a dam or water falling over the dam

Chemical Arts and the Origins of Modern Chemistry

Concept Review Questions

1.10 The alchemical, medical, and technological traditions were precursors to chemistry. State a contribution that each made to the development of the science of chemistry.

1.11 How did the phlogiston theory explain combustion?

1.12 One important observation that supporters of the phlogiston theory had trouble explaining was that the calx of a metal weighs more than the metal itself. Why was that observation important? How did the phlogistonists respond?

1.13 Lavoisier developed a new theory of combustion that overturned the phlogiston theory. What measurements were central to his theory, and what key discovery did he make?

The Scientific Approach: Developing a Model

Concept Review Questions

1.14 How are the key elements of scientific thinking used in the following scenario? While making toast, you notice it fails to pop out of the toaster. Thinking the spring mechanism is stuck, you notice that the bread is unchanged. Assuming you forgot to plug in the toaster, you check and find it is plugged in. When you take the toaster into the dining room and plug it into a different outlet, you find the toaster works. Returning to the kitchen, you turn on the switch for the overhead light and nothing happens.

1.15 Why is a quantitative observation more useful than a non-quantitative one? Which of the following is (are) quantitative? (a) The Sun rises in the east. (b) A person weighs one-sixth as much on the Moon as on Earth. (c) Ice floats on water. (d) A hand pump cannot draw water from a well more than 34 ft deep.

1.16 Describe the essential features of a well-designed experiment.

1.17 Describe the essential features of a scientific model.

Measurement in Scientific Study

(Sample Problems 1.3 to 1.8)

Concept Review Questions

1.18 Explain the difference between mass and weight. Why is your weight on the Moon one-sixth that on Earth?

1.19 When you convert feet to inches, how do you decide which part of the conversion factor should be in the numerator and which in the denominator?

1.20 For each of the following cases, state whether the density of the object increases, decreases, or remains the same:
(a) A sample of chlorine gas is compressed.
(b) A lead weight is carried up a high mountain.
(c) A sample of water is frozen.
(d) An iron bar is cooled.
(e) A diamond is submerged in water.

1.21 Explain the difference between heat and temperature. Does 1 L of water at 65°F have more, less, or the same quantity of energy as 1 L of water at 65°C?

1.22 A one-step conversion is sufficient to convert a temperature in the Celsius scale to the Kelvin scale, but not to the Fahrenheit scale. Explain.

1.23 Describe the difference between intensive and extensive properties. Which of the following properties are intensive: (a) mass; (b) density; (c) volume; (d) melting point?

Skill-Building Exercises (grouped in similar pairs)

1.24 Write the conversion factor(s) for
(a) in^2 to m^2 (b) km^2 to cm^2
(c) mi/h to m/s (d) lb/ft^3 to g/cm^3

1.25 Write the conversion factor(s) for
(a) cm/min to in/s (b) m^3 to in^3
(c) m/s^2 to km/h^2 (d) gal/h to L/min

1.26 The average radius of a molecule of lysozyme, an enzyme in tears, is 1430 pm. What is its radius in nanometers (nm)?

1.27 The radius of a barium atom is 2.22×10^{-10} m. What is its radius in angstroms (Å)?

1.28 What is the length in inches (in) of a 100.-m soccer field?

1.29 The center on your school's basketball team is 6 ft 10 in tall. How tall is the player in millimeters (mm)?

1.30 A small hole in the wing of a space shuttle requires a 20.7-cm^2 patch. (a) What is the patch's area in square kilometers (km^2)? (b) If the patching material costs NASA \$3.25/in^2, what is the cost of the patch?

1.31 The area of a telescope lens is 7903 mm^2. (a) What is the area in square feet (ft^2)? (b) If it takes a technician 45 s to polish 135 mm^2, how long does it take her to polish the entire lens?

1.32 Express your body weight in kilograms (kg).

1.33 There are 2.60×10^{15} short tons of oxygen in the atmosphere (1 short ton = 2000 lb). How many metric tons of oxygen are present (1 metric ton = 1000 kg)?

1.34 The average density of Earth is 5.52 g/cm^3. What is its density in (a) kg/m^3; (b) lb/ft^3?

1.35 The speed of light in a vacuum is 2.998×10^8 m/s. What is its speed in (a) km/h; (b) mi/min?

1.36 The volume of a certain bacterial cell is 2.56 μm^3. (a) What is its volume in cubic millimeters (mm^3)? (b) What is the volume of 10^5 cells in liters (L)?

1.37 (a) How many cubic meters of milk are in 1 qt (946.4 mL)? (b) How many liters of milk are in 835 gal (1 gal = 4 qt)?

1.38 An empty vial weighs 55.32 g. (a) If the vial weighs 185.56 g when filled with liquid mercury (d = 13.53 g/cm^3), what is its volume? (b) How much would the vial weigh if it were filled with water (d = 0.997 g/cm^3 at 25°C)?

1.39 An empty Erlenmeyer flask weighs 241.3 g. When filled with water (d = 1.00 g/cm^3), the flask and its contents weigh 489.1 g. (a) What is the flask's volume? (b) How much does the flask weigh when filled with chloroform (d = 1.48 g/cm^3)?

1.40 A small cube of aluminum measures 15.6 mm on a side and weighs 10.25 g. What is the density of aluminum in g/cm^3?

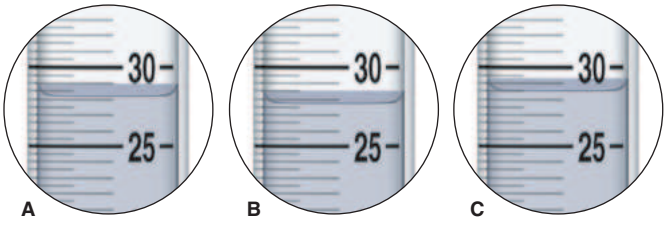
1.41 A steel ball-bearing with a circumference of 32.5 mm weighs 4.20 g. What is the density of the steel in g/cm^3 (V of a sphere = $\frac{4}{3}\pi r^3$; circumference of a circle = $2\pi r$)?

1.42 Perform the following conversions:
(a) 68°F (a pleasant spring day) to °C and K
(b) −164°C (the boiling point of methane, the main component of natural gas) to K and °F
(c) 0 K (absolute zero, theoretically the coldest possible temperature) to °C and °F

1.43 Perform the following conversions:
(a) 106°F (the body temperature of many birds) to K and °C
(b) 3410°C (the melting point of tungsten, the highest for any metallic element) to K and °F
(c) 6.1×10^3 K (the surface temperature of the Sun) to °F and °C

Problems in Context

1.44 A 25.0-g sample of each of three unknown metals is added to 25.0 mL of water in graduated cylinders A, B, and C, and the final volumes are depicted in the circles below. Given their densities, identify the metal in each cylinder: zinc (7.14 g/mL), iron (7.87 g/mL), or nickel (8.91 g/mL).



1.45 The distance between two adjacent peaks on a wave is called the *wavelength.*
(a) The wavelength of a beam of ultraviolet light is 247 nanometers (nm). What is its wavelength in meters?
(b) The wavelength of a beam of red light is 6760 pm. What is its wavelength in angstroms (Å)?

1.46 Each of the beakers depicted below contains two liquids that do not dissolve in each other. Three of the liquids are designated A, B, and C, and water is designated W.

(a) Which of the liquids is (are) more dense than water and which less dense?
(b) If the densities of W, C, and A are 1.0 g/mL, 0.88 g/mL, and 1.4 g/mL, respectively, which of the following densities is possible for liquid B: 0.79 g/mL, 0.86 g/mL, 0.94 g/mL, or 1.2 g/mL?

1.47 A cylindrical tube 9.5 cm high and 0.85 cm in diameter is used to collect blood samples. How many cubic decimeters (dm^3) of blood can it hold (V of a cylinder = $\pi r^2 h$)?

1.48 Copper can be drawn into thin wires. How many meters of 34-gauge wire (diameter = 6.304×10^{-3} in) can be produced from the copper in 5.01 lb of covellite, an ore of copper that is 66% copper by mass? (*Hint:* Treat the wire as a cylinder: V of cylinder = $\pi r^2 h$; d of copper = 8.95 g/cm^3.)

Uncertainty in Measurement: Significant Figures

(Sample Problems 1.9 and 1.10)

Concept Review Questions

1.49 What is an exact number? How are exact numbers treated differently from other numbers in a calculation?

1.50 Which procedure(s) decrease(s) the random error of a measurement: (1) taking the average of more measurements; (2) calibrating the instrument; (3) taking fewer measurements? Explain.

1.51 A newspaper reported that the attendance at Slippery Rock's home football game was 16,532. (a) How many significant figures does this number contain? (b) Was the actual number of people counted? (c) After Slippery Rock's next home game, the newspaper reported an attendance of 15,000. If you assume that this number contains two significant figures, how many people could actually have been at the game?

Skill-Building Exercises (grouped in similar pairs)

1.52 Underline the significant zeros in the following numbers:
(a) 0.41 (b) 0.041 (c) 0.0410 (d) 4.0100×10^4

1.53 Underline the significant zeros in the following numbers:
(a) 5.08 (b) 508 (c) 5.080×10^3 (d) 0.05080

1.54 Round off each number to the indicated number of significant figures (sf): (a) 0.0003554 (to 2 sf); (b) 35.8348 (to 4 sf); (c) 22.4555 (to 3 sf).

1.55 Round off each number to the indicated number of significant figures (sf): (a) 231.554 (to 4 sf); (b) 0.00845 (to 2 sf); (c) 144,000 (to 2 sf).

1.56 Round off each number in the following calculation to one fewer significant figure, and find the answer:

$$\frac{19 \times 155 \times 8.3}{3.2 \times 2.9 \times 4.7}$$

1.57 Round off each number in the following calculation to one fewer significant figure, and find the answer:

$$\frac{10.8 \times 6.18 \times 2.381}{24.3 \times 1.8 \times 19.5}$$

1.58 Carry out the following calculations, making sure that your answer has the correct number of significant figures:
(a) $\dfrac{2.795\text{ m} \times 3.10\text{ m}}{6.48\text{ m}}$
(b) $V = \frac{4}{3}\pi r^3$, where r = 17.282 mm
(c) 1.110 cm + 17.3 cm + 108.2 cm + 316 cm

1.59 Carry out the following calculations, making sure that your answer has the correct number of significant figures:
(a) $\dfrac{2.420\text{ g} + 15.6\text{ g}}{4.8\text{ g}}$ (b) $\dfrac{7.87\text{ mL}}{16.1\text{ mL} - 8.44\text{ mL}}$
(c) $V = \pi r^2 h$, where r = 6.23 cm and h = 4.630 cm

1.60 Write the following numbers in scientific notation:
(a) 131,000.0 (b) 0.00047 (c) 210,006 (d) 2160.5

1.61 Write the following numbers in scientific notation:
(a) 282.0 (b) 0.0380 (c) 4270.8 (d) 58,200.9

1.62 Write the following numbers in standard notation. Use a terminal decimal point when needed.
(a) 5.55×10^{3} (b) 1.0070×10^{4} (c) 8.85×10^{-7} (d) 3.004×10^{-3}

1.63 Write the following numbers in standard notation. Use a terminal decimal point when needed.
(a) 6.500×10^{3} (b) 3.46×10^{-5} (c) 7.5×10^{2} (d) 1.8856×10^{2}

1.64 Convert the following into correct scientific notation:
(a) 802.5×10^{2} (b) 1009.8×10^{-6} (c) 0.077×10^{-9}

1.65 Convert the following into correct scientific notation:
(a) 14.3×10^{1} (b) 851×10^{-2} (c) 7500×10^{-3}

1.66 Carry out each calculation, paying special attention to significant figures, rounding, and units (J = joule, the SI unit of energy; mol = mole, the SI unit for amount of substance):

(a) $$\frac{(6.626\times10^{-34}\ \text{J·s})(2.9979\times10^{8}\ \text{m/s})}{489\times10^{-9}\ \text{m}}$$

(b) $$\frac{(6.022\times10^{23}\ \text{molecules/mol})(1.23\times10^{2}\ \text{g})}{46.07\ \text{g/mol}}$$

(c) $(6.022\times10^{23}\ \text{atoms/mol})(2.18\times10^{-18}\ \text{J/atom})\left(\frac{1}{2^2}-\frac{1}{3^2}\right)$,

where the numbers 2 and 3 in the last term are exact

1.67 Carry out each calculation, paying special attention to significant figures, rounding, and units:

(a) $$\frac{4.32\times10^{7}\ \text{g}}{\frac{4}{3}(3.1416)(1.95\times10^{2}\ \text{cm})^3}$$ (The term $\frac{4}{3}$ is exact.)

(b) $$\frac{(1.84\times10^{2}\ \text{g})(44.7\ \text{m/s})^2}{2}$$ (The term 2 is exact.)

(c) $$\frac{(1.07\times10^{-4}\ \text{mol/L})^2(3.8\times10^{-3}\ \text{mol/L})}{(8.35\times10^{-5}\ \text{mol/L})(1.48\times10^{-2}\ \text{mol/L})^3}$$

1.68 Which statements include exact numbers?
(a) Angel Falls is 3212 ft high.
(b) There are 8 known planets in the Solar System.
(c) There are 453.59 g in 1 lb.
(d) There are 1000 mm in 1 m.

1.69 Which of the following include exact numbers?
(a) The speed of light in a vacuum is a physical constant; to six significant figures, it is 2.99792×10^{8} m/s.
(b) The density of mercury at 25°C is 13.53 g/mL.
(c) There are 3600 s in 1 h.
(d) In 2012, the United States had 50 states.

Problems in Context

1.70 How long is the metal strip shown below? Be sure to answer with the correct number of significant figures.

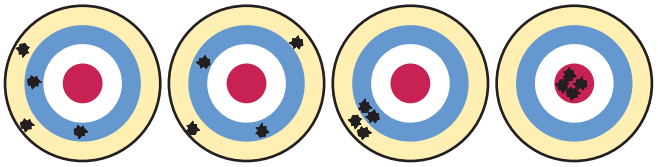
1.71 These organic solvents are used to clean compact discs:

Solvent	Density (g/mL) at 20°C
Chloroform	1.492
Diethyl ether	0.714
Ethanol	0.789
Isopropanol	0.785
Toluene	0.867

(a) If a 15.00-mL sample of CD cleaner weighs 11.775 g at 20°C, which solvent does the sample most likely contain?
(b) The chemist analyzing the cleaner calibrates her equipment and finds that the pipet is accurate to ±0.02 mL, and the balance is accurate to ±0.003 g. Is this equipment precise enough to distinguish between ethanol and isopropanol?

1.72 A laboratory instructor gives a sample of amino-acid powder to each of four students, I, II, III, and IV, and they weigh the samples. The true value is 8.72 g. Their results for three trials are
I: 8.72 g, 8.74 g, 8.70 g II: 8.56 g, 8.77 g, 8.83 g
III: 8.50 g, 8.48 g, 8.51 g IV: 8.41 g, 8.72 g, 8.55 g
(a) Calculate the average mass from each set of data, and tell which set is the most accurate.
(b) Precision is a measure of the average of the deviations of each piece of data from the average value. Which set of data is the most precise? Is this set also the most accurate?
(c) Which set of data is both the most accurate and the most precise?
(d) Which set of data is both the least accurate and the least precise?

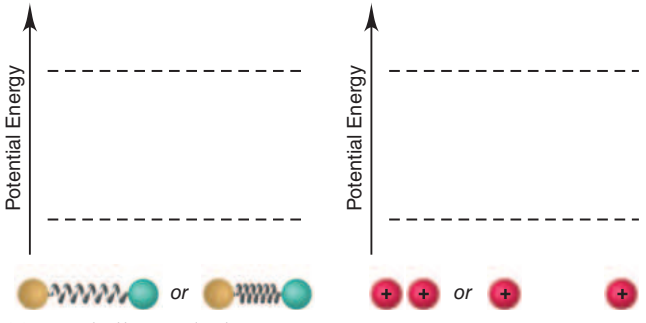
1.73 The following dartboards illustrate the types of errors often seen in measurements. The bull's-eye represents the actual value, and the darts represent the data.



(a) Which experiments yield the same average result?
(b) Which experiment(s) display(s) high precision?
(c) Which experiment(s) display(s) high accuracy?
(d) Which experiment(s) show(s) a systematic error?

Comprehensive Problems

1.74 Two blank potential energy diagrams appear below. Beneath each diagram are objects to place in the diagram. Draw the objects on the dashed lines to indicate higher or lower potential energy and label each case as more or less stable:



(a) Two balls attached to a relaxed *or* a compressed spring
(b) Two positive charges near *or* apart from each other

1.75 The scenes below illustrate two different mixtures. When mixture A at 273 K is heated to 473 K, mixture B results.

(a) How many different chemical changes occur?
(b) How many different physical changes occur?

1.76 Bromine is used to prepare the pesticide methyl bromide and flame retardants for plastic electronic housings. It is recovered from seawater, underground brines, and the Dead Sea. The average concentrations of bromine in seawater (d = 1.024 g/mL) and the Dead Sea (d = 1.22 g/mL) are 0.065 g/L and 0.50 g/L, respectively. What is the mass ratio of bromine in the Dead Sea to that in seawater?

1.77 An Olympic-size pool is 50.0 m long and 25.0 m wide. (a) How many gallons of water (d = 1.0 g/mL) are needed to fill the pool to an average depth of 4.8 ft? (b) What is the mass (in kg) of water in the pool?

1.78 At room temperature (20°C) and pressure, the density of air is 1.189 g/L. An object will float in air if its density is less than that of air. In a buoyancy experiment with a new plastic, a chemist creates a rigid, thin-walled ball that weighs 0.12 g and has a volume of 560 cm^3.
(a) Will the ball float if it is evacuated?
(b) Will it float if filled with carbon dioxide (d = 1.830 g/L)?
(c) Will it float if filled with hydrogen (d = 0.0899 g/L)?
(d) Will it float if filled with oxygen (d = 1.330 g/L)?
(e) Will it float if filled with nitrogen (d = 1.165 g/L)?
(f) For any case in which the ball will float, how much weight must be added to make it sink?

1.79 Asbestos is a fibrous silicate mineral with remarkably high tensile strength. But it is no longer used because airborne asbestos particles can cause lung cancer. Grunerite, a type of asbestos, has a tensile strength of 3.5×10^2 kg/mm^2 (thus, a strand of grunerite with a 1-mm^2 cross-sectional area can hold up to 3.5×10^2 kg). The tensile strengths of aluminum and Steel No. 5137 are 2.5×10^4 lb/in^2 and 5.0×10^4 lb/in^2, respectively. Calculate the cross-sectional areas (in mm^2) of wires of aluminum and of Steel No. 5137 that have the same tensile strength as a fiber of grunerite with a cross-sectional area of 1.0 μm^2.

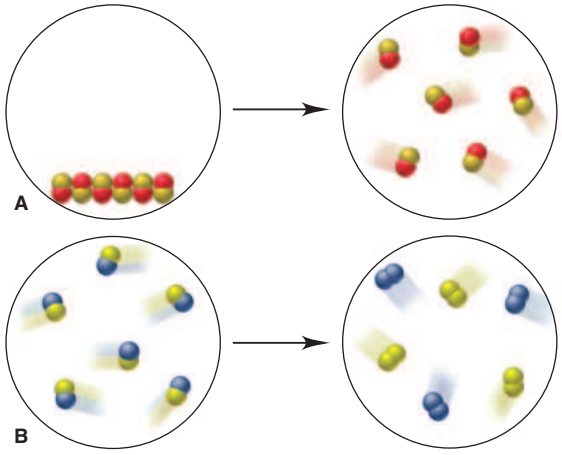
1.80 Earth's oceans have an average depth of 3800 m, a total surface area of 3.63×10^8 km^2, and an average concentration of dissolved gold of 5.8×10^{-9} g/L. (a) How many grams of gold are in the oceans? (b) How many cubic meters of gold are in the oceans? (c) Assuming the price of gold is $1595/troy oz, what is the value of gold in the oceans (1 troy oz = 31.1 g; d of gold = 19.3 g/cm^3)?

1.81 Brass is an alloy of copper and zinc. Varying the mass percentages of the two metals produces brasses with different properties. A brass called *yellow zinc* has high ductility and strength and is 34–37% zinc by mass. (a) Find the mass range (in g) of copper in 185 g of yellow zinc. (b) What is the mass range (in g) of zinc in a sample of yellow zinc that contains 46.5 g of copper?

1.82 Liquid nitrogen is obtained from liquefied air and is used industrially to prepare frozen foods. It boils at 77.36 K. (a) What is this temperature in °C? (b) What is this temperature in °F? (c) At the boiling point, the density of the liquid is 809 g/L and that of the gas is 4.566 g/L. How many liters of liquid nitrogen are produced when 895.0 L of nitrogen gas is liquefied at 77.36 K?

1.83 A jogger runs at an average speed of 5.9 mi/h. (a) How fast is she running in m/s? (b) How many kilometers does she run in 98 min? (c) If she starts a run at 11:15 am, what time is it after she covers 4.75×10^4 ft?

1.84 Scenes A and B depict changes in matter at the atomic scale:



(a) Which show(s) a physical change?
(b) Which show(s) a chemical change?
(c) Which result(s) in different physical properties?
(d) Which result(s) in different chemical properties?
(e) Which result(s) in a change in state?

1.85 If a temperature scale were based on the freezing point (5.5°C) and boiling point (80.1°C) of benzene and the temperature difference between these points was divided into 50 units (called °X), what would be the freezing and boiling points of water in °X? (See Figure 1.11, p. 25.)

1.86 Earth's surface area is 5.10×10^8 km^2; its crust has a mean thickness of 35 km and a mean density of 2.8 g/cm^3. The two most abundant elements in the crust are oxygen (4.55×10^5 g/t, where t stands for "metric ton"; 1 t = 1000 kg) and silicon (2.72×10^5 g/t), and the two rarest nonradioactive elements are ruthenium and rhodium, each with an abundance of 1×10^{-4} g/t. What is the total mass of each of these elements in Earth's crust?

2 The Components of Matter

2.1 Elements, Compounds, and Mixtures: An Atomic Overview

2.2 The Observations That Led to an Atomic View of Matter
Mass Conservation
Definite Composition
Multiple Proportions

2.3 Dalton's Atomic Theory
Postulates of the Theory
Explanation of the Mass Laws

2.4 The Observations That Led to the Nuclear Atom Model
Discovery of the Electron
Discovery of the Nucleus

2.9 Mixtures: Classification and Separation
An Overview of the Components of Matter

Concepts and Skills to Review Before You Study This Chapter

- physical and chemical change (Section 1.1)
- states of matter (Section 1.1)
- attraction and repulsion between charged particles (Section 1.1)
- meaning of a scientific model (Section 1.3)
- SI units and conversion factors (Section 1.4)
- significant figures in calculations (Section 1.5)

Look closely at almost any sample of matter—a rock, a piece of wood, a butterfly wing, especially an electronic device *(photo)*—and you'll see that it's made of smaller parts. With a microscope, you'll see still smaller parts. And, if you could zoom in a billion times closer, you'd find, on the atomic scale, the ultimate particles that make up all things.

Modern scientists are certainly not the first to wonder what things are made of. The philosophers of ancient Greece did too, and most believed that everything was made of one or, at most, a few elemental substances (elements), whose hotness, wetness, hardness, and other properties gave rise to the properties of everything else. Democritus (c. 460–370 BC), the father of atomism, took a different approach, and his reasoning went something like this: if you cut a piece of, say, aluminum foil smaller and smaller, you must eventually reach a particle of aluminum so small that it can no longer be cut. Therefore, matter is ultimately composed of indivisible particles with nothing but empty space between them. He called the particles *atoms* (Greek *atomos,* "uncuttable") and proclaimed: "According to convention, there is a sweet and a bitter, a hot and a cold, and . . . there is order. In truth, there are atoms and a void." But, Aristotle, one of the greatest and most influential philosophers of Western culture, said it was impossible for "nothing" to exist, and the concept of atoms was suppressed for 2000 years.

Finally, in the 17th century, the English scientist Robert Boyle argued that, by definition, an element is composed of "simple Bodies, not made of any other Bodies, of which all mixed Bodies are compounded, and into which they are ultimately resolved," a description remarkably close to our idea of an element, with atoms being the "simple Bodies." The next two centuries saw rapid progress in chemistry and the development of a "billiard-ball" image of the atom. Then, an early 20th-century burst of creativity led to our current model of an atom with a complex internal structure.

IN THIS CHAPTER . . . *We examine the properties and composition of matter on the macroscopic and atomic scales.*

- We relate the three types of observable matter—elements, compounds, and mixtures—to the atoms, ions, and molecules they consist of.
- We see how the defining properties of the types of matter relate to 18th-century laws concerning the masses of substances that react with each other.
- We examine the 19th-century atomic model proposed to explain these laws.
- We describe some 20th- and 21st-century experiments that have led to our current understanding of atomic structure and atomic mass.
- We focus on the general organization of the elements in the periodic table and introduce the two major ways that elements combine.
- We derive names and formulas of compounds and calculate their masses on the atomic scale.
- We examine some of the ways chemists depict molecules.
- We classify mixtures and see how to separate them in the lab.
- We present a final overview of the components of matter.

2.1 ELEMENTS, COMPOUNDS, AND MIXTURES: AN ATOMIC OVERVIEW

Based on its composition, matter can be classified into three types—elements, compounds, and mixtures. Elements and compounds are called **substances,** matter with a *fixed* composition; mixtures are not substances because they have a variable composition.

1. *Elements.* An **element** is *the simplest type of matter with unique physical and chemical properties. It consists of only one kind of atom* and, therefore, cannot be broken down into a simpler type of matter by any physical or chemical methods. Each element has a name, such as silicon, oxygen, or copper. A sample of silicon contains only silicon atoms. The *macroscopic* properties of a piece of silicon, such as color, density, and combustibility, are different from those of a piece of copper because the *submicroscopic* properties of silicon atoms are different from those of copper atoms; that is, *each element is unique because the properties of its atoms are unique.*

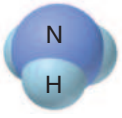
In nature, most elements exist as populations of atoms, either separated or in contact with each other, depending on the physical state. Figure 2.1A shows atoms of an element in its gaseous state. Several elements occur in molecular form: a **molecule** is an independent structure of two or more atoms bound together (Figure 2.1B). Oxygen, for example, occurs in air as *diatomic* (two-atom) molecules.

2. *Compounds.* A **compound** *consists of two or more different elements that are bonded chemically* (Figure 2.1C). That is, the elements in a compound are not just mixed together: their atoms have joined in a chemical reaction. Many compounds, such as ammonia, water, and carbon dioxide, consist of molecules. But many others, like sodium sulfate (which we'll discuss shortly) and silicon dioxide, do not.

All compounds have two defining features:

- *The elements are present in fixed parts by mass* (fixed mass ratio). This is so because *each unit of the compound consists of a fixed number of atoms of each element.* For example, consider a sample of ammonia. It is 14 parts nitrogen by mass and 3 parts hydrogen by mass *because* 1 nitrogen atom has 14 times the mass of 1 hydrogen atom, and each ammonia molecule consists of 1 nitrogen atom and 3 hydrogen atoms:

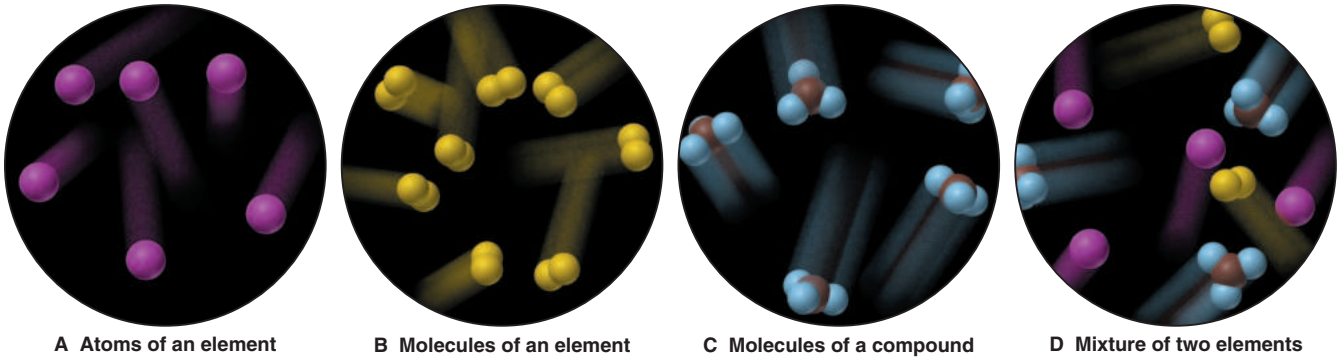
  Ammonia gas is 14 parts N by mass and 3 parts H by mass.
  1 N atom has 14 times the mass of 1 H atom.
  Each ammonia molecule consists of 1 N atom and 3 H atoms.



- *A compound's properties are different from the properties of its elements.* Table 2.1 shows a striking example: soft, silvery sodium metal and yellow-green, poisonous chlorine gas are very different from the compound they form—white, crystalline sodium chloride, or common table salt!

In practical terms, unlike an element, *a compound can be broken down into simpler substances*—its component elements. For example, an electric current breaks down molten sodium chloride into metallic sodium and chlorine gas. By definition, this breakdown is a *chemical change,* not a physical one.

Figure 2.1 Elements, compounds, and mixtures on the atomic scale. The samples depicted here are gases, but the three types of matter also occur as liquids and solids.



A Atoms of an element | B Molecules of an element | C Molecules of a compound | D Mixture of two elements and a compound

Table 2.1 Some of the Very Different Properties of Sodium, Chlorine, and Sodium Chloride

Property	Sodium	+	Chlorine	⟶	Sodium Chloride
Melting point	97.8°C		−101°C		801°C
Boiling point	881.4°C		−34°C		1413°C
Color	Silvery		Yellow-green		Colorless (white)
Density	0.97 g/cm^3		0.0032 g/cm^3		2.16 g/cm^3
Behavior in water	Reacts		Dissolves slightly		Dissolves freely

3. *Mixtures.* A **mixture** *consists of two or more substances (elements and/or compounds) that are physically intermingled,* ***not*** *chemically combined.* Because a mixture is *not* a substance, *the components* ***can*** *vary in their parts by mass*. A mixture of the compounds sodium chloride and water, for example, can have many different parts by mass of salt to water. On the atomic scale, a mixture consists of the individual units of its component elements and/or compounds (Figure 2.1D). It makes sense, then, that *a mixture retains many of the properties of its components.* Saltwater, for instance, is colorless like water and tastes salty like sodium chloride.

Unlike compounds, mixtures can be separated into their components by *physical changes;* chemical changes are not needed. For example, the water in saltwater can be boiled off, a physical process that leaves behind solid sodium chloride. The following sample problem will help you to differentiate these types of matter.

SAMPLE PROBLEM 2.1 Distinguishing Elements, Compounds, and Mixtures at the Atomic Scale

Problem The scenes below represent atomic-scale views of three samples of matter:

(a) 
(b) 
(c) 
Describe each sample as an element, compound, or mixture.

Plan We have to determine the type of matter by examining the component particles. If a sample contains only one type of particle, it is either an element or a compound; if it contains more than one type, it is a mixture. Particles of an element have only one kind of atom (one color), and particles of a compound have two or more kinds of atoms.

Solution **(a)** Mixture: there are three different types of particles. Two types contain only one kind of atom, either green or purple, so they are elements, and the third type contains two red atoms for every one yellow, so it is a compound.

(b) Element: the sample consists of only blue atoms.

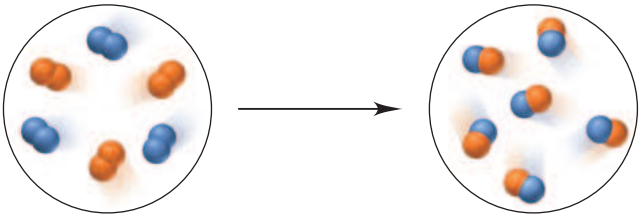
(c) Compound: the sample consists of molecules that each have two black and six blue atoms.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

2.1A Does each of the following scenes best represent an element, a compound, or a mixture?

(a) 
(b) 
(c) 
2.1B Describe the following representation of a reaction in terms of elements, compounds, and mixtures.



SOME SIMILAR PROBLEMS 2.3, 2.4, and 2.9

Summary of Section 2.1

- All matter exists as either elements, compounds, or mixtures.
- Every element or compound is a substance, matter with a fixed composition.
- An element consists of only one type of atom and occurs as collections of individual atoms or molecules; a molecule consists of two or more atoms chemically bonded together.
- A compound contains two or more elements chemically combined and exhibits different properties from its component elements. The elements occur in fixed parts by mass because each unit of the compound has a fixed number of each type of atom. Only a chemical change can break down a compound into its elements.
- A mixture consists of two or more substances mixed together, *not* chemically combined. The components exhibit their individual properties, can be present in any proportion, and can be separated by physical changes.

2.2 THE OBSERVATIONS THAT LED TO AN ATOMIC VIEW OF MATTER

Any model of the composition of matter had to explain three so-called mass laws: the *law of mass conservation,* the *law of definite (or constant) composition,* and the *law of multiple proportions.*

Mass Conservation

The most fundamental chemical observation of the 18th century was the **law of mass conservation:** *the total mass of substances does not change during a chemical reaction.* The *number* of substances may change and, by definition, their properties must, but the *total amount* of matter remains constant. (Lavoisier first stated this law on the basis of his combustion experiments.) Figure 2.2 illustrates mass conservation because

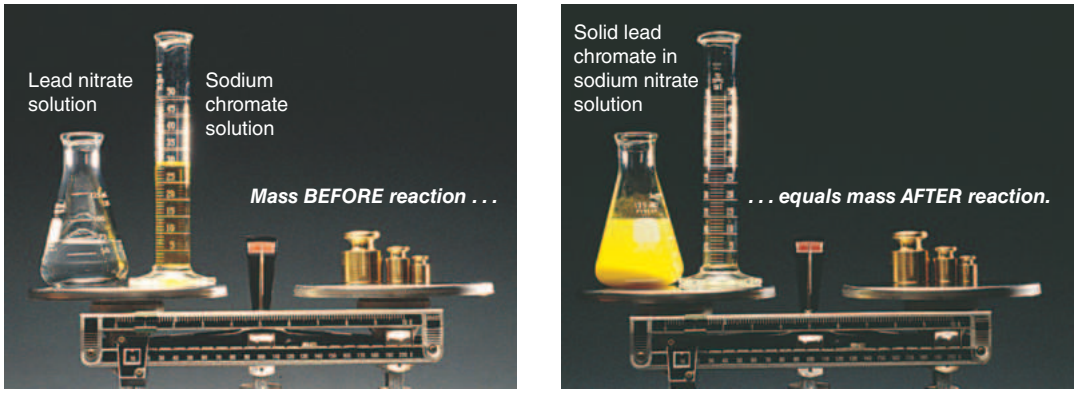


Figure 2.2 The law of mass conservation.

the lead nitrate and sodium chromate solutions *(left)* have the same mass as the solid lead chromate in sodium nitrate solution *(right)* that forms after their reaction.

Even in a complex biochemical change, such as the metabolism of the sugar glucose, which involves many reactions, mass is conserved. For example, in the reaction of, say, 180 g of glucose, we have

$$\begin{aligned} 180\text{ g glucose} + 192\text{ g oxygen gas} &\longrightarrow 264\text{ g carbon dioxide} + 108\text{ g water} \\ 372\text{ g material before} &\longrightarrow 372\text{ g material after} \end{aligned}$$

Mass conservation means that, based on all chemical experience, *matter cannot be created or destroyed.*

To be precise about it, however, we now know, based on the work of Albert Einstein (1879–1955), that the mass before and after a reaction is not *exactly* the same. Some mass is converted to energy, or vice versa, but the difference is too small to measure, even with the best balance. For example, when 100 g of carbon burns, the carbon dioxide formed weighs 0.000000036 g (3.6×10^{-8} g) less than the sum of the carbon and oxygen that reacted. Because the energy changes of *chemical* reactions are so small, for all practical purposes, mass *is* conserved. Later in the text, you'll see that energy changes in *nuclear* reactions are so large that mass changes are easy to measure.

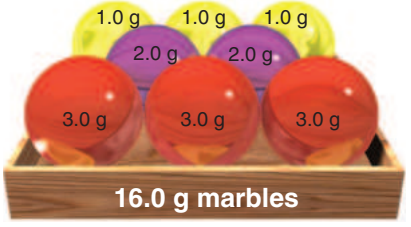
Definite Composition

The sodium chloride in your salt shaker is the same substance whether it comes from a salt mine, a salt flat, or any other source. This fact is expressed in the **law of definite (or constant) composition,** which states that *no matter what its source, a particular compound is composed of the same elements in the same parts (fractions) by mass.* The **fraction by mass (mass fraction)** is the part of the compound's mass that each element contributes. It is obtained by dividing the mass of each element in the compound by the mass of the compound. The **percent by mass (mass percent, mass %)** is the fraction by mass expressed as a percentage (multiplied by 100):

$$\text{Mass fraction} = \frac{\text{mass of element X in compound A}}{\text{mass of compound A}}$$

$$\text{Mass percent} = \text{mass fraction} \times 100$$

For an everyday example, consider a box that contains three types of marbles *(see margin):* yellow ones weigh 1.0 g each, purple 2.0 g each, and red 3.0 g each. Each type makes up a fraction of the total mass of marbles, 16.0 g. The *mass fraction* of yellow marbles is their number times their mass divided by the total mass:



$$\text{Mass fraction of yellow marbles} = \frac{\text{no. of yellow marbles} \times \text{mass of yellow marbles}}{\text{total mass of marbles}}$$

$$= \frac{3\ \cancel{\text{marbles}} \times 1.0\ \text{g}/\cancel{\text{marble}}}{16.0\ \text{g}} = 0.19$$

The *mass percent* (parts per 100 parts) of yellow marbles is $0.19 \times 100 = 19\%$ by mass. Similarly, the purple marbles have a mass fraction of 0.25 and are 25% by mass of the total, and the red marbles have a mass fraction of 0.56 and are 56% by mass.

In the same way, each element in a compound has a *fixed* mass fraction (and mass percent). For example, calcium carbonate, the major compound in seashells, marble, and coral, is composed of three elements—calcium, carbon, and oxygen. The following results are obtained from a mass analysis of 20.0 g of calcium carbonate:

Analysis by Mass (grams/20.0 g)	Mass Fraction (parts/1.00 part)	Percent by Mass (parts/100 parts)
8.0 g calcium	0.40 calcium	40% calcium
2.4 g carbon	0.12 carbon	12% carbon
9.6 g oxygen	0.48 oxygen	48% oxygen
20.0 g	1.00 part by mass	100% by mass

The mass of each element depends on the mass of the sample—that is, more than 20.0 g of compound would contain more than 8.0 g of calcium—but *the mass fraction is fixed no matter what the size of the sample.* The sum of the mass fractions (or mass

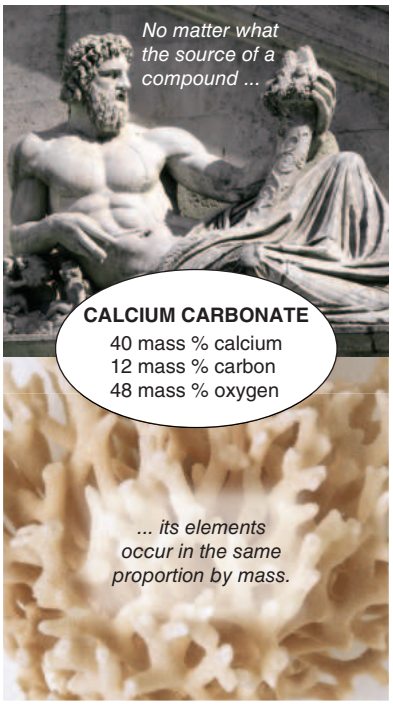


Figure 2.3 The law of definite composition. Calcium carbonate occurs in many forms (such as marble, *top,* and coral, *bottom*).

percents) equals 1.00 part (or 100%) by mass. The law of definite composition tells us that pure samples of calcium carbonate, no matter where they come from, always contain 40% calcium, 12% carbon, and 48% oxygen by mass (Figure 2.3).

Because a given element always constitutes the same mass fraction of a given compound, we can use that mass fraction to find the actual mass of the element in any sample of the compound:

$$\text{Mass of element} = \text{mass of compound} \times \text{mass fraction}$$

Or, more simply, we can skip the need to find the mass fraction first and use the results of mass analysis directly:

$$\text{Mass of element in sample} = \text{mass of compound in sample} \times \frac{\text{mass of element in compound}}{\text{mass of compound}} \qquad (2.1)$$

Road Map

Mass (kg) of pitchblende
↓ multiply by mass ratio of uranium to pitchblende from analysis
Mass (kg) of uranium
↓ 1 kg = 1000 g
Mass (g) of uranium

SAMPLE PROBLEM 2.2 Calculating the Mass of an Element in a Compound

Problem Pitchblende is the most important compound of uranium. Mass analysis of an 84.2-g sample shows that it contains 71.4 g of uranium, with oxygen the only other element. How many grams of uranium are in 102 kg of pitchblende?

Plan We have to find the mass (in g) of uranium in a known mass (102 kg) of pitchblende, given the mass of uranium (71.4 g) in a different mass of pitchblende (84.2 g). The mass *ratio* of uranium to pitchblende in grams is the same as it is in kilograms. Therefore, using Equation 2.1, we multiply the mass (in kg) of the pitchblende sample by the ratio of uranium to pitchblende (in kg) from the mass analysis. This gives the mass (in kg) of uranium, and we convert kilograms to grams.

Solution Finding the mass (kg) of uranium in 102 kg of pitchblende:

$$\text{Mass (kg) of uranium} = \text{mass (kg) of pitchblende} \times \frac{\text{mass (kg) of uranium in pitchblende}}{\text{mass (kg) of pitchblende}}$$

$$= 102 \text{ kg pitchblende} \times \frac{71.4 \text{ kg uranium}}{84.2 \text{ kg pitchblende}} = 86.5 \text{ kg uranium}$$

Converting the mass of uranium from kg to g:

$$\text{Mass (g) of uranium} = 86.5 \text{ kg uranium} \times \frac{1000 \text{ g}}{1 \text{ kg}} = 8.65\times10^4 \text{ g uranium}$$

Check The analysis showed that most of the mass of pitchblende is due to uranium, so the large mass of uranium makes sense. Rounding off to check the math gives

$$\sim 100 \text{ kg pitchblende} \times \frac{70}{85} = 82 \text{ kg uranium}$$

FOLLOW-UP PROBLEMS

2.2A How many metric tons (t) of oxygen are in a sample of pitchblende that contains 2.3 t of uranium? (*Hint:* Remember that oxygen is the only other element present.)

2.2B Silver bromide is the light-sensitive compound coated onto black-and-white film. A 26.8-g sample contains 15.4 g of silver, with bromine the only other element. How many grams of each element are on a roll of film that contains 3.57 g of silver bromide?

SOME SIMILAR PROBLEMS 2.22–2.25

Multiple Proportions

It's quite common for the same two elements to form more than one compound—sulfur and fluorine do this, as do phosphorus and chlorine and many other pairs of elements. The **law of multiple proportions** applies in these cases: *if elements A and B react to form two compounds, the different masses of B that combine with a fixed mass of A can*

be expressed as a ratio of small whole numbers. Consider two compounds of carbon and oxygen; let's call them carbon oxides I and II. These compounds have very different properties: the density of carbon oxide I is 1.25 g/L, whereas that of II is 1.98 g/L; I is poisonous and flammable, but II is not. Mass analysis shows that

Carbon oxide I is 57.1 mass % oxygen and 42.9 mass % carbon
Carbon oxide II is 72.7 mass % oxygen and 27.3 mass % carbon

To see the phenomenon of multiple proportions, we use the mass percents of oxygen and of carbon to find their masses in a given mass, say 100 g, of each compound. Then we divide the mass of oxygen by the mass of carbon in each compound to obtain the mass of oxygen that combines with a fixed mass of carbon:

	Carbon Oxide I	Carbon Oxide II
g oxygen/100 g compound	57.1	72.7
g carbon/100 g compound	42.9	27.3
g oxygen/g carbon	$\frac{57.1}{42.9} = 1.33$	$\frac{72.7}{27.3} = 2.66$

If we then divide the grams of oxygen per gram of carbon in II by that in I, we obtain a ratio of small whole numbers:

$$\frac{2.66 \text{ g oxygen/g carbon in II}}{1.33 \text{ g oxygen/g carbon in I}} = \frac{2}{1}$$

The law of multiple proportions tells us that in two compounds of the same elements, the mass fraction of one element relative to the other element changes in *increments based on ratios of small whole numbers.* In this case, the ratio is 2/1—for a given mass of carbon, compound II contains *2 times* as much oxygen as I, not 1.583 times, 1.716 times, or any other intermediate amount. In the next section, we'll discuss the model that explains the mass laws on the atomic scale and learn the identities of the two carbon oxides.

Summary of Section 2.2

- The law of mass conservation states that the total mass remains constant during a chemical reaction.
- The law of definite composition states that any sample of a given compound has the same elements present in the same parts by mass.
- The law of multiple proportions states that, in different compounds of the same elements, the masses of one element that combine with a fixed mass of the other can be expressed as a ratio of small whole numbers.

2.3 DALTON'S ATOMIC THEORY

With over 200 years of hindsight, it may be easy to see how the mass laws could be explained by the idea that matter exists in indestructible units, each with a particular mass and set of properties, but it was a major breakthrough in 1808 when John Dalton (1766–1844) presented his atomic theory of matter.

Postulates of the Atomic Theory

Dalton expressed his theory in a series of postulates, presented here in modern terms:

1. All matter consists of **atoms,** tiny indivisible units of an element that cannot be created or destroyed. (This derives from the "eternal, indestructible atoms" proposed by Democritus more than 2000 years earlier and reflects mass conservation as stated by Lavoisier.)
2. Atoms of one element *cannot* be converted into atoms of another element. In chemical reactions, the atoms of the original substances recombine to form different substances. (This rejects the alchemical belief in the magical transmutation of elements.)

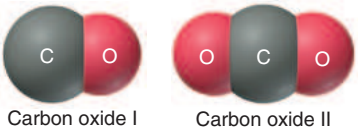
3. Atoms of an element are identical in mass and other properties and are different from atoms of any other element. (This contains Dalton's major new ideas: *unique mass and properties* for the atoms of a given element.)
4. Compounds result from the chemical combination of a specific ratio of atoms of different elements. (This follows directly from the law of definite composition.)

How the Theory Explains the Mass Laws

Let's see how Dalton's postulates explain the mass laws:

- *Mass conservation.* Atoms cannot be created or destroyed (postulate 1) or converted into other types of atoms (postulate 2). Therefore, a chemical reaction cannot possibly result in a mass change because atoms are just combined differently.
- *Definite composition.* A compound is a combination of a *specific* ratio of different atoms (postulate 4), each of which has a particular mass (postulate 3). Thus, each element in a compound must constitute a fixed fraction of the total mass.
- *Multiple proportions.* Atoms of an element have the same mass (postulate 3) and are indivisible (postulate 1). The masses of element B that combine with a fixed mass of element A must give a small, whole-number ratio because different numbers of B atoms combine with each A atom in different compounds.

The *simplest* arrangement consistent with the mass data for carbon oxides I and II in our earlier example is that one atom of oxygen combines with one atom of carbon in compound I (carbon monoxide) and that two atoms of oxygen combine with one atom of carbon in compound II (carbon dioxide):

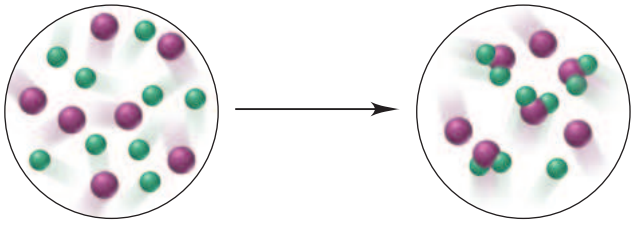


Carbon oxide I (carbon monoxide) Carbon oxide II (carbon dioxide)

Let's work through a sample problem that reviews the mass laws.

SAMPLE PROBLEM 2.3 Visualizing the Mass Laws

Problem The scenes below represent an atomic-scale view of a chemical reaction:



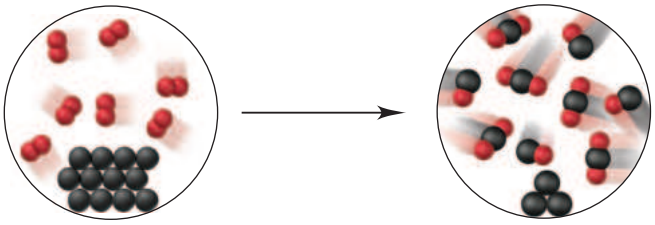
Which of the mass laws—mass conservation, definite composition, or multiple proportions—is (are) illustrated?

Plan From the depictions, we note the numbers, colors, and combinations of atoms (spheres) to see which mass laws pertain. If the numbers of each atom are the same before and after the reaction, the total mass did not change (mass conservation). If a compound forms that always has the same atom ratio, the elements are present in fixed parts by mass (definite composition). If the same elements form different compounds and the ratio of the atoms of one element that combine with one atom of the other element is a small whole number, the ratio of their masses is a small whole number as well (multiple proportions).

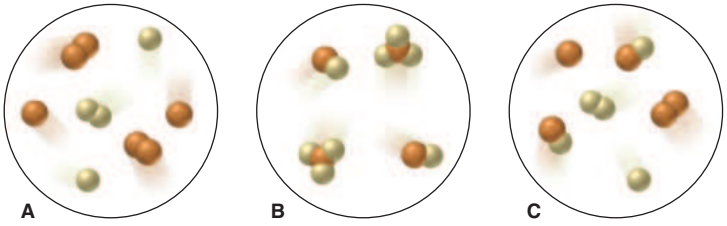
Solution There are seven purple and nine green atoms in each circle, so mass is conserved. The compound formed has one purple and two green atoms, so it has definite composition. Only one compound forms, so the law of multiple proportions does not pertain.

FOLLOW-UP PROBLEMS

2.3A The following scenes represent a chemical change. Which of the mass laws is (are) illustrated?



2.3B Which sample(s) best display(s) the fact that compounds of bromine *(orange)* and fluorine *(yellow)* exhibit the law of multiple proportions? Explain.



SOME SIMILAR PROBLEMS 2.14 and 2.15

Summary of Section 2.3

- Dalton's atomic theory explained the mass laws by proposing that all matter consists of indivisible, unchangeable atoms of fixed, unique mass.
- Mass is conserved during a reaction because the atoms retain their identities but are combined differently.
- Each compound has a fixed mass fraction of each of its elements because it is composed of a fixed number of each type of atom.
- Different compounds of the same elements exhibit multiple proportions because they each consist of whole atoms.

2.4 THE OBSERVATIONS THAT LED TO THE NUCLEAR ATOM MODEL

Dalton's model established that masses of elements reacting could be explained in terms of atoms but not why atoms bond as they do: why, for example, do two, and not three, hydrogen atoms bond with one oxygen atom in a water molecule?

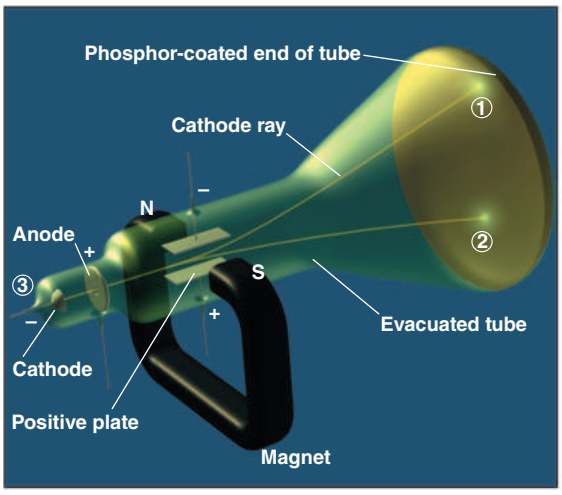
Moreover, Dalton's "billiard-ball" model of the atom did not predict the existence of subatomic charged particles, which were observed in later experiments that led to the discovery of *electrons* and the atomic *nucleus*. Let's examine some of these experiments and the more complex atomic model that emerged from them.

Discovery of the Electron and Its Properties

For many years, scientists had known that matter and electric charge were related. When amber is rubbed with fur, or glass with silk, positive and negative charges form—the same charges that make your hair crackle and cling to your comb on a dry day *(see photo)*. They also knew that an electric current could decompose certain compounds into their elements. But they did not know what a current was made of.

Effect of electric charges.

Cathode Rays To discover the nature of an electric current, some investigators tried passing it through nearly evacuated glass tubes fitted with metal electrodes. When the electric power source was turned on, a "ray" could be seen striking the phosphor-coated end of the tube, which emitted a glowing spot of light. The rays were called



OBSERVATION	⟹	CONCLUSION
① *Ray bends in magnetic field.*	⟹	Consists of charged particles
② *Ray bends toward positive plate in electric field.*	⟹	Consists of negative particles
③ *Ray is identical for any cathode.*	⟹	Particles found in all matter

Figure 2.4 **Observations that established the properties of cathode rays.**

cathode rays because they originated at the negative electrode (cathode) and moved to the positive electrode (anode).

Figure 2.4 shows some properties of cathode rays based on these observations. The main conclusion was that *cathode rays consist of negatively charged particles found in all matter.* The rays become visible as their particles collide with the few remaining gas molecules in the evacuated tube. Cathode ray particles were later named *electrons.* There are many familiar cases of the effects of charged particles colliding with gases or hitting a phosphor-coated screen:

Aurora borealis display.

- In a "neon" sign, electrons collide with the gas particles in the tube, causing them to give off light.
- The aurora borealis, or northern lights *(see photo),* occurs when Earth's magnetic field bends streams of charged particles coming from the Sun, which then collide with gas particles in the atmosphere to give off light.
- In older televisions and computer monitors, the cathode ray passes back and forth over the coated screen, creating a pattern that we see as a picture.

Mass and Charge of the Electron Two classic experiments and their conclusion revealed the mass and charge of the electron:

1. *Mass/charge ratio*. In 1897, the British physicist J. J. Thomson (1856–1940) measured the ratio of the mass of a cathode ray particle to its charge. By comparing this value with the mass/charge ratio for the lightest charged particle in solution, Thomson estimated that the cathode ray particle weighed less than $\frac{1}{1000}$ as much as hydrogen, the lightest atom! He was shocked because this implied that, contrary to Dalton's atomic theory, *atoms contain even smaller particles.* Fellow scientists reacted with disbelief to Thomson's conclusion; some even thought he was joking.

2. *Charge.* In 1909, the American physicist Robert Millikan (1868–1953) measured the *charge* of the electron. He did so by observing the movement of tiny oil droplets in an apparatus that contained electrically charged plates and an x-ray source (Figure 2.5). X-rays knocked electrons from gas molecules in the air within the apparatus, and the electrons stuck to an oil droplet falling through a hole in a positively charged plate. With the electric field off, Millikan measured the mass of the now negatively charged droplet from its rate of fall. Then, by adjusting the field's strength, he made the droplet slow and hang suspended, which allowed him to measure its total charge.

After many tries, Millikan found that the total charge of the various droplets was always some *whole-number multiple of a minimum charge.* If different oil droplets picked up different numbers of electrons, he reasoned that this minimum charge must be the charge of the electron itself. Remarkably, the value that he calculated over a century ago was within 1% of the modern value of the electron's charge, -1.602×10^{-19} C (C stands for *coulomb,* the SI unit of charge).

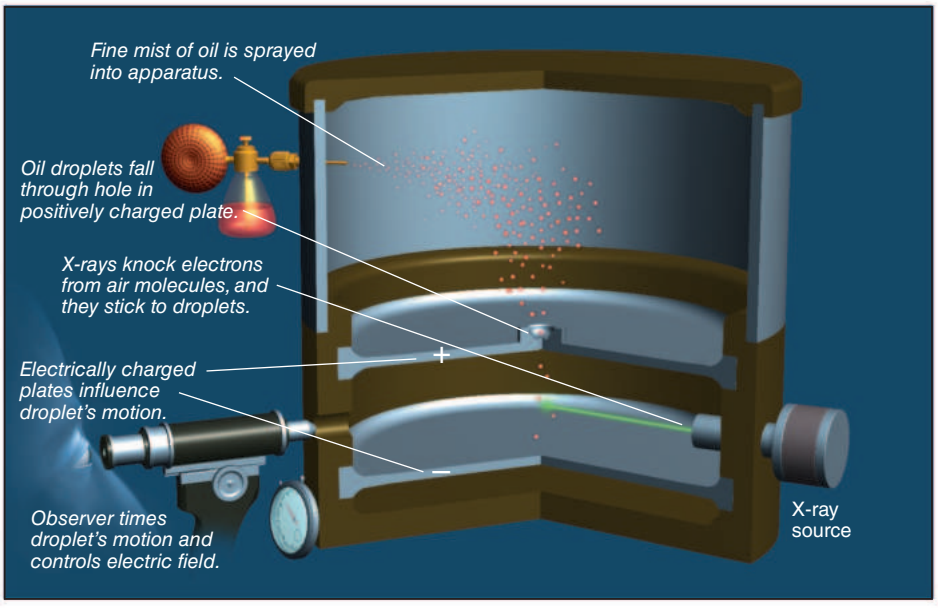


Figure 2.5 Millikan's oil-drop experiment for measuring an electron's charge. The total charge on an oil droplet is some whole-number multiple of the charge of the electron.

3. *Conclusion: calculating the electron's mass.* The electron's mass/charge ratio, from work by Thomson and others, multiplied by the value for the electron's charge gives the electron's mass, which is *extremely* small:

$$\text{Mass of electron} = \frac{\text{mass}}{\cancel{\text{charge}}} \times \cancel{\text{charge}} = \left(-5.686\times10^{-12}\ \frac{\text{kg}}{\cancel{C}}\right)(-1.602\times10^{-19}\ \cancel{C})$$
$$= 9.109\times10^{-31}\ \text{kg} = 9.109\times10^{-28}\ \text{g}$$

Discovery of the Atomic Nucleus

The presence of electrons in all matter brought up two major questions about the structure of atoms. Matter is electrically neutral, so atoms must be also. But if atoms contain negatively charged electrons, what positive charges balance them? And if an electron has such a tiny mass, what accounts for an atom's much larger mass? To address these issues, Thomson proposed his "plum-pudding" model—a spherical atom composed of diffuse, positively charged matter with electrons embedded in it like "raisins in a plum pudding."

In 1910, New Zealand–born physicist Ernest Rutherford (1871–1937) tested this model and obtained a very unexpected result (Figure 2.6, *next page*):

1. *Experimental design.* Figure 2.6A shows the experimental setup, in which tiny, dense, positively charged alpha (α) particles emitted from radium are aimed at gold foil. A circular, zinc-sulfide screen registers the deflection (scattering angle) of the α particles emerging from the foil by emitting light flashes when the particles strike it.
2. *Hypothesis and expected results.* With Thomson's model in mind (Figure 2.6B), Rutherford expected only minor, if any, deflections of the α particles because they should act as bullets and go right through the gold atoms. After all, he reasoned, an electron should not be able to deflect an α particle any more than a Ping-Pong ball could deflect a baseball.
3. *Actual results.* Initial results were consistent with this hypothesis, but then the unexpected happened (Figure 2.6C). As Rutherford recalled: "I remember two or three days later Geiger [one of his coworkers] coming to me in great excitement and saying, 'We have been able to get some of the α particles coming backwards . . .' It was quite the most incredible event that has ever happened to me in my life. It was almost as incredible as if you fired a 15-inch shell at a piece of tissue paper and it came back and hit you." The data showed very few α particles deflected at all and only 1 in 20,000 deflected by more than 90° ("coming backwards").

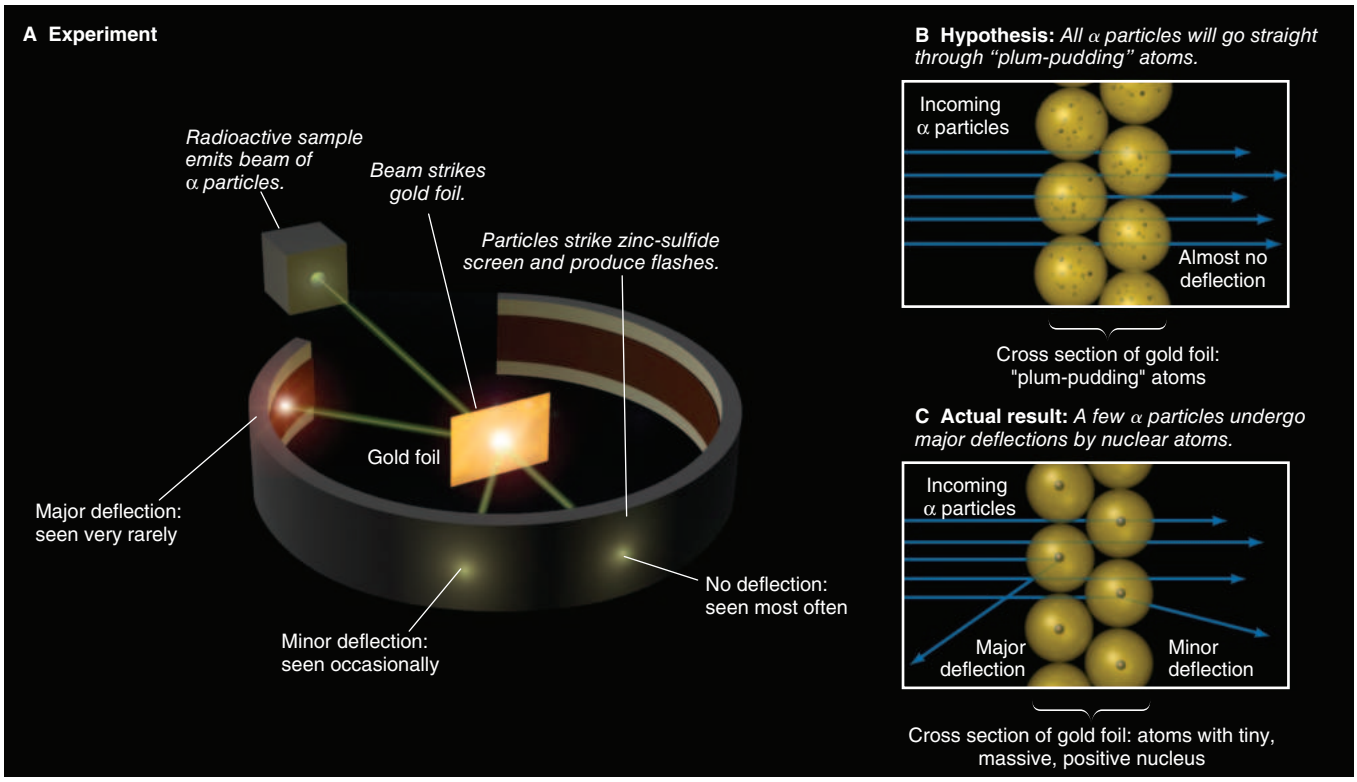

Figure 2.6 Rutherford's α-scattering experiment and discovery of the atomic nucleus.

4. *Rutherford's conclusion.* Rutherford concluded that these few α particles were being repelled by something small, dense, and positive within the gold atoms. Calculations based on the mass, charge, and velocity of the α particles and the fraction of these large-angle deflections showed that
   - An atom is mostly space occupied by electrons.
   - In the center is a tiny region, which Rutherford called the **nucleus,** that contains all the positive charge and essentially all the mass of the atom.

   He proposed that positive particles lay within the nucleus and called them *protons.*

Rutherford's model explained the charged nature of matter, but it could not account for all the atom's mass. After more than 20 years, in 1932, James Chadwick (1891–1974) discovered the *neutron,* an uncharged dense particle that also resides in the nucleus.

Summary of Section 2.4

- Several major discoveries at the turn of the 20th century resolved questions about Dalton's model and led to our current model of atomic structure.
- Cathode rays were shown to consist of negative particles (electrons) that exist in all matter. J. J. Thomson measured their mass/charge ratio and concluded that they are much smaller and lighter than atoms.
- Robert Millikan determined the charge of the electron, which he combined with other data to calculate its mass.
- Ernest Rutherford proposed that atoms consist of a tiny, massive, positive nucleus surrounded by electrons.

2.5 THE ATOMIC THEORY TODAY

Dalton's model of an indivisible particle has given way to our current model of an atom with an elaborate internal architecture of subatomic particles.

Structure of the Atom

An *atom* is an electrically neutral, spherical entity composed of a positively charged central nucleus surrounded by one or more negatively charged electrons (Figure 2.7). The electrons move rapidly within the available volume, held there by the attraction of the nucleus. (As such, they are often depicted as a cloudy blur of color, darkest around a central dot—the nucleus—and becoming paler toward the outer edge.) An atom's diameter ($\sim 1\times10^{-10}$ m) is about 20,000 times the diameter of its nucleus ($\sim 5\times10^{-15}$ m). The nucleus contributes 99.97% of the atom's mass, but occupies only about 1 quadrillionth of its volume, so it is incredibly dense: about 10^{14} g/mL!

The Tiny, Massive Nucleus

A few analogies can help you grasp the incredible properties of the atomic nucleus. A nucleus the size of the period at the end of a sentence would weigh about 100 tons, as much as 50 cars! An atom the size of the Houston Astrodome would have a nucleus the size of a green pea that would contain virtually all the stadium's mass. If the nucleus were the size depicted at the right in Figure 2.7 (about 1 cm across), the atom would be about 200 m across, or more than the length of two football fields!

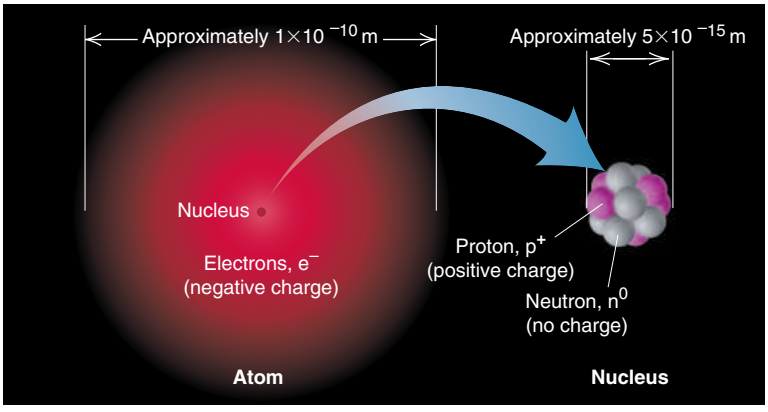

Figure 2.7 General features of the atom.

An atomic nucleus consists of protons and neutrons (the only exception is the simplest hydrogen nucleus, which is just a proton). The **proton (p^+)** has a positive charge, and the **neutron (n^0)** has no charge; thus, the positive charge of the nucleus results from its protons. The *magnitudes* of the charges possessed by a proton and by an **electron (e^-)** are equal, but the *signs* of the charges are opposite. *An atom is neutral because the number of protons in the nucleus equals the number of electrons surrounding the nucleus.* Some properties of these three subatomic particles are listed in Table 2.2.

Atomic Number, Mass Number, and Atomic Symbol

The **atomic number (Z)** of an element equals the number of protons in the nucleus of each of its atoms. *All atoms of an element have the same atomic number, and the atomic number of each element is different from that of any other element.* All carbon atoms ($Z = 6$) have 6 protons, all oxygen atoms ($Z = 8$) have 8 protons, and all uranium atoms ($Z = 92$) have 92 protons. There are currently 118 known elements, of which 90 occur in nature and 28 have been synthesized by nuclear scientists.

The **mass number (A)** is the total number of protons and neutrons in the nucleus of an atom. Each proton and each neutron contributes one unit to the mass number. Thus, a carbon atom with 6 protons and 6 neutrons in its nucleus has a mass number

Table 2.2 Properties of the Three Key Subatomic Particles

	Charge		Mass		
Name (Symbol)	**Relative**	**Absolute (C)***	**Relative (amu)†**	**Absolute (g)**	**Location in Atom**
Proton (p^+)	1+	$+1.60218\times10^{-19}$	1.00727	1.67262×10^{-24}	Nucleus
Neutron (n^0)	0	0	1.00866	1.67493×10^{-24}	Nucleus
Electron (e^-)	1−	-1.60218×10^{-19}	0.00054858	9.10939×10^{-28}	Outside nucleus

*The coulomb (C) is the SI unit of charge.
†The atomic mass unit (amu) equals 1.66054×10^{-24} g; discussed later in this section.

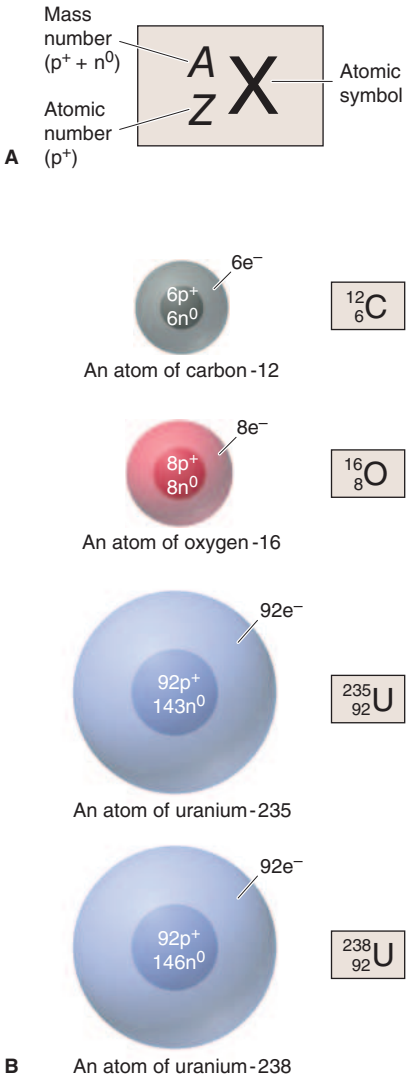

Figure 2.8 **Atom notation. A,** The meaning of the $^{A}_{Z}X$ notation. **B,** Notations and spherical representations for four atoms. (The nuclei are not drawn to scale.)

of 12, and a uranium atom with 92 protons and 146 neutrons in its nucleus has a mass number of 238.

The **atomic symbol** (or *element symbol*) of an element is based on its English, Latin, or Greek name, such as C for carbon, S for sulfur, and Na for sodium (Latin *natrium*). Often written with the symbol are the atomic number (Z) as a left *sub*script and the mass number (A) as a left *super*script, so element X would be $^{A}_{Z}X$ (Figure 2.8A). Since the mass number is the sum of protons and neutrons, the number of neutrons (N) equals the mass number minus the atomic number:

$$\text{Number of neutrons} = \text{mass number} - \text{atomic number}, \quad \text{or} \quad N = A - Z \qquad \textbf{(2.2)}$$

Thus, a chlorine atom, symbolized $^{35}_{17}Cl$, has $A = 35$, $Z = 17$, and $N = 35 - 17 = 18$. Because each element has its own atomic number, we also know the atomic number from the symbol. For example, instead of writing $^{12}_{6}C$ for carbon with mass number 12, we can write ^{12}C (spoken "carbon twelve"), with $Z = 6$ understood. Another way to name this atom is carbon-12.

Isotopes

All atoms of an element have the same atomic number but not the same mass number. **Isotopes** of an element are atoms that have *different numbers of neutrons* and therefore different mass numbers. Most elements occur in nature in a particular *isotopic composition,* which specifies the proportional abundance of each of its isotopes. For example, all carbon atoms ($Z = 6$) have 6 protons and 6 electrons, but only 98.89% of naturally occurring carbon atoms have 6 neutrons ($A = 12$). A small percentage (1.11%) have 7 neutrons ($A = 13$), and even fewer (less than 0.01%) have 8 ($A = 14$). These are carbon's three naturally occurring isotopes—^{12}C, ^{13}C, and ^{14}C. *A natural sample of carbon has these three isotopes in these relative proportions.* Five other carbon isotopes—^{9}C, ^{10}C, ^{11}C, ^{15}C, and ^{16}C—have been created in the laboratory. Figure 2.8B depicts the atomic number, mass number, and symbol for four atoms, two of which are isotopes of the element uranium.

A key point is that the chemical properties of an element are primarily determined by the number of electrons, so *all isotopes of an element have nearly identical chemical behavior,* even though they have different masses.

SAMPLE PROBLEM 2.4 Determining the Number of Subatomic Particles in the Isotopes of an Element

Problem Silicon (Si) is a major component of semiconductor chips. It has three naturally occurring isotopes: ^{28}Si, ^{29}Si, and ^{30}Si. Determine the numbers of protons, electrons, and neutrons in an atom of each silicon isotope.

Plan The mass number (A; left superscript) of each of the three isotopes is given, which is the sum of protons and neutrons. From the elements list on the text's inside front cover, we find the atomic number (Z, number of protons), which equals the number of electrons. We obtain the number of neutrons by subtracting Z from A (Equation 2.2).

Solution From the elements list, the atomic number of silicon is 14. Therefore,

^{28}Si has $14p^+$, $14e^-$, and $14n^0$ $(28 - 14)$
^{29}Si has $14p^+$, $14e^-$, and $15n^0$ $(29 - 14)$
^{30}Si has $14p^+$, $14e^-$, and $16n^0$ $(30 - 14)$

FOLLOW-UP PROBLEMS

2.4A Titanium, the ninth most abundant element, is used structurally in many objects, such as electric turbines, aircraft bodies, and bicycle frames. It has five naturally occurring isotopes: ^{46}Ti, ^{47}Ti, ^{48}Ti, ^{49}Ti, and ^{50}Ti. How many protons, electrons, and neutrons are in an atom of each isotope?

2.4B How many protons, electrons, and neutrons are in an atom of each of the following, and which elements are represented by Q, R, and X? **(a)** $^{11}_{5}Q$ **(b)** $^{41}_{20}R$ **(c)** $^{131}_{53}X$

SOME SIMILAR PROBLEMS 2.39–2.42

Atomic Masses of the Elements

The mass of an atom is measured *relative* to the mass of an atomic standard. The modern standard is the carbon-12 atom, whose mass is defined as *exactly* 12 atomic mass units. Thus, the **atomic mass unit (amu)** is $\frac{1}{12}$ the mass of a carbon-12 atom. Based on this standard, the ^{1}H atom has a mass of 1.008 amu; in other words, a ^{12}C atom has almost 12 times the mass of an ^{1}H atom. We will continue to use the term *atomic mass unit* in the text, although the name of the unit has been changed to the **dalton (Da);** thus, one ^{12}C atom has a mass of 12 daltons (12 Da, or 12 amu). The atomic mass unit is a unit of relative mass, but it has an absolute mass of 1.66054×10^{-24} g.

Finding Atomic Mass from Isotopic Composition The isotopic composition of an element is determined by **mass spectrometry,** a method for measuring the relative masses and abundances of atomic-scale particles very precisely (see the Tools of the Laboratory essay on page 57). For example, using a mass spectrometer, we measure the mass ratio of ^{28}Si to ^{12}C as

$$\frac{\text{Mass of } ^{28}\text{Si atom}}{\text{Mass of } ^{12}\text{C standard}} = 2.331411$$

From this mass ratio, we find the **isotopic mass** of the ^{28}Si atom, the relative mass of this silicon isotope:

$$\begin{aligned}\text{Isotopic mass of } ^{28}\text{Si} &= \text{measured mass ratio} \times \text{mass of } ^{12}\text{C} \\ &= 2.331411 \times 12 \text{ amu} = 27.97693 \text{ amu}\end{aligned}$$

Along with the isotopic mass, the mass spectrometer gives the relative abundance as a percentage (or fraction) of each isotope in a sample of the element. For example, the relative abundance of ^{28}Si is 92.23% (or 0.9223).

From such data, we can obtain the **atomic mass** (also called *atomic weight*) of an element, the *average* of the masses of its naturally occurring isotopes weighted according to their abundances. Each naturally occurring isotope of an element contributes a certain portion to the atomic mass. For instance, multiplying the isotopic mass of ^{28}Si by its fractional abundance gives the portion of the atomic mass of Si contributed by ^{28}Si:

$$\text{Portion of Si atomic mass from } ^{28}\text{Si} = 27.97693 \text{ amu} \times 0.9223 = 25.8031 \text{ amu}$$

(retaining two additional significant figures)

Similar calculations give the portions contributed by ^{29}Si (28.976495 amu × 0.0467 = 1.3532 amu) and by ^{30}Si (29.973770 amu × 0.0310 = 0.9292 amu). Adding the three portions together (rounding to two decimal places at the end) gives the atomic mass of silicon:

$$\begin{aligned}\text{Atomic mass of Si} &= 25.8031 \text{ amu} + 1.3532 \text{ amu} + 0.9292 \text{ amu} \\ &= 28.0855 \text{ amu} = 28.09 \text{ amu}\end{aligned}$$

The atomic mass is an average value; thus, while no individual silicon atom has a mass of 28.09 amu, in the laboratory, we consider a sample of silicon to consist of atoms with this average mass.

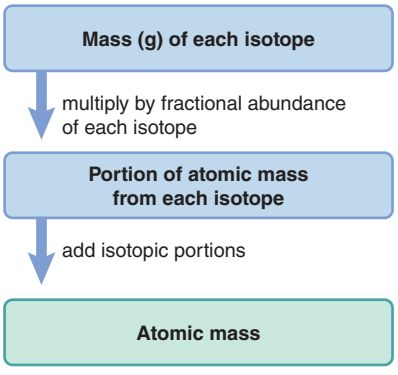
SAMPLE PROBLEM 2.5 Calculating the Atomic Mass of an Element

Problem Silver (Ag; $Z = 47$) has 46 known isotopes, but only two occur naturally, ^{107}Ag and ^{109}Ag. Given the following data, calculate the atomic mass of Ag:

Isotope	Mass (amu)	Abundance (%)
^{107}Ag	106.90509	51.84
^{109}Ag	108.90476	48.16

Plan From the mass and abundance of the two Ag isotopes, we have to find the atomic mass of Ag (weighted average of the isotopic masses). We divide each percent abundance by 100 to get the fractional abundance and then multiply that by each isotopic mass to find the portion of the atomic mass contributed by each isotope. The sum of the isotopic portions is the atomic mass.

Road Map



Solution Finding the fractional abundances:

Fractional abundance of $^{107}Ag = 51.84/100 = 0.5184$; similarly, $^{109}Ag = 0.4816$

Finding the portion of the atomic mass from each isotope:

Portion of atomic mass from ^{107}Ag = isotopic mass × fractional abundance
= 106.90509 amu × 0.5184 = 55.42 amu

Portion of atomic mass from ^{109}Ag = 108.90476 amu × 0.4816 = 52.45 amu

Finding the atomic mass of silver:

Atomic mass of Ag = 55.42 amu + 52.45 amu = 107.87 amu

Check The individual portions seem right: ~100 amu × 0.50 = 50 amu. The portions should be almost the same because the two isotopic abundances are almost the same. We rounded each portion to four significant figures because that is the number of significant figures in the abundance values. This is the correct atomic mass (to two decimal places); in the list of elements (inside front cover), it is rounded to 107.9 amu.

FOLLOW-UP PROBLEMS

2.5A Neon, a trace element in air, gives off color when electrified. Use the isotopic abundance data from the Tools of the Laboratory essay (p. 57) and the following isotopic masses to determine the atomic mass of neon: ^{20}Ne has a mass of 19.99244 amu, ^{21}Ne has a mass of 20.99385 amu, and ^{22}Ne has a mass of 21.99139 amu.

2.5B Boron (B; $Z = 5$) has two naturally occurring isotopes. Find the percent abundances of ^{10}B and ^{11}B given these data: atomic mass of B = 10.81 amu, isotopic mass of ^{10}B = 10.0129 amu, and isotopic mass of ^{11}B = 11.0093 amu. (*Hint:* The sum of the fractional abundances is 1. If x = abundance of ^{10}B, then $1 - x$ = abundance of ^{11}B.)

SOME SIMILAR PROBLEMS 2.47–2.50

The Atomic-Mass Interval From the time Dalton proposed his atomic theory through much of the 20th century, atomic masses were considered constants of nature, like the speed of light. However, in 1969, the International Union of Pure and Applied Chemistry (IUPAC) rejected this idea because results from more advanced mass spectrometers showed consistent variations in isotopic composition from source to source.

In 2009, IUPAC proposed that an *atomic-mass interval* be used for 10 elements with exceptionally large variations in isotopic composition: hydrogen (H), lithium (Li), boron (B), carbon (C), nitrogen (N), oxygen (O), silicon (Si), sulfur (S), chlorine (Cl), and thallium (Th). For example, because the isotopic composition of hydrogen from oceans, rivers, and lakes, from various minerals, and from organic sediments varies so much, its atomic mass is now given as the interval [1.00784; 1.00811], which means that the mass is greater than or equal to 1.00784 and less than or equal to 1.00811. It's important to realize that *the mass of any given isotope of an element is constant, but the* ***proportion*** *of isotopes varies from source to source*.

The atomic-mass interval is important for very precise work, but because this text uses four significant figures for atomic masses in calculations—for example, 1.008 amu for the atomic mass of H—the change does not affect our discussions (see the list of elements inside the front cover). Also, such small differences in composition do not overturn the basic idea of the law of definite composition: elements occur in a fixed proportion by mass in a compound, no matter what the source (p. 45).

Summary of Section 2.5

- An atom has a central nucleus, which contains positively charged protons and uncharged neutrons and is surrounded by negatively charged electrons. An atom is neutral because the number of electrons equals the number of protons.
- An atom is represented by the notation ${}^{A}_{Z}X$, in which Z is the atomic number (number of protons), A the mass number (sum of protons and neutrons), and X the atomic symbol.

Mass Spectrometry

Mass spectrometry is a powerful technique for measuring the mass and abundance of charged particles from their mass/charge ratio *(m/e)*. When a high-energy electron collides with a particle, say, an atom of neon-20, one of the atom's electrons is knocked away and the resulting particle has one positive charge, Ne^+ (Figure B2.1). Thus, its *m/e* equals the mass divided by 1+.

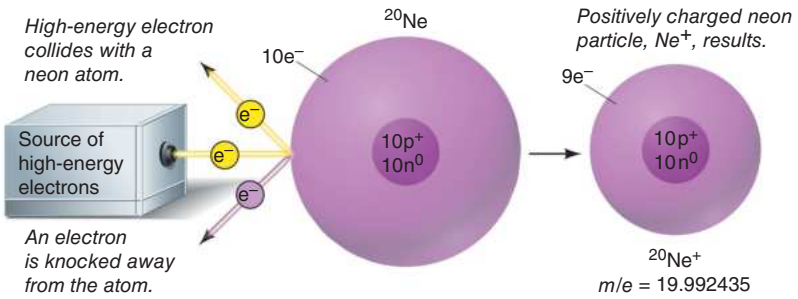


Figure B2.1 Formation of a positively charged neon particle (Ne^+).

Figure B2.2, part A, depicts the core of one type of mass spectrometer. The sample is introduced (and vaporized if liquid or solid), then bombarded by high-energy electrons to form positively charged particles, in this case, of the different neon isotopes. These are attracted toward a series of negatively charged plates with slits in them. Some particles pass through the slits into an evacuated tube exposed to a magnetic field. As the particles enter this region, their paths are bent, the lightest particles (lowest *m/e*) are deflected most and the heaviest particles (highest *m/e*) least. At the end of the magnetic region, the particles strike a detector, which records their relative positions and abundances (Figure B2.2, parts B and C).

Mass spectrometry is now employed to measure the mass of virtually any atom, molecule, or molecular fragment. The technique is being used to study catalyst surfaces, forensic materials, fuel mixtures, medicinal agents, and many other samples, especially proteins (Figure B2.2, part D); in fact, John B. Fenn and Koichi Tanaka shared part of the 2002 Nobel Prize in chemistry for developing methods to study proteins by mass spectrometry.

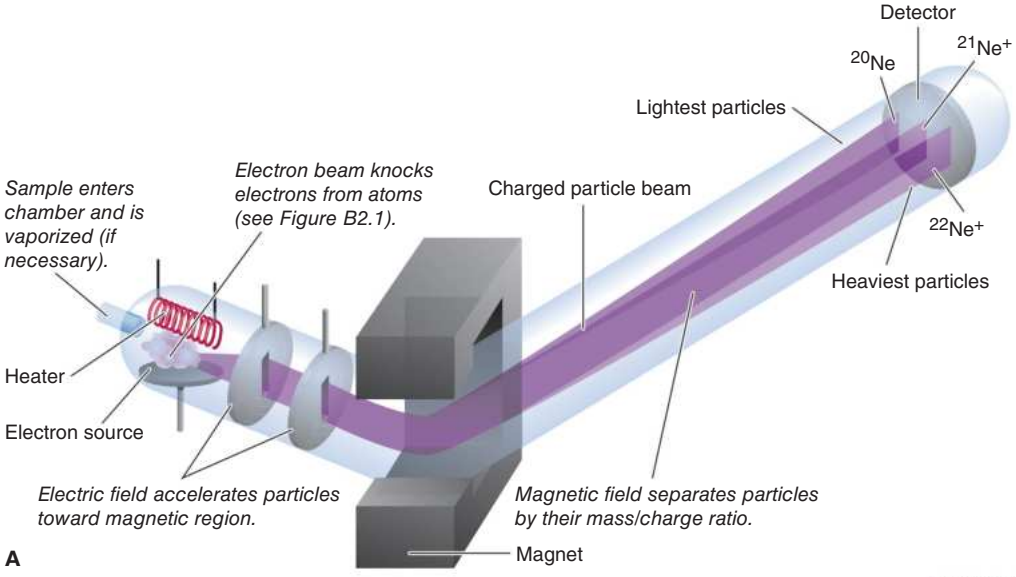
Problems

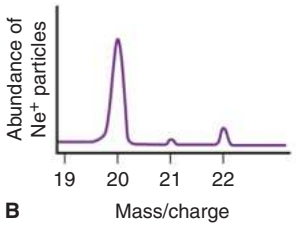
B2.1 Chlorine has two naturally occurring isotopes, ^{35}Cl (abundance 76%) and ^{37}Cl (abundance 24%), and it occurs as diatomic (two-atom) molecules. In a mass spectrum, peaks are seen for the molecule and for the separated atoms.

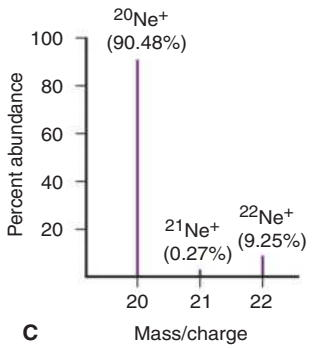
(a) How many peaks are in the mass spectrum?

(b) What is the *m/e* value of the heaviest particle and of the lightest particle?

B2.2 When a sample of pure carbon is analyzed by mass spectrometry, peaks X, Y, and Z are obtained. Peak Y is taller than X and Z, and Z is taller than X. What is the *m/e* value of the isotope responsible for peak Z?







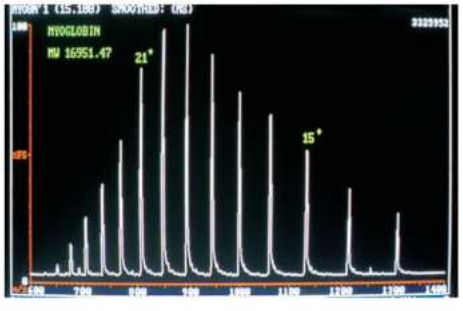


Figure B2.2 **The mass spectrometer and its data. A,** Particles are separated by their *m/e* values. **B,** The relative abundances of three Ne isotopes. **C,** The percent abundance of each isotope. **D,** The mass spectrum of a protein molecule. Each peak represents a molecular fragment.

- An element occurs naturally as a mixture of isotopes, atoms with the same number of protons but different numbers of neutrons. Each isotope has a mass relative to the ^{12}C mass standard.
- The atomic mass of an element is the average of its isotopic masses weighted according to their natural abundances. It is determined using a mass spectrometer.

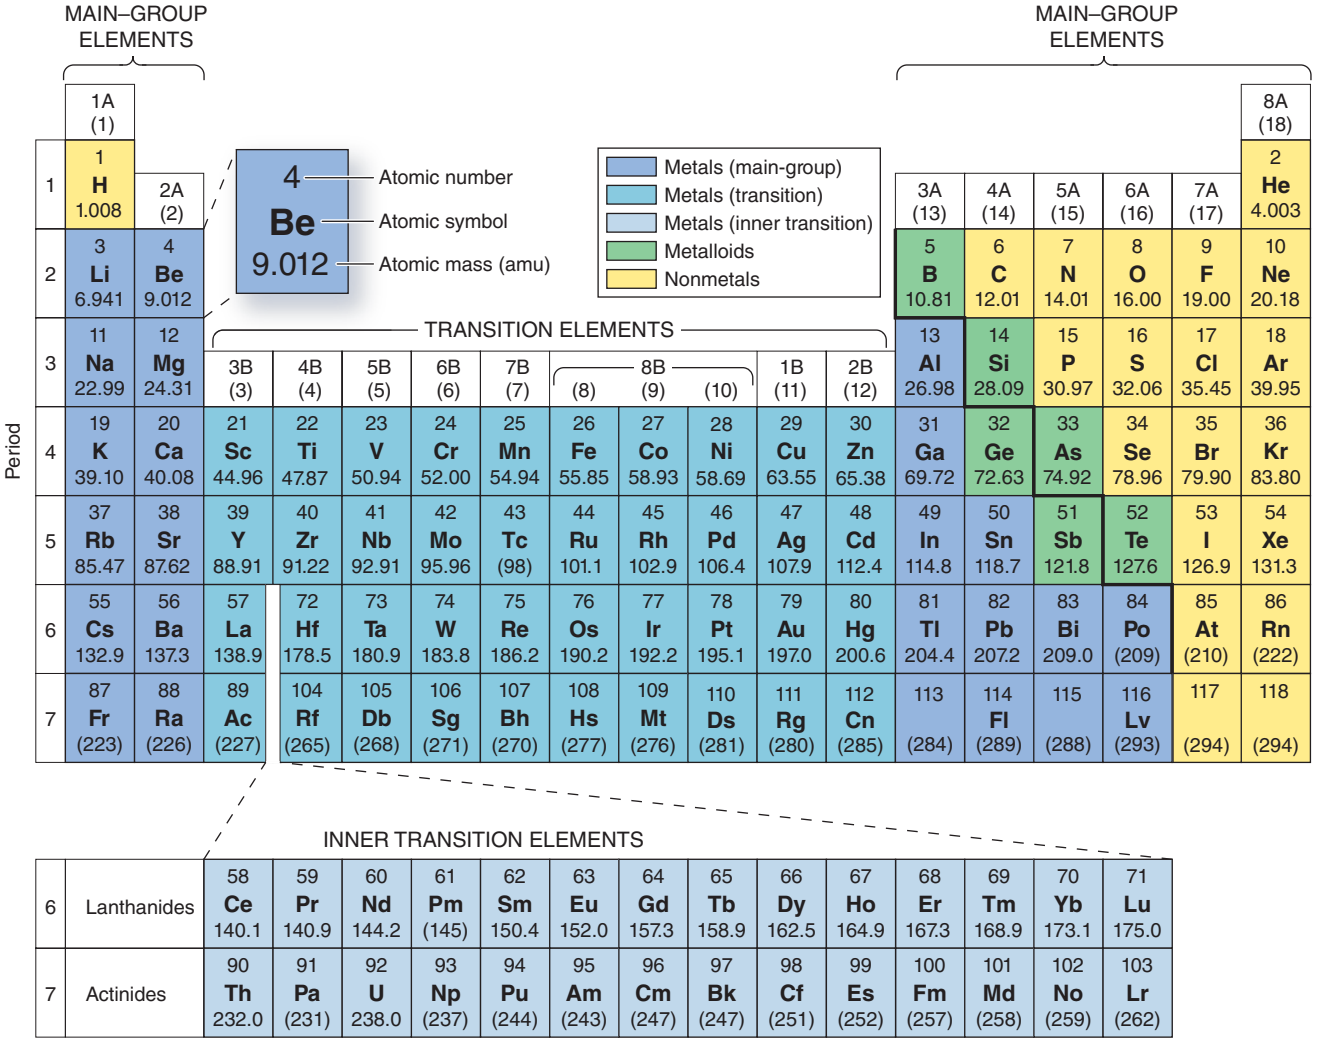
2.6 ELEMENTS: A FIRST LOOK AT THE PERIODIC TABLE

At the end of the 18th century, Lavoisier compiled a list of the 23 elements known at that time; by 1870, 65 were known; by 1925, 88; today, there are 118! By the mid-19th century, enormous amounts of information concerning reactions, properties, and atomic masses of the elements had been accumulated. Several researchers noted recurring, or *periodic,* patterns of behavior and proposed schemes to organize the elements according to some fundamental property.

In 1871, the Russian chemist Dmitri Mendeleev (1836–1907) published the most successful of these organizing schemes as a table of the elements listed by increasing atomic mass and arranged so that elements with similar chemical properties fell in the same column. The modern **periodic table of the elements,** based on Mendeleev's version (but arranged by *atomic number,* not mass), is one of the great classifying schemes in science and an indispensable tool to chemists—and chemistry students.

Organization of the Periodic Table One common version of the modern periodic table appears in Figure 2.9 (and inside the front cover). It is formatted as follows:

Figure 2.9 The modern periodic table. As of late 2013, elements 113, 115, 117, and 118 had not been named.



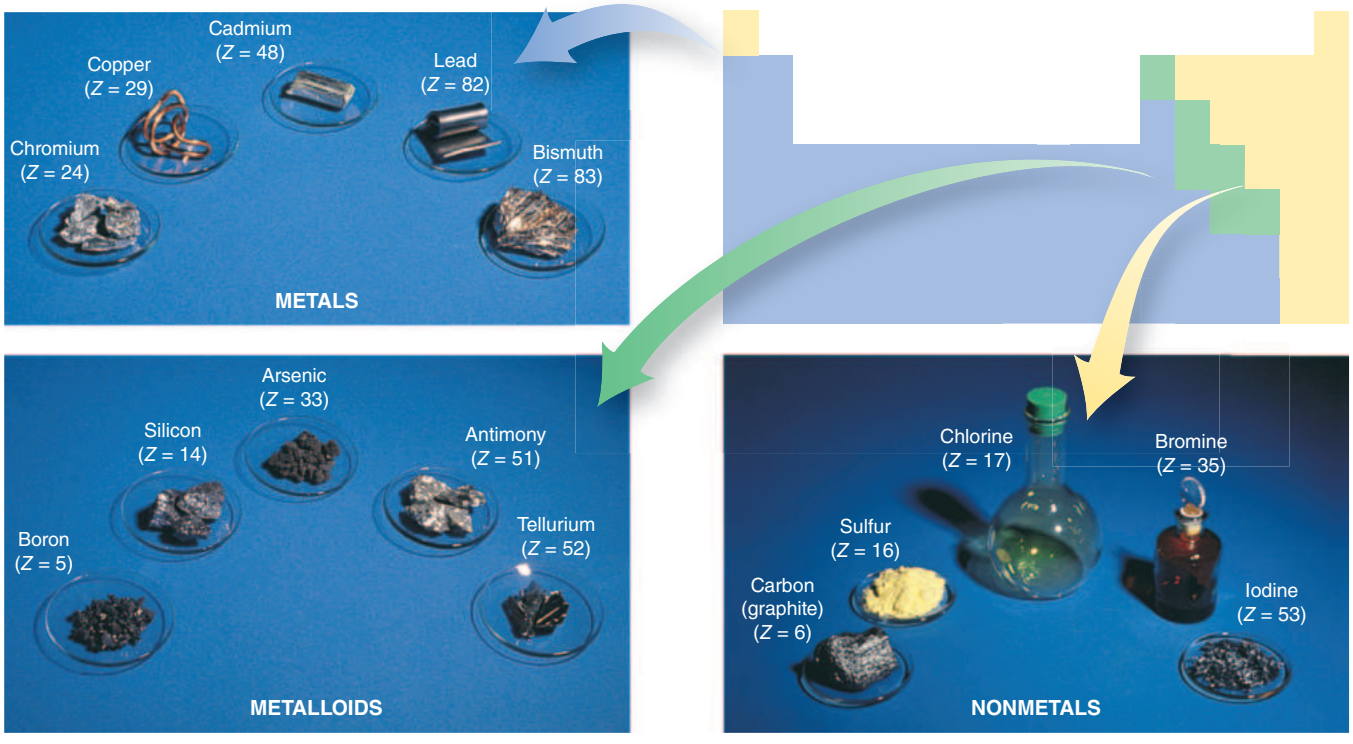
1. Each element has a box that contains its atomic number, atomic symbol, and atomic mass. (A mass in parentheses is the mass number of the most stable isotope of that element.) The boxes lie, from left to right, in order of *increasing atomic number* (number of protons in the nucleus).
2. The boxes are arranged into a grid of **periods** (horizontal rows) and **groups** (vertical columns). Each period has a number from 1 to 7. Each group has a number from 1 to 8 *and* either the letter A or B. A newer system, with group numbers from 1 to 18 but no letters, appears in parentheses under the number-letter designations. (The text uses the number-letter system and shows the newer group number in parentheses.)
3. The eight A groups (two on the left and six on the right) contain the *main-group elements.* The ten B groups, located between Groups 2A(2) and 3A(13), contain the *transition elements.* Two horizontal series of *inner transition elements,* the lanthanides and the actinides, fit *between* the elements in Group 3B(3) and Group 4B(4) and are placed below the main body of the table.

Classifying the Elements One of the clearest ways to classify the elements is as metals, nonmetals, and metalloids. The "staircase" line that runs from the top of Group 3A(13) to the bottom of Group 6A(16) is a dividing line:

- The **metals** (three shades of blue in Figure 2.9) lie in the large lower-left portion of the table. About three-quarters of the elements are metals, including many main-group elements and all the transition and inner transition elements. They are generally shiny solids at room temperature (mercury is the only liquid) that conduct heat and electricity well. They can be tooled into sheets (are malleable) and wires (are ductile).
- The **nonmetals** (yellow) lie in the small upper-right portion of the table. They are generally gases or dull, brittle solids at room temperature (bromine is the only liquid) and conduct heat and electricity poorly.
- The **metalloids** (green; also called **semimetals**), which lie along the staircase line, have properties between those of metals and nonmetals.

Figure 2.10 shows examples of these three classes of elements.

Figure 2.10 **Some metals, metalloids, and nonmetals.**



Two major points to keep in mind:

1. In general, elements in a group have *similar* chemical properties and elements in a period have *different* chemical properties.
2. Despite this classification of three types of elements, in reality, there is a gradation in properties from left to right and top to bottom.

It is important to learn some of the group (family) names. Group 1A(1), except for hydrogen, consists of the *alkali metals,* and Group 2A(2) consists of the *alkaline earth metals.* Both groups consist of highly reactive elements. The *halogens,* Group 7A(17), are highly reactive nonmetals, whereas the *noble gases,* Group 8A(18), are relatively unreactive nonmetals. Other main groups [3A(13) to 6A(16)] are often named for the first element in the group; for example, Group 6A(16) is the *oxygen family.*

Two of the major branches of chemistry have traditionally been defined by the elements that each studies. *Organic chemistry* studies the compounds of carbon, specifically those that contain hydrogen and often oxygen, nitrogen, and a few other elements. This branch is concerned with fuels, drugs, dyes, and the like. *Inorganic chemistry,* on the other hand, focuses on the compounds of all the other elements and is concerned with catalysts, electronic materials, metal alloys, mineral salts, and the like. With the explosive growth in biomedical and materials sciences, the line between these branches has, in practice, virtually disappeared.

SAMPLE PROBLEM 2.6 Identifying an Element from Its *Z* Value

Problem From each of the following *Z* values, give the name, symbol, and group and period numbers of the element, and classify it as a main-group metal, transition metal, inner transition metal, nonmetal, or metalloid: **(a)** $Z = 38$; **(b)** $Z = 17$; **(c)** $Z = 27$.

Plan The *Z* value is the atomic number of an element. The list of elements inside the front cover is alphabetical, so we look up the name and symbol of the element. Then we use the periodic table to find the group number (top of the column) and the period number (left end of the row) in which the element is located. We classify the element from the color coding in the periodic table.

Solution **(a)** Strontium, Sr, is in Group 2A(2) and Period 5, and it is a main-group metal.
(b) Chlorine, Cl, is in Group 7A(17) and Period 3, and it is a nonmetal.
(c) Cobalt, Co, is in Group 8B(9) and Period 4, and it is a transition metal.

Check You can work backwards by starting at the top of the group and moving down to the period to check that you get the correct *Z* value.

Comment Strontium is one of the alkaline earth metals, and chlorine is a halogen.

FOLLOW-UP PROBLEMS

2.6A Identify each of the following elements from its *Z* value; give the name, symbol, and group and period numbers, and classify it as a main-group metal, transition metal, inner transition metal, nonmetal, or metalloid: **(a)** $Z = 14$; **(b)** $Z = 55$; **(c)** $Z = 54$.

2.6B Identify each of the following elements from its *Z* value; give the name, symbol, and group and period numbers, and classify it as a main-group metal, transition metal, inner transition metal, nonmetal, or metalloid: **(a)** $Z = 12$; **(b)** $Z = 7$; **(c)** $Z = 30$.

SOME SIMILAR PROBLEMS 2.56 and 2.57

Summary of Section 2.6

- In the periodic table, the elements are arranged by atomic number into horizontal periods and vertical groups.
- Nonmetals appear in the upper-right portion of the table, metalloids lie along a staircase line, and metals fill the rest of the table.
- Elements within a group have similar behavior, whereas elements within a period have dissimilar behavior.

2.7 COMPOUNDS: INTRODUCTION TO BONDING

Aside from a few exceptions, *the overwhelming majority of elements occur in compounds combined with other elements.* Only a few elements occur free in nature. The noble gases—helium (He), neon (Ne), argon (Ar), krypton (Kr), xenon (Xe), and radon (Rn)—occur in air as separate atoms. In addition to occurring in compounds, oxygen (O), nitrogen (N), and sulfur (S) occur in their most common elemental form as the molecules O_2, N_2, and S_8, and carbon (C) occurs in vast, nearly pure deposits of coal. And some metals—copper (Cu), silver (Ag), gold (Au), and platinum (Pt)—are also sometimes found uncombined.

Elements combine in two general ways and both involve *the electrons of the atoms of interacting elements:*

1. *Transferring electrons* from one element to another to form **ionic compounds**
2. *Sharing electrons* between atoms of different elements to form **covalent compounds**

These processes generate **chemical bonds,** the forces that hold the atoms together in a compound. This section introduces compound formation, which we'll discuss in much more detail in later chapters.

The Formation of Ionic Compounds

Ionic compounds are composed of **ions,** charged particles that form when an atom (or small group of atoms) gains or loses one or more electrons. The simplest type of ionic compound is a **binary ionic compound,** one composed of two elements. It typically forms *when a metal reacts with a nonmetal:*

- Each metal atom *loses* one or more electrons and becomes a **cation,** a positively charged ion.
- Each nonmetal atom *gains* one or more of the electrons lost by the metal atom and becomes an **anion,** a negatively charged ion.

In effect, the metal atoms *transfer electrons* to the nonmetal atoms. The resulting large numbers of cations and anions attract each other and form the ionic compound. A cation or anion derived from a single atom is called a **monatomic ion;** we'll discuss *polyatomic ions,* those derived from a small group of atoms, later.

The Case of Sodium Chloride *All binary ionic compounds are solid arrays of oppositely charged ions.* The formation of the binary ionic compound sodium chloride, common table salt, from its elements is depicted in Figure 2.11. In the electron transfer, a sodium atom loses one electron and forms a sodium cation, Na^+. (The charge on the ion is written as a *right superscript.*) A chlorine atom *gains* the electron and becomes a chloride anion, Cl^-. (The name change when the nonmetal atom becomes an anion is discussed in the next section.) The oppositely charged ions (Na^+ and Cl^-) attract each other, and the similarly charged ions (Na^+ and Na^+, or Cl^- and Cl^-) repel each other. The resulting solid aggregation is a regular array of alternating Na^+ and Cl^- ions that extends in all three dimensions. Even the tiniest visible grain of table salt contains an enormous number of sodium and chloride ions.

Coulomb's Law The strength of the ionic bonding depends to a great extent on the net strength of these attractions and repulsions and is described by *Coulomb's law,* which can be expressed as follows: *the energy of attraction (or repulsion) between two particles is directly proportional to the product of the charges and inversely proportional to the distance between them.*

$$\text{Energy} \propto \frac{\text{charge 1} \times \text{charge 2}}{\text{distance}}$$

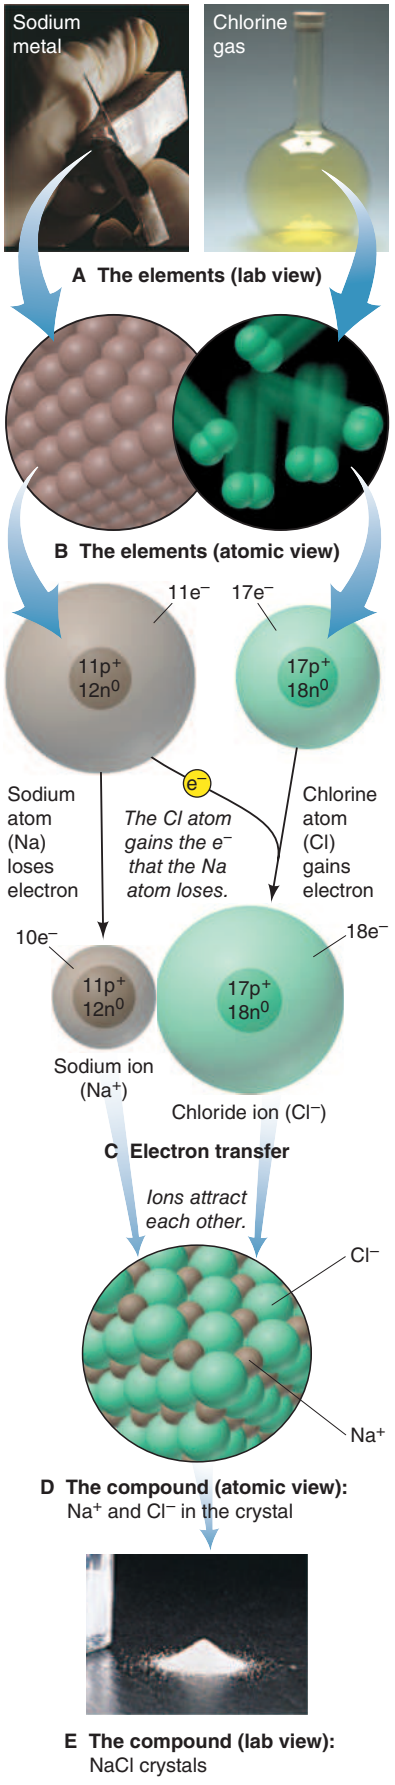


Figure 2.11 **The formation of an ionic compound. A,** The two elements as seen in the laboratory. **B,** The elements on the atomic scale. **C,** The electron transfer from Na atom to Cl atom to form Na^+ and Cl^- ions, shown schematically. **D,** Countless Na^+ and Cl^- ions attract each other and form a regular three-dimensional array. **E,** Crystalline NaCl occurs naturally as the mineral halite.

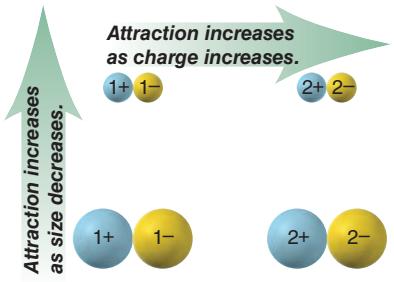

Figure 2.12 Factors that influence the strength of ionic bonding.

In other words, as is summarized in Figure 2.12,

- Ions with higher charges attract (or repel) each other more strongly than ions with lower charges.
- Smaller ions attract (or repel) each other more strongly than larger ions, because the charges are closer to each other.

Predicting the Number of Electrons Lost or Gained *Ionic compounds are neutral* because they contain equal numbers of positive and negative *charges.* Thus, there are equal numbers of Na^+ and Cl^- ions in sodium chloride, because both ions are singly charged. But there are two Na^+ ions for each oxide ion, O^{2-}, in sodium oxide because it takes two 1+ ions to balance one 2− ion.

Can we predict the number of electrons a given atom will lose or gain when it forms an ion? For A-group elements, we usually find that metal atoms lose electrons and nonmetal atoms gain electrons to *form ions with the same number of electrons as in an atom of the nearest noble gas* [Group 8A(18)]. Noble gases have a stability that is related to their number (and arrangement) of electrons. Thus, a sodium atom ($11e^-$) can attain the stability of a neon atom ($10e^-$), the nearest noble gas, by losing one electron. Similarly, a chlorine atom ($17e^-$) attains the stability of an argon atom ($18e^-$), its nearest noble gas, by gaining one electron. Thus, in general, when an element located near a noble gas forms a monatomic ion,

- *Metals lose electrons:* elements in Group 1A(1) lose one electron, elements in Group 2A(2) lose two, and aluminum in Group 3A(13) loses three.
- *Nonmetals gain electrons:* elements in Group 7A(17) gain one electron, oxygen and sulfur in Group 6A(16) gain two, and nitrogen in Group 5A(15) gains three.

In the periodic table in Figure 2.9, it looks like the elements in Group 7A(17) are "closer" to the noble gases than the elements in Group 1A(1). In truth, both groups are only one electron away from the number of electrons in the nearest noble gas. Figure 2.13 shows a periodic table of monatomic ions that is cut and rejoined as a cylinder. Note that fluorine (F; $Z = 9$) has one electron *fewer* than the noble gas neon (Ne; $Z = 10$) and sodium (Na; $Z = 11$) has one electron *more;* thus, they form the F^- and Na^+ ions. Similarly, oxygen (O; $Z = 8$) gains two electrons and magnesium (Mg; $Z = 12$) loses two to form the O^{2-} and Mg^{2+} ions and attain the same number of electrons as neon. In Figure 2.13, species in a row have the same number of electrons.

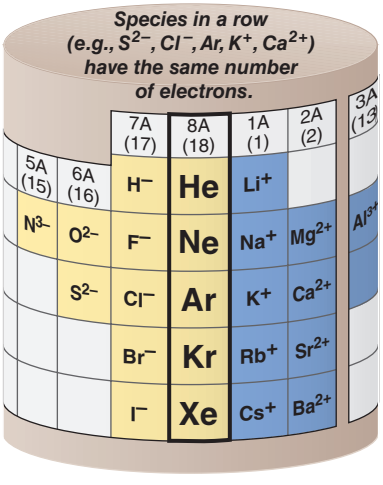

Figure 2.13 The relationship between ion formed and the nearest noble gas.

SAMPLE PROBLEM 2.7 Predicting the Ion an Element Forms

Problem What monatomic ions would you expect the following elements to form?
(a) Iodine ($Z = 53$) **(b)** Calcium ($Z = 20$) **(c)** Aluminum ($Z = 13$)

Plan We use the given Z value to find the element in the periodic table and see where its group lies relative to the noble gases. Elements in Groups 1A, 2A, and 3A *lose* electrons to attain the same number as the nearest noble gas and become positive ions; those in Groups 5A, 6A, and 7A *gain* electrons and become negative ions.

Solution **(a)** I^- Iodine ($_{53}I$) is in Group 7A(17), the halogens. Like any member of this group, it gains 1 electron to attain the same number as the nearest Group 8A(18) member, in this case, $_{54}Xe$.
(b) Ca^{2+} Calcium ($_{20}Ca$) is in Group 2A(2), the alkaline earth metals. Like any Group 2A member, it loses 2 electrons to attain the same number as the nearest noble gas, $_{18}Ar$.
(c) Al^{3+} Aluminum ($_{13}Al$) is a metal in the boron family [Group 3A(13)] and thus loses 3 electrons to attain the same number as its nearest noble gas, $_{10}Ne$.

FOLLOW-UP PROBLEMS

2.7A What monatomic ion would you expect each of the following elements to form: **(a)** $_{16}S$; **(b)** $_{37}Rb$; **(c)** $_{56}Ba$?

2.7B What monatomic ion would you expect each of the following elements to form: **(a)** $_{38}Sr$; **(b)** $_{8}O$; **(c)** $_{55}Cs$?

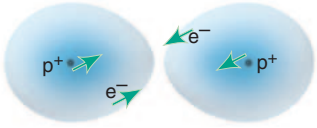
SOME SIMILAR PROBLEMS 2.70 and 2.71

The Formation of Covalent Substances

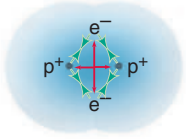
Covalent substances form when atoms of elements share electrons, which usually occurs between nonmetals.

Covalent Bonding in Elements and Some Simple Compounds The simplest case of electron sharing occurs not in a compound but in elemental hydrogen, between two hydrogen atoms (H; $Z = 1$). Imagine two separated H atoms approaching each other (Figure 2.14). As they get closer, the nucleus of each atom attracts the electron of the other atom more and more strongly. As the separated atoms begin to interpenetrate each other, repulsions between the nuclei and between the electrons begin to increase. At some optimum distance between the nuclei, the two atoms form a **covalent bond,** a pair of electrons mutually attracted by the two nuclei. The result is a hydrogen molecule, in which each electron no longer "belongs" to a particular H atom: the two electrons are *shared* by the two nuclei. A sample of hydrogen gas consists of these diatomic molecules (H_2)—pairs of atoms that are chemically bound, each pair behaving as a unit—*not* separate H atoms. Figure 2.15 shows other nonmetals that exist as molecules at room temperature.

Atoms far apart: *No interactions.*



Atoms closer: *Attractions* (green arrows) *between nucleus of one atom and electron of the other increase. Repulsions between nuclei and between electrons are very weak.*



Optimum distance: *H_2 molecule forms because attractions* (green arrows) *balance repulsions* (red arrows).

Figure 2.14 Formation of a covalent bond between two H atoms.

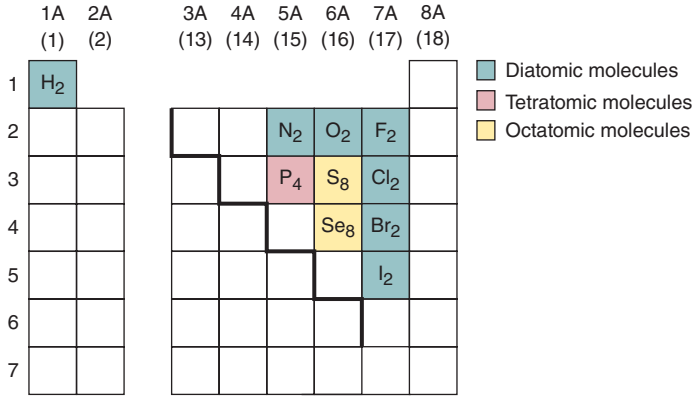


Figure 2.15 Elements that occur as molecules.

*Atoms of **different** elements share electrons to form the molecules of a covalent compound.* A sample of hydrogen fluoride, for example, consists of molecules in which one H atom forms a covalent bond with one F atom; water consists of molecules in which one O atom forms covalent bonds with two H atoms:

Distinguishing the Entities in Covalent and Ionic Substances There are two key distinctions between the chemical entities in covalent substances and those in ionic substances.

1. *Most covalent substances consist of molecules.* A cup of water, for example, consists of individual water molecules lying near each other. In contrast, under ordinary conditions, *there are no molecules in an ionic compound.* A piece of sodium chloride, for example, is a continuous array in three dimensions of oppositely charged sodium and chloride ions, *not* a collection of individual sodium chloride "molecules."
2. *The nature of the particles attracting each other in covalent and in ionic substances is fundamentally different.* Covalent bonding involves the mutual attraction between two (positively charged) nuclei and the two (negatively charged) electrons that reside between them. Ionic bonding involves the mutual attraction between positive and negative ions.

Polyatomic Ions: Covalent Bonds Within Ions Many ionic compounds contain **polyatomic ions,** which consist of two or more atoms bonded *covalently* and have a net positive or negative charge. For example, Figure 2.16 shows that a crystalline form of calcium carbonate *(left)* occurs on the atomic scale *(center)* as an array of polyatomic carbonate anions and monatomic calcium cations. The carbonate ion *(right)* consists of a carbon atom covalently bonded to three oxygen atoms, and two additional electrons give the ion its 2− charge. In many reactions, the polyatomic ion stays together as a unit.

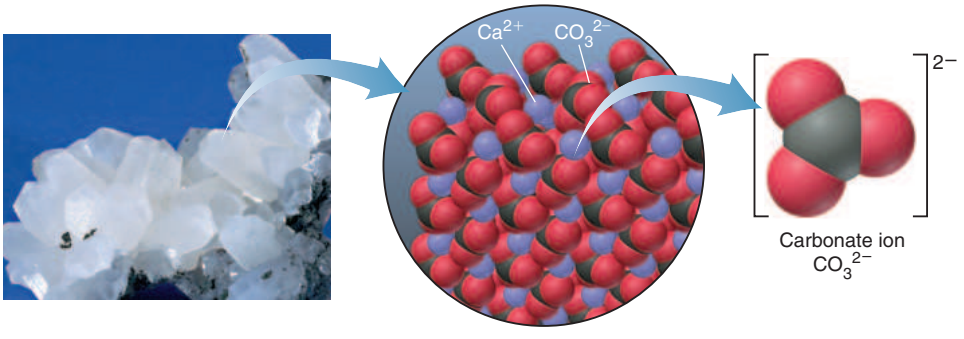

Figure 2.16 **The carbonate ion in calcium carbonate.**

Summary of Section 2.7

- Although a few elements occur uncombined in nature, the great majority exist in compounds.
- Ionic compounds form when a metal *transfers* electrons to a nonmetal, and the resulting positive and negative ions attract each other to form a three-dimensional array. In many cases, metal atoms lose and nonmetal atoms gain enough electrons to attain the same number of electrons as in atoms of the nearest noble gas.
- Covalent compounds form when elements, usually nonmetals, *share* electrons. Each covalent bond is an electron pair mutually attracted by two atomic nuclei.
- Monatomic ions are derived from single atoms. Polyatomic ions consist of two or more covalently bonded atoms that have a net positive or negative charge due to a deficit or excess of electrons.

2.8 COMPOUNDS: FORMULAS, NAMES, AND MASSES

In a **chemical formula,** element symbols and, often, numerical subscripts show the type and number of each atom in the smallest unit of the substance. In this section, you'll learn how to write the names and formulas of ionic and simple covalent compounds, how to calculate the mass of a compound from its formula, and how to visualize molecules with three-dimensional models. To make learning the names and formula of compounds easier, we'll rely on various rules, so be prepared for a bit of memorization and a lot of practice.

Binary Ionic Compounds

Let's begin with two general rules:

- For *all* ionic compounds, *names and formulas give the positive ion (cation) first and the negative ion (anion) second.*
- For all *binary* ionic compounds, *the name of the cation is the name of the metal, and the name of the anion has the suffix -ide added to the root of the name of the nonmetal.*

For example, the anion formed from brom*ine* is named brom*ide* (brom+ide). Therefore, the compound formed from the metal calcium and the nonmetal bromine is named *calcium bromide.*

In general, if the metal of a binary ionic compound is a main-group element (A groups) it usually forms a single type of ion; if it is a transition element (B groups), it often forms more than one. We discuss each case in turn.

Compounds of Elements That Form One Ion The periodic table presents some key points about the formulas of main-group monatomic ions (Figure 2.17):

- Monatomic ions of elements in the same main group have the same ionic charge; the alkali metals—Li, Na, K, Rb, Cs, and Fr—form ions with a 1+ charge; the halogens—F, Cl, Br, and I—form ions with a 1− charge; and so forth.
- For cations, ion charge equals A-group number: Na is in Group 1A and forms Na^+, Ba is in Group 2A and forms Ba^{2+}. (Exceptions in Figure 2.17 are Sn^{2+} and Pb^{2+}.)
- For anions, ion charge equals A-group number minus 8; for example, S is in Group 6A ($6 - 8 = -2$) and thus forms S^{2-}.

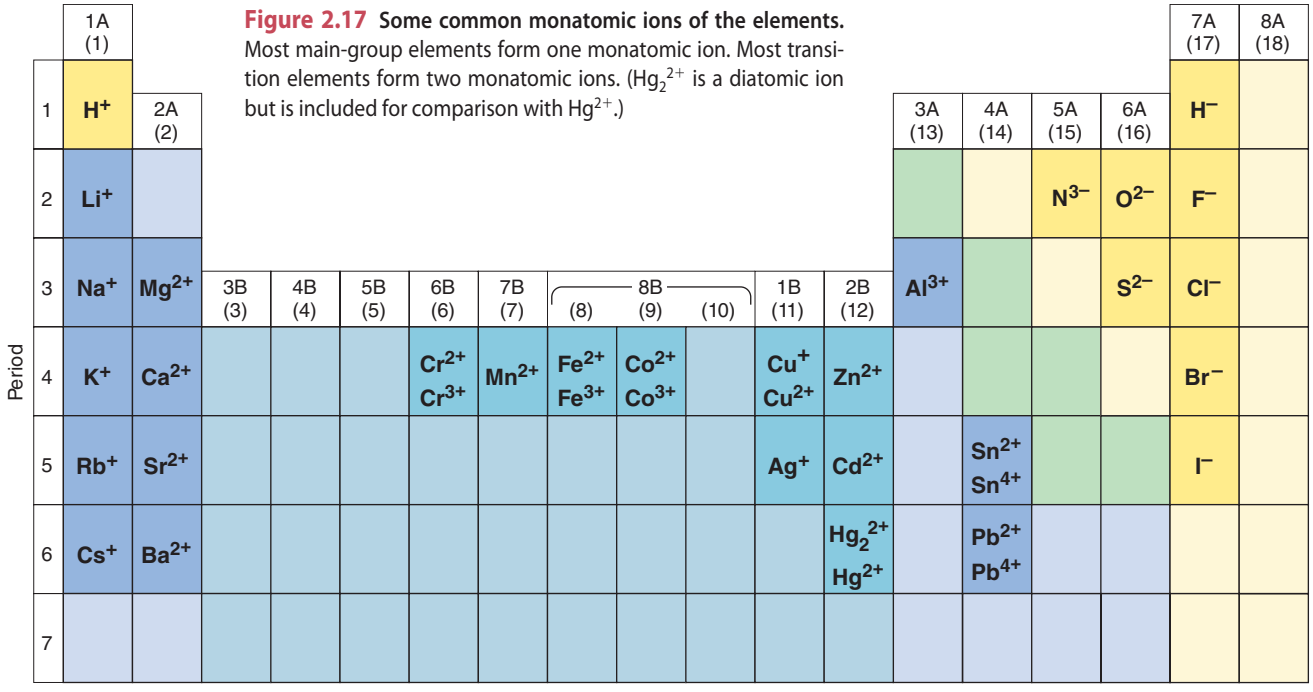

Figure 2.17 Some common monatomic ions of the elements. Most main-group elements form one monatomic ion. Most transition elements form two monatomic ions. (Hg_2^{2+} is a diatomic ion but is included for comparison with Hg^{2+}.)

Table 2.3 Common Monatomic Ions*

Charge	Formula	Name
Cations		
1+	H^+	hydrogen
	Li^+	**lithium**
	Na^+	**sodium**
	K^+	**potassium**
	Cs^+	cesium
	Ag^+	**silver**
2+	**Mg^{2+}**	**magnesium**
	Ca^{2+}	**calcium**
	Sr^{2+}	strontium
	Ba^{2+}	**barium**
	Zn^{2+}	**zinc**
	Cd^{2+}	cadmium
3+	Al^{3+}	aluminum
Anions		
1−	H^-	hydride
	F^-	**fluoride**
	Cl^-	**chloride**
	Br^-	**bromide**
	I^-	**iodide**
2−	**O^{2-}**	**oxide**
	S^{2-}	**sulfide**
3−	N^{3-}	nitride

*Listed by charge; those in **boldface** are most common.

Try to memorize the A-group monatomic ions in Table 2.3 (all except Ag^+, Zn^{2+}, and Cd^{2+}) according to their positions in Figure 2.17. These ions have *the same number of electrons as an atom of the nearest noble gas.*

Because an ionic compound consists of an array of ions rather than separate molecules, its formula represents the **formula unit,** the *relative* numbers of cations and anions in the compound. The compound has zero net charge, so the positive charges of the cations balance the negative charges of the anions. For example, calcium bromide is composed of Ca^{2+} ions and Br^- ions, so two Br^- balance each Ca^{2+}. The formula is $CaBr_2$, not Ca_2Br. In this and all other formulas,

- The subscript refers to the element symbol *preceding* it.
- The *subscript 1 is understood* from the presence of the element symbol alone (that is, we do not write Ca_1Br_2).
- The charge (without the sign) of one ion becomes the subscript of the other:

- Reduce the subscripts to the smallest whole numbers that retain the ratio of ions. Thus, for example, for the Ca^{2+} and O^{2-} ions in calcium oxide, we get Ca_2O_2, which we reduce to the formula CaO.*

The following two sample problems apply these rules. In Sample Problem 2.8, we name the compound from its elements, and in Sample Problem 2.9, we find the formula.

SAMPLE PROBLEM 2.8 Naming Binary Ionic Compounds

Problem Name the ionic compound formed from the following pairs of elements:
(a) Magnesium and nitrogen
(b) Iodine and cadmium
(c) Strontium and fluorine
(d) Sulfur and cesium

Plan The key to naming a binary ionic compound is to recognize which element is the metal and which is the nonmetal. When in doubt, check the periodic table. We place the cation name first, add the suffix *-ide* to the nonmetal root, and place the anion name last.

Solution **(a)** Magnes*ium* is the metal; *nitr-* is the nonmetal root: magnesium nitride
(b) Cadm*ium* is the metal; *iod-* is the nonmetal root: cadmium iodide
(c) Stront*ium* is the metal; *fluor-* is the nonmetal root: strontium fluoride (Note the spelling is fl*uo*ride, not fl*ou*ride.)
(d) Ces*ium* is the metal; *sulf-* is the nonmetal root: cesium sulfide

FOLLOW-UP PROBLEMS

2.8A For the following ionic compounds, give the name and periodic table group number of each element present:
(a) Zinc oxide
(b) Silver bromide
(c) Lithium chloride
(d) Aluminum sulfide

2.8B For the following ionic compounds, give the name and periodic table group number of each element present:
(a) Potassium sulfide
(b) Barium chloride
(c) Cesium nitride
(d) Sodium hydride

SOME SIMILAR PROBLEMS 2.84–2.87

*Compounds of the mercury(I) ion, such as Hg_2Cl_2, and peroxides of the alkali metals, such as Na_2O_2, are the only two common exceptions to this step: reducing the subscripts for these compounds would give the incorrect formulas HgCl and NaO.

SAMPLE PROBLEM 2.9 Determining Formulas of Binary Ionic Compounds

Problem Write formulas for the compounds named in Sample Problem 2.8.

Plan We write the formula by finding the smallest number of each ion that gives the neutral compound. These numbers appear as *right subscripts* to the element symbol.

Solution

(a) Mg^{2+} and N^{3-}; three Mg^{2+} ions (6+) balance two N^{3-} ions (6−): Mg_3N_2
(b) Cd^{2+} and I^-; one Cd^{2+} ion (2+) balances two I^- ions (2−): CdI_2
(c) Sr^{2+} and F^-; one Sr^{2+} ion (2+) balances two F^- ions (2−): SrF_2
(d) Cs^+ and S^{2-}; two Cs^+ ions (2+) balance one S^{2-} ion (2−): Cs_2S

Comment **1.** The subscript 1 is understood and so not written; thus, in (b), we do *not* write Cd_1I_2.
2. Ion charges do *not* appear in the compound formula; thus, in (c), we do *not* write $Sr^{2+}F_2{}^-$.

FOLLOW-UP PROBLEMS

2.9A Write the formula of each compound named in Follow-up Problem 2.8A.
2.9B Write the formula of each compound named in Follow-up Problem 2.8B.
SOME SIMILAR PROBLEMS 2.84–2.87

Compounds of Metals That Form More Than One Ion As noted earlier, many metals, particularly the transition elements (B groups), can form more than one ion. Table 2.4 lists some examples; see Figure 2.17 for their placement in the periodic table. Names of compounds containing these elements include a *Roman numeral within parentheses* immediately after the metal ion's name to indicate its ionic charge. For example, iron can form Fe^{2+} and Fe^{3+} ions. Iron forms two compounds with chlorine: $FeCl_2$, named iron(II) chloride (spoken "iron two chloride"), which contains Fe^{2+}; and $FeCl_3$, named iron(III) chloride, which contains Fe^{3+}.

We are focusing here on systematic names, but some common (trivial) names are still used. In common names for certain metal ions, the Latin root of the metal is followed by either of two suffixes (see Table 2.4):

- The suffix *-ous* for the ion with the lower charge
- The suffix *-ic* for the ion with the higher charge

Thus, iron(II) chloride is also called ferr*ous* chloride and iron(III) chloride is ferr*ic* chloride. (Memory aid: there is an ***o*** in *-**o**us* and *l**o**wer,* and an ***i*** in *-**i**c* and *h**i**gher.*)

Table 2.4 Some Metals That Form More Than One Monatomic Ion*

Element	Ion Formula	Systematic Name	Common (Trivial) Name
Chromium	Cr^{2+}	chromium(II)	chromous
	Cr^{3+}	**chromium(III)**	chromic
Cobalt	Co^{2+}	cobalt(II)	
	Co^{3+}	cobalt(III)	
Copper	**Cu^+**	**copper(I)**	cuprous
	Cu^{2+}	**copper(II)**	cupric
Iron	**Fe^{2+}**	**iron(II)**	ferrous
	Fe^{3+}	**iron(III)**	ferric
Lead	**Pb^{2+}**	**lead(II)**	
	Pb^{4+}	lead(IV)	
Mercury	$Hg_2{}^{2+}$	mercury(I)	mercurous
	Hg^{2+}	**mercury(II)**	mercuric
Tin	**Sn^{2+}**	**tin(II)**	stannous
	Sn^{4+}	tin(IV)	stannic

*Listed alphabetically by metal name; the ions in **boldface** are most common.

Table 2.5 Common Polyatomic Ions*

Formula	Name
Cations	
NH_4^+	**ammonium**
H_3O^+	**hydronium**
Anions	
CH_3COO^- (or **$C_2H_3O_2^-$**)	**acetate**
CN^-	cyanide
OH^-	**hydroxide**
ClO^-	hypochlorite
ClO_2^-	chlorite
ClO_3^-	**chlorate**
ClO_4^-	**perchlorate**
NO_2^-	nitrite
NO_3^-	**nitrate**
MnO_4^-	**permanganate**
CO_3^{2-}	**carbonate**
HCO_3^-	**hydrogen carbonate** (or **bicarbonate**)
CrO_4^{2-}	chromate
$Cr_2O_7^{2-}$	**dichromate**
O_2^{2-}	peroxide
PO_4^{3-}	**phosphate**
HPO_4^{2-}	hydrogen phosphate
$H_2PO_4^-$	dihydrogen phosphate
SO_3^{2-}	sulfite
SO_4^{2-}	**sulfate**
HSO_4^-	hydrogen sulfate (or bisulfate)

*Boldface ions are most common.

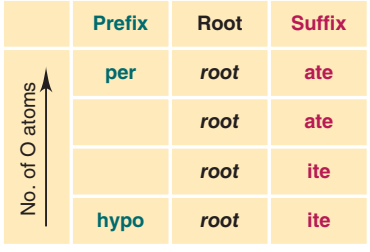

Figure 2.18 Naming oxoanions. Prefixes and suffixes indicate the number of O atoms in the anion.

SAMPLE PROBLEM 2.10 Determining Names and Formulas of Ionic Compounds of Metals That Form More Than One Ion

Problem Give the systematic name for the formula or the formula for the name:
(a) Tin(II) fluoride **(b)** CrI_3 **(c)** Ferric oxide **(d)** CoS

Solution **(a)** Tin(II) ion is Sn^{2+}; fluoride is F^-. Two F^- ions balance one Sn^{2+} ion: tin(II) fluoride is SnF_2. (The common name is stannous fluoride.)
(b) The anion is I^-, iodide, and the formula shows three I^-. Therefore, the cation must be Cr^{3+}, chromium(III) ion: CrI_3 is chromium(III) iodide. (The common name is chromic iodide.)
(c) *Ferric* is the common name for iron(III) ion, Fe^{3+}; oxide ion is O^{2-}. To balance the charges, the formula is Fe_2O_3. [The systematic name is iron(III) oxide.]
(d) The anion is sulfide, S^{2-}, which requires that the cation be Co^{2+}. The name is cobalt(II) sulfide.

FOLLOW-UP PROBLEMS

2.10A Give the systematic name for the formula or the formula for the name:
(a) lead(IV) oxide (a component of car batteries); **(b)** Cu_2S; **(c)** $FeBr_2$; **(d)** mercuric chloride.

2.10B Give the systematic name for the formula or the formula for the name:
(a) stannous fluoride (the decay-preventing compound in toothpaste); **(b)** PbI_2;
(c) chromic sulfide; **(d)** FeO.

A SIMILAR PROBLEM 2.88

Compounds That Contain Polyatomic Ions

Many ionic compounds contain polyatomic ions. Table 2.5 lists some common polyatomic ions. Remember that *the polyatomic ion stays together as a charged unit.* The formula for potassium nitrate is KNO_3: each K^+ balances one NO_3^-. The formula for sodium carbonate is Na_2CO_3: two Na^+ balance one CO_3^{2-}. *When two or more of the same polyatomic ion are present in the formula unit, that ion appears in parentheses with the subscript written outside.* For example, calcium nitrate contains one Ca^{2+} and two NO_3^- ions and has the formula $Ca(NO_3)_2$. Parentheses and a subscript are *only* used if *more than one* of a given polyatomic ion is present; thus, sodium nitrate is $NaNO_3$, *not* $Na(NO_3)$.

Families of Oxoanions As Table 2.5 shows, most polyatomic ions are **oxoanions** (or *oxyanions*), those in which an element, usually a nonmetal, is bonded to one or more oxygen atoms. There are several families of two or four oxoanions that differ only in the number of oxygen atoms. The following naming conventions are used with these ions.

With two oxoanions in the family:

- The ion with *more* O atoms takes the nonmetal root and the suffix *-ate*.
- The ion with *fewer* O atoms takes the nonmetal root and the suffix *-ite*.

For example, SO_4^{2-} is the sulf*ate* ion, and SO_3^{2-} is the sulf*ite* ion; similarly, NO_3^- is nitr*ate*, and NO_2^- is nitr*ite*.

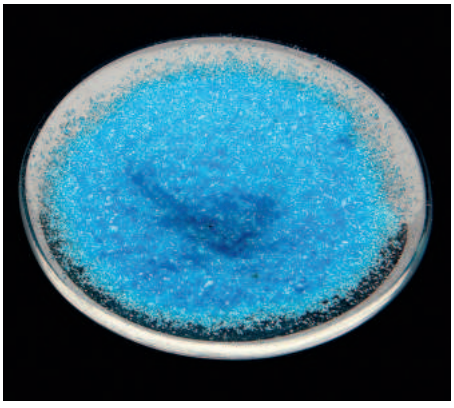
With four oxoanions in the family (a halogen bonded to O) (Figure 2.18):

- The ion with *most* O atoms has the prefix *per-*, the nonmetal root, and the suffix *-ate*.
- The ion with *one fewer* O atom has just the root and the suffix *-ate*.
- The ion with *two fewer* O atoms has just the root and the suffix *-ite*.
- The ion with *least (three fewer)* O atoms has the prefix *hypo-*, the root, and the suffix *-ite*.

For example, for the four chlorine oxoanions,

ClO_4^- is *per*chlor*ate*, ClO_3^- is chlor*ate*, ClO_2^- is chlor*ite*, ClO^- is *hypo*chlor*ite*

Hydrated Ionic Compounds Ionic compounds called **hydrates** have a specific number of water molecules in each formula unit. They are shown after a centered dot in the formula and named with a Greek numerical prefix before the word *hydrate* (Table 2.6). For example, Epsom salt has seven water molecules in each formula unit: the formula is $MgSO_4 \cdot 7H_2O$, and the name is magnesium sulfate *hepta*hydrate. Similarly, the mineral gypsum has the formula $CaSO_4 \cdot 2H_2O$ and the name calcium sulfate *di*hydrate. The water molecules, referred to as "waters of hydration," are part of the hydrate's structure. Heating can remove some or all of them, leading to a different substance. For example, when heated strongly, blue copper(II) sulfate pentahydrate ($CuSO_4 \cdot 5H_2O$) is converted to white copper(II) sulfate ($CuSO_4$).



Copper(II) sulfate pentahydrate

Copper(II) sulfate

Table 2.6 Numerical Prefixes for Hydrates and Binary Covalent Compounds*

Number	Prefix
1	mono-
2	di-
3	tri-
4	tetra-
5	penta-
6	hexa-
7	hepta-
8	octa-
9	nona-
10	deca-

*It is common practice to drop the final *a* from the prefix when naming binary covalent oxides (see Sample Problem 2.14).

SAMPLE PROBLEM 2.11 Determining Names and Formulas of Ionic Compounds Containing Polyatomic Ions

Problem Give the systematic name for the formula or the formula for the name:
(a) $Fe(ClO_4)_2$ **(b)** Sodium sulfite **(c)** $Ba(OH)_2 \cdot 8H_2O$

Solution **(a)** ClO_4^- is perchlorate, which has a 1− charge, so the cation must be Fe^{2+}. The name is iron(II) perchlorate. (The common name is ferrous perchlorate.)
(b) Sodium is Na^+; sulfite is SO_3^{2-}, and two Na^+ ions balance one SO_3^{2-} ion. The formula is Na_2SO_3.
(c) Ba^{2+} is barium; OH^- is hydroxide. There are eight (*octa-*) water molecules in each formula unit. The name is barium hydroxide octahydrate.

FOLLOW-UP PROBLEMS

2.11A Give the systematic name for the formula or the formula for the name:
(a) cupric nitrate trihydrate; **(b)** zinc hydroxide; **(c)** LiCN.

2.11B Give the systematic name for the formula or the formula for the name:
(a) ammonium sulfate; **(b)** $Ni(NO_3)_2 \cdot 6H_2O$; **(c)** potassium bicarbonate.

SOME SIMILAR PROBLEMS 2.89–2.91

SAMPLE PROBLEM 2.12 Recognizing Incorrect Names and Formulas of Ionic Compounds

Problem Explain what is wrong with the name or formula at the end of each statement, and correct it:
(a) $Ba(C_2H_3O_2)_2$ is called barium diacetate.
(b) Sodium sulfide has the formula $(Na)_2SO_3$.
(c) Iron(II) sulfate has the formula $Fe_2(SO_4)_3$.
(d) Cesium carbonate has the formula $Cs_2(CO_3)$.

Solution **(a)** The charge of the Ba^{2+} ion *must* be balanced by *two* $C_2H_3O_2^-$ ions, so the prefix *di-* is unnecessary. For ionic compounds, we do not indicate the number of ions with numerical prefixes. The correct name is barium acetate.
(b) Two mistakes occur here. The sodium ion is monatomic, so it does *not* require parentheses. The sulfide ion is S^{2-}, *not* SO_3^{2-} (which is sulfite). The correct formula is Na_2S.
(c) The Roman numeral refers to the charge of the ion, *not* the number of ions in the formula. Fe^{2+} is the cation, so it requires one SO_4^{2-} to balance its charge. The correct formula is $FeSO_4$. [$Fe_2(SO_4)_3$ is the formula for iron(III) sulfate.]
(d) Parentheses are *not* required when only one polyatomic ion of a kind is present. The correct formula is Cs_2CO_3.

FOLLOW-UP PROBLEMS

2.12A State why the formula or name at the end of each statement is incorrect, and correct it:
(a) Ammonium phosphate is $(NH_3)_4PO_4$.
(b) Aluminum hydroxide is $AlOH_3$.
(c) $Mg(HCO_3)_2$ is manganese(II) carbonate.

2.12B State why the formula or name at the end of each statement is incorrect, and correct it:
(a) $Cr(NO_3)_3$ is chromic(III) nitride.
(b) $Ca(NO_2)_2$ is cadmium nitrate.
(c) Potassium chlorate is $P(ClO_4)$.

SOME SIMILAR PROBLEMS 2.92 and 2.93

Acid Names from Anion Names

Acids are an important group of hydrogen-containing compounds that have been used in chemical reactions since before alchemical times. In the laboratory, acids are typically used in water solution. When naming them and writing their formulas, we consider acids as anions that have one or more hydrogen ions (H^+) added to them to give a neutral compound. The two common types of acids are binary acids and oxoacids:

1. *Binary acid* solutions form when certain gaseous compounds dissolve in water. For example, when gaseous hydrogen chloride (HCl) dissolves in water, it forms hydrochloric acid, which is named as follows:

Prefix *hydro-* + nonmetal *root* + suffix *-ic* + separate word *acid*
hydro + chlor + ic + acid

or *hydrochloric acid.* This naming pattern holds for many compounds in which hydrogen combines with an anion that has an *-ide* suffix.

2. *Oxoacid* names are similar to those of the oxoanions, except for two suffix changes:
   - *-ate* in the anion becomes *-ic* in the acid
   - *-ite* in the anion becomes *-ous* in the acid

   The oxoanion prefixes *hypo-* and *per-* are retained. Thus,

BrO_4^- is *per*brom*ate*, and $HBrO_4$ is *per*brom*ic* acid.
IO_2^- is iod*ite*, and HIO_2 is iod*ous* acid.

SAMPLE PROBLEM 2.13 **Determining Names and Formulas of Anions and Acids**

Problem Name each of the following anions, and give the name and formula of the acid derived from it: **(a)** Br^-; **(b)** IO_3^-; **(c)** CN^-; **(d)** HSO_4^-.

Solution **(a)** The anion is bromide; the acid is hydrobromic acid, HBr.
(b) The anion is iodate; the acid is iodic acid, HIO_3.
(c) The anion is cyanide; the acid is hydrocyanic acid, HCN.
(d) The anion is hydrogen sulfate; the acid is sulfuric acid, H_2SO_4. (In this case, the suffix is added to the element name *sulfur,* not to the root, *sulf-*.)

FOLLOW-UP PROBLEMS

2.13A Write the formula and name for the anion of each acid: **(a)** chloric acid; **(b)** hydrofluoric acid; **(c)** acetic acid; **(d)** nitrous acid.

2.13B Name each of the following acids, and give the name and formula of its anion: **(a)** H_2SO_3 (two anions); **(b)** HBrO; **(c)** $HClO_2$; **(d)** HI.

SOME SIMILAR PROBLEMS 2.94 and 2.95

Binary Covalent Compounds

Binary covalent compounds are typically formed by the combination of two nonmetals. Some are so familiar that we use their common names, such as ammonia (NH_3), methane (CH_4), and water (H_2O), but most are named systematically:

- The element with the lower group number in the periodic table comes first in the name. The element with the higher group number comes second and is named with its root and the suffix *-ide*. For example, nitrogen [Group 5A(15)] and fluorine [Group 7A(17)] form a compound that has three fluorine atoms for every nitrogen atom. The name and formula are nitrogen trifluoride, NF_3. (*Exception:* When the compound contains oxygen and any of the halogens chlorine, bromine, or iodine, the halogen is named first.)
- If both elements are in the same group, the one with the higher period number is named first. Thus, one compound that the Group 6A(16) elements sulfur (Period 3) and oxygen (Period 2) form is sulfur dioxide, SO_2.
- Covalent compounds use Greek numerical prefixes (see Table 2.6) to indicate the number of atoms of each element. The first element in the name has a prefix *only* when more than one atom of it is present; the second element *usually* has a prefix.

SAMPLE PROBLEM 2.14 Determining Names and Formulas of Binary Covalent Compounds

Problem **(a)** What is the formula of carbon disulfide?
(b) What is the name of PCl_5?
(c) Give the name and formula of the compound whose molecules each consist of two N atoms and four O atoms.

Solution **(a)** The prefix *di-* means "two." The formula is CS_2.
(b) P is the symbol for phosphorus; there are five chlorine atoms, which is indicated by the prefix *penta-*. The name is phosphorus pentachloride.
(c) Nitrogen (N) comes first in the name (lower group number). The compound is dinitrogen tetroxide, N_2O_4.

Comment Note that, in (c), the *a* at the end of the Greek prefix is dropped when the prefix is added to *-oxide.* Similarly, "hexa-oxide" becomes *hexoxide,* "deca-oxide" becomes *decoxide,* and so forth.

FOLLOW-UP PROBLEMS

2.14A Give the name or formula for **(a)** SO_3; **(b)** SiO_2; **(c)** dinitrogen monoxide; **(d)** selenium hexafluoride.

2.14B Give the name or formula for **(a)** SCl_2; **(b)** N_2O_5; **(c)** boron trifluoride; **(d)** iodine tribromide.

SOME SIMILAR PROBLEMS 2.98 and 2.99

SAMPLE PROBLEM 2.15 Recognizing Incorrect Names and Formulas of Binary Covalent Compounds

Problem Explain what is wrong with the name or formula at the end of each statement, and correct it:
(a) SF_4 is monosulfur pentafluoride.
(b) Dichlorine heptoxide is Cl_2O_6.
(c) N_2O_3 is dinitrotrioxide.

Solution **(a)** There are two mistakes. *Mono-* is not needed if there is only one atom of the first element, and the prefix for four is *tetra-*, not *penta-*. The correct name is sulfur tetrafluoride.
(b) The prefix *hepta-* indicates seven, not six. The correct formula is Cl_2O_7.
(c) The full name of the first element is needed, and a space separates the two element names. The correct name is dinitrogen trioxide.

FOLLOW-UP PROBLEMS

2.15A Explain what is wrong with the name or formula at the end of each statement, and correct it:
(a) S_2Cl_2 is disulfurous dichloride.
(b) Nitrogen monoxide is N_2O.
(c) $BrCl_3$ is trichlorine bromide.

2.15B Explain what is wrong with the name or formula at the end of each statement, and correct it:
(a) P_4O_6 is tetraphosphorous hexaoxide.
(b) SF_6 is hexafluorosulfide.
(c) Nitrogen tribromide is $NiBR_3$.

SOME SIMILAR PROBLEMS 2.100 and 2.101

The Simplest Organic Compounds: Straight-Chain Alkanes

Organic compounds typically have complex structures that consist of chains, branches, and/or rings of carbon atoms that are also bonded to hydrogen atoms and, often, to atoms of oxygen, nitrogen, and a few other elements. At this point, we'll name just the simplest organic compounds. Rules for naming other organic compounds are detailed in Chapter 15.

Hydrocarbons, the simplest type of organic compound, contain *only* carbon and hydrogen. *Alkanes* are the simplest type of hydrocarbon; many function as important fuels, such as methane, propane, butane, and the mixture that makes up gasoline. The simplest alkanes to name are the *straight-chain alkanes* because the carbon chains have no branches. Alkanes are named with a *root,* based on the number of C atoms in the chain, followed by the suffix *-ane.*

Table 2.7 gives the names, molecular formulas, and space-filling models (discussed shortly) of the first 10 straight-chain alkanes. Note that the roots of the four smallest ones are new, but those for the larger ones are the same as the Greek prefixes shown in Table 2.6 (with the final *-a* dropped).

Table 2.7 The First 10 Straight-Chain Alkanes

Name (Formula)	Model
Methane (CH_4)	
Ethane (C_2H_6)	
Propane (C_3H_8)	
Butane (C_4H_{10})	
Pentane (C_5H_{12})	
Hexane (C_6H_{14})	Heptane (C_7H_{16})	Octane (C_8H_{18})	Nonane (C_9H_{20})	Decane ($C_{10}H_{22}$)	
Molecular Masses from Chemical Formulas

In Section 2.5, we calculated the atomic mass of an element. Using the periodic table and the formula of a compound, we calculate the **molecular mass** (also called the *molecular weight*) of a formula unit of the compound as the sum of the atomic masses:

$$\text{Molecular mass} = \text{sum of atomic masses} \qquad (2.3)$$

The molecular mass of a water molecule (using atomic masses to four significant figures from the periodic table) is

$$\begin{aligned}\text{Molecular mass of } H_2O &= (2 \times \text{atomic mass of H}) + (1 \times \text{atomic mass of O}) \\ &= (2 \times 1.008 \text{ amu}) + 16.00 \text{ amu} = 18.02 \text{ amu}\end{aligned}$$

Ionic compounds don't consist of molecules, so the mass of a formula unit is called the **formula mass** instead of *molecular mass.* For example, for calcium chloride, we have

$$\begin{aligned}\text{Formula mass of } CaCl_2 &= (1 \times \text{atomic mass of Ca}) + (2 \times \text{atomic mass of Cl}) \\ &= 40.08 \text{ amu} + (2 \times 35.45 \text{ amu}) = 110.98 \text{ amu}\end{aligned}$$

We can use atomic masses, not ionic masses, because electron loss equals electron gain, so electron mass is balanced.

To calculate the formula mass of a compound with a polyatomic ion, *the number of atoms of each element inside the parentheses is multiplied by the subscript outside the parentheses.* For barium nitrate, $Ba(NO_3)_2$,

$$\begin{aligned}&\text{Formula mass of } Ba(NO_3)_2 \\ &= (1 \times \text{atomic mass of Ba}) + (2 \times \text{atomic mass of N}) + (6 \times \text{atomic mass of O}) \\ &= 137.3 \text{ amu} + (2 \times 14.01 \text{ amu}) + (6 \times 16.00 \text{ amu}) = 261.3 \text{ amu}\end{aligned}$$

In the next two sample problems, the name or molecular depiction is used to find a compound's molecular or formula mass.

SAMPLE PROBLEM 2.16 Calculating the Molecular Mass of a Compound

Problem Using the periodic table, calculate the molecular (or formula) mass of
(a) Tetraphosphorus trisulfide
(b) Ammonium nitrate

Plan We first write the formula, then multiply the number of atoms (or ions) of each element by its atomic mass (from the periodic table), and find the sum.

Solution **(a)** The formula is P_4S_3.

$$\begin{aligned}\text{Molecular mass} &= (4 \times \text{atomic mass of P}) + (3 \times \text{atomic mass of S}) \\ &= (4 \times 30.97 \text{ amu}) + (3 \times 32.06 \text{ amu}) \\ &= 220.06 \text{ amu}\end{aligned}$$

(b) The formula is NH_4NO_3. We count the total number of N atoms even though they belong to different ions:

$$\begin{aligned}&\text{Formula mass} \\ &= (2 \times \text{atomic mass of N}) + (4 \times \text{atomic mass of H}) + (3 \times \text{atomic mass of O}) \\ &= (2 \times 14.01 \text{ amu}) + (4 \times 1.007 \text{ amu}) + (3 \times 16.00 \text{ amu}) \\ &= 80.05 \text{ amu}\end{aligned}$$

Check You can often find large errors by rounding atomic masses to the nearest 5 and adding: **(a)** $(4 \times 30) + (3 \times 30) = 210 \approx 220.09$. The sum has two decimal places because the atomic masses have two. **(b)** $(2 \times 15) + 4 + (3 \times 15) = 79 \approx 80.05$.

FOLLOW-UP PROBLEMS

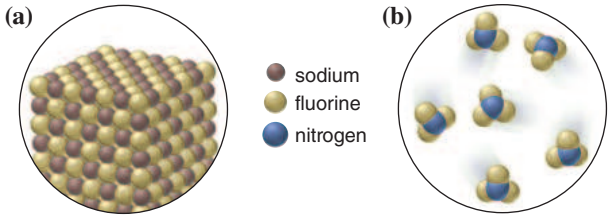
2.16A What is the molecular (or formula) mass of each of the following?
(a) Hydrogen peroxide
(b) Cesium carbonate

2.16B What is the molecular (or formula) mass of each of the following?
(a) Sulfuric acid
(b) Potassium sulfate

SOME SIMILAR PROBLEMS 2.104 and 2.105

SAMPLE PROBLEM 2.17 Using Molecular Depictions to Determine Formula, Name, and Mass

Problem Each scene represents a binary compound. Determine its formula, name, and molecular (or formula) mass.



Plan Each of the compounds contains only two elements, so to find the formula, we find the simplest whole-number ratio of one atom to the other. From the formula, we determine the name and the molecular (or formula) mass.

Solution **(a)** There is one brown sphere (sodium) for each yellow sphere (fluorine), so the formula is NaF. A metal and nonmetal form an ionic compound, in which the metal is named first: sodium fluoride.

$$\text{Formula mass} = (1 \times \text{atomic mass of Na}) + (1 \times \text{atomic mass of F})$$
$$= 22.99 \text{ amu} + 19.00 \text{ amu} = 41.99 \text{ amu}$$

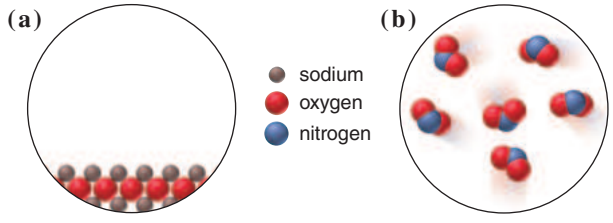
(b) There are three yellow spheres (fluorine) for each blue sphere (nitrogen), so the formula is NF_3. Two nonmetals form a covalent compound. Nitrogen has a lower group number, so it is named first: nitrogen trifluoride.

$$\text{Molecular mass} = (1 \times \text{atomic mass of N}) + (3 \times \text{atomic mass of F})$$
$$= 14.01 \text{ amu} + (3 \times 19.00) = 71.01 \text{ amu}$$

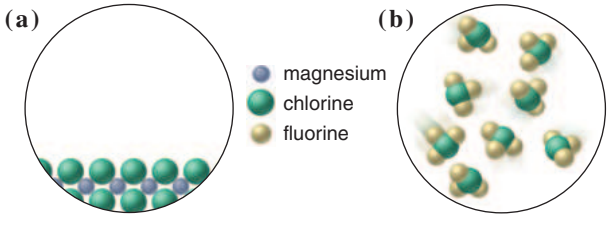
Check **(a)** For binary ionic compounds, we predict ionic charges from the periodic table (see Figure 2.13). Na forms a 1+ ion, and F forms a 1− ion, so the charges balance with one Na^+ per F^-. Also, ionic compounds are solids, consistent with the picture. **(b)** Covalent compounds often occur as individual molecules, as in the picture. Rounding in (a) gives 25 + 20 = 45; in (b), we get 15 + (3 × 20) = 75, so there are no large errors.

FOLLOW-UP PROBLEMS

2.17A Determine the name, formula, and molecular (or formula) mass of the compound in each scene below:



2.17B Determine the name, formula, and molecular (or formula) mass of the compound in each scene below:



SOME SIMILAR PROBLEMS 2.108 and 2.109

Representing Molecules with Formulas and Models

In order to represent objects too small to see, chemists employ a variety of formulas and models. Each conveys different information, as shown for water below:

- A *molecular formula* uses element symbols and, often, numerical subscripts to give the *actual* number of atoms of each element in a molecule of the compound. (Recall that, for ionic compounds, the *formula unit* gives the *relative* number of each type of ion.) The molecular formula of water is H_2O: there are two H atoms and one O atom in each molecule.

$$\mathbf{H_2O}$$

- A *structural formula* shows the relative placement and connections of atoms in the molecule. It uses symbols for the atoms *and* either a pair of dots *(electron-dot formula, left)* or a line *(bond-line formula, right)* to show the bonds between the atoms. In water, each H atom is bonded to the O atom, but not to the other H atom.

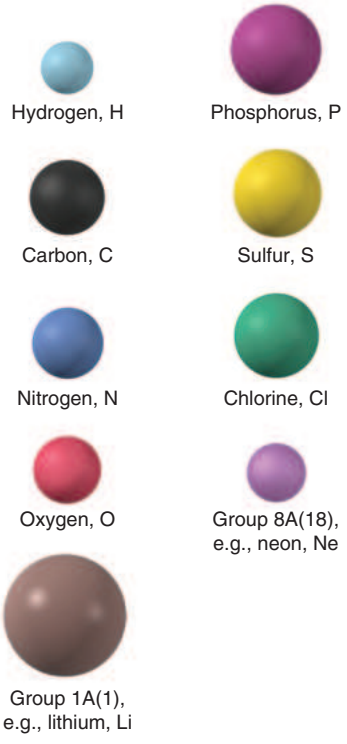
H:O:H **H–O–H**

In models shown throughout this text, colored balls represent atoms *(see margin).*

- A *ball-and-stick model* shows atoms as balls and bonds as sticks, and the angles between the bonds are accurate. Note that water is a bent molecule (with a bond angle of 104.5°). This type of model doesn't show the bonded atoms overlapping (see Figure 2.14) or their accurate sizes, so it exaggerates the distance between them.

- A *space-filling model* is an accurately scaled-up image of the molecule, so it shows the relative sizes of the atoms, the relative distances between the nuclei (centers of the spheres), and the angles between the bonds. However, bonds are not shown, and it can be difficult to see each atom in a complex molecule.

Every molecule is minute, but the range of molecular sizes, and thus molecular masses, is enormous. Table 2.8 on the next page shows the two types of formulas and models for some diatomic and small polyatomic molecules, as well as space-filling models of a portion of two extremely large molecules, called *macromolecules,* deoxyribonucleic acid (DNA) and nylon.



Summary of Section 2.8

- An ionic compound is named with cation first and anion second. For metals that can form more than one ion, the charge is shown with a Roman numeral.
- Oxoanions have suffixes, and sometimes prefixes, attached to the root of the element name to indicate the number of oxygen atoms.
- Names of hydrates have a numerical prefix indicating the number of associated water molecules.
- Acid names are based on anion names.
- For binary covalent compounds, the first word of the name is the element farther left or lower down in the periodic table, and prefixes show the numbers of each atom.
- The molecular (or formula) mass of a compound is the sum of the atomic masses.
- Chemical formulas give the number of atoms (molecular) or the arrangement of atoms (structural) of one unit of a compound.
- Molecular models convey information about bond angles (ball-and-stick) and relative atomic sizes and distances between atoms (space-filling).

Table 2.8 Representing Molecules

Name	Molecular Formula (Molecular Mass, in amu)	Bond-Line Formula	Ball-and-Stick Model	Space-Filling Model
Carbon monoxide	CO (28.01)			
Nitrogen dioxide	NO_2 (46.01)			
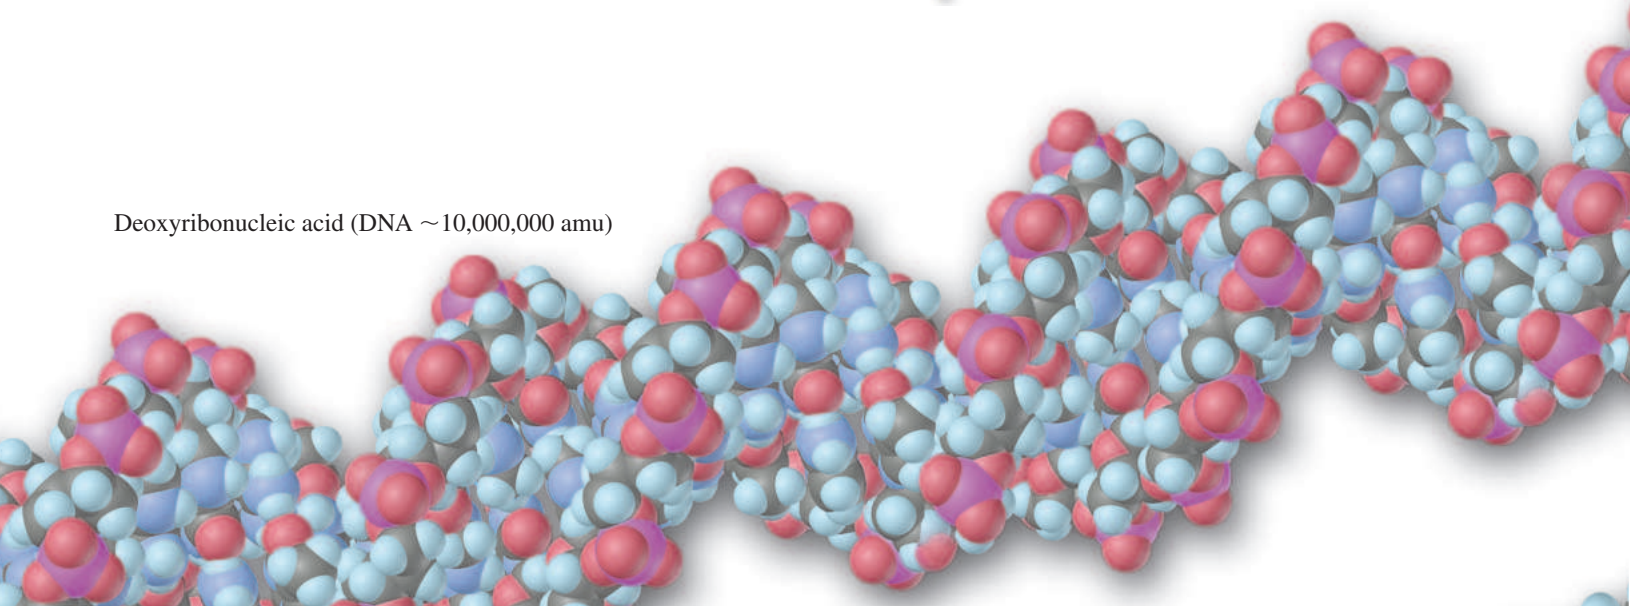
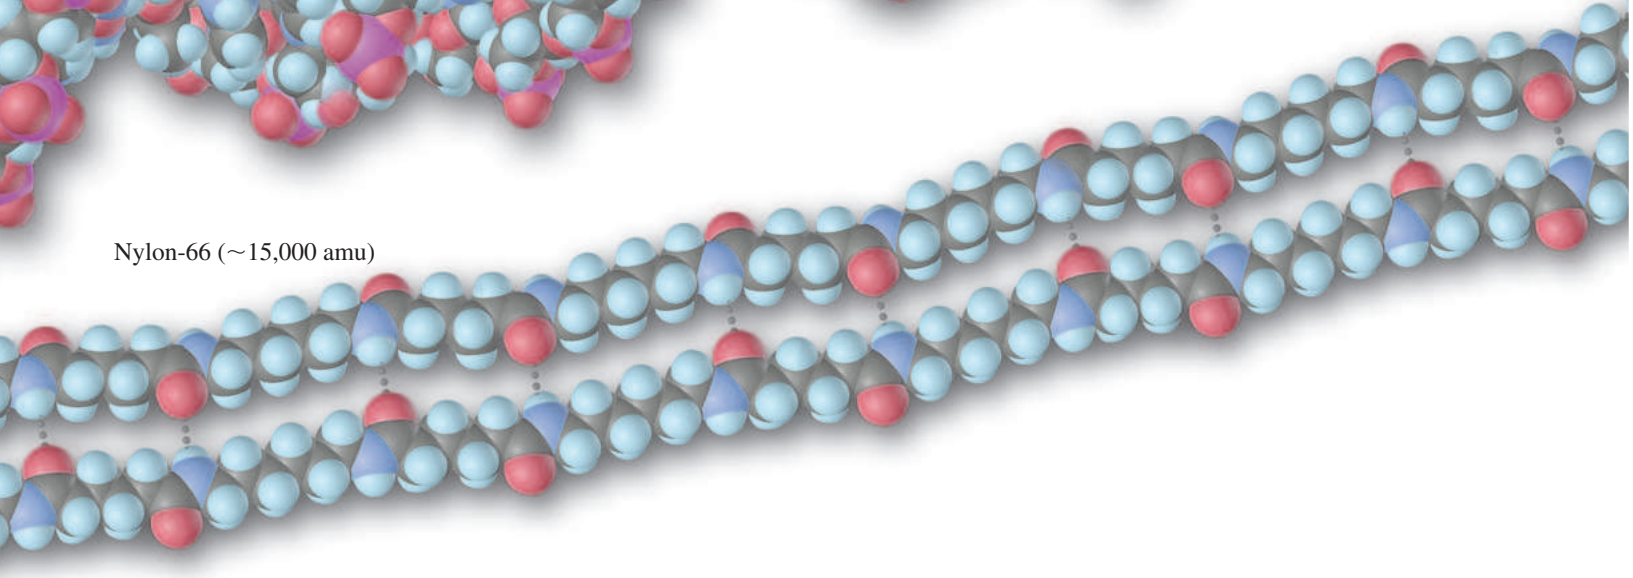
Butane	C_4H_{10} (58.12)			Aspirin (acetylsalicylic acid)	$C_9H_8O_4$ (180.15)			
Deoxyribonucleic acid (DNA ~10,000,000 amu)



Nylon-66 (~15,000 amu)



2.9 MIXTURES: CLASSIFICATION AND SEPARATION

In the natural world, *matter usually occurs as mixtures.* A sample of clean air, for example, consists of many elements and compounds physically mixed together, including O_2, N_2, CO_2, the noble gases [Group 8A(18)], and water vapor (H_2O). The oceans are complex mixtures of dissolved ions and covalent substances, including Na^+, Mg^{2+}, Cl^-, SO_4^{2-}, O_2, CO_2, and of course H_2O. Rocks and soils are mixtures of numerous compounds, including calcium carbonate ($CaCO_3$), silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), and iron(III) oxide (Fe_2O_3). And living things contain thousands of substances—carbohydrates, lipids, proteins, nucleic acids, and many simpler ionic and covalent compounds.

There are two broad classes of mixtures:

- A **heterogeneous mixture** has one or more visible boundaries between the components. Thus, its composition is *not* uniform, but rather varies from one region to another. Many rocks are heterogeneous, having individual grains of different minerals. In some heterogeneous mixtures, such as milk and blood, the boundaries can be seen only with a microscope.
- A **homogeneous mixture** (or **solution**) has no visible boundaries because the components are individual atoms, ions, or molecules. Thus, its composition *is* uniform. A mixture of sugar dissolved in water is homogeneous, for example, because the sugar molecules and water molecules are uniformly intermingled on the molecular level. We have no way to tell visually whether a sample of matter is a substance (element or compound) or a homogeneous mixture.

Although we usually think of solutions as liquid, they exist in all three physical states. For example, air is a gaseous solution of mostly oxygen and nitrogen molecules, and wax is a solid solution of several fatty substances. Solutions in water, called **aqueous solutions,** are especially important in chemistry and comprise a major portion of the environment and of all organisms.

Recall that mixtures differ from compounds in three major ways:

1. The proportions of the components can vary.
2. The individual properties of the components are observable.
3. The components can be separated by physical means.

The difference between a mixture and a compound is well illustrated using iron and sulfur as components (Figure 2.19). Any proportions of iron metal filings and powdered sulfur form a mixture. The components can be separated with a magnet because iron metal is magnetic. But if we heat the container strongly, the components form the compound iron(II) sulfide (FeS). The magnet can no longer remove the iron because it exists as Fe^{2+} ions chemically bound to S^{2-} ions.

Chemists have devised many procedures for separating a mixture into its components, and the Tools of the Laboratory essay (p. 79) describes some common ones.

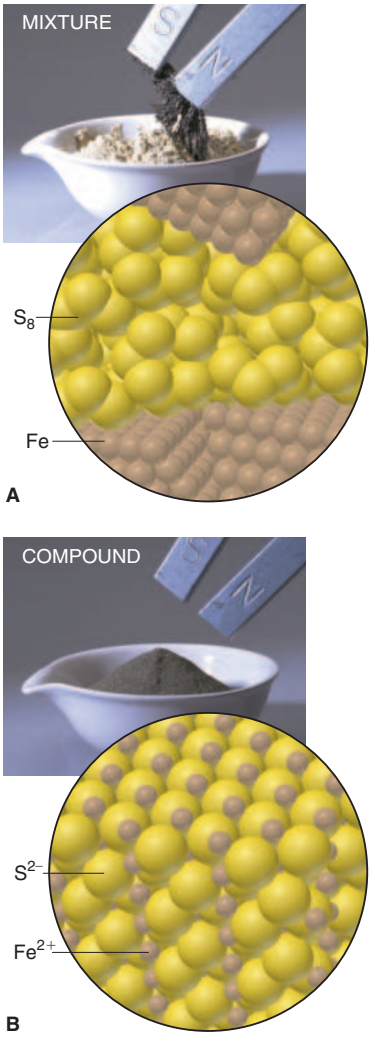


Figure 2.19 The distinction between mixtures and compounds. A, A *mixture* of iron and sulfur consists of the two elements. **B,** The *compound* iron(II) sulfide consists of an array of Fe^{2+} and S^{2-} ions.

An Overview of the Components of Matter

Understanding matter at the observable and atomic scales is the essence of chemistry. Figure 2.20 on the next page is a visual overview of many key terms and ideas in this chapter.

Summary of Section 2.9

- Heterogeneous mixtures have visible boundaries between the components.
- Homogeneous mixtures (solutions) have no visible boundaries because mixing occurs at the molecular level. They can occur in any physical state.
- Components of mixtures (unlike those of compounds) can have variable proportions, can be separated physically, and retain their properties.
- Separation methods are based on differences in physical properties and include filtration (particle size), crystallization (solubility), distillation (volatility), and chromatography (solubility).

MATTER
- Anything with mass and volume
- Exists in three physical states: solid, liquid, gas

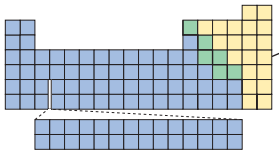
MIXTURES
- Two or more elements or compounds in variable proportions
- Components retain their properties

Heterogeneous Mixtures
- Visible parts
- Differing regional composition

Homogeneous Mixtures (Solutions)
- No visible parts
- Same composition throughout

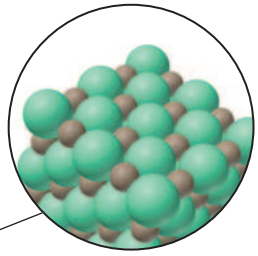
PHYSICAL CHANGES
- Filtration
- Crystallization
- Distillation
- Chromatography

SUBSTANCES
- Fixed composition throughout

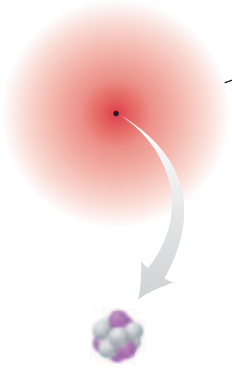


Elements
- Composed of one type of atom
- Classified as metal, nonmetal, or metalloid
- Simplest type of matter that retains characteristic properties
- May occur as individual atoms or diatomic or polyatomic molecules
- Atomic mass is average of isotopic masses weighted by abundance

Compounds
- Two or more elements combined in fixed parts by mass
- Properties differ from those of component elements
- Molecular (formula) mass is sum of atomic masses



CHEMICAL CHANGES



Atoms
- Protons (p^+) and neutrons (n^0) in tiny, massive, positive nucleus
- Atomic number (Z) = no. of p^+
- Mass number (A) = no. of p^+ + no. of n^0
- Electrons (e^-) occupy surrounding volume; no. of p^+ = no. of e^-

Ionic
- Ions arise through e^- transfer from metal to nonmetal
- Solids composed of array of mutually attracting cations and anions
- Formula unit represents the fixed cation/anion ratio

Covalent
- Often consist of separate molecules
- Atoms (usually nonmetals) bonded by e^- pair mutually attracted (shared) by both nuclei

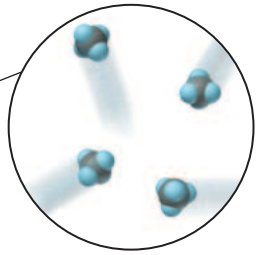


Figure 2.20 The classification of matter from a chemical point of view.

Basic Separation Techniques

Some of the most challenging laboratory procedures involve separating mixtures and purifying the components. All of the techniques described here depend on the *physical properties* of the substances in the mixture; no chemical changes occur.

Filtration is based on *differences in particle size* and is often used to separate a solid from a liquid, which flows through the tiny holes in filter paper as the solid is retained. In vacuum filtration, reduced pressure below the filter speeds the flow of the liquid through it. Filtration is used in the purification of tap water.

Crystallization is based on *differences in solubility.* The *solubility* of a substance is the amount that dissolves in a fixed volume of solvent at a given temperature. Since solubility often increases with temperature, the impure solid is dissolved in hot solvent and when the solution cools, the purified compound solidifies (crystallizes). A key component of computer chips is purified by a type of crystallization.

Distillation separates components through *differences in* ***volatility,*** the tendency of a substance to become a gas. *Simple* distillation separates components with *large* differences in volatility, such as water from dissolved ionic compounds (Figure B2.3). As the mixture boils, the vapor is richer in the more volatile component, in this case, water, which is condensed and collected separately. *Fractional* distillation (discussed in Chapter 13) uses many vaporization-condensation steps to separate components with small volatility differences, such as those in petroleum.

Chromatography is also based on *differences in solubility*. The mixture is dissolved in a gas or liquid, and the components are separated as this solution, called the *mobile phase,* flows through a solid (or viscous liquid) called the *stationary phase.* A component with lower solubility in the stationary phase moves through it faster than a component with a higher solubility. Figure B2.4 depicts the separation of inks by *column chromatography*.

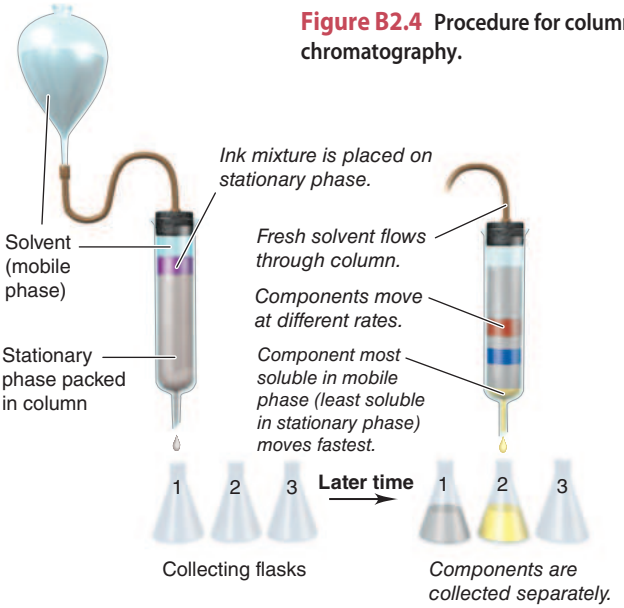

Figure B2.4 Procedure for column chromatography.

In a related technique called *gas-liquid chromatography (GLC),* the mobile phase is an inert gas, such as helium, that carries a gaseous mixture of components into a long tube packed with the stationary phase (Figure B2.5, part A). The components emerge separately and reach a detector. A chromatogram has numerous peaks, each representing the amount of a specific component (Figure B2.5, part B). *High-performance (high-pressure) liquid chromatography (HPLC)* is similar to GLC, but the mixture need not be vaporized, so more heat-sensitive components can be separated.

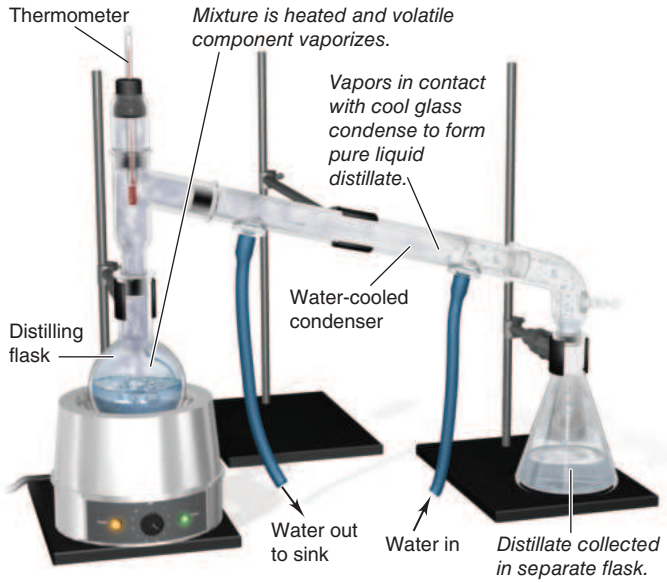

Figure B2.3 Distillation.

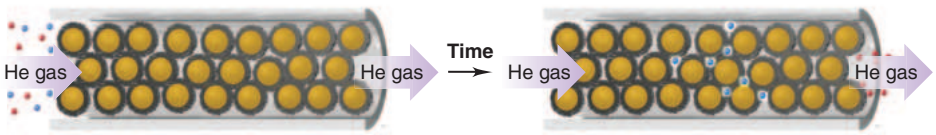
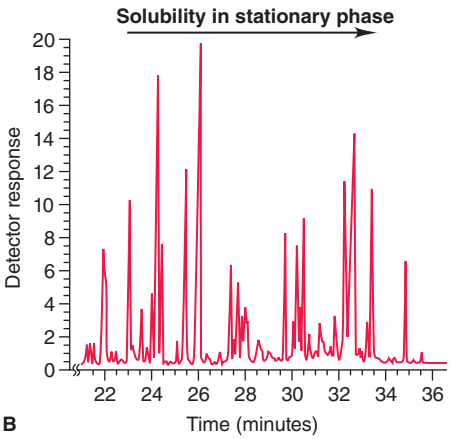
Problem

B2.3 Name the technique(s) and briefly describe the procedure for separating each of the following mixtures into pure components: (a) table salt and pepper; (b) drinking water contaminated with soot; (c) crushed ice and crushed glass; (d) table sugar dissolved in ethanol; (e) two pigments (chlorophyll *a* and chlorophyll *b*) from spinach leaves.



A *Gaseous mixture* (blue and red) *is carried into column with mobile phase.* *Component* (blue) *that is more soluble in stationary phase moves slower.*



B

Figure B2.5 **Principle of gas-liquid chromatography (GLC).** The stationary phase is shown as a viscous liquid *(gray circles)* coating the solid beads *(yellow)* of an inert packing.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The defining characteristics of the three types of matter—element, compound, and mixture—on the macroscopic and atomic levels, and of the particles within them—atoms, molecules, and ions (§2.1)
2. The significance of the three mass laws—mass conservation, definite composition, and multiple proportions (§2.2)
3. The postulates of Dalton's atomic theory and how it explains the mass laws (§2.3)
4. The major contribution of experiments by Thomson, Millikan, and Rutherford to our understanding of atomic structure (§2.4)
5. The structure of the atom, the main features of the subatomic particles, and the importance of isotopes in determining atomic mass (§2.5)
6. The format of the periodic table and general location and characteristics of metals, metalloids, and nonmetals (§2.6)
7. The essential features of ionic and covalent compounds and the distinction between them (§2.7)
8. The types of mixtures and their properties (§2.9)

Master These Skills

1. Distinguishing elements, compounds, and mixtures at the atomic scale (SP 2.1)
2. Using the mass ratio of element to compound to find the mass of an element in a compound (SP 2.2)
3. Visualizing the mass laws (SP 2.3)
4. Using atomic notation to express the subatomic makeup of an isotope (SP 2.4)
5. Calculating an atomic mass from isotopic composition (SP 2.5)
6. Identifying an element from its Z values (SP 2.6)
7. Predicting the monatomic ion formed from a main-group element (SP 2.7)
8. Naming and writing the formula of an ionic compound formed from the ions in Tables 2.3–2.5 (SPs 2.8–2.12, 2.17)
9. Naming and writing the formula of an acid and its anion (SP 2.13)
10. Naming and writing the formula of a binary covalent compound (SPs 2.14, 2.15, 2.17)
11. Calculating the molecular or formula mass of a compound (SP 2.16, 2.17)

Key Equations and Relationships

Page numbers appear in parentheses.

2.1 Finding the mass of an element in a given mass of compound (46):

$$\text{Mass of element in sample} = \text{mass of compound in sample} \times \frac{\text{mass of element in compound}}{\text{mass of compound}}$$

2.2 Calculating the number of neutrons in an atom (54):

$$\text{Number of neutrons} = \text{mass number} - \text{atomic number}$$

or

$$N = A - Z$$

2.3 Determining the molecular mass of a formula unit of a compound (72):

$$\text{Molecular mass} = \text{sum of atomic masses}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

2.1A (a) There is only one type of atom (blue) present, so this is an element. (b) Two different atoms (brown and green) appear in a fixed ratio of 1/1, so this is a compound. (c) These molecules consist of one type of atom (orange), so this is an element.

2.1B There are two types of particles reacting (left circle), one with two blue atoms and the other with two orange; the depiction shows a mixture of two elements. In the product (right circle), all the particles have one blue atom and one orange; this is a compound.

2.2A Mass (t) of pitchblende

$$= 2.3 \text{ t } \cancel{\text{uranium}} \times \frac{84.2 \text{ t pitchblende}}{71.4 \text{ t } \cancel{\text{uranium}}} = 2.7 \text{ t pitchblende}$$

Mass (t) of oxygen

$$= 2.7 \text{ t } \cancel{\text{pitchblende}} \times \frac{(84.2 - 71.4 \text{ t oxygen})}{84.2 \text{ t } \cancel{\text{pitchblende}}} = 0.41 \text{ t oxygen}$$

2.2B Mass (g) of silver

$$= 3.57 \text{ g } \cancel{\text{silver bromide}} \times \frac{15.4 \text{ g silver}}{26.8 \text{ g } \cancel{\text{silver bromide}}}$$

$$= 2.05 \text{ g silver}$$

Mass (g) of bromine

$$= 3.57 \text{ g } \cancel{\text{silver bromide}} \times \frac{(26.8 - 15.4 \text{ g bromine})}{26.8 \text{ g } \cancel{\text{silver bromide}}}$$

$$= 1.52 \text{ g bromine}$$

2.3A There are 12 black atoms and 14 red atoms in each circle (mass conservation). In the right circle, there are molecules of two compounds—one compound has one black and one red atom, and the other has one black and two red atoms (multiple proportions). Each compound has a fixed ratio of black-to-red atoms (definite composition).

2.3B Sample B. Two bromine-fluorine compounds appear. In one, there are three fluorine atoms for each bromine; in the other, there is one fluorine for each bromine. Therefore, the masses of fluorine that combine with a given mass of bromine are in a 3/1 ratio.

2.4A ^{46}Ti has 22p$^+$, 22e$^-$, and 24n^0
^{47}Ti has 22p$^+$, 22e$^-$, and 25n^0
^{48}Ti has 22p$^+$, 22e$^-$, and 26n^0
^{49}Ti has 22p$^+$, 22e$^-$, and 27n^0
^{50}Ti has 22p$^+$, 22e$^-$, and 28n^0

2.4B (a) 5p$^+$, 5e$^-$, 6n^0; Q = B
(b) 20p$^+$, 20e$^-$, 21n^0; R = Ca
(c) 53p$^+$, 53e$^-$, 78n^0; X = I

2.5A First, divide the percent abundance value (Figure B2.2C, Tools of the Laboratory, p. 57) by 100 to obtain the fractional value for each isotope. Multiply each isotopic mass by the fractional value, and add the resulting masses to obtain neon's atomic mass:

^{20}Ne = 19.99244 amu × 0.9048 = 18.09 amu
^{21}Ne = 20.99385 amu × 0.0027 = 0.057 amu
^{22}Ne = 21.99139 amu × 0.0925 = 2.03 amu
20.177 amu = 20.18 amu

2.5B $10.0129x + [11.0093(1 - x)] = 10.81$; $0.9964x = 0.1993$; $x = 0.2000$ and $1 - x = 0.8000$; % abundance of ^{10}B = 20.00%; % abundance of ^{11}B = 80.00%

2.6A (a) Silicon, Si; Group 4A(14) and Period 3; metalloid
(b) Cesium, Cs; Group 1A(1) and Period 6; main-group metal
(c) Xenon, Xe; Group 8A(18) and Period 5; nonmetal

2.6B (a) Magnesium, Mg; Group 2A(2) and Period 3; main-group metal
(b) Nitrogen, N; Group 5A(15) and Period 2; nonmetal
(c) Zinc, Zn; Group 2B(12) and Period 4; transition metal

2.7A (a) S^{2-}; (b) Rb^+; (c) Ba^{2+}

2.7B (a) Sr^{2+}; (b) O^{2-}; (c) Cs^+

2.8A (a) Zinc [Group 2B(12)] and oxygen [Group 6A(16)]
(b) Silver [Group 1B(11)] and bromine [Group 7A(17)]
(c) Lithium [Group 1A(1)] and chlorine [Group 7A(17)]
(d) Aluminum [Group 3A(13)] and sulfur [Group 6A(16)]

2.8B (a) Potassium [Group 1A(1)] and sulfur [Group 6A(16)]
(b) Barium [Group 2A(2)] and chlorine [Group 7A(17)]
(c) Cesium [Group 1A(1)] and nitrogen [Group 5A(15)]
(d) Sodium [Group 1A(1)] and hydrogen [Group 1A(1)]

2.9A (a) ZnO; (b) AgBr; (c) LiCl; (d) Al_2S_3

2.9B (a) K_2S; (b) $BaCl_2$; (c) Cs_3N; (d) NaH

2.10A (a) PbO_2; (b) copper(I) sulfide (cuprous sulfide); (c) iron(II) bromide (ferrous bromide); (d) $HgCl_2$

2.10B (a) SnF_2; (b) lead(II) iodide; (c) Cr_2S_3; (d) iron(II) oxide

2.11A (a) $Cu(NO_3)_2 \cdot 3H_2O$; (b) $Zn(OH)_2$; (c) lithium cyanide

2.11B (a) $(NH_4)_2SO_4$; (b) nickel(II) nitrate hexahydrate; (c) $KHCO_3$

2.12A (a) $(NH_4)_3PO_4$; ammonium is NH_4^+ and phosphate is PO_4^{3-}.
(b) $Al(OH)_3$; parentheses are needed around the polyatomic ion OH^-.
(c) Magnesium hydrogen carbonate; Mg^{2+} is magnesium and can have only a 2+ charge, so it does not need (II); HCO_3^- is hydrogen carbonate (or bicarbonate).

2.12B (a) Chromium(III) nitrate; the *-ic* ending is not used with Roman numerals; NO_3^- is nitr*ate*.
(b) Calcium nitrite; Ca^{2+} is calcium and NO_2^- is nitr*ite*.
(c) $KClO_3$; potassium is K^+ and chlorate is ClO_3^-; parentheses are not needed when only one polyatomic ion is present.

2.13A (a) ClO_3^-, chlorate; (b) F^-, fluoride; (c) CH_3COO^- (or $C_2H_3O_2^-$), acetate; (d) NO_2^-, nitrite

2.13B (a) Sulfurous acid; add one H^+ ion to hydrogen sulfite, HSO_3^-, or two H^+ to sulfite, SO_3^{2-}; (b) hypobromous acid, hypobromite, BrO^-; (c) chlorous acid, chlorite, ClO_2^-; (d) hydriodic acid, iodide, I^-

2.14A (a) Sulfur trioxide; (b) silicon dioxide; (c) N_2O; (d) SeF_6

2.14B (a) Sulfur dichloride; (b) dinitrogen pentoxide; (c) BF_3; (d) IBr_3

2.15A (a) Disulfur dichloride; the *-ous* suffix is not used.
(b) NO; the name indicates one nitrogen.
(c) Bromine trichloride; Br is in a higher period in Group 7A(17), so it is named first.

2.15B (a) Tetraphosphorus hexoxide; the name of the element phosphorus ends in *-us* not *-ous*, and the prefix *hexa-* is shortened to *hex-* before *oxide*. (b) Sulfur hexafluoride; sulfur has a lower

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

group number so it comes first, and fluorine gets the *-ide* ending.
(c) NBr_3; nitrogen's symbol is N, and the second letter of a symbol is lowercase: bromine is Br.

2.16A (a) H_2O_2, 34.02 amu; (b) Cs_2CO_3, 325.8 amu

2.16B (a) H_2SO_4, 98.08 amu; (b) K_2SO_4, 174.26 amu

2.17A (a) Na_2O. This is an ionic compound, so the name is sodium oxide.

Formula mass

= (2 × atomic mass of Na) + (1 × atomic mass of O)

= (2 × 22.99 amu) + 16.00 amu = 61.98 amu

(b) NO_2. This is a covalent compound, and N has the lower group number, so the name is nitrogen dioxide.

Molecular mass

= (1 × atomic mass of N) + (2 × atomic mass of O)

= 14.01 amu + (2 × 16.00 amu) = 46.01 amu

2.17B (a) Magnesium chloride, $MgCl_2$, 95.21 amu; (b) chlorine trifluoride, ClF_3, 92.45 amu

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Elements, Compounds, and Mixtures: An Atomic Overview
(Sample Problem 2.1)

Concept Review Questions

2.1 What is the key difference between an element and a compound?

2.2 List two differences between a compound and a mixture.

2.3 Which of the following are pure substances? Explain.
(a) Calcium chloride, used to melt ice on roads, consists of two elements, calcium and chlorine, in a fixed mass ratio.
(b) Sulfur consists of sulfur atoms combined into octatomic molecules.
(c) Baking powder, a leavening agent, contains 26% to 30% sodium hydrogen carbonate and 30% to 35% calcium dihydrogen phosphate by mass.
(d) Cytosine, a component of DNA, consists of H, C, N, and O atoms bonded in a specific arrangement.

2.4 Classify each substance in Problem 2.3 as an element, compound, or mixture, and explain your answers.

2.5 Explain the following statement: The smallest particles unique to an element may be atoms or molecules.

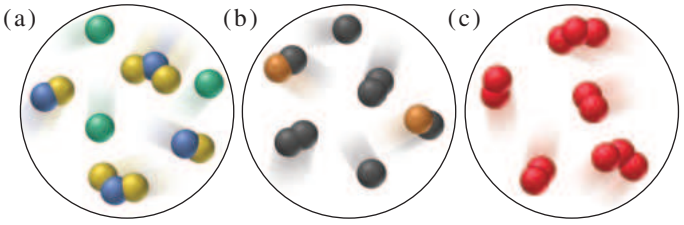
2.6 Explain the following statement: The smallest particles unique to a compound cannot be atoms.

2.7 Can the relative amounts of the components of a mixture vary? Can the relative amounts of the components of a compound vary? Explain.

Problems in Context

2.8 The tap water found in many areas of the United States leaves white deposits when it evaporates. Is this tap water a mixture or a compound? Explain.

2.9 Each scene below represents a mixture. Describe each one in terms of the number(s) of elements and/or compounds present.



2.10 Samples of illicit "street" drugs often contain an inactive component, such as ascorbic acid (vitamin C). After obtaining a sample of cocaine, government chemists calculate the mass of vitamin C per gram of drug sample, and use it to track the drug's distribution. For example, if different samples of cocaine obtained on the streets of New York, Los Angeles, and Paris all contain 0.6384 g of vitamin C per gram of sample, they very likely come from a common source. Do these street samples consist of a compound, element, or mixture? Explain.

The Observations That Led to an Atomic View of Matter
(Sample Problem 2.2)

Concept Review Questions

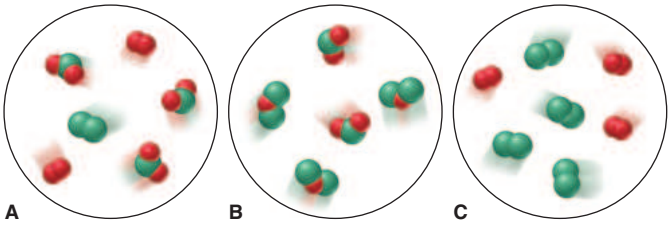
2.11 Why was it necessary for separation techniques and methods of chemical analysis to be developed before the laws of definite composition and multiple proportions could be formulated?

2.12 To which classes of matter—element, compound, and/or mixture—do the following apply: (a) law of mass conservation; (b) law of definite composition; (c) law of multiple proportions?

2.13 In our modern view of matter and energy, is the law of mass conservation still relevant to chemical reactions? Explain.

2.14 Identify the mass law that each of the following observations demonstrates, and explain your reasoning:
(a) A sample of potassium chloride from Chile contains the same percent by mass of potassium as one from Poland.
(b) A flashbulb contains magnesium and oxygen before use and magnesium oxide afterward, but its mass does not change.
(c) Arsenic and oxygen form one compound that is 65.2 mass % arsenic and another that is 75.8 mass % arsenic.

2.15 Which of the following scenes illustrate(s) the fact that compounds of chlorine (green) and oxygen (red) exhibit the law of multiple proportions? Name the compounds.



2.16 (a) Does the percent by mass of each element in a compound depend on the amount of compound? Explain.
(b) Does the mass of each element in a compound depend on the amount of compound? Explain.

2.17 Does the percent by mass of each element in a compound depend on the amount of that element used to make the compound? Explain.

Skill-Building Exercises (grouped in similar pairs)

2.18 State the mass law(s) demonstrated by the following experimental results, and explain your reasoning:

Experiment 1: A student heats 1.00 g of a blue compound and obtains 0.64 g of a white compound and 0.36 g of a colorless gas.

Experiment 2: A second student heats 3.25 g of the same blue compound and obtains 2.08 g of a white compound and 1.17 g of a colorless gas.

2.19 State the mass law(s) demonstrated by the following experimental results, and explain your reasoning:

Experiment 1: A student heats 1.27 g of copper and 3.50 g of iodine to produce 3.81 g of a white compound; 0.96 g of iodine remains.

Experiment 2: A second student heats 2.55 g of copper and 3.50 g of iodine to form 5.25 g of a white compound; 0.80 g of copper remains.

2.20 Fluorite, a mineral of calcium, is a compound of the metal with fluorine. Analysis shows that a 2.76-g sample of fluorite contains 1.42 g of calcium. Calculate the (a) mass of fluorine in the sample; (b) mass fractions of calcium and fluorine in fluorite; (c) mass percents of calcium and fluorine in fluorite.

2.21 Galena, a mineral of lead, is a compound of the metal with sulfur. Analysis shows that a 2.34-g sample of galena contains 2.03 g of lead. Calculate the (a) mass of sulfur in the sample; (b) mass fractions of lead and sulfur in galena; (c) mass percents of lead and sulfur in galena.

2.22 Magnesium oxide (MgO) forms when the metal burns in air.
(a) If 1.25 g of MgO contains 0.754 g of Mg, what is the mass ratio of magnesium to magnesium oxide?
(b) How many grams of Mg are in 534 g of MgO?

2.23 Zinc sulfide (ZnS) occurs in the zinc blende crystal structure.
(a) If 2.54 g of ZnS contains 1.70 g of Zn, what is the mass ratio of zinc to zinc sulfide?
(b) How many kilograms of Zn are in 3.82 kg of ZnS?

2.24 A compound of copper and sulfur contains 88.39 g of metal and 44.61 g of nonmetal. How many grams of copper are in 5264 kg of compound? How many grams of sulfur?

2.25 A compound of iodine and cesium contains 63.94 g of metal and 61.06 g of nonmetal. How many grams of cesium are in 38.77 g of compound? How many grams of iodine?

2.26 Show, with calculations, how the following data illustrate the law of multiple proportions:
Compound 1: 47.5 mass % sulfur and 52.5 mass % chlorine
Compound 2: 31.1 mass % sulfur and 68.9 mass % chlorine

2.27 Show, with calculations, how the following data illustrate the law of multiple proportions:
Compound 1: 77.6 mass % xenon and 22.4 mass % fluorine
Compound 2: 63.3 mass % xenon and 36.7 mass % fluorine

Problems in Context

2.28 Dolomite is a carbonate of magnesium and calcium. Analysis shows that 7.81 g of dolomite contains 1.70 g of Ca. Calculate the mass percent of Ca in dolomite. On the basis of the mass percent of Ca, and neglecting all other factors, which is the richer source of Ca, dolomite or fluorite (see Problem 2.20)?

2.29 The mass percent of sulfur in a sample of coal is a key factor in the environmental impact of the coal because the sulfur combines with oxygen when the coal is burned and the oxide can then be incorporated into acid rain. Which of the following coals would have the smallest environmental impact?

	Mass (g) of Sample	Mass (g) of Sulfur in Sample
Coal A	378	11.3
Coal B	495	19.0
Coal C	675	20.6

Dalton's Atomic Theory

(Sample Problem 2.3)

Concept Review Questions

2.30 Which of Dalton's postulates about atoms are inconsistent with later observations? Do these inconsistencies mean that Dalton was wrong? Is Dalton's model still useful? Explain.

2.31 Use Dalton's theory to explain why potassium nitrate from India or Italy has the same mass percents of K, N, and O.

The Observations That Led to the Nuclear Atom Model

Concept Review Questions

2.32 Thomson was able to determine the mass/charge ratio of the electron but not its mass. How did Millikan's experiment allow determination of the electron's mass?

2.33 The following charges on individual oil droplets were obtained during an experiment similar to Millikan's. Determine a charge for the electron (in C, coulombs), and explain your answer: -3.204×10^{-19} C; -4.806×10^{-19} C; -8.010×10^{-19} C; -1.442×10^{-18} C.

2.34 Describe Thomson's model of the atom. How might it account for the production of cathode rays?

2.35 When Rutherford's coworkers bombarded gold foil with α particles, they obtained results that overturned the existing (Thomson) model of the atom. Explain.

The Atomic Theory Today

(Sample Problems 2.4 and 2.5)

Concept Review Questions

2.36 Define *atomic number* and *mass number*. Which can vary without changing the identity of the element?

2.37 Choose the correct answer. The difference between the mass number of an isotope and its atomic number is (a) directly related to the identity of the element; (b) the number of electrons; (c) the number of neutrons; (d) the number of isotopes.

2.38 Even though several elements have only one naturally occurring isotope and all atomic nuclei have whole numbers of protons and neutrons, no atomic mass is a whole number. Use the data from Table 2.2 to explain this fact.

Skill-Building Exercises (grouped in similar pairs)

2.39 Argon has three naturally occurring isotopes, ^{36}Ar, ^{38}Ar, and ^{40}Ar. What is the mass number of each isotope? How many protons, neutrons, and electrons are present in each?

2.40 Chlorine has two naturally occurring isotopes, ^{35}Cl and ^{37}Cl. What is the mass number of each isotope? How many protons, neutrons, and electrons are present in each?

2.41 Do both members of the following pairs have the same number of protons? Neutrons? Electrons?

(a) $^{16}_{8}$O and $^{17}_{8}$O (b) $^{40}_{18}$Ar and $^{41}_{19}$K (c) $^{60}_{27}$Co and $^{60}_{28}$Ni

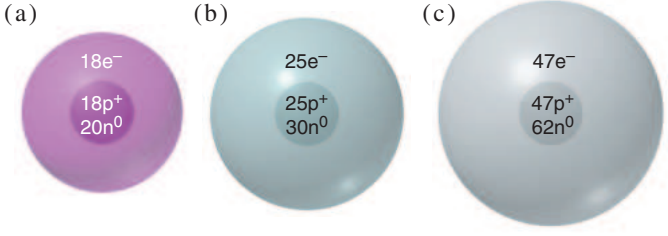
Which pair(s) consist(s) of atoms with the same Z value? N value? A value?

2.42 Do both members of the following pairs have the same number of protons? Neutrons? Electrons?

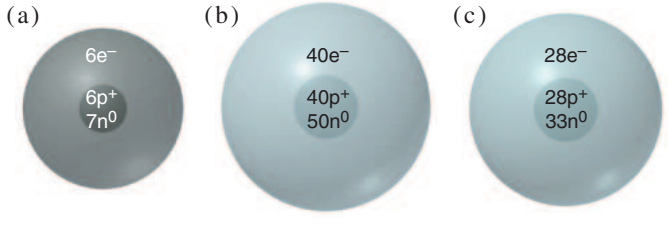
(a) $^{3}_{1}$H and $^{3}_{2}$He (b) $^{14}_{6}$C and $^{15}_{7}$N (c) $^{19}_{9}$F and $^{18}_{9}$F

Which pair(s) consist(s) of atoms with the same Z value? N value? A value?

2.43 Write the $^{A}_{Z}$X notation for each atomic depiction:



2.44 Write the $^{A}_{Z}$X notation for each atomic depiction:



2.45 Draw atomic depictions similar to those in Problem 2.43 for (a) $^{48}_{22}$Ti; (b) $^{79}_{34}$Se; (c) $^{11}_{5}$B.

2.46 Draw atomic depictions similar to those in Problem 2.43 for (a) $^{207}_{82}$Pb; (b) $^{9}_{4}$Be; (c) $^{75}_{33}$As.

2.47 Gallium has two naturally occurring isotopes, ^{69}Ga (isotopic mass = 68.9256 amu, abundance = 60.11%) and ^{71}Ga (isotopic mass = 70.9247 amu, abundance = 39.89%). Calculate the atomic mass of gallium.

2.48 Magnesium has three naturally occurring isotopes, ^{24}Mg (isotopic mass = 23.9850 amu, abundance = 78.99%), ^{25}Mg (isotopic mass = 24.9858 amu, abundance = 10.00%), and ^{26}Mg (isotopic mass = 25.9826 amu, abundance = 11.01%). Calculate the atomic mass of magnesium.

2.49 Chlorine has two naturally occurring isotopes, ^{35}Cl (isotopic mass = 34.9689 amu) and ^{37}Cl (isotopic mass = 36.9659 amu). If chlorine has an atomic mass of 35.4527 amu, what is the percent abundance of each isotope?

2.50 Copper has two naturally occurring isotopes, ^{63}Cu (isotopic mass = 62.9296 amu) and ^{65}Cu (isotopic mass = 64.9278 amu). If copper has an atomic mass of 63.546 amu, what is the percent abundance of each isotope?

Elements: A First Look at the Periodic Table

(Sample Problem 2.6)

Concept Review Questions

2.51 How can iodine (Z = 53) have a higher atomic number yet a lower atomic mass than tellurium (Z = 52)?

2.52 Correct each of the following statements:

(a) In the modern periodic table, the elements are arranged in order of increasing atomic mass.

(b) Elements in a period have similar chemical properties.

(c) Elements can be classified as either metalloids or nonmetals.

2.53 What class of elements lies along the "staircase" line in the periodic table? How do the properties of these elements compare with those of metals and nonmetals?

2.54 What are some characteristic properties of elements to the left of the elements along the "staircase"? To the right?

2.55 The elements in Groups 1A(1) and 7A(17) are all quite reactive. What is a major difference between them?

Skill-Building Exercises (grouped in similar pairs)

2.56 Give the name, atomic symbol, and group number of the element with each Z value, and classify it as a metal, metalloid, or nonmetal:

(a) Z = 32 (b) Z = 15 (c) Z = 2 (d) Z = 3 (e) Z = 42

2.57 Give the name, atomic symbol, and group number of the element with each Z value, and classify it as a metal, metalloid, or nonmetal:

(a) Z = 33 (b) Z = 20 (c) Z = 35 (d) Z = 19 (e) Z = 13

2.58 Fill in the blanks:

(a) The symbol and atomic number of the heaviest alkaline earth metal are _____ and _____.

(b) The symbol and atomic number of the lightest metalloid in Group 4A(14) are _____ and _____.

(c) Group 1B(11) consists of the *coinage metals*. The symbol and atomic mass of the coinage metal whose atoms have the fewest electrons are _____ and _____.

(d) The symbol and atomic mass of the halogen in Period 4 are _____ and _____.

2.59 Fill in the blanks:

(a) The symbol and atomic number of the heaviest nonradioactive noble gas are _____ and _____.

(b) The symbol and group number of the Period 5 transition element whose atoms have the fewest protons are _____ and _____.

(c) The elements in Group 6A(16) are sometimes called the *chalcogens*. The symbol and atomic number of the first metallic chalcogen are _____ and _____.

(d) The symbol and number of protons of the Period 4 alkali metal atom are _____ and _____.

Compounds: Introduction to Bonding

(Sample Problem 2.7)

Concept Review Questions

2.60 Describe the type and nature of the bonding that occurs between reactive metals and nonmetals.

2.61 Describe the type and nature of the bonding that often occurs between two nonmetals.

2.62 How can ionic compounds be neutral if they consist of positive and negative ions?

2.63 Given that the ions in LiF and in MgO are of similar size, which compound has stronger ionic bonding? Use Coulomb's law in your explanation.

2.64 Are molecules present in a sample of BaF_2? Explain.

2.65 Are ions present in a sample of P_4O_6? Explain.

2.66 The monatomic ions of Groups 1A(1) and 7A(17) are all singly charged. In what major way do they differ? Why?

2.67 Describe the formation of solid magnesium chloride ($MgCl_2$) from large numbers of magnesium and chlorine atoms.

2.68 Describe the formation of solid potassium sulfide (K_2S) from large numbers of potassium and sulfur atoms.

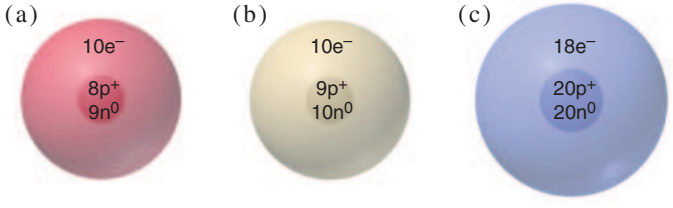
2.69 Does potassium nitrate (KNO_3) incorporate ionic bonding, covalent bonding, or both? Explain.

Skill-Building Exercises (grouped in similar pairs)

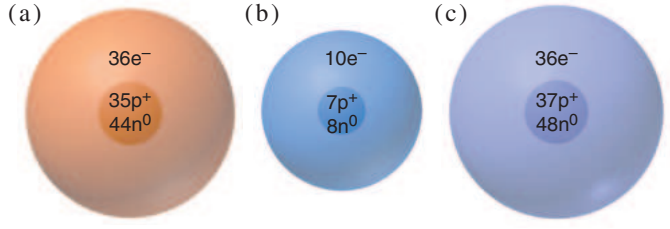
2.70 What monatomic ions would you expect potassium ($Z = 19$) and bromine ($Z = 35$) to form?

2.71 What monatomic ions would you expect radium ($Z = 88$) and selenium ($Z = 34$) to form?

2.72 For each ionic depiction, give the name of the parent atom, its mass number, and its group and period numbers:



2.73 For each ionic depiction, give the name of the parent atom, its mass number, and its group and period numbers:



2.74 An ionic compound forms when lithium ($Z = 3$) reacts with oxygen ($Z = 8$). If a sample of the compound contains 8.4×10^{21} lithium ions, how many oxide ions does it contain?

2.75 An ionic compound forms when calcium ($Z = 20$) reacts with iodine ($Z = 53$). If a sample of the compound contains 7.4×10^{21} calcium ions, how many iodide ions does it contain?

2.76 The radii of the sodium and potassium ions are 102 pm and 138 pm, respectively. Which compound has stronger ionic attractions, sodium chloride or potassium chloride?

2.77 The radii of the lithium and magnesium ions are 76 pm and 72 pm, respectively. Which compound has stronger ionic attractions, lithium oxide or magnesium oxide?

Compounds: Formulas, Names, and Masses

(Sample Problems 2.8 to 2.17)

Concept Review Questions

2.78 What information about the relative numbers of ions and the percent mass of elements is in the formula MgF_2?

2.79 How is a structural formula similar to a molecular formula? How is it different?

2.80 Consider a mixture of 10 billion O_2 molecules and 10 billion H_2 molecules. In what way is this mixture similar to a sample containing 10 billion hydrogen peroxide (H_2O_2) molecules? In what way is it different?

2.81 For what type(s) of compound do we use Roman numerals in the names?

2.82 For what type(s) of compound do we use Greek numerical prefixes in the names?

2.83 For what type of compound are we unable to write a molecular formula?

Skill-Building Exercises (grouped in similar pairs)

2.84 Give the name and formula of the compound formed from the following elements: (a) sodium and nitrogen; (b) oxygen and strontium; (c) aluminum and chlorine.

2.85 Give the name and formula of the compound formed from the following elements: (a) cesium and bromine; (b) sulfur and barium; (c) calcium and fluorine.

2.86 Give the name and formula of the compound formed from the following elements:
(a) $_{12}L$ and $_{9}M$ (b) $_{30}L$ and $_{16}M$ (c) $_{17}L$ and $_{38}M$

2.87 Give the name and formula of the compound formed from the following elements:
(a) $_{37}Q$ and $_{35}R$ (b) $_{8}Q$ and $_{13}R$ (c) $_{20}Q$ and $_{53}R$

2.88 Give the systematic names for the formulas or the formulas for the names: (a) tin(IV) chloride; (b) $FeBr_3$; (c) cuprous bromide; (d) Mn_2O_3.

2.89 Give the systematic names for the formulas or the formulas for the names: (a) Na_2HPO_4; (b) potassium carbonate dihydrate; (c) $NaNO_2$; (d) ammonium perchlorate.

2.90 Give the systematic names for the formulas or give the formulas for the names: (a) CoO; (b) mercury(I) chloride; (c) $Pb(C_2H_3O_2)_2\cdot3H_2O$; (d) chromic oxide.

2.91 Give the systematic names for the formulas or the formulas for the names: (a) $Sn(SO_3)_2$; (b) potassium dichromate; (c) $FeCO_3$; (d) copper(II) nitrate.

2.92 Correct each of the following formulas:
(a) Barium oxide is BaO_2
(b) Iron(II) nitrate is $Fe(NO_3)_3$
(c) Magnesium sulfide is $MnSO_3$

2.93 Correct each of the following names:
(a) CuI is cobalt(II) iodide
(b) $Fe(HSO_4)_3$ is iron(II) sulfate
(c) $MgCr_2O_7$ is magnesium dichromium heptaoxide

2.94 Give the name and formula for the acid derived from each of the following anions:
(a) hydrogen carbonate (b) IO_4^- (c) cyanide (d) HS^-

2.95 Give the name and formula for the acid derived from each of the following anions:
(a) perchlorate (b) NO_3^- (c) bromite (d) $H_2PO_4^-$

2.96 Many chemical names are similar at first glance. Give the formulas of the species in each set:
(a) Ammonium ion and ammonia
(b) Magnesium sulfide, magnesium sulfite, and magnesium sulfate
(c) Hydrochloric acid, chloric acid, and chlorous acid
(d) Cuprous bromide and cupric bromide

2.97 Give the formulas of the compounds in each set:
(a) Lead(II) oxide and lead(IV) oxide
(b) Lithium nitride, lithium nitrite, and lithium nitrate
(c) Strontium hydride and strontium hydroxide
(d) Magnesium oxide and manganese(II) oxide

2.98 Give the name and formula of the compound whose molecules consist of two sulfur atoms and four fluorine atoms.

2.99 Give the name and formula of the compound whose molecules consist of two chlorine atoms and one oxygen atom.

2.100 Correct the name to match the formula of the following compounds: (a) calcium(II) dichloride, $CaCl_2$; (b) copper(II) oxide, Cu_2O; (c) stannous tetrafluoride, SnF_4; (d) hydrogen chloride acid, HCl.

2.101 Correct the formula to match the name of the following compounds: (a) iron(III) oxide, Fe_3O_4; (b) chloric acid, HCl; (c) mercuric oxide, Hg_2O; (d) potassium iodide, P_2I_3.

2.102 Write the formula of each compound, and determine its molecular (formula) mass: (a) ammonium sulfate; (b) sodium dihydrogen phosphate; (c) potassium bicarbonate.

2.103 Write the formula of each compound, and determine its molecular (formula) mass: (a) sodium dichromate; (b) ammonium perchlorate; (c) magnesium nitrite trihydrate.

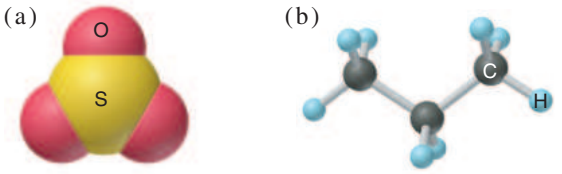
2.104 Calculate the molecular (formula) mass of each compound: (a) dinitrogen pentoxide; (b) lead(II) nitrate; (c) calcium peroxide.

2.105 Calculate the molecular (formula) mass of each compound: (a) iron(II) acetate tetrahydrate; (b) sulfur tetrachloride; (c) potassium permanganate.

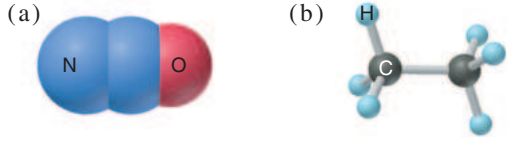
2.106 Give the number of atoms of the specified element in a formula unit of each of the following compounds, and calculate the molecular (formula) mass:
(a) Oxygen in aluminum sulfate, $Al_2(SO_4)_3$
(b) Hydrogen in ammonium hydrogen phosphate, $(NH_4)_2HPO_4$
(c) Oxygen in the mineral azurite, $Cu_3(OH)_2(CO_3)_2$

2.107 Give the number of atoms of the specified element in a formula unit of each of the following compounds, and calculate the molecular (formula) mass:
(a) Hydrogen in ammonium benzoate, $C_6H_5COONH_4$
(b) Nitrogen in hydrazinium sulfate, $N_2H_6SO_4$
(c) Oxygen in the mineral leadhillite, $Pb_4SO_4(CO_3)_2(OH)_2$

2.108 Give the formula, name, and molecular mass of the following molecules:



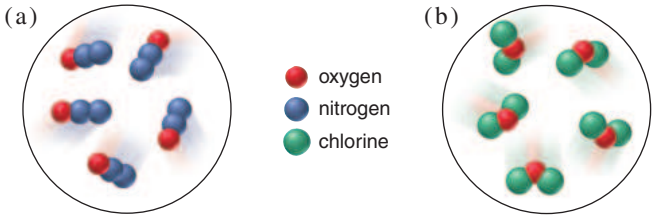
2.109 Give the formula, name, and molecular mass of the following molecules:



Problems in Context

2.110 Before the use of systematic names, many compounds had common names. Give the systematic name for each of the following:
(a) Blue vitriol, $CuSO_4 \cdot 5H_2O$
(b) Slaked lime, $Ca(OH)_2$
(c) Oil of vitriol, H_2SO_4
(d) Washing soda, Na_2CO_3
(e) Muriatic acid, HCl
(f) Epsom salt, $MgSO_4 \cdot 7H_2O$
(g) Chalk, $CaCO_3$
(h) Dry ice, CO_2
(i) Baking soda, $NaHCO_3$
(j) Lye, NaOH

2.111 Each circle contains a representation of a binary compound. Determine its name, formula, and molecular (formula) mass.



Mixtures: Classification and Separation

Concept Review Questions

2.112 In what main way is separating the components of a mixture different from separating the components of a compound?

2.113 What is the difference between a homogeneous and a heterogeneous mixture?

2.114 Is a solution a homogeneous or a heterogeneous mixture? Give an example of an aqueous solution.

Skill-Building Exercises (grouped in similar pairs)

2.115 Classify each of the following as a compound, a homogeneous mixture, or a heterogeneous mixture: (a) distilled water; (b) gasoline; (c) beach sand; (d) wine; (e) air.

2.116 Classify each of the following as a compound, a homogeneous mixture, or a heterogeneous mixture: (a) orange juice; (b) vegetable soup; (c) cement; (d) calcium sulfate; (e) tea.

Problems in Context

2.117 Which separation method is operating in each of the following procedures?
(a) Pouring a mixture of cooked pasta and boiling water into a colander
(b) Removing colored impurities from raw sugar to make refined sugar

2.118 A quality-control laboratory analyzes a product mixture using gas-liquid chromatography. The separation of components is more than adequate, but the process takes too long. Suggest two ways, other than changing the stationary phase, to shorten the analysis time.

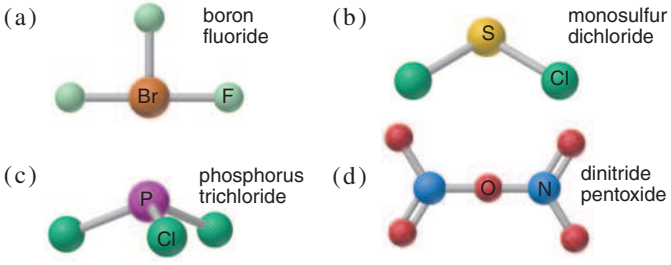
Comprehensive Problems

2.119 Helium is the lightest noble gas and the second most abundant element (after hydrogen) in the universe.
(a) The radius of a helium atom is 3.1×10^{-11} m; the radius of its nucleus is 2.5×10^{-15} m. What fraction of the spherical atomic volume is occupied by the nucleus (V of a sphere $=\frac{4}{3}\pi r^3$)?
(b) The mass of a helium-4 atom is 6.64648×10^{-24} g, and each of its two electrons has a mass of 9.10939×10^{-28} g. What fraction of this atom's mass is contributed by its nucleus?

2.120 From the following ions (with their radii in pm), choose the pair that forms the strongest ionic bond and the pair that forms the weakest:

Ion:	Mg^{2+}	K^+	Rb^+	Ba^{2+}	Cl^-	O^{2-}	I^-
Radius:	72	138	152	135	181	140	220

2.121 Give the molecular mass of each compound depicted below, and provide a correct name for any that are named incorrectly.



2.122 Polyatomic ions are named by patterns that apply to elements in a given group. Using the periodic table and Table 2.5, give the name of each of the following: (a) SeO_4^{2-}; (b) AsO_4^{3-}; (c) BrO_2^-; (d) $HSeO_4^-$; (e) TeO_3^{2-}.

2.123 Ammonium dihydrogen phosphate, formed from the reaction of phosphoric acid with ammonia, is used as a crop fertilizer as well as a component of some fire extinguishers. (a) What are the mass percentages of N and P in the compound? (b) How much ammonia is incorporated into 100. g of the compound?

2.124 Nitrogen forms more oxides than any other element. The percents by mass of N in three different nitrogen oxides are (I) 46.69%, (II) 36.85%, and (III) 25.94%. For each compound, determine (a) the simplest whole-number ratio of N to O and (b) the number of grams of oxygen per 1.00 g of nitrogen.

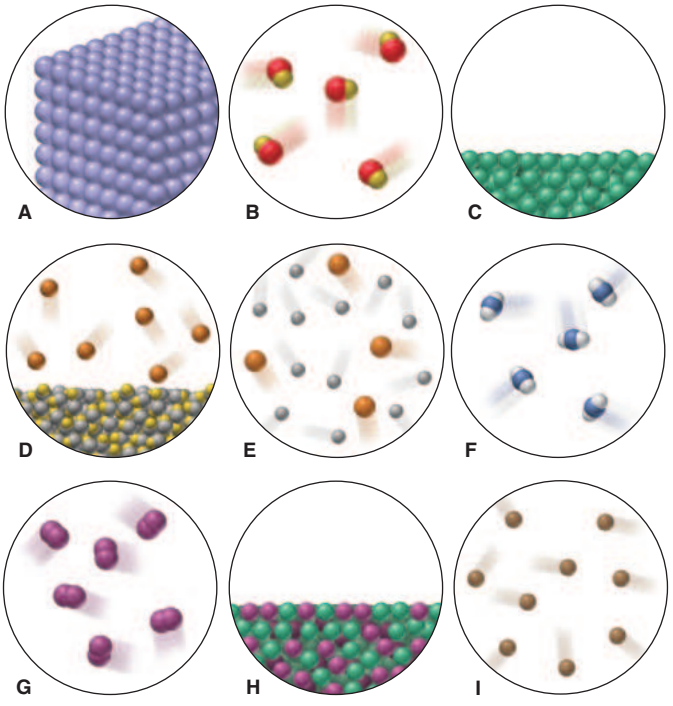
2.125 The number of atoms in 1 dm^3 of aluminum is nearly the same as the number of atoms in 1 dm^3 of lead, but the densities of these metals are very different (see Table 1.5). Explain.

2.126 You are working in the laboratory preparing sodium chloride. Consider the following results for three preparations of the compound:

Case 1: 39.34 g Na + 60.66 g Cl_2 ⟶ 100.00 g NaCl
Case 2: 39.34 g Na + 70.00 g Cl_2 ⟶ 100.00 g NaCl + 9.34 g Cl_2
Case 3: 50.00 g Na + 50.00 g Cl_2 ⟶ 82.43 g NaCl + 17.57 g Na

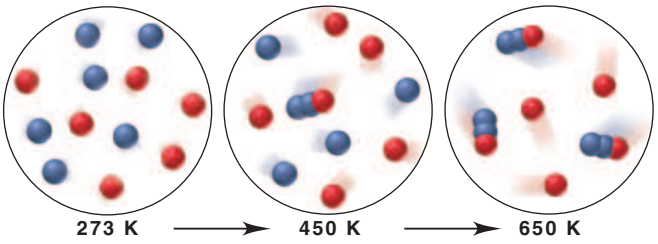
Explain these results in terms of the laws of conservation of mass and definite composition.

2.127 Scenes A–I depict various types of matter on the atomic scale. Choose the correct scene(s) for each of the following:
(a) A mixture that fills its container
(b) A substance that cannot be broken down into simpler ones
(c) An element with a very high resistance to flow
(d) A homogeneous mixture
(e) An element that conforms to the walls of its container and displays an upper surface
(f) A gas consisting of diatomic particles
(g) A gas that can be broken down into simpler substances
(h) A substance with a 2/1 ratio of its component atoms
(i) Matter that can be separated into its component substances by physical means
(j) A heterogeneous mixture
(k) Matter that obeys the law of definite composition



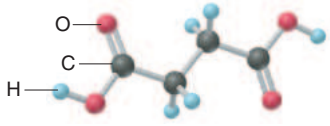
2.128 The seven most abundant ions in seawater make up more than 99% by mass of the dissolved compounds. Here are their abundances in units of mg ion/kg seawater: chloride 18,980; sodium 10,560; sulfate 2650; magnesium 1270; calcium 400; potassium 380; hydrogen carbonate 140.
(a) What is the mass % of each ion in seawater?
(b) What percent of the total mass of ions is sodium ion?
(c) How does the total mass % of alkaline earth metal ions compare with the total mass % of alkali metal ions?
(d) Which make up the larger mass fraction of dissolved components, anions or cations?

2.129 The scenes on the next page represent a mixture of two monatomic gases undergoing a reaction when heated. Which mass law(s) is (are) illustrated by this change?



2.130 When barium (Ba) reacts with sulfur (S) to form barium sulfide (BaS), each Ba atom reacts with an S atom. If 2.50 cm^3 of Ba reacts with 1.75 cm^3 of S, are there enough Ba atoms to react with the S atoms (d of Ba = 3.51 g/cm^3; d of S = 2.07 g/cm^3)?

2.131 Succinic acid (*below*) is an important metabolite in biological energy production. Give the molecular formula, molecular mass, and the mass percent of each element in succinic acid.

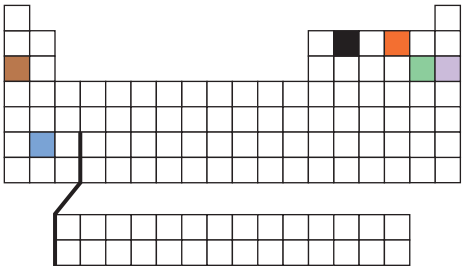


2.132 Fluoride ion is poisonous in relatively low amounts: 0.2 g of F^- per 70 kg of body weight can cause death. Nevertheless, in order to prevent tooth decay, F^- ions are added to drinking water at a concentration of 1 mg of F^- ion per L of water. How many liters of fluoridated drinking water would a 70-kg person have to consume in one day to reach this toxic level? How many kilograms of sodium fluoride would be needed to treat a 8.50×10^7-gal reservoir?

2.133 Antimony has many uses, for example, in infrared devices and as part of an alloy in lead storage batteries. The element has two naturally occurring isotopes, one with mass 120.904 amu, the other with mass 122.904 amu. (a) Write the ${}^{A}_{Z}X$ notation for each isotope. (b) Use the atomic mass of antimony from the periodic table to calculate the natural abundance of each isotope.

2.134 Dinitrogen monoxide (N_2O; nitrous oxide) is a greenhouse gas that enters the atmosphere principally from natural fertilizer breakdown. Some studies have shown that the isotope ratios of ^{15}N to ^{14}N and of ^{18}O to ^{16}O in N_2O depend on the source, which can thus be determined by measuring the relative abundance of molecular masses in a sample of N_2O.
(a) What different molecular masses are possible for N_2O?
(b) The percent abundance of ^{14}N is 99.6%, and that of ^{16}O is 99.8%. Which molecular mass of N_2O is least common, and which is most common?

2.135 Use the box color(s) in the periodic table below to identify the element(s) described by each of the following:



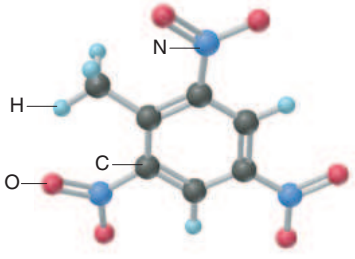
(a) Four elements that are nonmetals
(b) Two elements that are metals
(c) Three elements that are gases at room temperature
(d) Three elements that are solid at room temperature
(e) One pair of elements likely to form a covalent compound
(f) Another pair of elements likely to form a covalent compound
(g) One pair of elements likely to form an ionic compound with formula MX
(h) Another pair of elements likely to form an ionic compound with formula MX
(i) Two elements likely to form an ionic compound with formula M_2X
(j) Two elements likely to form an ionic compound with formula MX_2
(k) An element that forms no compounds
(l) A pair of elements whose compounds exhibit the law of multiple proportions

2.136 The two isotopes of potassium with significant abundance in nature are ^{39}K (isotopic mass 38.9637 amu, 93.258%) and ^{41}K (isotopic mass 40.9618 amu, 6.730%). Fluorine has only one naturally occurring isotope, ^{19}F (isotopic mass 18.9984 amu). Calculate the formula mass of potassium fluoride.

2.137 Boron trifluoride is used as a catalyst in the synthesis of organic compounds. When this compound is analyzed by mass spectrometry (see Tools of the Laboratory, p. 57), several different 1+ ions form, including ions representing the whole molecule as well as molecular fragments formed by the loss of one, two, and three F atoms. Given that boron has two naturally occurring isotopes, ^{10}B and ^{11}B, and fluorine has one, ^{19}F, calculate the masses of all possible 1+ ions.

2.138 Nitrogen monoxide (NO) is a bioactive molecule in blood. Low NO concentrations cause respiratory distress and the formation of blood clots. Doctors prescribe nitroglycerin, $C_3H_5N_3O_9$, and isoamyl nitrate, $(CH_3)_2CHCH_2CH_2ONO_2$, to increase NO. If each compound releases one molecule of NO per atom of N it contains, calculate the mass percent of NO in each.

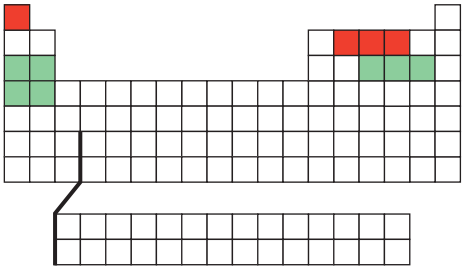
2.139 TNT (trinitrotoluene; *below*) is used as an explosive in construction. Calculate the mass of each element in 1.00 lb of TNT.



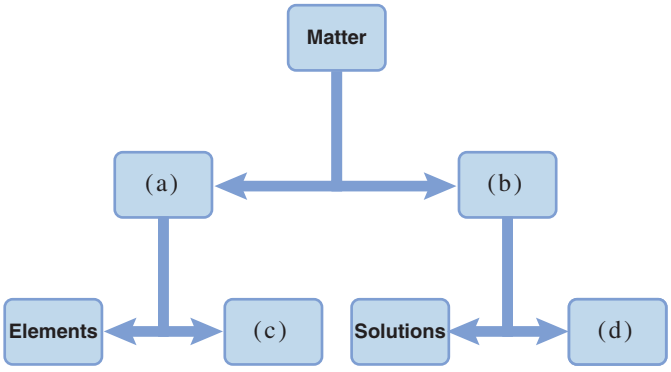
2.140 Nuclei differ in their stability, and some are so unstable that they undergo radioactive decay. The ratio of the number of neutrons to number of protons (N/Z) in a nucleus correlates with its stability. Calculate the N/Z ratio for (a) ^{144}Sm; (b) ^{56}Fe; (c) ^{20}Ne; (d) ^{107}Ag. (e) The radioactive isotope ^{238}U decays in a series of nuclear reactions that includes another uranium isotope, ^{234}U, and three lead isotopes, ^{214}Pb, ^{210}Pb, and ^{206}Pb. How many neutrons, protons, and electrons are in each of these five isotopes?

2.141 The anticancer drug Platinol (cisplatin), $Pt(NH_3)_2Cl_2$, reacts with the cancer cell's DNA and interferes with its growth. (a) What is the mass % of platinum (Pt) in Platinol? (b) If Pt costs \$51/g, how many grams of Platinol can be made for \$1.00 million (assume that the cost of Pt determines the cost of the drug)?

2.142 In the periodic table below, give the name, symbol, atomic number, atomic mass, period number, and group number of (a) the *building-block elements (red),* which occur in nearly every biological molecule, and (b) the *macronutrients (green),* which are either essential ions in cell fluids or are part of many biomolecules.



2.143 The block diagram below classifies the components of matter on the macroscopic scale. Identify blocks (a)–(d).



2.144 Which of the steps in the following process involve(s) a physical change and which involve(s) a chemical change?

Concepts and Skills to Review Before You Study This Chapter

- atomic mass (Section 2.5)
- names and formulas of compounds (Section 2.8)
- molecular (or formula) mass (Section 2.8)
- molecular and structural formulas, and ball-and-stick and space-filling models (Section 2.8)

Chemistry is, above all, a practical science. Imagine that you're a biochemist who has extracted a substance with medicinal activity from a tropical plant: what is its formula, and what quantity of metabolic products will establish a safe dosage level? Thousands of biologically active compounds have been found in plants and many are used in modern medicines. For example, in 1963, the U.S. Food and Drug Administration (FDA) approved the drug *vincristine,* which is derived from the Madagascar periwinkle *(photo),* for treatment of lymphomas and childhood cancers. Or, suppose you're a chemical engineer studying rocket-fuel thrust: what amount of propulsive gases will a fuel produce? Perhaps you're on a team of environmental chemists examining coal samples: what quantity of air pollutants will a sample produce when burned? Or, maybe you're a polymer chemist preparing a plastic with unusual properties: how much of this new material will the polymerization reaction yield? You can answer countless questions like these with a knowledge of **stoichiometry** (pronounced "stoy-key-AHM-uh-tree"; from the Greek *stoicheion,* "element or part," and *metron,* "measure"), the study of the quantitative aspects of formulas and reactions.

IN THIS CHAPTER . . . *We relate the mass of a substance to the number of chemical entities comprising it (atoms, ions, molecules, or formula units) and apply this relationship to formulas and equations.*

- We discuss the *mole,* the chemist's unit for amount of a substance, and use it to convert between mass and number of entities.
- We also use it to derive a chemical formula from the results of mass analysis.
- We see whether two key types of formulas relate to molecular structures.
- We learn how to write chemical equations and how to balance them in terms of the amounts of substances reacting and produced.
- We calculate the amounts of reactants and products in a reaction and see why one of the reactants limits the amount of product that can form and, thus, the reaction yield.

3.1 THE MOLE

In daily life, we often measure things by weighing or by counting: we weigh coffee beans or rice, but we count eggs or pencils. And we use mass units (a kilogram of coffee beans) or counting units (a dozen pencils) to express the amount. Similarly, daily life in the laboratory involves measuring substances. We want to know the numbers of chemical entities—atoms, ions, molecules, or formula units—that react with each other, but how can we possibly count or weigh such minute objects? As you'll see, chemists have devised a unit, called the *mole,* to *count chemical entities by weighing a very large number of them.*

Imagine a Mole of . . .

A mole of any ordinary object is a staggering amount: a mole of periods (.) lined up side by side would equal the radius of our galaxy; a mole of marbles stacked tightly together would cover the continental United States 70 miles deep. However, atoms and molecules are not ordinary objects: you can swallow a mole of water molecules (about 18 mL) in one gulp!

Defining the Mole

The **mole** (abbreviated **mol**) is the SI unit for *amount of substance*. It is defined as *the amount of a substance that contains the same number of entities as the number of atoms in 12 g of carbon-12.* This number, called **Avogadro's number** (in honor of the 19th-century Italian physicist Amedeo Avogadro), is enormous:

One mole (1 mol) contains 6.022×10^{23} entities (to four significant figures) **(3.1)**

A counting unit, like *dozen,* tells you the number of objects but not their mass; a mass unit, like *kilogram,* tells you the mass of the objects but not their number. The mole tells you both—the *number* of objects in a given *mass* of substance:

1 mol of carbon-12 contains 6.022×10^{23} carbon-12 atoms *and* has a mass of 12 g

What does it mean that the mole unit allows you to count entities by weighing the sample? Suppose you have a sample of carbon-12 and want to know the number of atoms present. You find that the sample weighs 6 g, so it is 0.5 mol of carbon-12 and contains $0.5(6.022\times10^{23})$ or 3.011×10^{23} atoms:

6 g of carbon-12 is 0.5 mol of carbon-12 and contains 3.011×10^{23} atoms

Knowing the amount (in moles), the mass (in grams), and the number of entities becomes very important when we mix different substances to run a reaction. The central relationship between masses on the atomic scale and on the macroscopic scale is the same for elements and compounds:

- *Elements.* The mass in *atomic mass units (amu)* of one atom of an element is the *same numerically* as the mass in *grams (g)* of 1 mole of atoms of the element. Recall from Chapter 2 that each atom of an element is considered to have the *atomic mass* given in the periodic table *(see margin)*. Thus,

16
S
32.06

1 atom of S	has a mass of	32.06 amu	and	1 mol (6.022×10^{23} atoms) of S	has a mass of 32.06 g
1 atom of Fe	has a mass of	55.85 amu	and	1 mol (6.022×10^{23} atoms) of Fe	has a mass of 55.85 g

Note, also, that since atomic masses are relative, 1 Fe atom weighs 55.85/32.06 as much as 1 S atom, and 1 mol of Fe weighs 55.85/32.06 as much as 1 mol of S.

- *Compounds.* The mass in *atomic mass units (amu)* of one molecule (or formula unit) of a compound is the *same numerically* as the mass in *grams (g)* of 1 mole of the compound. Thus, for example,

1 molecule of H_2O	has a mass of	18.02 amu	and	1 mol (6.022×10^{23} molecules) of H_2O	has a mass of 18.02 g
1 formula unit of NaCl	has a mass of	58.44 amu	and	1 mol (6.022×10^{23} formula units) of NaCl	has a mass of 58.44 g

Here, too, because masses are relative, 1 H_2O molecule weighs 18.02/58.44 as much as 1 NaCl formula unit, and 1 mol of H_2O weighs 18.02/58.44 as much as 1 mol of NaCl.

The two key points to remember about the importance of the mole unit are

- The *mole* lets us relate the *number* of entities to the *mass* of a sample of those entities.
- The mole maintains the *same numerical relationship* between mass on the atomic scale (atomic mass units, amu) and mass on the macroscopic scale (grams, g).

In everyday terms, a grocer *does not* know that there are 1 dozen eggs from their weight or that there is 1 kilogram of coffee beans from their count, because eggs and coffee beans do not have fixed masses. But, by weighing out 63.55 g (1 mol) of copper, a chemist *does* know that there are 6.022×10^{23} copper atoms, because all copper atoms have an atomic mass of 63.55 amu. Figure 3.1 shows 1 mole of some familiar elements and compounds.

Figure 3.1 One mole (6.022×10^{23} entities) of some familiar substances. From left to right: 1 mol of copper (63.55 g), of liquid H_2O (18.02 g), of sodium chloride (table salt, 58.44 g), of sucrose (table sugar, 342.3 g), and of aluminum (26.98 g).

Determining Molar Mass

The **molar mass** ($\mathcal{M}$) of a substance is the mass per mole of its entities (atoms, molecules, or formula units) and has units of grams per mole (g/mol). The periodic table is indispensable for calculating molar mass:

1. *Elements*. To find the molar mass, look up the atomic mass and note whether the element is monatomic or molecular.

- *Monatomic elements.* The molar mass is the periodic-table value in grams per mole.* For example, the molar mass of neon is 20.18 g/mol, and the molar mass of gold is 197.0 g/mol.
- *Molecular elements.* You must know the formula to determine the molar mass (see Figure 2.15). For example, in air, oxygen exists most commonly as diatomic molecules, so the molar mass of O_2 is twice that of O:

$$\text{Molar mass } (\mathcal{M}) \text{ of } O_2 = 2 \times \mathcal{M} \text{ of O} = 2 \times 16.00 \text{ g/mol} = 32.00 \text{ g/mol}$$

The most common form of sulfur exists as octatomic molecules, S_8:

$$\mathcal{M} \text{ of } S_8 = 8 \times \mathcal{M} \text{ of S} = 8 \times 32.06 \text{ g/mol} = 256.5 \text{ g/mol}$$

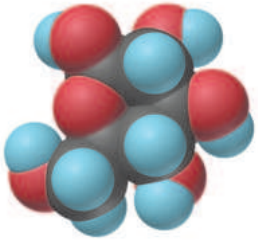
2. *Compounds. The molar mass is the sum of the molar masses of the atoms in the formula.* Thus, from the formula of sulfur dioxide, SO_2, we know that 1 mol of SO_2 molecules contains 1 mol of S atoms and 2 mol of O atoms:

$$\mathcal{M} \text{ of } SO_2 = \mathcal{M} \text{ of S} + (2 \times \mathcal{M} \text{ of O}) = 32.06 \text{ g/mol} + (2 \times 16.00 \text{ g/mol}) = 64.06 \text{ g/mol}$$

Similarly, for ionic compounds, such as potassium sulfide (K_2S), we have

$$\mathcal{M} \text{ of } K_2S = (2 \times \mathcal{M} \text{ of K}) + \mathcal{M} \text{ of S} = (2 \times 39.10 \text{ g/mol}) + 32.06 \text{ g/mol} = 110.26 \text{ g/mol}$$

Thus, *subscripts in a formula refer to individual atoms (or ions) as well as to moles of atoms (or ions).* Table 3.1 summarizes these ideas for glucose, $C_6H_{12}O_6$ *(see margin),* the essential sugar in energy metabolism.



Glucose

Table 3.1 **Information Contained in the Chemical Formula of Glucose, $C_6H_{12}O_6$ ($\mathcal{M}$ = 180.16 g/mol)**

	Carbon (C)	Hydrogen (H)	Oxygen (O)
Atoms/molecule of compound	6 atoms	12 atoms	6 atoms
Moles of atoms/mole of compound	6 mol of atoms	12 mol of atoms	6 mol of atoms
Atoms/mole of compound	$6(6.022\times10^{23})$ atoms	$12(6.022\times10^{23})$ atoms	$6(6.022\times10^{23})$ atoms
Mass/molecule of compound	6(12.01 amu) = 72.06 amu	12(1.008 amu) = 12.10 amu	6(16.00 amu) = 96.00 amu
Mass/mole of compound	72.06 g	12.10 g	96.00 g

Converting Between Amount, Mass, and Number of Chemical Entities

One of the most common skills in the lab—and on exams—is converting between amount (mol), mass (g), and number of entities of a substance.

1. *Converting between amount and mass.* If you know the amount of a substance, you can find its mass, and vice versa. The molar mass ($\mathcal{M}$), which expresses the equivalence between 1 mole of a substance and its mass in grams, is the conversion factor between amount and mass:

$$\frac{\text{no. of grams}}{1 \text{ mol}} \quad \text{or} \quad \frac{1 \text{ mol}}{\text{no. of grams}}$$

- *From amount (mol) to mass (g),* multiply by the molar mass to cancel the mole unit:

$$\text{Mass (g)} = \text{amount } (\cancel{\text{mol}}) \times \frac{\text{no. of grams}}{1 \ \cancel{\text{mol}}} \qquad \textbf{(3.2)}$$

*The mass value in the periodic table has no units because it is a *relative* atomic mass, given by the atomic mass (in amu) divided by 1 amu ($\frac{1}{12}$ mass of one ^{12}C atom in amu):

$$\text{Relative atomic mass} = \frac{\text{atomic mass } (\cancel{\text{amu}})}{\frac{1}{12} \text{ mass of } ^{12}C \ (\cancel{\text{amu}})}$$

Therefore, you use the same number (with different units) for the atomic mass and for the molar mass.

- *From mass (g) to amount (mol),* divide by the molar mass (multiply by $1/\mathcal{M}$) to cancel the mass unit:

$$\text{Amount (mol)} = \text{mass (g)} \times \frac{1 \text{ mol}}{\text{no. of grams}} \qquad \textbf{(3.3)}$$

2. *Converting between amount and number.* Similarly, if you know the amount (mol), you can find the number of entities, and vice versa. Avogadro's number, which expresses the equivalence between 1 mole of a substance and the number of entities it contains, is the conversion factor between amount and number of entities:

$$\frac{6.022\times10^{23} \text{ entities}}{1 \text{ mol}} \quad \text{or} \quad \frac{1 \text{ mol}}{6.022\times10^{23} \text{ entities}}$$

- *From amount (mol) to number of entities,* multiply by Avogadro's number to cancel the mole unit:

$$\text{No. of entities} = \text{amount (mol)} \times \frac{6.022\times10^{23} \text{ entities}}{1 \text{ mol}} \qquad \textbf{(3.4)}$$

- *From number of entities to amount (mol),* divide by Avogadro's number to cancel the number of entities:

$$\text{Amount (mol)} = \text{no. of entities} \times \frac{1 \text{ mol}}{6.022\times10^{23} \text{ entities}} \qquad \textbf{(3.5)}$$

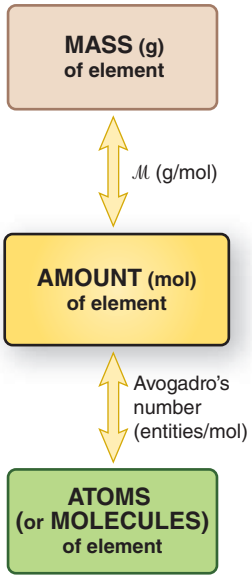


Figure 3.2 Mass-mole-number relationships for elements.

Amount-Mass-Number Conversions Involving Elements We begin with amount-mass-number relationships of elements. As Figure 3.2 shows, *convert mass or number of entities (atoms or molecules) to amount (mol) first.* For molecular elements, Avogadro's number gives *molecules* per mole.

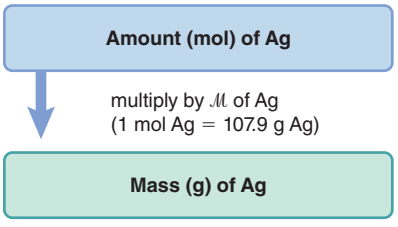
Let's work through a series of sample problems that show these conversions for both elements and compounds.

SAMPLE PROBLEM 3.1 Converting Between Mass and Amount of an Element

Problem Silver (Ag) is used in jewelry and tableware but no longer in U.S. coins. How many grams of Ag are in 0.0342 mol of Ag?

Plan We know the amount of Ag (0.0342 mol) and have to find the mass (g). To convert units of *moles* of Ag to *grams* of Ag, we multiply by the *molar mass* of Ag, which we find in the periodic table (see the road map).

Road Map



Solution Converting from amount (mol) of Ag to mass (g):

$$\text{Mass (g) of Ag} = 0.0342 \text{ mol Ag} \times \frac{107.9 \text{ g Ag}}{1 \text{ mol Ag}} = 3.69 \text{ g Ag}$$

Check We rounded the mass to three significant figures because the amount (in mol) has three. The units are correct. About 0.03 mol × 100 g/mol gives 3 g; the small mass makes sense because 0.0342 is a small fraction of a mole.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

3.1A Graphite is the crystalline form of carbon used in "lead" pencils. How many moles of carbon are in 315 mg of graphite? Include a road map that shows how you planned the solution.

3.1B A soda can contains about 14 g of aluminum (Al), the most abundant element in Earth's crust. How many soda cans can be made from 52 mol of Al? Include a road map that shows how you planned the solution.

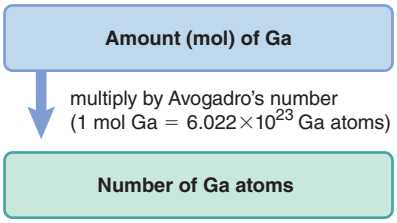
SOME SIMILAR PROBLEMS 3.12(a) and 3.13(a)

SAMPLE PROBLEM 3.2 Converting Between Number of Entities and Amount of an Element

Problem Gallium (Ga) is a key element in solar panels, calculators, and other light-sensitive electronic devices. How many Ga atoms are in 2.85×10^{-3} mol of gallium?

Plan We know the amount of gallium (2.85×10^{-3} mol) and need the number of Ga atoms. We multiply amount (mol) by Avogadro's number to find number of atoms (see the road map).

Road Map



Solution Converting from amount (mol) of Ga to number of atoms:

$$\text{No. of Ga atoms} = 2.85\times10^{-3}\ \cancel{\text{mol Ga}} \times \frac{6.022\times10^{23}\ \text{Ga atoms}}{1\ \cancel{\text{mol Ga}}}$$

$$= 1.72\times10^{21}\ \text{Ga atoms}$$

Check The number of atoms has three significant figures because the number of moles does. When we round amount (mol) of Ga and Avogadro's number, we have $\sim(3\times10^{-3}\ \text{mol})(6\times10^{23}\ \text{atoms/mol}) = 18\times10^{20}$, or 1.8×10^{21} atoms, so our answer seems correct.

FOLLOW-UP PROBLEMS

3.2A At rest, a person inhales 9.72×10^{21} nitrogen molecules in an average breath of air. How many moles of nitrogen atoms are inhaled? (*Hint:* In air, nitrogen occurs as a diatomic molecule.) Include a road map that shows how you planned the solution.

3.2B A tank contains 325 mol of compressed helium (He) gas. How many He atoms are in the tank? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 3.12(b) and 3.13(b)

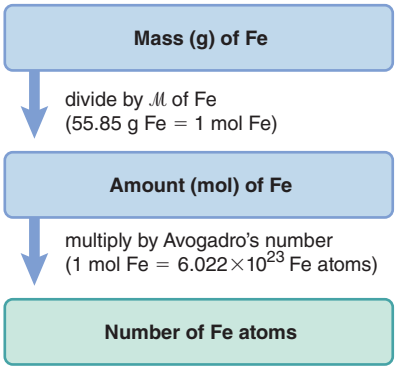
For the next sample problem, note that mass and number of entities relate directly to amount (mol), but *not* to each other. Therefore, *to convert between mass and number, first convert to amount.*

SAMPLE PROBLEM 3.3 Converting Between Number of Entities and Mass of an Element

Problem Iron (Fe) is the main component of steel and, thus, the most important metal in industrial society; it is also essential in the body. How many Fe atoms are in 95.8 g of Fe?

Plan We know the mass of Fe (95.8 g) and need the number of Fe atoms. We cannot convert directly from mass to number, so we first convert to amount (mol) by dividing mass of Fe by its molar mass. Then, we multiply amount (mol) by Avogadro's number to find number of atoms (see the road map).

Road Map



Solution Converting from mass (g) of Fe to amount (mol):

$$\text{Amount (mol) of Fe} = 95.8\ \cancel{\text{g Fe}} \times \frac{1\ \text{mol Fe}}{55.85\ \cancel{\text{g Fe}}} = 1.72\ \text{mol Fe}$$

Converting from amount (mol) of Fe to number of Fe atoms:

$$\text{No. of Fe atoms} = 1.72\ \cancel{\text{mol Fe}} \times \frac{6.022\times10^{23}\ \text{atoms Fe}}{1\ \cancel{\text{mol Fe}}}$$

$$= 10.4\times10^{23}\ \text{atoms Fe}$$

$$= 1.04\times10^{24}\ \text{atoms Fe}$$

Check Rounding the mass and the molar mass of Fe, we have $\sim100\ \text{g}/(\sim60\ \text{g/mol}) = 1.7$ mol. Therefore, the number of atoms should be a bit less than twice Avogadro's number: $<2(6\times10^{23}) = <1.2\times10^{24}$, so the answer seems correct.

FOLLOW-UP PROBLEMS

3.3A Manganese (Mn) is a transition element essential for the growth of bones. What is the mass in grams of 3.22×10^{20} Mn atoms, the number found in 1 kg of bone? Include a road map that shows how you planned the solution.

3.3B Pennies minted after 1982 are made of zinc plated with a thin coating of copper (Cu); the copper layer on each penny has a mass of 0.0625 g. How many Cu atoms are in a penny? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 3.12(c) and 3.13(c)

Amount-Mass-Number Conversions Involving Compounds Only one new step is needed to solve amount-mass-number problems involving compounds: we need the chemical formula to find the molar mass and the amount of each element in the compound. The relationships are shown in Figure 3.3, and Sample Problems 3.4 and 3.5 apply them to compounds with simple and more complicated formulas, respectively.

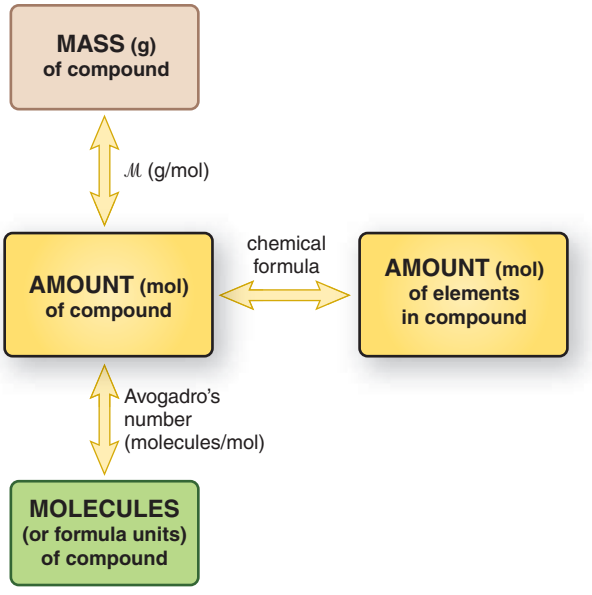


Figure 3.3 Amount-mass-number relationships for compounds. Use the chemical formula to find the amount (mol) of each element in a compound.

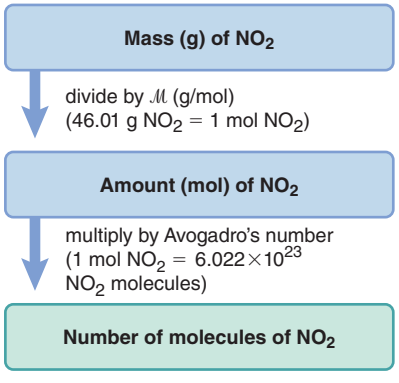
SAMPLE PROBLEM 3.4 Converting Between Number of Entities and Mass of a Compound I

Problem Nitrogen dioxide is a component of urban smog that forms from gases in car exhaust. How many molecules are in 8.92 g of nitrogen dioxide?

Plan We know the mass of compound (8.92 g) and need to find the number of molecules. As you just saw in Sample Problem 3.3, to convert mass to number of entities, we have to find the amount (mol). To do so, we divide the mass by the molar mass ($\mathcal{M}$), which we calculate from the molecular formula (see Sample Problem 2.16). Once we have the amount (mol), we multiply by Avogadro's number to find the number of molecules (see the road map).

Road Map



Solution The formula is NO_2. Calculating the molar mass:

$$\begin{aligned}\mathcal{M} &= (1 \times \mathcal{M} \text{ of N}) + (2 \times \mathcal{M} \text{ of O})\\ &= 14.01 \text{ g/mol} + (2 \times 16.00 \text{ g/mol})\\ &= 46.01 \text{ g/mol}\end{aligned}$$

Converting from mass (g) of NO_2 to amount (mol):

$$\text{Amount (mol) of } NO_2 = 8.92 \text{ g } \cancel{NO_2} \times \frac{1 \text{ mol } NO_2}{46.01 \text{ g } \cancel{NO_2}}$$

$$= 0.194 \text{ mol } NO_2$$

Converting from amount (mol) of NO_2 to number of molecules:

$$\text{No. of molecules} = 0.194 \text{ mol } NO_2 \times \frac{6.022\times10^{23} \text{ } NO_2 \text{ molecules}}{1 \text{ mol } NO_2}$$

$$= 1.17\times10^{23} \text{ } NO_2 \text{ molecules}$$

Check Rounding, we get $(\sim 0.2 \text{ mol})(6\times10^{23}) = 1.2\times10^{23}$, so the answer seems correct.

FOLLOW-UP PROBLEMS

3.4A Fluoride ion is added to drinking water to prevent tooth decay. What is the mass (g) of sodium fluoride in a liter of water that contains 1.19×10^{19} formula units of the compound? Include a road map that shows how you planned the solution.

3.4B Calcium chloride is applied to highways in winter to melt accumulated ice. A snow-plow truck applies 400 lb of $CaCl_2$ per mile of highway. How many formula units of the compound are applied per mile? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 3.14–3.19

SAMPLE PROBLEM 3.5 Converting Between Number of Entities and Mass of a Compound II

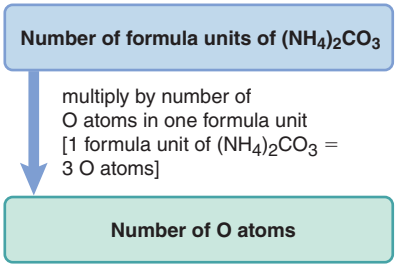
Problem Ammonium carbonate is a white solid that decomposes with warming. It has many uses, for example, as a component in baking powder, fire extinguishers, and smelling salts.

(a) How many formula units are in 41.6 g of ammonium carbonate?

(b) How many O atoms are in this sample?

Plan **(a)** We know the mass of compound (41.6 g) and need to find the number of formula units. As in Sample Problem 3.4, we find the amount (mol) and then multiply by Avogadro's number to find the number of formula units. (A road map for this step would be the same as the one in Sample Problem 3.4.) **(b)** To find the number of O atoms, we multiply the number of formula units by the number of O atoms in one formula unit (see the road map).

Road Map



Solution **(a)** The formula is $(NH_4)_2CO_3$ (see Table 2.5). Calculating the molar mass:

$$\mathcal{M} = (2 \times \mathcal{M} \text{ of N}) + (8 \times \mathcal{M} \text{ of H}) + (1 \times \mathcal{M} \text{ of C}) + (3 \times \mathcal{M} \text{ of O})$$

$$= (2 \times 14.01 \text{ g/mol N}) + (8 \times 1.008 \text{ g/mol H}) + 12.01 \text{ g/mol C} + (3 \times 16.00 \text{ g/mol O})$$

$$= 96.09 \text{ g/mol } (NH_4)_2CO_3$$

Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of } (NH_4)_2CO_3 = 41.6 \text{ g } (NH_4)_2CO_3 \times \frac{1 \text{ mol } (NH_4)_2CO_3}{96.09 \text{ g } (NH_4)_2CO_3}$$

$$= 0.433 \text{ mol } (NH_4)_2CO_3$$

Converting from amount (mol) to formula units:

$$\text{Formula units of } (NH_4)_2CO_3 = 0.433 \text{ mol } (NH_4)_2CO_3 \times \frac{6.022\times10^{23} \text{ formula units } (NH_4)_2CO_3}{1 \text{ mol } (NH_4)_2CO_3}$$

$$= 2.61\times10^{23} \text{ formula units } (NH_4)_2CO_3$$

(b) Finding the number of O atoms:

$$\text{No. of O atoms} = 2.61\times10^{23} \text{ formula units } (NH_4)_2CO_3 \times \frac{3 \text{ O atoms}}{1 \text{ formula unit } (NH_4)_2CO_3}$$

$$= 7.83\times10^{23} \text{ O atoms}$$

Check In (a), the units are correct. Since the mass is less than half the molar mass ($\sim 42/96 < 0.5$), the number of formula units should be less than half Avogadro's number ($\sim 2.6\times10^{23}/6.0\times10^{23} < 0.5$).

Comment A *common mistake* is to forget the subscript 2 outside the parentheses in $(NH_4)_2CO_3$, which would give a much lower molar mass.

FOLLOW-UP PROBLEMS

3.5A Tetraphosphorus decoxide reacts with water to form phosphoric acid, a major industrial acid. In the laboratory, the oxide is a drying agent.
(a) What is the mass (g) of 4.65×10^{22} molecules of tetraphosphorus decoxide?
(b) How many P atoms are present in this sample?

3.5B Calcium phosphate is added to some foods, such as yogurt, to boost the calcium content and is also used as an anticaking agent.
(a) How many formula units are in 75.5 g of calcium phosphate?
(b) How many phosphate ions are present in this sample?

SOME SIMILAR PROBLEMS 3.14–3.19

The Importance of Mass Percent

For many purposes, it is important to know how much of an element is present in a given amount of compound. A biochemist may want the ionic composition of a mineral nutrient; an atmospheric chemist may be studying the carbon content of a fuel; a materials scientist may want the metalloid composition of a semiconductor. In this section, we find the composition of a compound in terms of mass percent and use it to find the mass of each element in the compound.

Determining Mass Percent from a Chemical Formula Each element contributes a fraction of a compound's mass, and that fraction multiplied by 100 gives the element's mass percent. Finding the mass percent is similar on the molecular and molar scales:

- *For a molecule (or formula unit) of compound,* use the molecular (or formula) mass and chemical formula to find the mass percent of any element X in the compound:

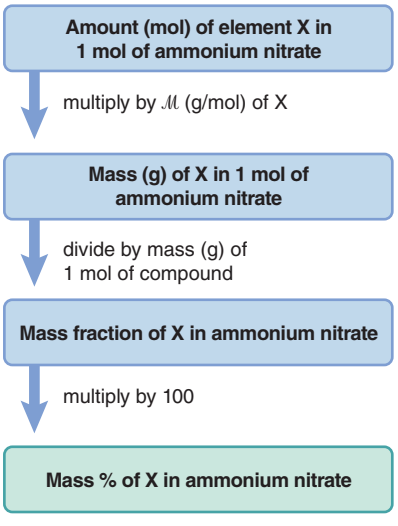
$$\text{Mass \% of element X} = \frac{\text{atoms of X in formula} \times \text{atomic mass of X (amu)}}{\text{molecular (or formula) mass of compound (amu)}} \times 100$$

- *For a mole of compound,* use the molar mass and formula to find the mass percent of each element on a mole basis:

$$\text{Mass \% of element X} = \frac{\text{moles of X in formula} \times \text{molar mass of X (g/mol)}}{\text{mass (g) of 1 mol of compound}} \times 100 \qquad \textbf{(3.6)}$$

As always, the individual mass percents add up to 100% (within rounding). In Sample Problem 3.6, we determine the mass percent of each element in a compound.

Road Map



SAMPLE PROBLEM 3.6 **Calculating the Mass Percent of Each Element in a Compound from the Formula**

Problem The effectiveness of fertilizers depends on their nitrogen content. Ammonium nitrate is a common fertilizer. What is the mass percent of each element in ammonium nitrate?

Plan We know the relative amounts (mol) of the elements from the formula, and we have to find the mass % of each element. We multiply the amount of each element by its molar mass to find its mass. Dividing each element's mass by 1 mol of ammonium nitrate gives the mass fraction of that element, and multiplying the mass fraction by 100 gives the mass %. The calculation steps for any element (X) are shown in the road map.

Solution The formula is NH_4NO_3 (see Table 2.5). In 1 mol of NH_4NO_3, there are 2 mol of N, 4 mol of H, and 3 mol of O.
Converting amount (mol) of N to mass (g): We have 2 mol of N in 1 mol of NH_4NO_3, so

$$\text{Mass (g) of N} = 2\ \cancel{\text{mol N}} \times \frac{14.01\ \text{g N}}{1\ \cancel{\text{mol N}}} = 28.02\ \text{g N}$$

Calculating the mass of 1 mol of NH_4NO_3:

$$\begin{aligned}\mathcal{M} &= (2 \times \mathcal{M} \text{ of N}) + (4 \times \mathcal{M} \text{ of H}) + (3 \times \mathcal{M} \text{ of O}) \\ &= (2 \times 14.01 \text{ g/mol N}) + (4 \times 1.008 \text{ g/mol H}) + (3 \times 16.00 \text{ g/mol O}) \\ &= 80.05 \text{ g/mol } NH_4NO_3\end{aligned}$$

Finding the mass fraction of N in NH_4NO_3:

$$\text{Mass fraction of N} = \frac{\text{total mass of N}}{\text{mass of 1 mol } NH_4NO_3} = \frac{28.02 \text{ g N}}{80.05 \text{ g } NH_4NO_3} = 0.3500$$

Changing to mass %:

$$\begin{aligned}\text{Mass \% of N} &= \text{mass fraction of N} \times 100 = 0.3500 \times 100 \\ &= \boxed{35.00 \text{ mass \% N}}\end{aligned}$$

Combining the steps for each of the other elements in NH_4NO_3:

$$\text{Mass \% of H} = \frac{\text{mol H} \times \mathcal{M} \text{ of H}}{\text{mass of 1 mol } NH_4NO_3} \times 100 = \frac{4 \text{ mol H} \times \dfrac{1.008 \text{ g H}}{1 \text{ mol H}}}{80.05 \text{ g } NH_4NO_3} \times 100$$

$$= \boxed{5.037 \text{ mass \% H}}$$

$$\text{Mass \% of O} = \frac{\text{mol O} \times \mathcal{M} \text{ of O}}{\text{mass of 1 mol of } NH_4NO_3} \times 100 = \frac{3 \text{ mol O} \times \dfrac{16.00 \text{ g O}}{1 \text{ mol O}}}{80.05 \text{ g } NH_4NO_3} \times 100$$

$$= \boxed{59.96 \text{ mass \% O}}$$

Check The answers make sense. The mass % of O is greater than that of N because there are more moles of O in the compound and the molar mass of O is greater. The mass % of H is small because its molar mass is small. The sum of the mass percents is 100.00%.

Comment From here on, you should be able to determine the molar mass of a compound, so that calculation will no longer be shown.

FOLLOW-UP PROBLEMS

3.6A In mammals, lactose (milk sugar) is metabolized to glucose ($C_6H_{12}O_6$), the key nutrient for generating chemical potential energy. Calculate the mass percent of C in glucose.

3.6B For many years, compounds known as *chlorofluorocarbons* were used as refrigerants, until it was discovered that the chlorine atoms in these compounds destroy ozone molecules in the atmosphere. The compound CCl_3F is a chlorofluorocarbon with a high chlorine content. Calculate the mass percent of Cl in CCl_3F.

SOME SIMILAR PROBLEMS 3.20–3.23

Determining the Mass of an Element from Its Mass Fraction

Sample Problem 3.6 shows that *an element always constitutes the same fraction of the mass of a given compound* (see Equation 3.6). We can use that fraction to find the mass of element in any mass of a compound:

$$\text{Mass of element} = \text{mass of compound} \times \frac{\text{mass of element in 1 mol of compound}}{\text{mass of 1 mol of compound}} \quad \textbf{(3.7)}$$

For example, to find the mass of oxygen in 15.5 g of nitrogen dioxide, we have

$$\text{Mass (g) of O} = 15.5 \text{ g } NO_2 \times \frac{2 \text{ mol} \times \mathcal{M} \text{ of O (g/mol)}}{\text{mass (g) of 1 mol } NO_2}$$

$$= 15.5 \text{ g } \cancel{NO_2} \times \frac{32.00 \text{ g O}}{46.01 \text{ g } \cancel{NO_2}} = 10.8 \text{ g O}$$

SAMPLE PROBLEM 3.7 Calculating the Mass of an Element in a Compound

Problem Use the information in Sample Problem 3.6 to determine the mass (g) of nitrogen in 650. g of ammonium nitrate.

Plan To find the mass of N in the sample of ammonium nitrate, we multiply the mass of the sample by the mass of 2 mol of N divided by the mass of 1 mol of ammonium nitrate.

Solution Finding the mass of N in a given mass of ammonium nitrate:

$$\text{Mass (g) of N} = \text{mass (g) of } NH_4NO_3 \times \frac{2 \text{ mol N} \times \mathcal{M} \text{ of N (g/mol)}}{\text{mass (g) of 1 mol } NH_4NO_3}$$

$$= 650.\ \text{g } \cancel{NH_4NO_3} \times \frac{28.02 \text{ g N}}{80.05\ \text{g } \cancel{NH_4NO_3}} = 228 \text{ g N}$$

Check Rounding shows that the answer is "in the right ballpark": N accounts for about one-third of the mass of NH_4NO_3 and $\frac{1}{3}$ of 700 g is 233 g.

FOLLOW-UP PROBLEMS

3.7A Use the information in Follow-up Problem 3.6A to find the mass (g) of C in 16.55 g of glucose.

3.7B Use the information in Follow-up Problem 3.6B to find the mass (g) of Cl in 112 g of CCl_3F.

SOME SIMILAR PROBLEMS 3.27 and 3.28

Summary of Section 3.1

- A mole of substance is the amount that contains Avogadro's number (6.022×10^{23}) of chemical entities (atoms, ions, molecules, or formula units).
- The mass (in grams) of a mole of a given entity (atom, ion, molecule, or formula unit) has the same numerical value as the mass (in amu) of the entity. Thus, the mole allows us to count entities by weighing them.
- Using the molar mass ($\mathcal{M}$, g/mol) of an element (or compound) and Avogadro's number as conversion factors, we can convert among amount (mol), mass (g), and number of entities.
- The mass fraction of element X in a compound is used to find the mass of X in a given amount of the compound.

3.2 DETERMINING THE FORMULA OF AN UNKNOWN COMPOUND

In Sample Problems 3.6 and 3.7, we used a compound's formula to find the mass percent (or mass fraction) of each element in it *and* the mass of each element in any size sample of it. In this section, we do the reverse: we use the masses of elements in a compound to find the formula. Then, we look briefly at the relationship between molecular formula and molecular structure.

Let's compare three common types of formula, using hydrogen peroxide as an example:

- The **empirical formula** is derived from mass analysis. It shows the *lowest* whole number of moles, and thus the *relative* number of atoms, of each element in the compound. For example, in hydrogen peroxide, there is 1 part by mass of hydrogen for every 16 parts by mass of oxygen. Because the atomic mass of hydrogen is 1.008 amu and that of oxygen is 16.00 amu, there is one H atom for every O atom. Thus, the empirical formula is HO.

Recall from Section 2.8, p. 75, that

- The **molecular formula** shows the *actual* number of atoms of each element in a molecule: the molecular formula of hydrogen peroxide is H_2O_2, twice the empirical formula.
- The **structural formula** shows the relative *placement and connections of atoms* in the molecule: the structural formula is H—O—O—H.

Let's focus here on how to determine empirical and molecular formulas.

Empirical Formulas

A chemist studying an unknown compound goes through a three-step process to find the empirical formula:

1. Determine the mass (g) of each component element.
2. Convert each mass (g) to amount (mol), and write a preliminary formula.
3. Convert the amounts (mol) mathematically to whole-number (integer) subscripts. To accomplish this math conversion,
   - Divide each subscript by the smallest subscript, and
   - If necessary, multiply through by the *smallest integer* that turns all subscripts into integers.

Sample Problem 3.8 demonstrates these math steps.

SAMPLE PROBLEM 3.8 Determining an Empirical Formula from Amounts of Elements

Problem A sample of an unknown compound contains 0.21 mol of zinc, 0.14 mol of phosphorus, and 0.56 mol of oxygen. What is the empirical formula?

Plan We are given the amount (mol) of each element as a fraction. We use these fractional amounts directly in a preliminary formula as subscripts of the element symbols. Then, we convert the fractions to whole numbers.

Solution Using the fractions to write a preliminary formula, with the symbols Zn for zinc, P for phosphorus, and O for oxygen:

$$Zn_{0.21}P_{0.14}O_{0.56}$$

Converting the fractions to whole numbers:

1. Divide each subscript by the smallest one, which in this case is 0.14:

$$Zn_{\frac{0.21}{0.14}}P_{\frac{0.14}{0.14}}O_{\frac{0.56}{0.14}} \longrightarrow Zn_{1.5}P_{1.0}O_{4.0}$$

2. Multiply through by the *smallest integer* that turns all subscripts into integers. We multiply by 2 to make 1.5 (the subscript for Zn) into an integer:

$$Zn_{(1.5\times2)}P_{(1.0\times2)}O_{(4.0\times2)} \longrightarrow Zn_{3.0}P_{2.0}O_{8.0}, \quad \text{or} \quad Zn_3P_2O_8$$

Check The integer subscripts must be the smallest integers with the same ratio as the original fractional numbers of moles: 3/2/8 is *the same ratio* as 0.21/0.14/0.56.

Comment A more conventional way to write this formula is $Zn_3(PO_4)_2$; this compound is zinc phosphate, formerly used widely as a dental cement.

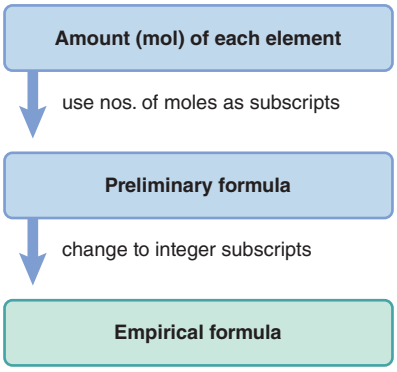
FOLLOW-UP PROBLEMS

3.8A A sample of a white solid contains 0.170 mol of boron and 0.255 mol of oxygen. What is the empirical formula?

3.8B A sample of an unknown compound contains 6.80 mol of carbon and 18.1 mol of hydrogen. What is the empirical formula?

SOME SIMILAR PROBLEMS 3.42(a) and 3.43(a)

Road Map



Sample Problems 3.9–3.11 show how other types of compositional data are used to determine chemical formulas.

SAMPLE PROBLEM 3.9 Determining an Empirical Formula from Masses of Elements

Problem Analysis of a sample of an ionic compound yields 2.82 g of Na, 4.35 g of Cl, and 7.83 g of O. What are the empirical formula and the name of the compound?

Plan This problem is similar to Sample Problem 3.8, except that we are given element *masses* that we must convert into integer subscripts. We first divide each mass by the element's molar mass to find the amount (mol). Then we construct a preliminary formula and convert the amounts (mol) to integers.

Solution Finding amount (mol) of each element:

$$\text{Amount (mol) of Na} = 2.82\ \cancel{\text{g Na}} \times \frac{1\ \text{mol Na}}{22.99\ \cancel{\text{g Na}}} = 0.123\ \text{mol Na}$$

$$\text{Amount (mol) of Cl} = 4.35\ \cancel{\text{g Cl}} \times \frac{1\ \text{mol Cl}}{35.45\ \cancel{\text{g Cl}}} = 0.123\ \text{mol Cl}$$

$$\text{Amount (mol) of O} = 7.83\ \cancel{\text{g O}} \times \frac{1\ \text{mol O}}{16.00\ \cancel{\text{g O}}} = 0.489\ \text{mol O}$$

Constructing a preliminary formula: $Na_{0.123}Cl_{0.123}O_{0.489}$

Converting to integer subscripts (dividing all by the smallest subscript):

$$Na_{\frac{0.123}{0.123}}Cl_{\frac{0.123}{0.123}}O_{\frac{0.489}{0.123}} \longrightarrow Na_{1.00}Cl_{1.00}O_{3.98} \approx Na_1Cl_1O_4, \quad \text{or} \quad NaClO_4$$

The empirical formula is $NaClO_4$; the name is sodium perchlorate.

Check The numbers of moles seem correct because the masses of Na and Cl are slightly more than 0.1 of their molar masses. The mass of O is greatest and its molar mass is smallest, so it should have the greatest number of moles. The ratio of subscripts, 1/1/4, is the same as the ratio of moles, 0.123/0.123/0.489 (within rounding).

FOLLOW-UP PROBLEMS

3.9A A sample of an unknown compound is found to contain 1.23 g of H, 12.64 g of P, and 26.12 g of O. What is the empirical formula?

3.9B An unknown metal M reacts with sulfur to form a compound with the formula M_2S_3. If 3.12 g of M reacts with 2.88 g of S, what are the names of M and M_2S_3? [*Hint:* Determine the amount (mol) of S, and use the formula to find the amount (mol) of M.]

SOME SIMILAR PROBLEMS 3.42(b), 3.43(b), 3.46(b), and 3.47(b)

Molecular Formulas

If we know the molar mass of a compound, we can use the empirical formula to obtain the molecular formula, which uses as subscripts the *actual* numbers of moles of each element in 1 mol of compound. For some compounds, such as water (H_2O), ammonia (NH_3), and methane (CH_4), the empirical and molecular formulas are identical, but for many others, the molecular formula is a *whole-number multiple* of the empirical formula. As you saw, hydrogen peroxide has the empirical formula HO. Dividing the molar mass of hydrogen peroxide (34.02 g/mol) by the empirical formula mass of HO (17.01 g/mol) gives the whole-number multiple:

$$\text{Whole-number multiple} = \frac{\text{molar mass (g/mol)}}{\text{empirical formula mass (g/mol)}} = \frac{34.02\ \cancel{\text{g/mol}}}{17.01\ \cancel{\text{g/mol}}} = 2.000 = 2$$

Multiplying the empirical formula subscripts by 2 gives the molecular formula:

$$H_{(1\times2)}O_{(1\times2)}\ \text{gives}\ H_2O_2$$

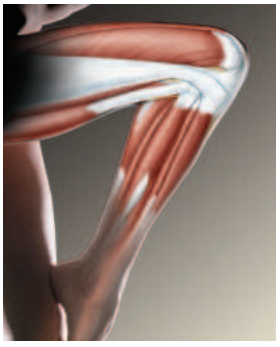
Since the molar mass of hydrogen peroxide is twice as large as the empirical formula mass, the molecular formula has twice the number of atoms as the empirical formula.

Instead of giving compositional data as masses of each element, analytical laboratories provide mass percents. We use this kind of data as follows:

1. Assume 100.0 g of compound to express each mass percent directly as mass (g).
2. Convert each mass (g) to amount (mol).

3. Derive the empirical formula.
4. Divide the molar mass of the compound by the empirical formula mass to find the whole-number multiple and the molecular formula.

SAMPLE PROBLEM 3.10 Determining a Molecular Formula from Elemental Analysis and Molar Mass



Problem During excessive physical activity, lactic acid ($\mathcal{M}$ = 90.08 g/mol) forms in muscle tissue and is responsible for muscle soreness. Elemental analysis shows that this compound has 40.0 mass % C, 6.71 mass % H, and 53.3 mass % O.
(a) Determine the empirical formula of lactic acid.
(b) Determine the molecular formula.

(a) Determining the empirical formula

Plan We know the mass % of each element and must convert each to an integer subscript. The mass of the sample of lactic acid is not given, but the mass percents are the same for any sample of it. Therefore, we assume there is 100.0 g of lactic acid and express each mass % as a number of grams. Then, we construct the empirical formula as in Sample Problem 3.9.

Solution Expressing mass % as mass (g) by assuming 100.0 g of lactic acid:

$$\text{Mass (g) of C} = \frac{\text{40.0 parts C by mass}}{\text{100 parts by mass}} \times \text{100.0 g} = \text{40.0 g C}$$

Similarly, we have 6.71 g of H and 53.3 g of O.

Converting from mass (g) of each element to amount (mol):

$$\text{Amount (mol) of C} = \text{mass of C} \times \frac{1}{\mathcal{M} \text{ of C}} = 40.0 \text{ g C} \times \frac{\text{1 mol C}}{\text{12.01 g C}} = \text{3.33 mol C}$$

Similarly, we have 6.66 mol of H and 3.33 mol of O.

Constructing the preliminary formula: $C_{3.33}H_{6.66}O_{3.33}$

Converting to integer subscripts:

$$C_{\frac{3.33}{3.33}}H_{\frac{6.66}{3.33}}O_{\frac{3.33}{3.33}} \longrightarrow C_{1.00}H_{2.00}O_{1.00} = C_1H_2O_1, \text{ the empirical formula is } \boxed{CH_2O}$$

Check The numbers of moles seem correct: the masses of C and O are each slightly more than 3 times their molar masses (e.g., for C, 40 g/(12 g/mol) > 3 mol), and the mass of H is over 6 times its molar mass of 1.

(b) Determining the molecular formula

Plan The molecular formula subscripts are whole-number multiples of the empirical formula subscripts. To find this multiple, we divide the given molar mass (90.08 g/mol) by the empirical formula mass, which we find from the sum of the elements' molar masses. Then we multiply each subscript in the empirical formula by the multiple.

Solution The empirical formula mass is 30.03 g/mol. Finding the whole-number multiple:

$$\text{Whole-number multiple} = \frac{\mathcal{M} \text{ of lactic acid}}{\mathcal{M} \text{ of empirical formula}} = \frac{90.08 \text{ g/mol}}{30.03 \text{ g/mol}} = 3.000 = 3$$

Determining the molecular formula:

$$C_{(1\times3)}H_{(2\times3)}O_{(1\times3)} = \boxed{C_3H_6O_3}$$

Check The calculated molecular formula has the same ratio of moles of elements (3/6/3) as the empirical formula (1/2/1) and corresponds to the given molar mass:

$$\begin{aligned}\mathcal{M} \text{ of lactic acid} &= (3 \times \mathcal{M} \text{ of C}) + (6 \times \mathcal{M} \text{ of H}) + (3 \times \mathcal{M} \text{ of O}) \\ &= (3 \times \text{12.01 g/mol}) + (6 \times \text{1.008 g/mol}) + (3 \times \text{16.00 g/mol}) \\ &= \text{90.08 g/mol}\end{aligned}$$

FOLLOW-UP PROBLEMS

3.10A One of the most widespread environmental carcinogens (cancer-causing agents) is benzo[*a*]pyrene ($\mathcal{M}$ = 252.30 g/mol). It is found in coal dust, cigarette smoke, and even charcoal-grilled meat. Analysis of this hydrocarbon shows 95.21 mass % C and 4.79 mass % H. What is the molecular formula of benzo[*a*]pyrene?

3.10B Caffeine ($\mathcal{M}$ = 194.2 g/mol) is a stimulant found in coffee, tea, soft drinks, and chocolate. Elemental analysis of caffeine shows 49.47 mass % C, 5.19 mass % H, 28.86 mass % N, and 16.48 mass % O. What is the molecular formula of caffeine?
SOME SIMILAR PROBLEMS 3.44, 3.45, and 3.49

Combustion Analysis of Organic Compounds Still another type of compositional data is obtained through **combustion analysis,** used to measure the amounts of carbon and hydrogen in a combustible organic compound. The unknown compound is burned in an excess of pure O_2; during the combustion, the compound's carbon and hydrogen react with the oxygen to form CO_2 and H_2O, respectively, which are absorbed in separate containers (Figure 3.4). By weighing the absorbers before and after combustion, we find the masses of CO_2 and H_2O and use them to find the masses of C and H in the compound; from these results, we find the empirical formula. Many organic compounds also contain oxygen, nitrogen, or a halogen. As long as the third element doesn't interfere with the absorption of H_2O and CO_2, we calculate its mass by subtracting the masses of C and H from the original mass of the compound.

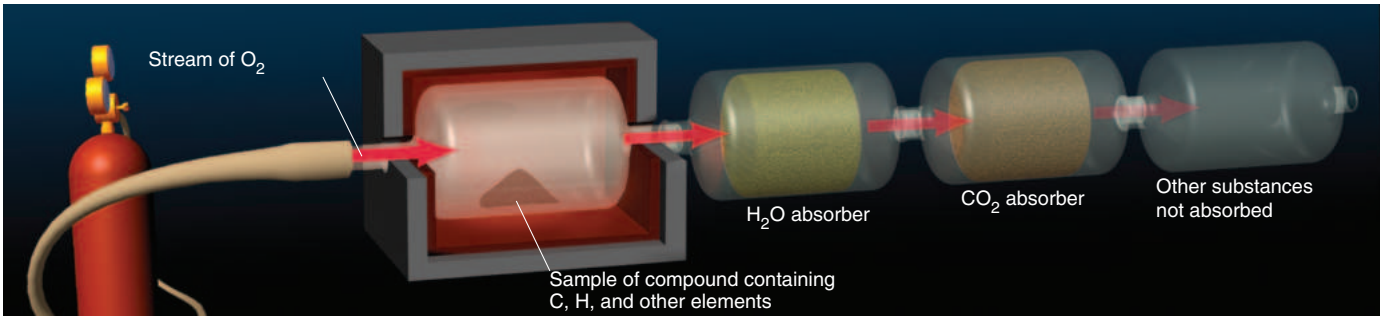


Figure 3.4 Combustion apparatus for determining formulas of organic compounds. A sample of an organic compound is burned in a stream of O_2. The resulting H_2O is absorbed by $Mg(ClO_4)_2$, and the CO_2 is absorbed by NaOH on asbestos.

SAMPLE PROBLEM 3.11 Determining a Molecular Formula from Combustion Analysis

Problem Vitamin C ($\mathcal{M}$ = 176.12 g/mol) is a compound of C, H, and O found in many natural sources, especially citrus fruits. When a 1.000-g sample of vitamin C is burned in a combustion apparatus, the following data are obtained:

Mass of CO_2 absorber after combustion = 85.35 g
Mass of CO_2 absorber before combustion = 83.85 g
Mass of H_2O absorber after combustion = 37.96 g
Mass of H_2O absorber before combustion = 37.55 g

What is the molecular formula of vitamin C?

Plan We find the masses of CO_2 and H_2O by subtracting the masses of the absorbers before and after the combustion. From the mass of CO_2, we use Equation 3.7 to find the mass of C. Similarly, we find the mass of H from the mass of H_2O. The mass of vitamin C (1.000 g) minus the sum of the masses of C and H gives the mass of O, the third element present. Then, we proceed as in Sample Problem 3.10: calculate amount (mol) of each element using its molar mass, construct the empirical formula, determine the whole-number multiple from the given molar mass, and construct the molecular formula.

Solution Finding the masses of combustion products:

$$\text{Mass (g) of } CO_2 = \text{mass of } CO_2 \text{ absorber after} - \text{mass before}$$
$$= 85.35\text{ g} - 83.85\text{ g} = 1.50\text{ g } CO_2$$
$$\text{Mass (g) of } H_2O = \text{mass of } H_2O \text{ absorber after} - \text{mass before}$$
$$= 37.96\text{ g} - 37.55\text{ g} = 0.41\text{ g } H_2O$$

Calculating masses (g) of C and H using Equation 3.7:

$$\text{Mass of element} = \text{mass of compound} \times \frac{\text{mass of element in 1 mol of compound}}{\text{mass of 1 mol of compound}}$$

$$\text{Mass (g) of C} = \text{mass of } CO_2 \times \frac{1 \text{ mol C} \times \mathcal{M} \text{ of C}}{\text{mass of 1 mol } CO_2} = 1.50 \text{ g } \cancel{CO_2} \times \frac{12.01 \text{ g C}}{44.01 \text{ g } \cancel{CO_2}}$$

$$= 0.409 \text{ g C}$$

$$\text{Mass (g) of H} = \text{mass of } H_2O \times \frac{2 \text{ mol H} \times \mathcal{M} \text{ of H}}{\text{mass of 1 mol } H_2O} = 0.41 \text{ g } \cancel{H_2O} \times \frac{2.016 \text{ g H}}{18.02 \text{ g } \cancel{H_2O}}$$

$$= 0.046 \text{ g H}$$

Calculating mass (g) of O:

$$\text{Mass (g) of O} = \text{mass of vitamin C sample} - (\text{mass of C} + \text{mass of H})$$
$$= 1.000 \text{ g} - (0.409 \text{ g} + 0.046 \text{ g}) = 0.545 \text{ g O}$$

Finding the amounts (mol) of elements: Dividing the mass (g) of each element by its molar mass gives 0.0341 mol of C, 0.046 mol of H, and 0.0341 mol of O.

Constructing the preliminary formula: $C_{0.0341}H_{0.046}O_{0.0341}$

Determining the empirical formula: Dividing through by the smallest subscript gives

$$C_{\frac{0.0341}{0.0341}}H_{\frac{0.046}{0.0341}}O_{\frac{0.0341}{0.0341}} = C_{1.00}H_{1.3}O_{1.00}$$

We find that 3 is the smallest integer that makes all subscripts into integers:

$$C_{(1.00\times3)}H_{(1.3\times3)}O_{(1.00\times3)} = C_{3.00}H_{3.9}O_{3.00} \approx C_3H_4O_3$$

Determining the molecular formula:

$$\text{Whole-number multiple} = \frac{\mathcal{M} \text{ of vitamin C}}{\mathcal{M} \text{ of empirical formula}} = \frac{176.12 \text{ } \cancel{\text{g/mol}}}{88.06 \text{ } \cancel{\text{g/mol}}} = 2.000 = 2$$

$$C_{(3\times2)}H_{(4\times2)}O_{(3\times2)} = C_6H_8O_6$$

Check The element masses seem correct: carbon makes up slightly more than 0.25 of the mass of CO_2 (12 g/44 g > 0.25), as do the masses in the problem (0.409 g/1.50 g > 0.25). Hydrogen makes up slightly more than 0.10 of the mass of H_2O (2 g/18 g > 0.10), as do the masses in the problem (0.046 g/0.41 g > 0.10). The molecular formula has the same ratio of subscripts (6/8/6) as the empirical formula (3/4/3) and the preliminary formula (0.0341/0.046/0.0341), and it gives the known molar mass:

$$(6 \times \mathcal{M} \text{ of C}) + (8 \times \mathcal{M} \text{ of H}) + (6 \times \mathcal{M} \text{ of O}) = \mathcal{M} \text{ of vitamin C}$$
$$(6 \times 12.01 \text{ g/mol}) + (8 \times 1.008 \text{ g/mol}) + (6 \times 16.00 \text{ g/mol}) = 176.12 \text{ g/mol}$$

Comment The subscript we calculated for H was 3.9, which we rounded to 4. But, if we had strung the calculation steps together, we would have obtained 4.0:

$$\text{Subscript of H} = 0.41 \text{ g } H_2O \times \frac{2.016 \text{ g H}}{18.02 \text{ g } H_2O} \times \frac{1 \text{ mol H}}{1.008 \text{ g H}} \times \frac{1}{0.0341 \text{ mol}} \times 3 = 4.0$$

FOLLOW-UP PROBLEMS

3.11A A dry-cleaning solvent ($\mathcal{M}$ = 146.99 g/mol) that contains C, H, and Cl is suspected to be a cancer-causing agent. When a 0.250-g sample was studied by combustion analysis, 0.451 g of CO_2 and 0.0617 g of H_2O were formed. Find the molecular formula.

3.11B Anabolic steroids are sometimes used illegally by athletes to increase muscle strength. A forensic chemist analyzes some tablets suspected of being a popular steroid. He determines that the substance in the tablets contains only C, H, and O and has a molar mass of 300.42 g/mol. When a 1.200-g sample is studied by combustion analysis, 3.516 g of CO_2 and 1.007 g of H_2O are collected. What is the molecular formula of the substance in the tablets?

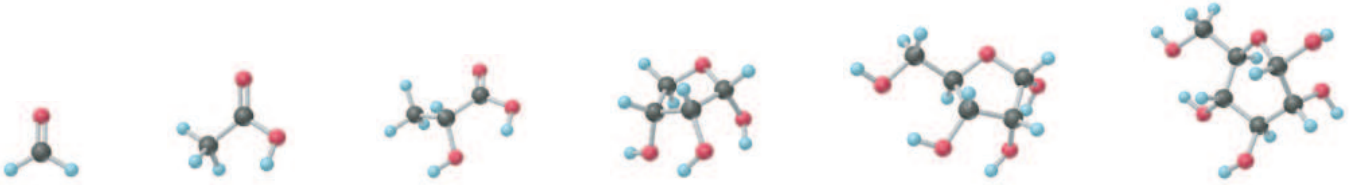
A SIMILAR PROBLEM 3.51

Chemical Formulas and Molecular Structures; Isomers

A formula represents a real, three-dimensional object. The structural formula makes this point, with its relative placement of atoms, but do empirical and molecular formulas contain structural information?

Table 3.2 Some Compounds with Empirical Formula CH_2O (Composition by Mass: 40.0% C, 6.71% H, 53.3% O)

Name	Molecular Formula	Whole-Number Multiple	$\mathcal{M}$ (g/mol)	Use or Function
Formaldehyde	CH_2O	1	30.03	Disinfectant; biological preservative
Acetic acid	$C_2H_4O_2$	2	60.05	Acetate polymers; vinegar (5% solution)
Lactic acid	$C_3H_6O_3$	3	90.08	Causes milk to sour; forms in muscles during exercise
Erythrose	$C_4H_8O_4$	4	120.10	Forms during sugar metabolism
Ribose	$C_5H_{10}O_5$	5	150.13	Component of many nucleic acids and vitamin B_2
Glucose	$C_6H_{12}O_6$	6	180.16	Major nutrient for energy in cells



CH_2O $C_2H_4O_2$ $C_3H_6O_3$ $C_4H_8O_4$ $C_5H_{10}O_5$ $C_6H_{12}O_6$

1. *Different compounds with the same empirical formula*. The empirical formula tells nothing about molecular structure because it is based solely on mass analysis. In fact, different compounds can have the *same* empirical formula. NO_2 and N_2O_4 are inorganic cases, and there are numerous organic ones. For example, many compounds have the empirical formula CH_2 (the general formula is C_nH_{2n}, with n an integer greater than or equal to 2), such as ethylene (C_2H_4) and propylene (C_3H_6), starting materials for two common plastics. Table 3.2 shows some biological compounds with the same empirical formula, CH_2O.

2. *Isomers: Different compounds with the same molecular formula.* A molecular formula also tells nothing about structure. Different compounds can have the *same* molecular formula because their atoms can bond in different arrangements to give more than one *structural formula.* **Isomers** are compounds with the same molecular formula, and thus molar mass, but different properties. *Constitutional,* or *structural, isomers* occur when the atoms link together in different arrangements. Table 3.3 shows two pairs of examples. The left pair, butane and 2-methylpropane, share the molecular formula C_4H_{10}. One has a four-C chain and the other a one-C branch off a three-C chain. Both

Table 3.3 Two Pairs of Constitutional Isomers

	C_4H_{10}		C_2H_6O	
Property	**Butane**	**2-Methylpropane**	**Ethanol**	**Dimethyl Ether**
$\mathcal{M}$ (g/mol)	58.12	58.12	46.07	46.07
Boiling point	−0.5°C	−11.6°C	78.5°C	−25°C
Density (at 20°C)	0.00244 g/mL (gas)	0.00247 g/mL (gas)	0.789 g/mL (liquid)	0.00195 g/mL (gas)
Structural formula				Space-filling model				
are small alkanes, so their properties are similar, but not identical. The two compounds with the molecular formula C_2H_6O have very different properties; indeed, they are different classes of organic compound—one is an alcohol and the other an ether.

As the number and kinds of atoms increase, the number of constitutional isomers—that is, the number of structural formulas that can be written for a given molecular formula—also increases: C_2H_6O has two structural formulas (Table 3.3), C_3H_8O has three, and $C_4H_{10}O$ seven. Imagine how many there are for $C_{16}H_{19}N_3O_4S$! Of all the possible isomers with this molecular formula, only one is the antibiotic ampicillin (Figure 3.5). We'll discuss these and other types of isomerism fully later in the text.

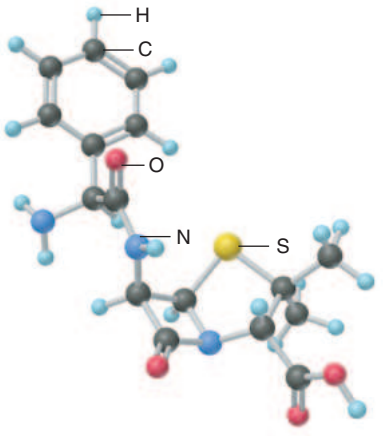

Figure 3.5 The antibiotic ampicillin.

Summary of Section 3.2

- From the masses of elements in a compound, their relative numbers of moles are found, which gives the empirical formula.
- If the molar mass of the compound is known, the molecular formula, the actual numbers of moles of each element, can also be determined, because the molecular formula is a whole-number multiple of the empirical formula.
- Combustion analysis provides data on the masses of carbon and hydrogen in an organic compound, which are used to obtain the formula.
- Atoms can bond in different arrangements (structural formulas). Two or more compounds with the same molecular formula are constitutional isomers.

3.3 WRITING AND BALANCING CHEMICAL EQUATIONS

Thinking in terms of amounts, rather than masses, allows us to view reactions as large populations of interacting particles rather than as grams of material. For example, for the formation of HF from H_2 and F_2, if we weigh the substances, we find that

Macroscopic level (grams): 2.016 g of H_2 and 38.00 g of F_2 react to form 40.02 g of HF

This information tells us little except that mass is conserved. However, if we convert these masses (g) to amounts (mol), we find that

Macroscopic level (moles): 1 mol of H_2 and 1 mol of F_2 react to form 2 mol of HF

This information reveals that an enormous number of H_2 molecules react with just as many F_2 molecules to form twice as many HF molecules. Dividing by Avogadro's number gives the reaction between individual molecules:

Molecular level: 1 molecule of H_2 and 1 molecule of F_2 react to form 2 molecules of HF

Thus, *the macroscopic (molar) change corresponds to the submicroscopic (molecular) change* (Figure 3.6). This information forms the essence of a **chemical equation,** a statement that uses formulas to express the identities and quantities of substances in a chemical or physical change.

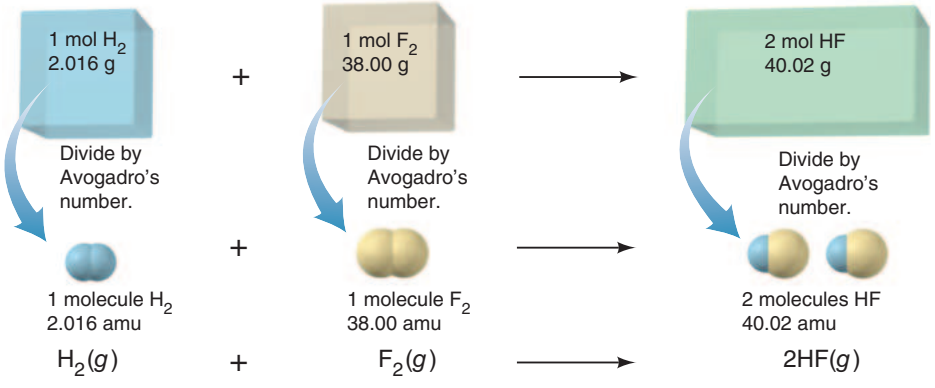

Figure 3.6 The formation of HF on the macroscopic and molecular levels and written as a balanced chemical equation.

Steps for Balancing an Equation To present a chemical change quantitatively, the equation must be *balanced: the same number of each type of atom must appear on both sides.* As an example, here is a description of a chemical change that occurs in many fireworks and in a common lecture demonstration: a magnesium strip burns in oxygen gas to yield powdery magnesium oxide. (Light and heat are also produced, but we are concerned here only with substances.) Converting this description into a balanced equation involves the following steps:

1. *Translating the statement.* We first translate the chemical statement into a "skeleton" equation: the substances present *before* the change, called **reactants,** are placed to the left of a yield arrow, which points to the substances produced *during* the change, called **products:**

   At the beginning of the balancing process, we put a blank *in front of* each formula to remind us that we have to account for its atoms.

2. *Balancing the atoms.* By shifting our attention back and forth, we *match the numbers of each type of atom on the left and the right of the yield arrow.* In each blank, we place a **balancing (stoichiometric) coefficient,** a numerical multiplier of *all the atoms* in the formula that follows it. In general, balancing is easiest when we
   - Start with the most complex substance, the one with the largest number of different types of atoms.
   - End with the least complex substance, such as an element by itself.

   In this case, MgO is the most complex, so we place a coefficient 1 in that blank:

   To balance the Mg in MgO, we place a 1 in front of Mg on the left:

   The O atom in MgO must be balanced by one O atom on the left. One-half an O_2 molecule provides one O atom:

   In terms of numbers of each type of atom, the equation is balanced.

3. *Adjusting the coefficients.* There are several conventions about the final coefficients:
   - In most cases, *the smallest whole-number coefficients are preferred.* In this case, one-half of an O_2 molecule cannot exist, so we multiply the equation by 2:

   - We used the coefficient 1 to remind us to balance each substance. But, a coefficient of 1 is implied by the presence of the formula, so we don't write it:

   (This convention is similar to not writing a subscript 1 in a formula.)

4. *Checking.* After balancing and adjusting the coefficients, we always check that the equation is balanced:

5. *Specifying the states of matter.* The final equation also indicates the physical state of each substance or whether it is dissolved in water. The abbreviations used for these states are shown in the margin. From the original statement, we know that a Mg "strip" is solid, O_2 is a gas, and "powdery" MgO is also solid. The balanced equation, therefore, is

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$$

g for gas
l for liquid
s for solid
aq for aqueous solution

As you saw in Figure 3.6, *balancing coefficients refer to both individual chemical entities and moles of entities*. Thus,

2 atoms of Mg and 1 molecule of O_2 yield 2 formula units of MgO

2 moles of Mg and 1 mole of O_2 yield 2 moles of MgO

Figure 3.7 depicts this reaction on three levels:

- *Macroscopic level (photos),* as it appears in the laboratory
- *Atomic level (blow-up circles),* as chemists imagine it (with darker colored atoms representing the stoichiometry)
- *Symbolic level,* in the form of the balanced chemical equation

Keep in mind several key points about the balancing process:

- A coefficient operates on *all* the atoms in the formula that follows it:

  $2MgO$ *means* $2 \times (MgO)$, or 2 Mg atoms + 2 O atoms

  $2Ca(NO_3)_2$ *means* $2 \times [Ca(NO_3)_2]$, or 2 Ca atoms + 4 N atoms + 12 O atoms

- Chemical formulas *cannot* be altered. Thus, in step 2 of the example, we *cannot* balance the O atoms by changing MgO to MgO_2 because MgO_2 is a different compound.
- Other reactants or products *cannot* be added. Thus, we *cannot* balance the O atoms by changing the reactant from O_2 molecules to O atoms or by adding an O atom to the products. The description of the reaction mentions oxygen gas, which consists of O_2 molecules, *not* separate O atoms.
- A balanced equation remains balanced if you multiply all the coefficients by the same number. For example,

  $$4Mg(s) + 2O_2(g) \longrightarrow 4MgO(s)$$

  is also balanced because the coefficients have just been multiplied by 2. However, *by convention,* we balance an equation with the *smallest* whole-number coefficients.

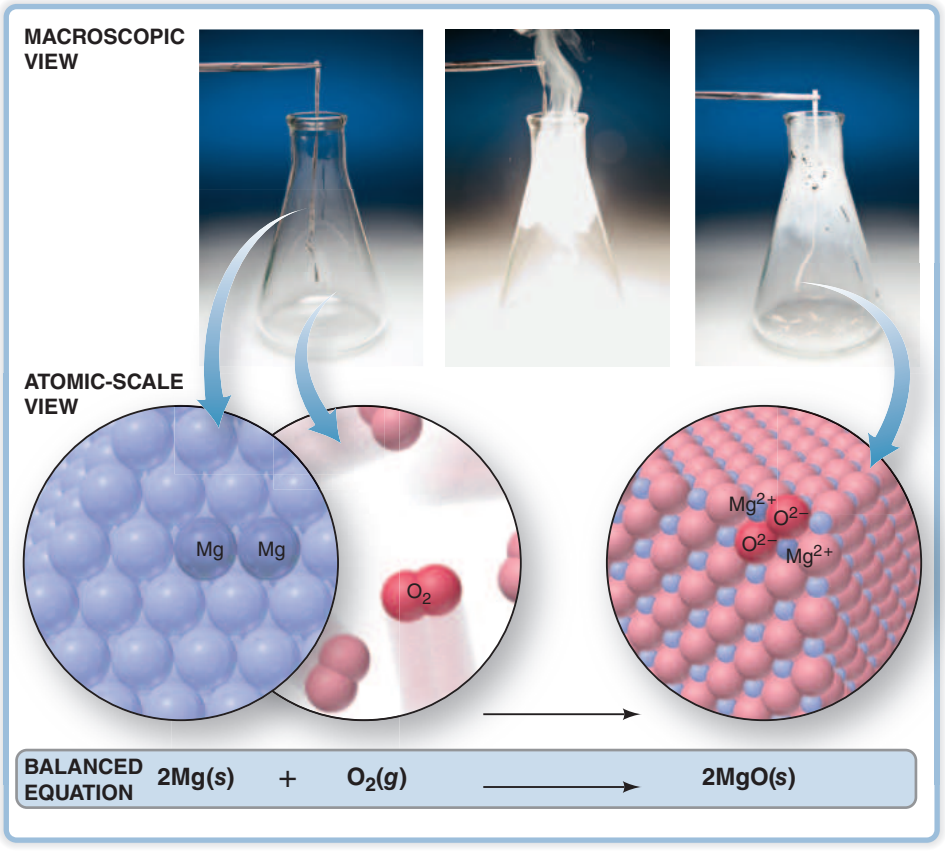

Figure 3.7 A three-level view of the reaction between magnesium and oxygen.

SAMPLE PROBLEM 3.12 Balancing Chemical Equations

Problem Within the cylinders of a car's engine, the hydrocarbon octane (C_8H_{18}), one of many components of gasoline, mixes with oxygen from the air and burns to form carbon dioxide and water vapor. Write a balanced equation for this reaction.

Solution **1.** *Translate* the statement into a skeleton equation (with coefficient blanks). Octane and oxygen are reactants; "oxygen from the air" implies molecular oxygen, O_2. Carbon dioxide and water vapor are products:

$$__C_8H_{18} + __O_2 \longrightarrow __CO_2 + __H_2O$$

2. *Balance the atoms.* Start with the most complex substance, C_8H_{18}, and balance O_2 last:

$$\underline{1}\,C_8H_{18} + __O_2 \longrightarrow __CO_2 + __H_2O$$

The C atoms in C_8H_{18} end up in CO_2. Each CO_2 contains one C atom, so 8 molecules of CO_2 are needed to balance the 8 C atoms in each C_8H_{18}:

$$\underline{1}\,C_8H_{18} + __O_2 \longrightarrow \underline{8}\,CO_2 + __H_2O$$

The H atoms in C_8H_{18} end up in H_2O. The 18 H atoms in C_8H_{18} require the coefficient 9 in front of H_2O:

$$\underline{1}\,C_8H_{18} + __O_2 \longrightarrow \underline{8}\,CO_2 + \underline{9}\,H_2O$$

There are 25 atoms of O on the right (16 in $8CO_2$ plus 9 in $9H_2O$), so we place the coefficient $\frac{25}{2}$ in front of O_2:

$$\underline{1}\,C_8H_{18} + \underline{\tfrac{25}{2}}\,O_2 \longrightarrow \underline{8}\,CO_2 + \underline{9}\,H_2O$$

3. *Adjust the coefficients*. Multiply through by 2 to obtain whole numbers:

$$2C_8H_{18} + 25O_2 \longrightarrow 16CO_2 + 18H_2O$$

4. *Check* that the equation is balanced:

$$\text{Reactants (16 C, 36 H, 50 O)} \longrightarrow \text{products (16 C, 36 H, 50 O)}$$

5. *Specify* states of matter. C_8H_{18} is liquid; O_2, CO_2, and H_2O vapor are gases:

$$2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(g)$$

Comment This is an example of a combustion reaction. *Any* compound containing C and H that burns in an excess of air produces CO_2 and H_2O.

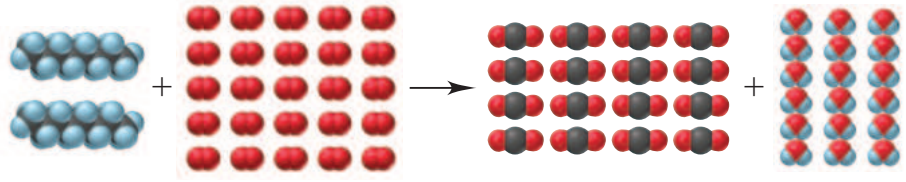
FOLLOW-UP PROBLEMS

3.12A Write a balanced equation for each of the following:
(a) A characteristic reaction of Group 1A(1) elements: chunks of sodium react violently with water to form hydrogen gas and sodium hydroxide solution.
(b) The destruction of marble statuary by acid rain: aqueous nitric acid reacts with calcium carbonate to form carbon dioxide, water, and aqueous calcium nitrate.
(c) Halogen compounds exchanging bonding partners: phosphorus trifluoride is prepared by the reaction of phosphorus trichloride and hydrogen fluoride; hydrogen chloride is the other product. The reaction involves gases only.

3.12B Write a balanced equation for each of the following:
(a) Explosive decomposition of dynamite: liquid nitroglycerine ($C_3H_5N_3O_9$) explodes to produce a mixture of gases—carbon dioxide, water vapor, nitrogen, and oxygen.
(b) A reaction that takes place in a self-contained breathing apparatus: solid potassium superoxide (KO_2) reacts with carbon dioxide gas to produce oxygen gas and solid potassium carbonate.
(c) The production of iron from its ore in a blast furnace: solid iron(III) oxide reacts with carbon monoxide gas to produce solid iron metal and carbon dioxide gas.

SOME SIMILAR PROBLEMS 3.56–3.61

Visualizing a Reaction with a Molecular Scene A great way to focus on the rearrangement of atoms from reactants to products is by visualizing an equation as a molecular scene. Here's a representation of the combustion of octane we just balanced:

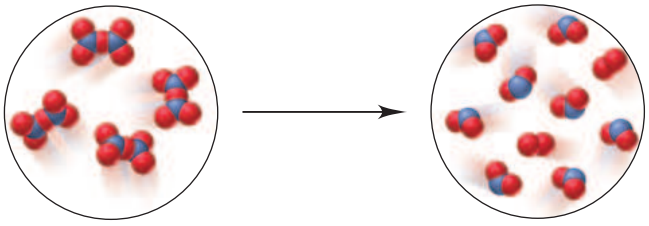


$2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(g)$

Now let's work through a sample problem to do the reverse—derive a balanced equation from a molecular scene.

SAMPLE PROBLEM 3.13 Balancing an Equation from a Molecular Scene

Problem The following molecular scenes depict an important reaction in nitrogen chemistry (nitrogen is blue; oxygen is red):



Write a balanced equation for this reaction.

Plan To write a balanced equation, we first have to determine the formulas of the molecules and obtain coefficients by counting the number of each type of molecule. Then, we arrange this information in the correct equation format, using the smallest whole-number coefficients and including states of matter.

Solution The reactant circle shows only one type of molecule. It has two N and five O atoms, so the formula is N_2O_5; there are four of these molecules. The product circle shows two different molecules, one with one N and two O atoms, and the other with two O atoms; there are eight NO_2 and two O_2. Thus, we have

$$4N_2O_5 \longrightarrow 8NO_2 + 2O_2$$

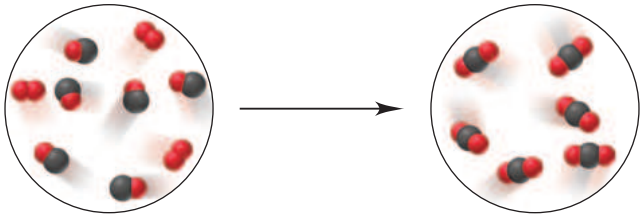
Writing the balanced equation with the smallest whole-number coefficients and all substances as gases:

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$$

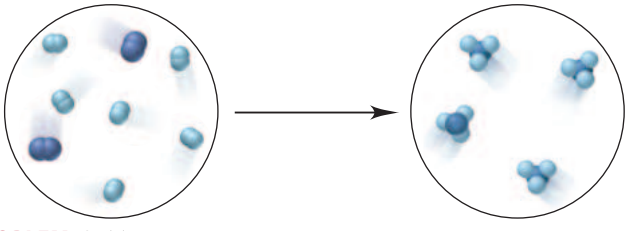
Check Reactant (4 N, 10 O) $\longrightarrow$ products (4 N, 8 + 2 = 10 O)

FOLLOW-UP PROBLEMS

3.13A Write a balanced equation for the important atmospheric reaction depicted below (carbon is black; oxygen is red):



3.13B Write a balanced equation for the important industrial reaction depicted below (nitrogen is dark blue; hydrogen is light blue):



A SIMILAR PROBLEM 3.55

Summary of Section 3.3

- A chemical equation has reactant formulas on the left of a yield arrow and product formulas on the right.
- A balanced equation has the same number of each type of atom on both sides.
- Balancing coefficients are integer multipliers for *all* the atoms in a formula and apply to the individual entity or to moles of entities.

3.4 CALCULATING QUANTITIES OF REACTANT AND PRODUCT

A balanced equation is essential for all calculations involving chemical change: *if you know the number of moles of one substance, the balanced equation tells you the number of moles of the others.*

Stoichiometrically Equivalent Molar Ratios from the Balanced Equation

In a balanced equation, *the amounts (mol) of substances are stoichiometrically equivalent to each other,* which means that a specific amount of one substance is formed from, produces, or reacts with a specific amount of the other. The quantitative relationships are expressed as *stoichiometrically equivalent molar ratios* that we use as conversion factors to calculate the amounts. For example, consider the equation for the combustion of propane, a hydrocarbon fuel used in cooking and water heating:

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g)$$

If we view the reaction quantitatively in terms of C_3H_8, we see that

1 mol of C_3H_8 reacts with 5 mol of O_2
1 mol of C_3H_8 produces 3 mol of CO_2
1 mol of C_3H_8 produces 4 mol of H_2O

Therefore, in this reaction,

1 mol of C_3H_8 is stoichiometrically equivalent to 5 mol of O_2
1 mol of C_3H_8 is stoichiometrically equivalent to 3 mol of CO_2
1 mol of C_3H_8 is stoichiometrically equivalent to 4 mol of H_2O

We chose to look at C_3H_8, but any two of the substances are stoichiometrically equivalent to each other. Thus,

3 mol of CO_2 is stoichiometrically equivalent to 4 mol of H_2O
5 mol of O_2 is stoichiometrically equivalent to 3 mol of CO_2

and so on. A balanced equation contains a wealth of quantitative information relating individual chemical entities, amounts (mol) of substances, and masses of substances, and Table 3.4 presents the quantitative information contained in this equation.

Here's a typical problem that shows how stoichiometric equivalence is used to create conversion factors: in the combustion of propane, how many moles of O_2 are consumed when 10.0 mol of H_2O are produced? To solve this problem, we have to find the molar ratio between O_2 and H_2O. From the balanced equation, we see that for every 5 mol of O_2 consumed, 4 mol of H_2O is formed:

5 mol of O_2 is stoichiometrically equivalent to 4 mol of H_2O

As with any equivalent quantities, we can construct two conversion factors, depending on the quantity we want to find:

$$\frac{5 \text{ mol } O_2}{4 \text{ mol } H_2O} \quad \text{or} \quad \frac{4 \text{ mol } H_2O}{5 \text{ mol } O_2}$$

Since we want to find the amount (mol) of O_2 and we know the amount (mol) of H_2O, we choose "5 mol O_2/4 mol H_2O" *(above left)* to cancel "mol H_2O":

$$\text{Amount (mol) of } O_2 \text{ consumed} = 10.0 \cancel{\text{ mol } H_2O} \times \frac{5 \text{ mol } O_2}{4 \cancel{\text{ mol } H_2O}} = 12.5 \text{ mol } O_2$$

mol H_2O ⟹ (molar ratio as conversion factor) mol O_2

Table 3.4 Information Contained in a Balanced Equation

Viewed in Terms of	Reactants			Products
	$C_3H_8(g)$	+ $5O_2(g)$	⟶	$3CO_2(g)$ + $4H_2O(g)$
Molecules	1 molecule C_3H_8	+ 5 molecules O_2	⟶	3 molecules CO_2 + 4 molecules H_2O
			⟶	Amount (mol)	1 mol C_3H_8	+ 5 mol O_2	⟶	3 mol CO_2 + 4 mol H_2O
Mass (amu)	44.09 amu C_3H_8	+ 160.00 amu O_2	⟶	132.03 amu CO_2 + 72.06 amu H_2O
Mass (g)	44.09 g C_3H_8	+ 160.00 g O_2	⟶	132.03 g CO_2 + 72.06 g H_2O
Total mass (g)	204.09 g		⟶	204.09 g

*You **cannot** solve this type of problem without the balanced equation.* Here is an approach for solving *any* stoichiometry problem that involves a reaction:

1. Write the balanced equation.
2. When necessary, convert the known mass (or number of entities) of one substance to amount (mol) using its molar mass (or Avogadro's number).
3. Use the molar ratio to calculate the unknown amount (mol) of the other substance.
4. When necessary, convert the amount of that other substance to the desired mass (or number of entities) using its molar mass (or Avogadro's number).

Figure 3.8 summarizes the possible relationships among quantities of substances in a reaction, and Sample Problems 3.14–3.16 apply three of them in the first chemical step of converting copper ore to copper metal.

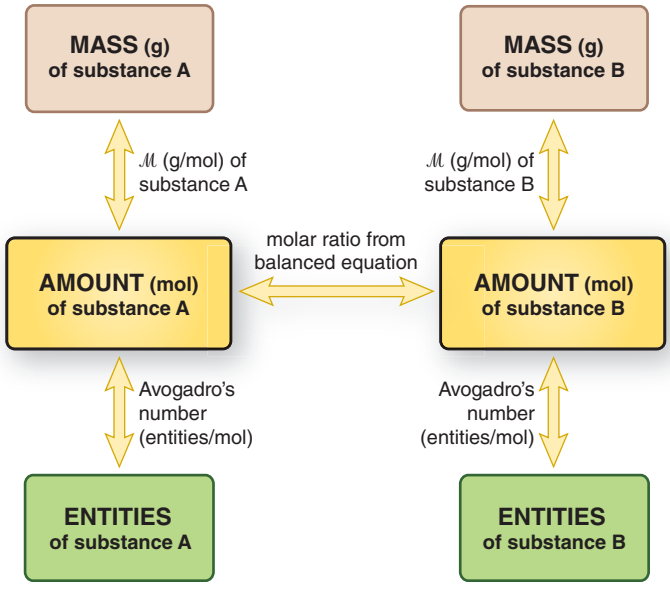

Figure 3.8 Summary of amount-mass-number relationships in a chemical equation. Start at any box (known) and move to any other (unknown) by using the conversion factor on the arrow. As always, convert to amount (mol) first.

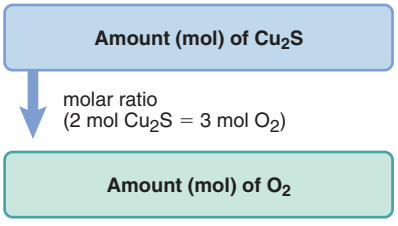
SAMPLE PROBLEM 3.14 Calculating Quantities of Reactants and Products: Amount (mol) to Amount (mol)

Road Map



Problem In a lifetime, the average American uses more than a half ton (>500 kg) of copper in coins, plumbing, and wiring. Copper is obtained from sulfide ores, such as chalcocite [copper(I) sulfide] by a multistep process. After initial grinding, the ore is "roasted" (heated strongly with oxygen gas) to form powdered copper(I) oxide and gaseous sulfur dioxide. How many moles of oxygen are required to roast 10.0 mol of copper(I) sulfide?

Plan We *always* write the balanced equation first. The formulas of the reactants are Cu_2S and O_2, and the formulas of the products are Cu_2O and SO_2, so we have

$$2Cu_2S(s) + 3O_2(g) \longrightarrow 2Cu_2O(s) + 2SO_2(g)$$

We know the amount of Cu_2S (10.0 mol) and must find the amount (mol) of O_2 that is needed to roast it. The balanced equation shows that 3 mol of O_2 is needed for 2 mol of Cu_2S, so the conversion factor for finding amount (mol) of O_2 is "3 mol O_2/2 mol Cu_2S" (see the road map).

Solution Calculating the amount of O_2:

$$\text{Amount (mol) of } O_2 = 10.0 \text{ mol } Cu_2S \times \frac{3 \text{ mol } O_2}{2 \text{ mol } Cu_2S} = 15.0 \text{ mol } O_2$$

Check The units are correct, and the answer is reasonable because this molar ratio of O_2 to Cu_2S (15/10) is identical to the ratio in the balanced equation (3/2).

Comment A *common mistake* is to invert the conversion factor; that calculation would be

$$\text{Amount (mol) of } O_2 = 10.0 \text{ mol } Cu_2S \times \frac{2 \text{ mol } Cu_2S}{3 \text{ mol } O_2} = \frac{6.67 \text{ mol}^2 \text{ } Cu_2S}{1 \text{ mol } O_2}$$

The strange units should alert you that an error was made in setting up the conversion factor. Also note that this answer, 6.67, is *less* than 10.0, whereas the equation shows that there should be *more* moles of O_2 (3 mol) than moles of Cu_2S (2 mol). Be sure to think through the calculation when setting up the conversion factor and canceling units.

FOLLOW-UP PROBLEMS

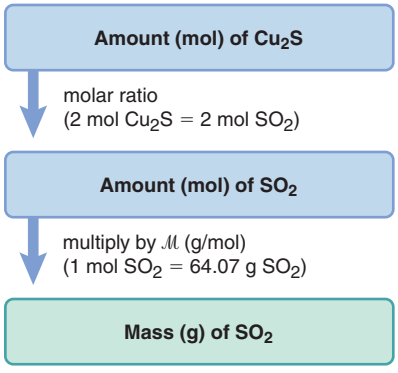
3.14A Thermite is a mixture of iron(III) oxide and aluminum powders that was once used to weld railroad tracks. It undergoes a spectacular reaction to yield solid aluminum oxide and molten iron. How many moles of iron(III) oxide are needed to form 3.60×10^3 mol of iron? Include a road map that shows how you planned the solution.

3.14B The tarnish that forms on objects made of silver is solid silver sulfide; it can be removed by reacting it with aluminum metal to produce silver metal and solid aluminum sulfide. How many moles of aluminum are required to remove 0.253 mol of silver sulfide from a silver bowl? Include a road map that shows how you planned the solution.

A SIMILAR PROBLEM 3.68(a)

SAMPLE PROBLEM 3.15 Calculating Quantities of Reactants and Products: Amount (mol) to Mass (g)

Road Map



Problem During the roasting process, how many grams of sulfur dioxide form when 10.0 mol of copper(I) sulfide reacts?

Plan Referring to the balanced equation in Sample Problem 3.14, here we are given amount of reactant (10.0 mol of Cu_2S) and need the mass (g) of product (SO_2) that forms. We find the amount (mol) of SO_2 using the molar ratio (2 mol SO_2/2 mol Cu_2S) and then multiply by its molar mass (64.07 g/mol) to find the mass (g) of SO_2 (see the road map).

Solution Combining the two conversion steps into one calculation, we have

$$\text{Mass (g) of } SO_2 = 10.0 \text{ mol } Cu_2S \times \frac{2 \text{ mol } SO_2}{2 \text{ mol } Cu_2S} \times \frac{64.07 \text{ g } SO_2}{1 \text{ mol } SO_2} = 641 \text{ g } SO_2$$

Check The answer makes sense, since the molar ratio shows that 10.0 mol of SO_2 is formed and each mole weighs about 64 g. We rounded to three significant figures.

FOLLOW-UP PROBLEMS

3.15A In the thermite reaction (see Follow-up Problem 3.14A), what amount (mol) of iron forms when 1.85×10^{25} formula units of iron(III) oxide reacts? Write a road map to show how to plan the solution.

3.15B In the reaction that removes silver tarnish (see Follow-up Problem 3.14B), how many moles of silver are produced when 32.6 g of silver sulfide reacts? Write a road map to show how you planned the solution.

SOME SIMILAR PROBLEMS 3.68(b), 3.69, 3.70(a), and 3.71(a)

SAMPLE PROBLEM 3.16 Calculating Quantities of Reactants and Products: Mass to Mass

Problem During the roasting of chalcocite, how many kilograms of oxygen are required to form 2.86 kg of copper(I) oxide?

Plan In this problem, we know the mass of the product, Cu_2O (2.86 kg), and we need the mass (kg) of O_2 that reacts to form it. Therefore, we must convert from mass of product to amount of product to amount of reactant to mass of reactant. We convert the mass of Cu_2O from kg to g and then to amount (mol). Then, we use the molar ratio (3 mol O_2/2 mol Cu_2O) to find the amount (mol) of O_2 required. Finally, we convert the amount of O_2 to g and then kg (see the road map).

Solution Converting from kilograms of Cu_2O to moles of Cu_2O: Combining the mass unit conversion with the mass-to-amount conversion gives

$$\text{Amount (mol) of } Cu_2O = 2.86 \text{ kg } Cu_2O \times \frac{10^3 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol } Cu_2O}{143.10 \text{ g } Cu_2O} = 20.0 \text{ mol } Cu_2O$$

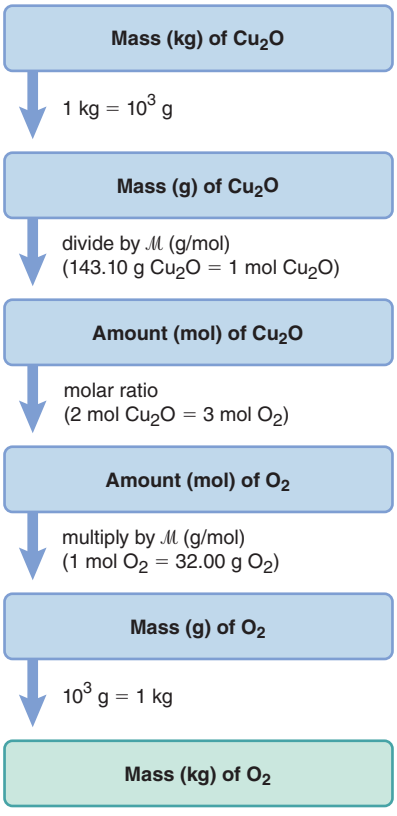
Converting from moles of Cu_2O to moles of O_2:

$$\text{Amount (mol) of } O_2 = 20.0 \text{ mol } Cu_2O \times \frac{3 \text{ mol } O_2}{2 \text{ mol } Cu_2O} = 30.0 \text{ mol } O_2$$

Converting from moles of O_2 to kilograms of O_2: Combining the amount-to-mass conversion with the mass unit conversion gives

$$\text{Mass (kg) of } O_2 = 30.0 \text{ mol } O_2 \times \frac{32.00 \text{ g } O_2}{1 \text{ mol } O_2} \times \frac{1 \text{ kg}}{10^3 \text{ g}} = 0.960 \text{ kg } O_2$$

Road Map



Check The units are correct. Rounding to check the math, for example, in the final step, ~30 mol × 30 g/mol × 1 kg/10^3 g = 0.90 kg. The answer seems reasonable: even though the amount (mol) of O_2 is greater than the amount (mol) of Cu_2O, the mass of O_2 is less than the mass of Cu_2O because $\mathcal{M}$ of O_2 is less than $\mathcal{M}$ of Cu_2O.

Comment The three related sample problems (3.14–3.16) highlight the main point for solving stoichiometry problems: *convert the information given into amount (mol).* Then, use the appropriate molar ratio and any other conversion factors to complete the solution.

FOLLOW-UP PROBLEMS

3.16A During the thermite reaction (see Follow-up Problems 3.14A and 3.15A), how many atoms of aluminum react for every 1.00 g of aluminum oxide that forms? Include a road map that shows how you planned the solution.

3.16B During the reaction that removes silver tarnish (see Follow-up Problems 3.14B and 3.15B), how many grams of aluminum react to form 12.1 g of aluminum sulfide? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 3.70(b), 3.71(b), and 3.72–3.75

Reactions That Occur in a Sequence

In many situations, a product of one reaction becomes a reactant for the next in a sequence of reactions. For stoichiometric purposes, when the same (common) substance forms in one reaction and reacts in the next, we eliminate it in an **overall (net) equation.** The steps in writing the overall equation are

1. Write the sequence of balanced equations.
2. Adjust the equations arithmetically to cancel the common substance(s).
3. Add the adjusted equations together to obtain the overall balanced equation.

Sample Problem 3.17 shows the approach by continuing with the copper recovery process that started in Sample Problem 3.14.

SAMPLE PROBLEM 3.17 Writing an Overall Equation for a Reaction Sequence

Problem Roasting is the first step in extracting copper from chalcocite. In the next step, copper(I) oxide reacts with powdered carbon to yield copper metal and carbon monoxide gas. Write a balanced overall equation for the two-step sequence.

Plan To obtain the overall equation, we write the individual equations in sequence, adjust coefficients to cancel the common substance (or substances), and add the equations together. In this case, only Cu_2O appears as a product in one equation and a reactant in the other, so it is the common substance.

Solution Writing the individual balanced equations:

$$2Cu_2S(s) + 3O_2(g) \longrightarrow 2Cu_2O(s) + 2SO_2(g) \quad [\text{equation 1; see Sample Problem 3.14}]$$
$$Cu_2O(s) + C(s) \longrightarrow 2Cu(s) + CO(g) \quad [\text{equation 2}]$$

Adjusting the coefficients: Since 2 mol of Cu_2O form in equation 1 but 1 mol of Cu_2O reacts in equation 2, we double *all* the coefficients in equation 2 to use up the Cu_2O:

$$2Cu_2S(s) + 3O_2(g) \longrightarrow 2Cu_2O(s) + 2SO_2(g) \quad [\text{equation 1}]$$
$$2Cu_2O(s) + 2C(s) \longrightarrow 4Cu(s) + 2CO(g) \quad [\text{equation 2, doubled}]$$

Adding the two equations and canceling the common substance: We keep the reactants of both equations on the left and the products of both equations on the right:

$$2Cu_2S(s) + 3O_2(g) + \cancel{2Cu_2O(s)} + 2C(s) \longrightarrow \cancel{2Cu_2O(s)} + 2SO_2(g) + 4Cu(s) + 2CO(g)$$

or,
$$2Cu_2S(s) + 3O_2(g) + 2C(s) \longrightarrow 2SO_2(g) + 4Cu(s) + 2CO(g)$$

Check Reactants (4 Cu, 2 S, 6 O, 2 C) ⟶ products (4 Cu, 2 S, 6 O, 2 C)

Comment **1.** Even though Cu_2O *does* participate in the chemical change, it is not involved in the reaction stoichiometry. An overall equation *may not* show which substances actually react; for example, $C(s)$ and $Cu_2S(s)$ do not interact directly in this reaction sequence, even though both are shown as reactants.
2. The SO_2 formed in copper recovery contributes to acid rain, so chemists have devised microbial and electrochemical methods to extract metals without roasting sulfide ores. Such methods are examples of *green chemistry;* we'll discuss another on page 124.
3. These reactions were shown to explain how to obtain an overall equation. The actual extraction of copper is more complex, as you'll see in Chapter 22.

FOLLOW-UP PROBLEMS

3.17A The SO_2 formed in copper recovery reacts in air with oxygen and forms sulfur trioxide. This gas, in turn, reacts with water to form a sulfuric acid solution that falls in rain. Write a balanced overall equation for this process.

3.17B During a lightning strike, nitrogen gas can react with oxygen gas to produce nitrogen monoxide. This gas then reacts with the gas ozone, O_3, to produce nitrogen dioxide gas and oxygen gas. The nitrogen dioxide that is produced is a pollutant in smog. Write a balanced overall equation for this process.

SOME SIMILAR PROBLEMS 3.76 and 3.77

Reaction Sequences in Organisms Multistep reaction sequences called *metabolic pathways* occur throughout biological systems. (We discuss them again in Chapter 17.) For example, in most cells, the chemical energy in glucose is released through a sequence of about 30 individual reactions. The product of each reaction step is the reactant of the next, so that all the common substances cancel, and the overall equation is

$$C_6H_{12}O_6(aq) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(l)$$

We eat food that contains glucose, inhale O_2, and excrete CO_2 and H_2O. In our cells, these reactants and products are many steps apart: O_2 never reacts *directly* with glucose, and CO_2 and H_2O are formed at various, often distant, steps along the sequence of reactions. Even so, the molar ratios in the overall equation are the same as if the glucose burned in a combustion chamber filled with O_2 and formed CO_2 and H_2O directly (Figure 3.9).

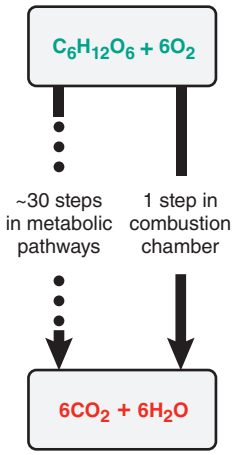


Figure 3.9 **An overall equation equals the sum of the individual steps.**

Reactions That Involve a Limiting Reactant

In problems up to now, the amount of *one* reactant was given, and we assumed there was enough of the other reactants to react with it completely. For example, suppose we want the amount (mol) of SO_2 that forms when 5.2 mol of Cu_2S reacts with O_2:

$$2Cu_2S(s) + 3O_2(g) \longrightarrow 2Cu_2O(s) + 2SO_2(g) \text{ [equation 1; see Sample Problem 3.14]}$$

We assume the 5.2 mol of Cu_2S reacts with as much O_2 as needed. Because all the Cu_2S reacts, its initial amount of 5.2 mol determines, or *limits,* the amount of SO_2 that can form, no matter how much more O_2 is present. In this situation, we call Cu_2S the **limiting reactant** (or *limiting reagent*).

Suppose, however, you know the amounts of both Cu_2S *and* O_2 and need to find out how much SO_2 forms. You first have to determine whether Cu_2S *or* O_2 is the limiting reactant—that is, which one is completely used up—because that reactant limits how much SO_2 can form. The reactant that is *not* limiting is present *in excess,* which means the amount that doesn't react is left over. ❯ To determine which is the limiting reactant, we use the molar ratios in the balanced equation to perform a series of calculations to see *which reactant forms* ***less*** *product*.

Determining the Limiting Reactant Let's clarify these ideas in a much more appetizing situation. Suppose you have a job making ice cream sundaes. Each sundae requires two scoops (12 oz) of ice cream, one cherry, and 50 mL of syrup:

$$2 \text{ scoops (12 oz)} + 1 \text{ cherry} + 50 \text{ mL syrup} \longrightarrow 1 \text{ sundae}$$

A mob of 25 ravenous school kids enters, and each one wants a sundae with vanilla ice cream and chocolate syrup. You have 300 oz of vanilla ice cream (at 6 oz per scoop), 30 cherries, and 1 L of syrup: can you feed them all? A series of calculations based on the balanced equation shows the number of sundaes you can make from each ingredient:

$$\text{Ice cream: No. of sundaes} = 300 \cancel{\text{oz}} \times \frac{1 \cancel{\text{scoop}}}{6 \cancel{\text{oz}}} \times \frac{1 \text{ sundae}}{2 \cancel{\text{scoops}}} = 25 \text{ sundaes}$$

$$\text{Cherries: No. of sundaes} = 30 \cancel{\text{cherries}} \times \frac{1 \text{ sundae}}{1 \cancel{\text{cherry}}} = 30 \text{ sundaes}$$

$$\text{Syrup: No. of sundaes} = 1000 \cancel{\text{mL syrup}} \times \frac{1 \text{ sundae}}{50 \cancel{\text{mL syrup}}} = 20 \text{ sundaes}$$

Of the reactants (ice cream, cherry, syrup), the syrup forms the *least* product (sundaes), so it is the limiting "reactant." When all the syrup has been used up, some ice cream and cherries are "unreacted" so they are in excess:

$$300 \text{ oz (50 scoops)} + 30 \text{ cherries} + 1 \text{ L syrup} \longrightarrow \mathbf{20 \text{ sundaes}} + 60 \text{ oz (10 scoops)} + 10 \text{ cherries}$$

Figure 3.10 on the next page shows a similar example with different initial (starting) quantities.

Limiting "Reactants" in Everyday Life

Limiting-"reactant" situations arise in business all the time. A car assembly-plant manager must order more tires if there are 1500 car bodies and only 4000 tires, and a clothes manufacturer must cut more sleeves if there are 320 sleeves for 170 shirt bodies. You've probably faced such situations in daily life as well. A muffin recipe calls for 2 cups of flour and 1 cup of sugar, but you have 3 cups of flour and only $\frac{3}{4}$ cup of sugar. Clearly, the flour is in excess and the sugar limits the number of muffins you can make. Or, you're in charge of making cheeseburgers for a picnic, and you have 10 buns, 12 meat patties, and 15 slices of cheese. Here, the number of buns limits how many cheeseburgers you can make. Or, there are 26 students and only 23 microscopes in a cell biology lab. You'll find that limiting-"reactant" situations are almost limitless.

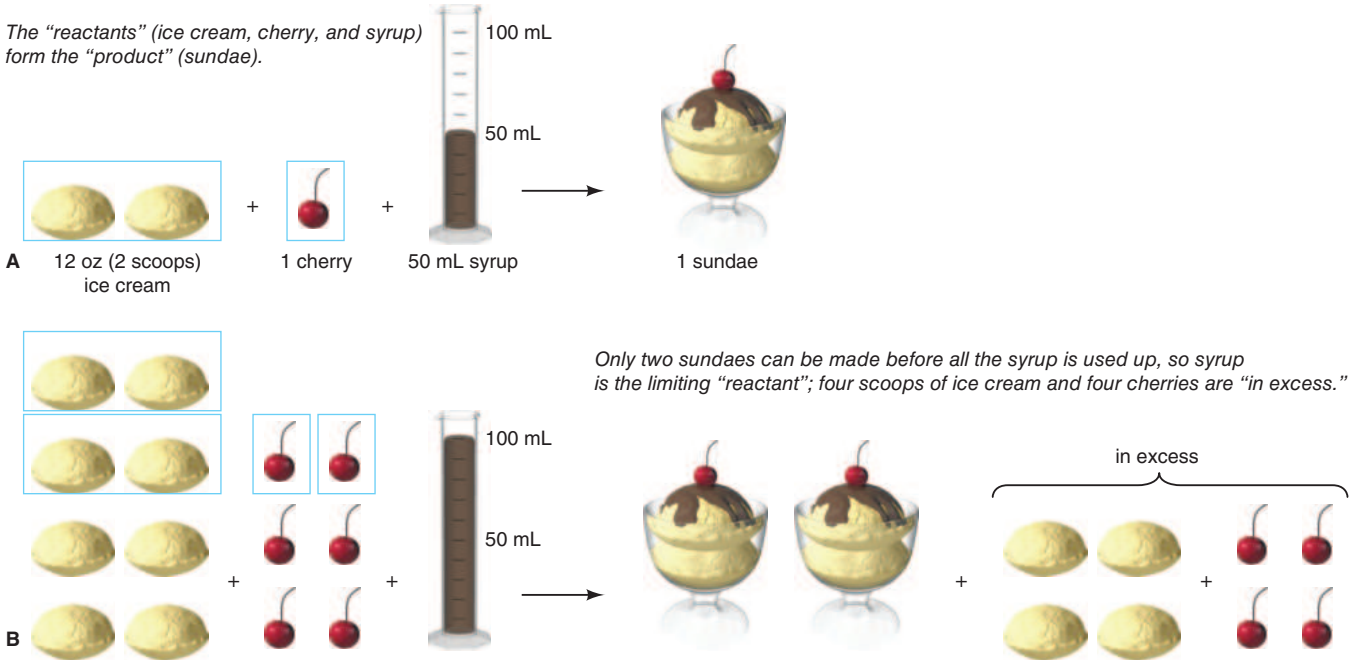

Figure 3.10 An ice cream sundae analogy for limiting reactants.

Using Reaction Tables in Limiting-Reactant Problems A good way to keep track of the quantities in a limiting-reactant problem is with a *reaction table*. The balanced equation appears at the top for the column heads. The table shows the

- *Initial* quantities of reactants and products *before* the reaction
- *Change* in the quantities of reactants and products *during* the reaction
- *Final* quantities of reactants and products remaining *after* the reaction

For example, for the ice-cream sundae "reaction," the reaction table would be

Quantity	12 oz (2 scoops)	+	1 cherry	+	50 mL syrup	⟶	1 sundae
Initial	300 oz (50 scoops)		30 cherries		1000 mL syrup		0 sundaes
Change	−240 oz (40 scoops)		−20 cherries		−1000 mL syrup		+20 sundaes
Final	60 oz (10 scoops)		10 cherries		0 mL syrup		20 sundaes

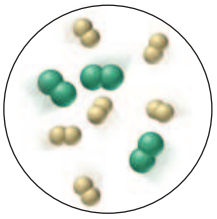
The body of the table shows the following important points:

- In the **Initial** line, "product" has not yet formed, so the entry is "0 sundaes."
- In the **Change** line, since the reactants (ice cream, cherries, and syrup) are used during the reaction, their quantities decrease, so the changes in their quantities have a *negative* sign. At the same time, the quantity of product (sundaes) increases, so the change in its quantity has a *positive* sign.
- For the **Final** line, we *add* the Change and Initial lines. Notice that some reactants (ice cream and cherries) are in excess, while the limiting reactant (syrup) is used up.

Solving Limiting-Reactant Problems In limiting-reactant problems, *the amounts of two (or more) reactants are given, and we first determine which is limiting*. To do this, just as we did with the ice cream sundaes, we use the balanced equation to solve a series of calculations to see how much product forms from the given amount of each reactant: the limiting reactant is the one that yields the *least* amount of product.

The following problems examine these ideas from several aspects. In Sample Problem 3.18, we solve the problem by looking at a molecular scene; in Sample Problem 3.19, we start with the amounts (mol) of two reactants; and in Sample Problem 3.20, we start with masses of two reactants.

SAMPLE PROBLEM 3.18 Using Molecular Depictions in a Limiting-Reactant Problem



Problem Nuclear engineers use chlorine trifluoride to prepare uranium fuel for power plants. The compound is formed as a gas by the reaction of elemental chlorine and fluorine. The circle in the margin shows a representative portion of the reaction mixture before the reaction starts (chlorine is *green;* fluorine is *yellow*).
(a) Find the limiting reactant.
(b) Write a reaction table for the process.
(c) Draw a representative portion of the mixture after the reaction is complete. (*Hint:* The ClF_3 molecule has Cl bonded to three individual F atoms.)

Plan **(a)** We have to find the limiting reactant. The first step is to write the balanced equation, so we need the formulas and states of matter. From the name, chlorine trifluoride, we know the product consists of one Cl atom bonded to three F atoms, or ClF_3. Elemental chlorine and fluorine are the diatomic molecules Cl_2 and F_2, and all three substances are gases. To find the limiting reactant, we find the number of molecules of product that would form from the numbers of molecules of each reactant: whichever forms less product is the limiting reactant. **(b)** We use these numbers of molecules to write a reaction table. **(c)** We use the numbers in the Final line of the table to draw the scene.

Solution **(a)** The balanced equation is

$$Cl_2(g) + 3F_2(g) \longrightarrow 2ClF_3(g)$$

$$\text{For } Cl_2\text{: Molecules of } ClF_3 = 3 \text{ molecules of } Cl_2 \times \frac{2 \text{ molecules of } ClF_3}{1 \text{ molecule of } Cl_2}$$

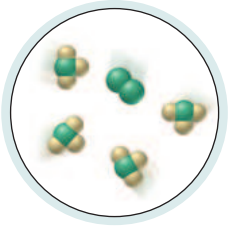
$$= 6 \text{ molecules of } ClF_3$$

$$\text{For } F_2\text{: Molecules of } ClF_3 = 6 \text{ molecules of } F_2 \times \frac{2 \text{ molecules of } ClF_3}{3 \text{ molecules of } F_2}$$

$$= \tfrac{12}{3} \text{ molecules of } ClF_3 = 4 \text{ molecules of } ClF_3$$

Because it forms less product, F_2 is the limiting reactant.
(b) Since F_2 is the limiting reactant, all of it (6 molecules) is used in the Change line of the reaction table:

Molecules	$Cl_2(g)$	+	$3F_2(g)$	⟶	$2ClF_3(g)$
Initial	3		6		0
Change	−2		−6		+4
Final	1		0		4

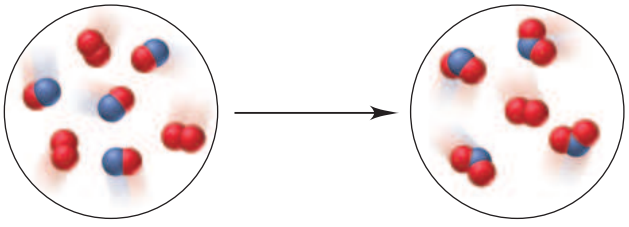


(c) The representative portion of the final reaction mixture *(see margin)* includes 1 molecule of Cl_2 (the reactant in excess) and 4 molecules of product ClF_3.

Check The equation is balanced: reactants (2 Cl, 6 F) ⟶ products (2 Cl, 6 F). And, as shown in the circles, the numbers of each type of atom before and after the reaction are equal. Let's think through our choice of limiting reactant. From the equation, one Cl_2 needs three F_2 to form two ClF_3. Therefore, the three Cl_2 molecules in the circle depicting reactants need nine (3×3) F_2. But there are only six F_2, so there is not enough F_2 to react with the available Cl_2; or put the other way, there is too much Cl_2 to react with the available F_2. From either point of view, F_2 is the limiting reactant.

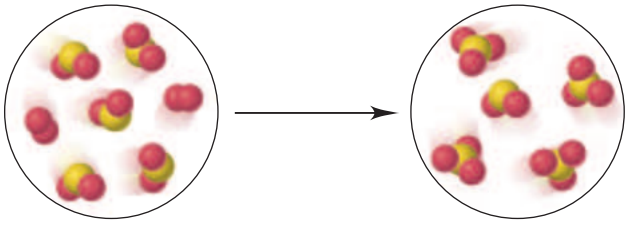
FOLLOW-UP PROBLEMS

3.18A B_2 (B is *red*) reacts with AB as shown below:



Write a balanced equation for the reaction, and determine the limiting reactant.

3.18B Sulfur dioxide gas reacts with oxygen gas to produce sulfur trioxide, as shown below (sulfur is *yellow*; oxygen is *red*):



Write a balanced equation for the reaction, and determine the limiting reactant.

A SIMILAR PROBLEM 3.64

SAMPLE PROBLEM 3.19 Calculating Quantities in a Limiting-Reactant Problem: Amount to Amount

Problem In another preparation of ClF_3 (see Sample Problem 3.18), 0.750 mol of Cl_2 reacts with 3.00 mol of F_2. **(a)** Find the limiting reactant. **(b)** Write a reaction table.

Plan **(a)** We find the limiting reactant by calculating the amount (mol) of ClF_3 formed from the amount (mol) of each reactant: the reactant that forms fewer moles of ClF_3 is limiting. **(b)** We enter those values into the reaction table.

Solution **(a)** Determining the limiting reactant:
Finding amount (mol) of ClF_3 from amount (mol) of Cl_2:

$$\text{Amount (mol) of } ClF_3 = 0.750 \text{ mol } \cancel{Cl_2} \times \frac{2 \text{ mol } ClF_3}{1 \text{ mol } \cancel{Cl_2}} = 1.50 \text{ mol } ClF_3$$

Finding amount (mol) of ClF_3 from amount (mol) of F_2:

$$\text{Amount (mol) of } ClF_3 = 3.00 \text{ mol } \cancel{F_2} \times \frac{2 \text{ mol } ClF_3}{3 \text{ mol } \cancel{F_2}} = 2.00 \text{ mol } ClF_3$$

In this case, Cl_2 is limiting because it forms fewer moles of ClF_3.
(b) Writing the reaction table, with Cl_2 limiting:

Amount (mol)	$Cl_2(g)$	+	$3F_2(g)$	⟶	$2ClF_3(g)$
Initial	0.750		3.00		0
Change	−0.750		−2.25		+1.50
Final	0		0.75		1.50

Check Let's check that Cl_2 is the limiting reactant by assuming, for the moment, that F_2 is limiting. If that were true, all 3.00 mol of F_2 would react to form 2.00 mol of ClF_3. However, based on the balanced equation, obtaining 2.00 mol of ClF_3 would require 1.00 mol of Cl_2, and only 0.750 mol of Cl_2 is present. Thus, Cl_2 must be the limiting reactant.

Comment A major point to note from Sample Problems 3.18 and 3.19 is that the relative amounts of reactants *do not* determine which is limiting, but rather the amount of product formed, which is based on the *molar ratio in the balanced equation*. In both problems, there is more F_2 than Cl_2. However,

- Sample Problem 3.18 has an F_2/Cl_2 ratio of 6/3, or 2/1, which is less than the required molar ratio of 3/1, so F_2 is limiting and Cl_2 is in excess.
- Sample Problem 3.19 has an F_2/Cl_2 ratio of 3.00/0.750, which is greater than the required molar ratio of 3/1, so Cl_2 is limiting and F_2 is in excess.

FOLLOW-UP PROBLEMS

3.19A In the reaction in Follow-up Problem 3.18A, how many moles of product form from 1.5 mol of each reactant?

3.19B In the reaction in Follow-up Problem 3.18B, 4.2 mol of SO_2 reacts with 3.6 mol of O_2. How many moles of SO_3 are produced?

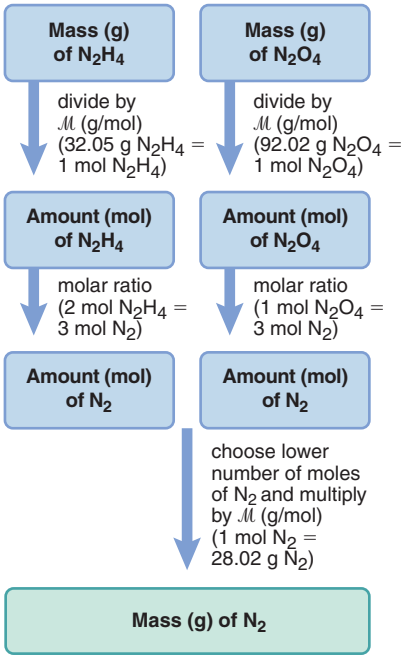
A SIMILAR PROBLEM 3.110

SAMPLE PROBLEM 3.20 Calculating Quantities in a Limiting-Reactant Problem: Mass to Mass

Problem A fuel mixture used in the early days of rocketry consisted of two liquids, hydrazine (N_2H_4) and dinitrogen tetroxide (N_2O_4), which ignite on contact to form nitrogen gas and water vapor.
(a) How many grams of nitrogen gas form when 1.00×10^2 g of N_2H_4 and 2.00×10^2 g of N_2O_4 are mixed?
(b) How many grams of the excess reactant remain unreacted when the reaction is over?
(c) Write a reaction table for this process.

Plan The amounts of two reactants are given, which means this is a limiting-reactant problem. **(a)** To determine the mass of product formed, we must find the limiting reactant by calculating which of the given masses of reactant forms *less* nitrogen gas. As always, we first write the balanced equation. We convert the grams of each reactant to moles using its molar mass and then use the molar ratio from the balanced equation to find the number of moles of N_2 each reactant forms. Next, we convert the lower amount of N_2 to mass (see the road map). **(b)** To determine the mass of excess reactant, we use the molar ratio to calculate the mass of excess reactant that is required to react with the given amount of the limiting reactant. We subtract that mass from the given amount of excess reactant; this difference is the mass of unreacted excess reactant.
(c) We use the values based on the limiting reactant for the reaction table.

Road Map



Solution **(a)** Writing the balanced equation:

$$2N_2H_4(l) + N_2O_4(l) \longrightarrow 3N_2(g) + 4H_2O(g)$$

Finding the amount (mol) of N_2 from the amount (mol) of each reactant

For N_2H_4: $$\text{Amount (mol) of } N_2H_4 = 1.00\times10^2 \text{ g } N_2H_4 \times \frac{1 \text{ mol } N_2H_4}{32.05 \text{ g } N_2H_4} = 3.12 \text{ mol } N_2H_4$$

$$\text{Amount (mol) of } N_2 = 3.12 \text{ mol } N_2H_4 \times \frac{3 \text{ mol } N_2}{2 \text{ mol } N_2H_4} = 4.68 \text{ mol } N_2$$

For N_2O_4: $$\text{Amount (mol) of } N_2O_4 = 2.00\times10^2 \text{ g } N_2O_4 \times \frac{1 \text{ mol } N_2O_4}{92.02 \text{ g } N_2O_4} = 2.17 \text{ mol } N_2O_4$$

$$\text{Amount (mol) of } N_2 = 2.17 \text{ mol } N_2O_4 \times \frac{3 \text{ mol } N_2}{1 \text{ mol } N_2O_4} = 6.51 \text{ mol } N_2$$

Thus, N_2H_4 is the limiting reactant because it yields less N_2.
Converting from amount (mol) of N_2 to mass (g):

$$\text{Mass (g) of } N_2 = 4.68 \text{ mol } N_2 \times \frac{28.02 \text{ g } N_2}{1 \text{ mol } N_2} = 131 \text{ g } N_2$$

(b) Finding the mass (g) of N_2O_4 that reacts with 1.00×10^2 g of N_2H_4:

$$\text{Mass (g) of } N_2O_4 = 1.00\times10^2 \text{ g } N_2H_4 \times \frac{1 \text{ mol } N_2H_4}{32.05 \text{ g } N_2H_4} \times \frac{1 \text{ mol } N_2O_4}{2 \text{ mol } N_2H_4} \times \frac{92.02 \text{ g } N_2O_4}{1 \text{ mol } N_2O_4}$$

$$= 144 \text{ g } N_2O_4$$

$$\text{Mass (g) of } N_2O_4 \text{ in excess} = \text{initial mass of } N_2O_4 - \text{mass of } N_2O_4 \text{ reacted}$$
$$= 2.00\times10^2 \text{ g } N_2O_4 - 144 \text{ g } N_2O_4 = 56 \text{ g } N_2O_4$$

(c) With N_2H_4 as the limiting reactant, the reaction table is

Amount (mol)	$2N_2H_4(l)$	+	$N_2O_4(l)$	$\longrightarrow$	$3N_2(g)$	+	$4H_2O(g)$
Initial	3.12		2.17		0		0
Change	−3.12		−1.56		+4.68		+6.24
Final	0		0.61		4.68		6.24

Check There are more grams of N_2O_4 than N_2H_4, but there are fewer moles of N_2O_4 because its $\mathcal{M}$ is much higher. Rounding for N_2H_4: 100 g N_2H_4 × 1 mol/32 g ≈ 3 mol; ~3 mol × $\frac{3}{2}$ ≈ 4.5 mol N_2; ~4.5 mol × 30 g/mol ≈ 135 g N_2.

Comment **1.** Recall this *common mistake* in solving limiting-reactant problems: The limiting reactant is not the *reactant* present in fewer moles (or grams). Rather, it is the reactant that forms fewer moles (or grams) of *product.*

2. An *alternative approach* to finding the limiting reactant compares "How much is needed?" with "How much is given?" That is, based on the balanced equation,

- Find the amount (mol) of each reactant needed to react with the other reactant.
- Compare that *needed* amount with the *given* amount in the problem statement. There will be *more* than enough of one reactant (excess) and *less* than enough of the other (limiting).

For example, the balanced equation for this problem shows that 2 mol of N_2H_4 reacts with 1 mol of N_2O_4. The amount (mol) of N_2O_4 needed to react with the given 3.12 mol of N_2H_4 is

$$\text{Amount (mol) of } N_2O_4 \text{ needed} = 3.12 \cancel{\text{ mol } N_2H_4} \times \frac{1 \text{ mol } N_2O_4}{2 \cancel{\text{ mol } N_2H_4}} = 1.56 \text{ mol } N_2O_4$$

The amount of N_2H_4 needed to react with the given 2.17 mol of N_2O_4 is

$$\text{Amount (mol) of } N_2H_4 \text{ needed} = 2.17 \cancel{\text{ mol } N_2O_4} \times \frac{2 \text{ mol } N_2H_4}{1 \cancel{\text{ mol } N_2O_4}} = 4.34 \text{ mol } N_2H_4$$

We are given 2.17 mol of N_2O_4, which is *more* than the 1.56 mol of N_2O_4 needed, and we are given 3.12 mol of N_2H_4, which is *less* than the 4.34 mol of N_2H_4 needed. Therefore, N_2H_4 is limiting, and N_2O_4 is in excess.

FOLLOW-UP PROBLEMS

3.20A How many grams of solid aluminum sulfide can be prepared by the reaction of 10.0 g of aluminum and 15.0 g of sulfur? How many grams of the nonlimiting reactant are in excess?

3.20B Butane gas (C_4H_{10}) is used as the fuel in disposable lighters. It burns in oxygen to form carbon dioxide gas and water vapor. What mass of carbon dioxide is produced when 4.65 g of butane is burned in 10.0 g of oxygen? How many grams of the excess reactant remain unreacted when the reaction is over?

SOME SIMILAR PROBLEMS 3.78–3.83

Figure 3.11 provides an overview of all of the stoichiometric relationships we've discussed in this chapter.

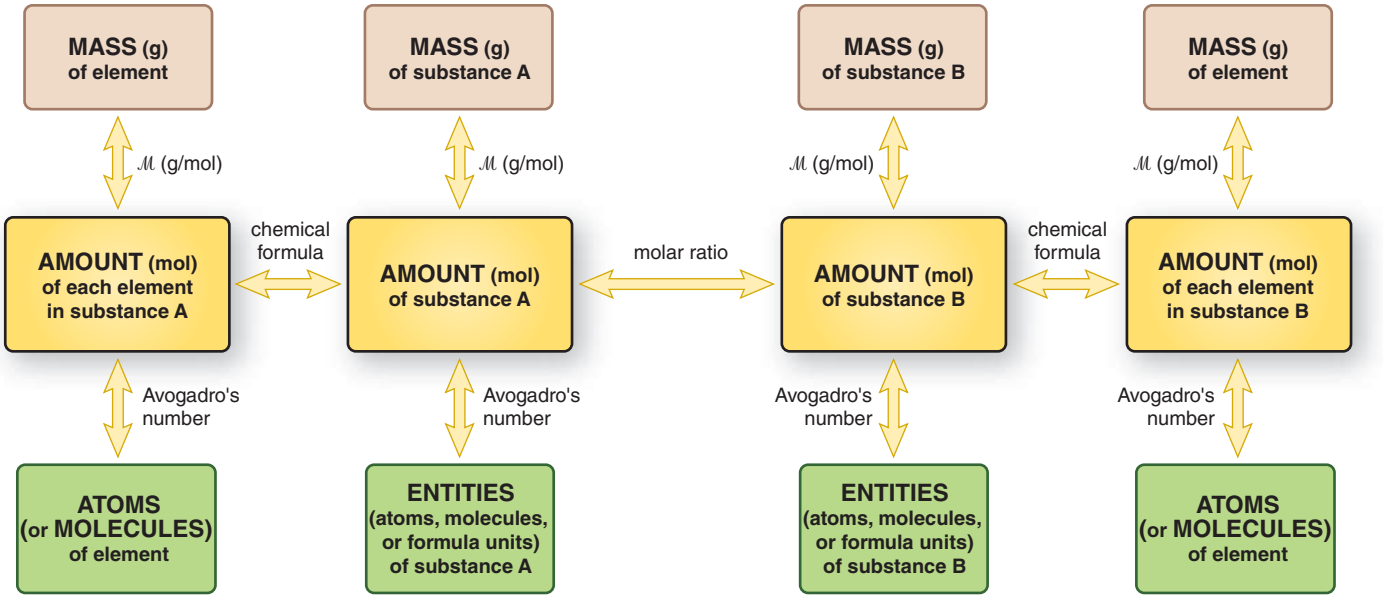


Figure 3.11 An overview of amount-mass-number stoichiometric relationships.

Theoretical, Actual, and Percent Reaction Yields

Up until now, we've assumed that 100% of the limiting reactant becomes product, that ideal methods exist for isolating the product, and that we have perfect lab technique and collect all the product. In theory, this may happen, but in reality, it doesn't, and chemists recognize three types of reaction yield:

1. *Theoretical yield.* The amount of product calculated from the molar ratio in the balanced equation is the **theoretical yield.** But, there are several reasons why the theoretical yield is *never* obtained:
   - Reactant mixtures often proceed through **side reactions** that form different products (Figure 3.12). In the rocket fuel reaction in Sample Problem 3.20, for example, the reactants might form some NO in the following side reaction:
     $$N_2H_4(l) + 2N_2O_4(l) \longrightarrow 6NO(g) + 2H_2O(g)$$
     This reaction decreases the amounts of reactants available for N_2 production.
   - Even more important, many reactions seem to stop before they are complete, so some limiting reactant is unused. (We'll see why in Chapter 4.)
   - Physical losses occur in every step of a separation (see Tools of the Laboratory, Section 2.9): some solid clings to filter paper, some distillate evaporates, and so forth. With careful technique, you can minimize, but never eliminate, such losses.
2. *Actual yield.* Given these reasons for obtaining less than the theoretical yield, the amount of product actually obtained is the **actual yield.** Theoretical and actual yields are expressed in units of amount (moles) or mass (grams).
3. *Percent yield.* The **percent yield (% yield)** is the actual yield expressed as a percentage of the theoretical yield:
   $$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100 \qquad (3.8)$$
   By definition, the actual yield is less than the theoretical yield, so the percent yield is *always* less than 100%.

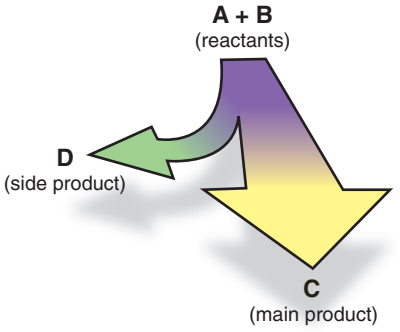

Figure 3.12 The effect of a side reaction on the yield of the main product.

SAMPLE PROBLEM 3.21 Calculating Percent Yield

Problem Silicon carbide (SiC) is an important ceramic material made by reacting sand (silicon dioxide, SiO_2) with powdered carbon at a high temperature. Carbon monoxide is also formed. When 100.0 kg of sand is processed, 51.4 kg of SiC is recovered. What is the percent yield of SiC from this process?

Plan We are given the actual yield of SiC (51.4 kg), so we need the theoretical yield to calculate the percent yield. After writing the balanced equation, we convert the given mass of SiO_2 (100.0 kg) to amount (mol). We use the molar ratio to find the amount of SiC formed and convert it to mass (kg) to obtain the theoretical yield. Then, we use Equation 3.8 to find the percent yield (see the road map).

Solution Writing the balanced equation:

$$SiO_2(s) + 3C(s) \longrightarrow SiC(s) + 2CO(g)$$

Converting from mass (kg) of SiO_2 to amount (mol):

$$\text{Amount (mol) of } SiO_2 = 100.0 \text{ kg } SiO_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol } SiO_2}{60.09 \text{ g } SiO_2} = 1664 \text{ mol } SiO_2$$

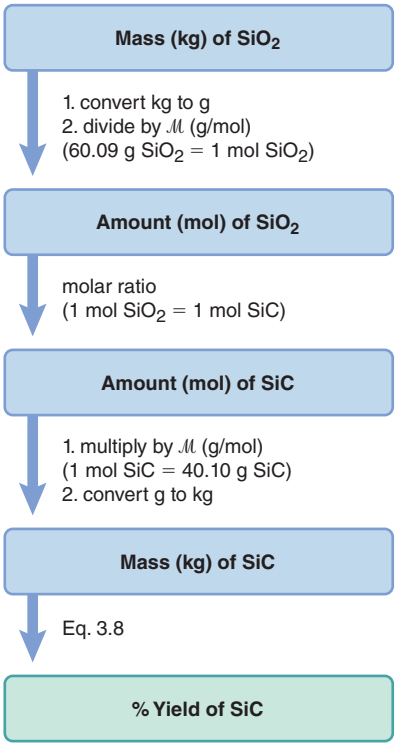
Converting from amount (mol) of SiO_2 to amount (mol) of SiC: The molar ratio is 1 mol SiC/1 mol SiO_2, so

$$\text{Amount (mol) of } SiO_2 = \text{moles of SiC} = 1664 \text{ mol SiC}$$

Converting from amount (mol) of SiC to mass (kg):

$$\text{Mass (kg) of SiC} = 1664 \text{ mol SiC} \times \frac{40.10 \text{ g SiC}}{1 \text{ mol SiC}} \times \frac{1 \text{ kg}}{1000 \text{ g}} = 66.73 \text{ kg SiC}$$

Road Map



Calculating the percent yield:

$$\%\ \text{yield of SiC} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100 = \frac{51.4\ \cancel{\text{kg SiC}}}{66.73\ \cancel{\text{kg SiC}}} \times 100 = \boxed{77.0\%}$$

Check Rounding shows that the mass of SiC seems correct: ~1500 mol × 40 g/mol × 1 kg/1000 g = 60 kg. The molar ratio of SiC/SiO_2 is 1/1, and $\mathcal{M}$ of SiC is about two-thirds ($\sim\frac{40}{60}$) of $\mathcal{M}$ of SiO_2, so 100 kg of SiO_2 should form about 66 kg of SiC.

FOLLOW-UP PROBLEMS

3.21A Marble (calcium carbonate) reacts with hydrochloric acid solution to form calcium chloride solution, water, and carbon dioxide. Find the percent yield of carbon dioxide if 3.65 g is collected when 10.0 g of marble reacts.

3.21B Sodium carbonate, also known as *soda ash,* is used in glassmaking. It is obtained from a reaction between sodium chloride and calcium carbonate; calcium chloride is the other product. Calculate the percent yield of sodium carbonate if 92.6 g is collected when 112 g of sodium chloride reacts with excess calcium carbonate.

SOME SIMILAR PROBLEMS 3.88–3.91

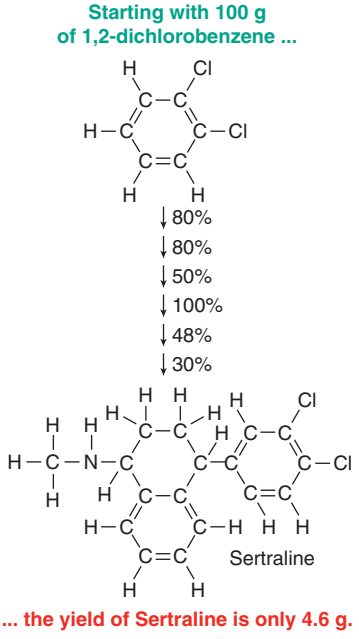


Figure 3.13 Low overall yield in a multistep synthesis.

Yields in Multistep Syntheses In the multistep synthesis of a complex compound, the overall yield can be surprisingly low, even if the yield of each step is high. For example, suppose a six-step synthesis has a 90.0% yield for each step. To find the overall percent yield, *express the yield of each step as a decimal, multiply all the decimal amounts together, and then convert back to a percentage*. The overall recovery is only slightly more than 50%:

$$\text{Overall \% yield} = (0.900 \times 0.900 \times 0.900 \times 0.900 \times 0.900 \times 0.900) \times 100 = 53.1\%$$

Such multistep sequences are common in laboratory syntheses of medicines, dyes, pesticides, and many other organic compounds. For example, the antidepressant Sertraline is prepared from a simple starting compound in six steps, with yields of 80%, 80%, 50%, 100%, 48%, and 30%, respectively, and an overall percent yield of only 4.6% (Figure 3.13). Because a typical synthesis begins with large amounts of inexpensive, simple reactants and ends with small amounts of expensive, complex products, the overall yield greatly influences the commercial potential of a product.

Atom Economy: A Green Chemistry Perspective on Yield In the relatively new field of **green chemistry,** academic, industrial, and government chemists develop methods that reduce or prevent the release of harmful substances into the environment and the wasting of energy resources.

One way that green chemists evaluate a synthetic route is to focus on its *atom economy,* the proportion of reactant atoms that end up in the desired product. The efficiency of a synthesis is quantified in terms of the *percent atom economy:*

$$\%\ \text{atom economy} = \frac{\text{no. of moles} \times \text{molar mass of desired product}}{\text{sum of (no. of moles} \times \text{molar mass) for all products}} \times 100$$

Consider two synthetic routes—one starting with benzene (C_6H_6), the other with butane (C_4H_{10})—for the production of maleic anhydride ($C_4H_2O_3$), a key substance in the manufacture of polymers, dyes, medicines, pesticides, and other products:

Route 1. $2C_6H_6(l) + 9O_2(g) \rightarrow \cdots \rightarrow 2C_4H_2O_3(l) + 4H_2O(l) + 4CO_2(g)$

Route 2. $2C_4H_{10}(g) + 7O_2(g) \rightarrow \cdots \rightarrow 2C_4H_2O_3(l) + 8H_2O(l)$

Let's compare the efficiency of these routes in terms of percent atom economy:

Route 1:

$$\%\ \text{atom economy} = \frac{2 \times \mathcal{M}\ \text{of}\ C_4H_2O_3}{(2 \times \mathcal{M}\ \text{of}\ C_4H_2O_3) + (4 \times \mathcal{M}\ \text{of}\ H_2O) + (4 \times \mathcal{M}\ \text{of}\ CO_2)} \times 100$$

$$= \frac{2 \times 98.06\ \cancel{g}}{(2 \times 98.06\ \cancel{g}) + (4 \times 18.02\ \cancel{g}) + (4 \times 44.01\ \cancel{g})} \times 100$$

$$= 44.15\%$$

Route 2:

$$\% \text{ atom economy} = \frac{2 \times \mathcal{M} \text{ of } C_4H_2O_3}{(2 \times \mathcal{M} \text{ of } C_4H_2O_3) + (8 \times \mathcal{M} \text{ of } H_2O)} \times 100$$

$$= \frac{2 \times 98.06\ \cancel{g}}{(2 \times 98.06\ \cancel{g}) + (8 \times 18.02\ \cancel{g})} \times 100$$

$$= 57.63\%$$

From the perspective of atom economy, route 2 is preferable because a larger percentage of reactant atoms end up in the desired product. It is also a "greener" approach than route 1 because it avoids the use of the toxic reactant benzene and does not produce CO_2, a gas that contributes to global warming.

Summary of Section 3.4

- The substances in a balanced equation are related to each other by stoichiometrically equivalent molar ratios, which are used as conversion factors to find the amount (mol) of one substance given the amount of another.
- In limiting-reactant problems, the quantities of two (or more) reactants are given, and the limiting reactant is the one that forms the lower quantity of product. Reaction tables show the initial and final quantities of all reactants and products, as well as the changes in those quantities.
- In practice, side reactions, incomplete reactions, and physical losses result in an actual yield of product that is less than the theoretical yield (the quantity based on the molar ratio from the balanced equation), giving a percent yield less than 100%. In multistep reaction sequences, the overall yield is found by multiplying the yields for each step.
- Atom economy, or the proportion of reactant atoms found in the product, is one criterion for choosing a "greener" reaction process.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The definition of the mole unit (§3.1)
2. Relation between the mass of a chemical entity (in amu) and the mass of a mole of that entity (in g) (§3.1)
3. The relations among amount of substance (in mol), mass (in g), and number of chemical entities (§3.1)
4. Mole-mass-number information in a chemical formula (§3.1)
5. The difference between empirical and molecular formulas of a compound (§3.2)
6. How more than one substance can have the same empirical formula and the same molecular formula (isomers) (§3.2)
7. The importance of balancing equations for the quantitative study of chemical reactions (§3.3)
8. Mole-mass-number information in a balanced equation (§3.4)
9. The relation between amounts of reactants and amounts of products (§3.4)
10. Why one reactant limits the amount of product (§3.4)
11. The causes of lower-than-expected yields and the distinction between theoretical and actual yields (§3.4)

Master These Skills

1. Calculating the molar mass of any substance (§3.1; SPs 3.4–3.6)
2. Converting between amount of substance (in moles), mass (in grams), and number of chemical entities (SPs 3.1–3.5)
3. Using mass percent to find the mass of an element in a given mass of compound (SPs 3.6, 3.7)
4. Determining empirical and molecular formulas of a compound from mass percents and molar masses of elements (SPs 3.8–3.10)
5. Determining a molecular formula from combustion analysis (SP 3.11)
6. Converting a chemical statement or a molecular depiction into a balanced equation (SPs 3.12, 3.13)
7. Using stoichiometrically equivalent molar ratios to convert between amounts of reactants and products in reactions (SPs 3.14–3.16)
8. Writing an overall equation from a series of equations (SP 3.17)
9. Solving limiting-reactant problems for reactions (SPs 3.18–3.20)
10. Calculating percent yield (SP 3.21)

Key Terms

Page numbers appear in parentheses.

side reaction (123)
actual yield (123)
percent yield (% yield) (123)
green chemistry (124)

Key Equations and Relationships

Page numbers appear in parentheses.

3.1 Number of entities in one mole (92):

1 mol contains 6.022×10^{23} entities (to 4 sf)

3.2 Converting amount (mol) to mass (g) using $\mathcal{M}$ (93):

$$\text{Mass (g)} = \text{amount (mol)} \times \frac{\text{no. of grams}}{1\ \text{mol}}$$

3.3 Converting mass (g) to amount (mol) using $1/\mathcal{M}$ (94):

$$\text{Amount (mol)} = \text{mass (g)} \times \frac{1\ \text{mol}}{\text{no. of grams}}$$

3.4 Converting amount (mol) to number of entities (94):

$$\text{No. of entities} = \text{amount (mol)} \times \frac{6.022\times10^{23}\ \text{entities}}{1\ \text{mol}}$$

3.5 Converting number of entities to amount (mol) (94):

$$\text{Amount (mol)} = \text{no. of entities} \times \frac{1\ \text{mol}}{6.022\times10^{23}\ \text{entities}}$$

3.6 Calculating mass % (98):

$$\text{Mass \% of element X} = \frac{\text{moles of X in formula} \times \text{molar mass of X (g/mol)}}{\text{mass (g) of 1 mol of compound}} \times 100$$

3.7 Finding the mass of an element in any mass of compound (99):

$$\text{Mass of element} = \text{mass of compound} \times \frac{\text{mass of element in 1 mol of compound}}{\text{mass of 1 mol of compound}}$$

3.8 Calculating percent yield (123):

$$\%\ \text{yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

3.1A $$\text{Amount (mol) of C} = 315\ \cancel{\text{mg C}} \times \frac{1\ \cancel{g}}{10^3\ \cancel{\text{mg}}} \times \frac{1\ \text{mol C}}{12.01\ \cancel{\text{g C}}}$$
$$= 2.62\times10^{-2}\ \text{mol C}$$

See Road Map 3.1A.

3.1B $$\text{Number of cans} = 52\ \cancel{\text{mol Al}} \times \frac{26.98\ \cancel{\text{g Al}}}{1\ \cancel{\text{mol Al}}} \times \frac{1\ \text{can}}{14\ \cancel{\text{g Al}}}$$
$$= 100\ \text{cans}$$

See Road Map 3.1B.

Road Map 3.1A

Mass (mg) of C
↓ 10^3 mg = 1 g
Mass (g) of C
↓ divide by $\mathcal{M}$ (g/mol) (12.01 g = 1 mol C)
Amount (mol) of C

Road Map 3.1B

Amount (mol) of Al
↓ multiply by $\mathcal{M}$ (g/mol) (1 mol Al = 26.98 g Al)
Mass (g) of Al
↓ 14 g Al = 1 soda can
No. of cans

3.2A $$\text{Amount (mol) of N} = 9.72\times10^{21}\ \cancel{\text{N}_2\ \text{molecules}} \times \frac{1\ \cancel{\text{mol N}_2}}{6.022\times10^{23}\ \cancel{\text{N}_2\ \text{molecules}}} \times \frac{2\ \text{mol N}}{1\ \cancel{\text{mol N}_2}}$$
$$= 3.23\times10^{-2}\ \text{mol N}$$

See Road Map 3.2A.

3.2B $$\text{No. of He atoms} = 325\ \cancel{\text{mol He}} \times \frac{6.022\times10^{23}\ \text{He atoms}}{1\ \cancel{\text{mol He}}}$$
$$= 1.96\times10^{26}\ \text{He atoms}$$

See Road Map 3.2B.

Road Map 3.2A

No. of N_2 molecules
↓ divide by Avogadro's number (6.022×10^{23} N_2 molecules = 1 mol N_2)
Amount (mol) of N_2
↓ use chemical formula (1 mol N_2 = 2 mol N)
Amount (mol) of N

Road Map 3.2B

Amount (mol) of He
↓ multiply by Avogadro's number (1 mol He = 6.022×10^{23} He atoms)
No. of He atoms

3.3A $$\text{Mass (g) of Mn} = 3.22\times10^{20}\ \cancel{\text{Mn atoms}} \times \frac{1\ \cancel{\text{mol Mn}}}{6.022\times10^{23}\ \cancel{\text{Mn atoms}}} \times \frac{54.94\ \text{g Mn}}{1\ \cancel{\text{mol Mn}}}$$
$$= 2.94\times10^{-2}\ \text{g Mn}$$

See Road Map 3.3A.

3.3B No. of Cu atoms $= 0.0625\ \text{g Cu} \times \frac{1\ \text{mol Cu}}{63.55\ \text{g Cu}} \times \frac{6.022\times10^{23}\ \text{Cu atoms}}{1\ \text{mol Cu}}$
$= 5.92\times10^{20}\ \text{Cu atoms}$

See Road Map 3.3B.

- Mass (g) of Cu
- divide by $\mathcal{M}$ (g/mol) (63.55 g Cu = 1 mol Cu)
- Amount (mol) of Cu
- multiply by Avogadro's number (1 mol Cu = 6.022×10^{23} Cu atoms)
- No. of Cu atoms

3.4A $\mathcal{M} = (1 \times \mathcal{M}\text{ of Na}) + (1 \times \mathcal{M}\text{ of F})$
$= 22.99\ \text{g/mol} + 19.00\ \text{g/mol} = 41.99\ \text{g/mol}$

Mass (g) of NaF
$= 1.19\times10^{19}\ \text{NaF formula units} \times \frac{1\ \text{mol NaF}}{6.022\times10^{23}\ \text{NaF formula units}} \times \frac{41.99\ \text{g NaF}}{1\ \text{mol NaF}}$
$= 8.30\times10^{-4}\ \text{g NaF}$

See Road Map 3.4A.

3.4B $\mathcal{M} = (1 \times \mathcal{M}\text{ of Ca}) + (2 \times \mathcal{M}\text{ of Cl})$
$= 40.08\ \text{g/mol} + (2 \times 35.45\ \text{g/mol}) = 110.98\ \text{g/mol}$

No. of $CaCl_2$ formula units $= 400\ \text{lb CaCl}_2 \times \frac{453.6\ \text{g}}{1\ \text{lb}} \times \frac{1\ \text{mol CaCl}_2}{110.98\ \text{g CaCl}_2} \times \frac{6.022\times10^{23}\ \text{CaCl}_2\ \text{formula units}}{1\ \text{mol CaCl}_2}$
$= 1\times10^{27}\ \text{CaCl}_2\ \text{formula units}$

See Road Map 3.4B.

Road Map 3.4A

- No. of formula units of NaF
- divide by Avogadro's number (6.022×10^{23} formula units = 1 mol NaF)
- Amount (mol) of NaF
- multiply by $\mathcal{M}$ (g/mol) (1 mol NaF = 41.99 g NaF)
- Mass (g) of NaF

Road Map 3.4B

- Mass (lb) of $CaCl_2$
- 1 lb = 453.6 g
- Mass (g) of $CaCl_2$
- divide by $\mathcal{M}$ (g/mol) (110.98 g $CaCl_2$ = 1 mol $CaCl_2$)
- Amount (mol) of $CaCl_2$
- multiply by Avogadro's number (1 mol $CaCl_2$ = 6.022×10^{23} $CaCl_2$ formula units)
- No. of formula units of $CaCl_2$

3.5A (a) Mass (g) of P_4O_{10}
$= 4.65\times10^{22}\ \text{molecules } P_4O_{10} \times \frac{1\ \text{mol } P_4O_{10}}{6.022\times10^{23}\ \text{molecules } P_4O_{10}} \times \frac{283.88\ \text{g } P_4O_{10}}{1\ \text{mol } P_4O_{10}}$
$= 21.9\ \text{g } P_4O_{10}$

(b) No. of P atoms $= 4.65\times10^{22}\ \text{molecules } P_4O_{10} \times \frac{4\ \text{atoms P}}{1\ \text{molecule } P_4O_{10}}$
$= 1.86\times10^{23}\ \text{P atoms}$

3.5B (a) No. of formula units of $Ca_3(PO_4)_2$
$= 75.5\ \text{g } Ca_3(PO_4)_2 \times \frac{1\ \text{mol } Ca_3(PO_4)_2}{310.18\ \text{g } Ca_3(PO_4)_2} \times \frac{6.022\times10^{23}\ \text{formula units } Ca_3(PO_4)_2}{1\ \text{mol } Ca_3(PO_4)_2}$
$= 1.47\times10^{23}\ \text{formula units } Ca_3(PO_4)_2$

(b) No. of PO_4^{3-} ions $= 1.47\times10^{23}\ \text{formula units } Ca_3(PO_4)_2 \times \frac{2\ PO_4^{3-}\ \text{ions}}{1\ \text{formula unit } Ca_3(PO_4)_2}$
$= 2.94\times10^{23}\ PO_4^{3-}\ \text{ions}$

3.6A Mass % of C $= \frac{6\ \text{mol C} \times \frac{12.01\ \text{g C}}{1\ \text{mol C}}}{180.16\ \text{g } C_6H_{12}O_6} \times 100$
$= 40.00\ \text{mass \% C}$

3.6B Mass % of Cl $= \frac{3\ \text{mol Cl} \times \frac{35.45\ \text{g Cl}}{1\ \text{mol Cl}}}{137.36\ \text{g } CCl_3F} \times 100$
$= 77.42\ \text{mass \% Cl}$

3.7A Mass (g) of C $= 16.55\ \text{g } C_6H_{12}O_6 \times \frac{72.06\ \text{g C}}{180.16\ \text{g } C_6H_{12}O_6}$
$= 6.620\ \text{g C}$

3.7B Mass (g) of Cl $= 112\ \text{g } CCl_3F \times \frac{106.35\ \text{g Cl}}{137.36\ \text{g } CCl_3F}$
$= 86.7\ \text{g Cl}$

3.8A Preliminary formula: $B_{0.170}O_{0.255}$

Divide by smaller subscript: $B_{\frac{0.170}{0.170}}O_{\frac{0.255}{0.170}} = B_{1.00}O_{1.50}$

Multiply by 2: $B_{2\times1.00}O_{2\times1.50} = B_{2.00}O_{3.00} = B_2O_3$

3.8B Preliminary formula: $C_{6.80}H_{18.1}$

Divide by smallest subscript: $C_{\frac{6.80}{6.80}}O_{\frac{18.1}{6.80}} = C_{1.00}H_{2.66}$

Multiply by 3: $C_{3\times1.00}H_{3\times2.66} = C_{3.00}H_{7.98} = C_3H_8$

3.9A Amount (mol) of H $= 1.23\ \text{g H} \times \frac{1\ \text{mol H}}{1.008\ \text{g H}}$
$= 1.22\ \text{mol H}$

Similarly, there are 0.408 mol P and 1.63 mol O.

Preliminary formula: $H_{1.22}P_{0.408}O_{1.63}$

Divide by smallest subscript:

$$H_{\frac{1.22}{0.408}}P_{\frac{0.408}{0.408}}O_{\frac{1.63}{0.408}} = H_{2.99}P_{1.00}O_{4.00} = H_3PO_4$$

3.9B Amount (mol) of S $= 2.88\ \text{g S} \times \frac{1\ \text{mol S}}{32.06\ \text{g S}}$
$= 0.0898\ \text{mol S}$

Amount (mol) of M $= 0.0898\ \text{mol S} \times \frac{2\ \text{mol M}}{3\ \text{mol S}} = 0.0599\ \text{mol M}$

Molar mass of M $= \frac{3.12\ \text{g M}}{0.0599\ \text{mol M}} = 52.1\ \text{g/mol}$

M is chromium, and M_2S_3 is chromium(III) sulfide.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

3.10A Assuming 100.00 g of compound, we have 95.21 g of C and 4.79 g of H:

$$\text{Amount (mol) of C} = 95.21 \text{ g } \cancel{\text{C}} \times \frac{1 \text{ mol C}}{12.01 \text{ g } \cancel{\text{C}}} = 7.928 \text{ mol C}$$

Similarly, there is 4.75 mol H.
Preliminary formula: $C_{7.928}H_{4.75} \approx C_{1.67}H_{1.00}$
Empirical formula: C_5H_3

$$\text{Whole-number multiple} = \frac{252.30 \text{ g/}\cancel{\text{mol}}}{63.07 \text{ g/}\cancel{\text{mol}}} = 4$$

Molecular formula: $C_{20}H_{12}$

3.10B Assuming 100.00 g of compound, we have 49.47 g C, 5.19 g H, 28.86 g N, and 16.48 g O:

$$\text{Amount (mol) of C} = 49.47 \text{ g } \cancel{\text{C}} \times \frac{1 \text{ mol C}}{12.01 \text{ g } \cancel{\text{C}}} = 4.119 \text{ mol C}$$

Similarly, there are 5.15 mol H, 2.060 mol N, and 1.030 mol O.
Preliminary formula: $C_{4.119}H_{5.15}N_{2.060}O_{1.030} = C_{4.00}H_{5.00}N_{2.00}O_{1.00}$
Empirical formula: $C_4H_5N_2O$

$$\text{Whole-number multiple} = \frac{194.2 \text{ g/}\cancel{\text{mol}}}{97.10 \text{ g/}\cancel{\text{mol}}} = 2$$

Molecular formula: $C_8H_{10}N_4O_2$

3.11A $$\text{Mass (g) of C} = 0.451 \text{ g } \cancel{CO_2} \times \frac{12.01 \text{ g C}}{44.01 \text{ g } \cancel{CO_2}} = 0.123 \text{ g C}$$

Similarly, there is 0.00690 g H.
Mass (g) of Cl = 0.250 g − (0.123 g + 0.00690 g) = 0.120 g Cl
Amount (mol) of elements: 0.0102 mol C; 0.00685 mol H; 0.00339 mol Cl
Empirical formula: C_3H_2Cl
Whole-number multiple = 2
Molecular formula: $C_6H_4Cl_2$

3.11B $$\text{Mass (g) of C} = 3.516 \text{ g } \cancel{CO_2} \times \frac{12.01 \text{ g C}}{44.01 \text{ g } \cancel{CO_2}} = 0.9595 \text{ g C}$$

Similarly, there is 0.1127 g H.
Mass (g) of O = 1.200 g − (0.9595 g + 0.1127 g) = 0.128 g O
Amount (mol) of elements: 0.07989 mol C; 0.1118 mol H; 0.00800 mol O
Empirical formula: $C_{10}H_{14}O$
Whole-number multiple: 2
Molecular formula: $C_{20}H_{28}O_2$

3.12A (a) $2Na(s) + 2H_2O(l) \longrightarrow H_2(g) + 2NaOH(aq)$
(b) $2HNO_3(aq) + CaCO_3(s) \longrightarrow CO_2(g) + H_2O(l) + Ca(NO_3)_2(aq)$
(c) $PCl_3(g) + 3HF(g) \longrightarrow PF_3(g) + 3HCl(g)$

3.12B (a) $4C_3H_5N_3O_9(l) \longrightarrow 12CO_2(g) + 10H_2O(g) + 6N_2(g) + O_2(g)$
(b) $4KO_2(s) + 2CO_2(g) \longrightarrow 3O_2(g) + 2K_2CO_3(s)$
(c) $Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g)$

3.13A From the depiction, we have

$$6CO + 3O_2 \longrightarrow 6CO_2$$

Or,

$$2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$$

3.13B From the depiction, we have

$$2N_2 + 6H_2 \longrightarrow 4NH_3$$

Or,

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

3.14A $Fe_2O_3(s) + 2Al(s) \longrightarrow Al_2O_3(s) + 2Fe(l)$

$$\text{Amount (mol) of } Fe_2O_3 = 3.60\times10^3 \text{ } \cancel{\text{mol Fe}} \times \frac{1 \text{ mol } Fe_2O_3}{2 \text{ } \cancel{\text{mol Fe}}} = 1.80\times10^3 \text{ mol } Fe_2O_3$$

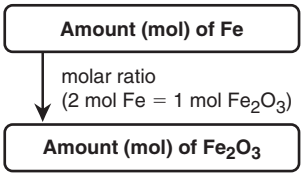
See Road Map 3.14A.

3.14B $3Ag_2S(s) + 2Al(s) \longrightarrow 6Ag(s) + Al_2S_3(s)$

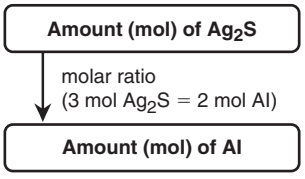
$$\text{Amount (mol) of Al} = 0.253 \text{ } \cancel{\text{mol } Ag_2S} \times \frac{2 \text{ mol Al}}{3 \text{ } \cancel{\text{mol } Ag_2S}} = 0.169 \text{ mol Al}$$

See Road Map 3.14B.

Road Map 3.14A



Road Map 3.14B



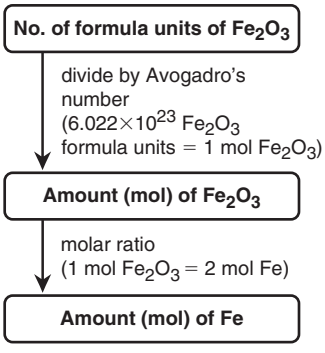
3.15A $$\text{Amount (mol) of Fe} = 1.85\times10^{25} \text{ } \cancel{\text{formula units } Fe_2O_3} \times \frac{1 \text{ } \cancel{\text{mol } Fe_2O_3}}{6.022\times10^{23} \text{ } \cancel{\text{formula units } Fe_2O_3}} \times \frac{2 \text{ mol Fe}}{1 \text{ } \cancel{\text{mol } Fe_2O_3}} = 61.4 \text{ mol Fe}$$

See Road Map 3.15A.

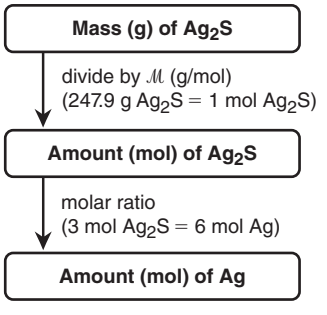
3.15B $$\text{Amount (mol) of Ag} = 32.6 \text{ g } \cancel{Ag_2S} \times \frac{1 \text{ mol } Ag_2S}{247.9 \text{ g } \cancel{Ag_2S}} \times \frac{6 \text{ mol Ag}}{3 \text{ mol } Ag_2S} = 0.263 \text{ mol Ag}$$

See Road Map 3.15B.

Road Map 3.15A



Road Map 3.15B



3.16A

$$\text{No. of Al atoms} = 1.00\ \text{g}\ \cancel{Al_2O_3} \times \frac{1\ \text{mol}\ \cancel{Al_2O_3}}{101.96\ \text{g}\ \cancel{Al_2O_3}} \times \frac{2\ \text{mol}\ \cancel{Al}}{1\ \text{mol}\ \cancel{Al_2O_3}} \times \frac{6.022\times10^{23}\ \text{Al atoms}}{1\ \text{mol}\ \cancel{Al}}$$
$$= 1.18\times10^{22}\ \text{Al atoms}$$

Mass (g) of Al_2O_3
↓ divide by $\mathcal{M}$ (g/mol) (101.96 g Al_2O_3 = 1 mol Al_2O_3)
Amount (mol) of Al_2O_3
↓ molar ratio (1 mol Al_2O_3 = 2 mol Al)
Amount (mol) of Al
↓ multiply by Avogadro's number (1 mol Al = 6.022×10^{23} Al atoms)
No. of Al atoms

3.16B

$$\text{Mass (g) of Al} = 12.1\ \text{g}\ \cancel{Al_2S_3} \times \frac{1\ \text{mol}\ \cancel{Al_2S_3}}{150.14\ \text{g}\ \cancel{Al_2S_3}} \times \frac{2\ \text{mol}\ \cancel{Al}}{1\ \text{mol}\ \cancel{Al_2S_3}} \times \frac{26.98\ \text{g Al}}{1\ \text{mol}\ \cancel{Al}}$$
$$= 4.35\ \text{g Al}$$

Mass (g) of Al_2S_3
↓ divide by $\mathcal{M}$ (g/mol) (150.14 g Al_2S_3 = 1 mol Al_2S_3)
Amount (mol) of Al_2S_3
↓ molar ratio (1 mol Al_2S_3 = 2 mol Al)
Amount (mol) of Al
↓ multiply by $\mathcal{M}$ (g/mol) (1 mol Al = 26.98 g Al)
Mass (g) of Al

3.17A

$$2SO_2(g) + O_2(g) \longrightarrow \cancel{2SO_3(g)}$$
$$\cancel{2SO_3(g)} + 2H_2O(l) \longrightarrow 2H_2SO_4(aq)$$
$$2SO_2(g) + O_2(g) + 2H_2O(l) \longrightarrow 2H_2SO_4(aq)$$

3.17B

$$N_2(g) + \cancel{O_2(g)} \longrightarrow \cancel{2NO(g)}$$
$$\cancel{2NO(g)} + 2O_3(g) \longrightarrow 2NO_2(g) + \cancel{2}O_2(g)$$
$$N_2(g) + 2O_3(g) \longrightarrow 2NO_2(g) + O_2(g)$$

3.18A $4AB(g) + 2B_2(g) \longrightarrow 4AB_2(g)$
Or $2AB(g) + B_2(g) \longrightarrow 2AB_2(g)$

For AB: Molecules of $AB_2 = 4\cancel{AB} \times \frac{2AB_2}{2\cancel{AB}} = 4AB_2$

For B_2: Molecules of $AB_2 = 3\cancel{B_2} \times \frac{2AB_2}{1\cancel{B_2}} = 6AB_2$

Thus, AB is the limiting reactant; one B_2 molecule is in excess.

3.18B $4SO_2(g) + 2O_2(g) \longrightarrow 4SO_3(g)$
Or $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$

For SO_2: Molecules of $SO_3 = 5\cancel{SO_2} \times \frac{2SO_3}{2\cancel{SO_2}} = 5SO_3$

For O_2: Molecules of $SO_3 = 2\cancel{O_2} \times \frac{2SO_3}{1\cancel{O_2}} = 4SO_3$

Thus, O_2 is the limiting reactant; one SO_2 molecule is in excess.

3.19A

$$\text{Amount (mol) of } AB_2 = 1.5\ \cancel{\text{mol AB}} \times \frac{2\ \text{mol}\ AB_2}{2\ \cancel{\text{mol AB}}} = 1.5\ \text{mol}\ AB_2$$

$$\text{Amount (mol) of } AB_2 = 1.5\ \cancel{\text{mol B}_2} \times \frac{2\ \text{mol}\ AB_2}{1\ \cancel{\text{mol B}_2}} = 3.0\ \text{mol}\ AB_2$$

Therefore, 1.5 mol of AB_2 can form.

3.19B

$$\text{Amount (mol) of } SO_3 = 4.2\ \cancel{\text{mol SO}_2} \times \frac{2\ \text{mol}\ SO_3}{2\ \cancel{\text{mol SO}_2}} = 4.2\ \text{mol}\ SO_3$$

$$\text{Amount (mol) of } SO_3 = 3.6\ \cancel{\text{mol O}_2} \times \frac{2\ \text{mol}\ SO_3}{1\ \cancel{\text{mol O}_2}} = 7.2\ \text{mol}\ SO_3$$

Therefore, 4.2 mol of SO_3 is produced.

3.20A $2Al(s) + 3S(s) \longrightarrow Al_2S_3(s)$

Mass (g) of Al_2S_3 formed from 10.0 g of Al

$$= 10.0\ \cancel{\text{g Al}} \times \frac{1\ \cancel{\text{mol Al}}}{26.98\ \cancel{\text{g Al}}} \times \frac{1\ \cancel{\text{mol Al}_2\text{S}_3}}{2\ \cancel{\text{mol Al}}} \times \frac{150.14\ \text{g}\ Al_2S_3}{1\ \cancel{\text{mol Al}_2\text{S}_3}}$$
$$= 27.8\ \text{g}\ Al_2S_3$$

Similarly, mass (g) of Al_2S_3 formed from 15.0 g of S = 23.4 g Al_2S_3. Thus, S is the limiting reactant, and 23.4 g of Al_2S_3 forms.

Mass (g) of Al in excess

$$= \text{total mass of Al} - \text{mass of Al used}$$
$$= 10.0\ \text{g Al} - \left(15.0\ \cancel{\text{g S}} \times \frac{1\ \cancel{\text{mol S}}}{32.06\ \cancel{\text{g S}}} \times \frac{2\ \cancel{\text{mol Al}}}{3\ \cancel{\text{mol S}}} \times \frac{26.98\ \text{g Al}}{1\ \cancel{\text{mol Al}}}\right)$$
$$= 1.6\ \text{g Al}$$

(We would obtain the same answer if sulfur were shown more correctly as S_8.)

3.20B $2C_4H_{10}(g) + 13O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$

Mass (g) of CO_2 formed from 4.65 g of C_4H_{10}

$$= 4.65\ \cancel{\text{g C}_4\text{H}_{10}} \times \frac{1\ \cancel{\text{mol C}_4\text{H}_{10}}}{58.12\ \cancel{\text{g C}_4\text{H}_{10}}} \times \frac{8\ \cancel{\text{mol CO}_2}}{2\ \cancel{\text{mol C}_4\text{H}_{10}}} \times \frac{44.01\ \text{g CO}_2}{1\ \cancel{\text{mol CO}_2}}$$
$$= 14.1\ \text{g}\ CO_2$$

Similarly, the mass (g) of CO_2 formed from 10.0 g of O_2 = 8.46 g CO_2.

Thus, O_2 is the limiting reactant, and 8.46 g of CO_2 forms.

Mass (g) of C_4H_{10} in excess

$$= \text{total mass of } C_4H_{10} - \text{mass of } C_4H_{10} \text{ used}$$
$$= 4.65\ \text{g} - \left(10.0\ \cancel{\text{g O}_2} \times \frac{1\ \cancel{\text{mol O}_2}}{32.00\ \cancel{\text{g O}_2}} \times \frac{2\ \cancel{\text{mol C}_4\text{H}_{10}}}{13\ \cancel{\text{mol O}_2}} \times \frac{58.12\ \text{g}\ C_4H_{10}}{1\ \cancel{\text{mol C}_4\text{H}_{10}}}\right)$$
$$= 1.86\ \text{g}\ C_4H_{10}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

3.21A $CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + H_2O(l) + CO_2(g)$

$$\text{Theoretical yield (g) of } CO_2 = 10.0 \text{ g } \cancel{CaCO_3} \times \frac{1 \text{ mol } \cancel{CaCO_3}}{100.09 \text{ g } \cancel{CaCO_3}} \times \frac{1 \text{ mol } \cancel{CO_2}}{1 \text{ mol } \cancel{CaCO_3}} \times \frac{44.01 \text{ g } CO_2}{1 \text{ mol } \cancel{CO_2}}$$

$$= 4.40 \text{ g } CO_2$$

$$\% \text{ yield} = \frac{3.65 \text{ g } \cancel{CO_2}}{4.40 \text{ g } \cancel{CO_2}} \times 100 = 83.0\%$$

3.21B $2NaCl(aq) + CaCO_3(s) \longrightarrow Na_2CO_3(s) + CaCl_2(aq)$

$$\text{Theoretical yield (g) of } Na_2CO_3 = 112 \text{ g } \cancel{NaCl} \times \frac{1 \text{ mol } \cancel{NaCl}}{58.44 \text{ g } \cancel{NaCl}} \times \frac{1 \text{ mol } \cancel{Na_2CO_3}}{2 \text{ mol } \cancel{NaCl}} \times \frac{105.99 \text{ g } Na_2CO_3}{1 \text{ mol } \cancel{Na_2CO_3}}$$

$$= 102 \text{ g } Na_2CO_3$$

$$\% \text{ yield} = \frac{92.6 \text{ g } \cancel{Na_2CO_3}}{102 \text{ g } \cancel{Na_2CO_3}} \times 100 = 90.8\%$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

The Mole

(Sample Problems 3.1 to 3.7)

Concept Review Questions

3.1 The atomic mass of Cl is 35.45 amu, and the atomic mass of Al is 26.98 amu. What are the masses in grams of 3 mol of Al atoms and of 2 mol of Cl atoms?

3.2 (a) How many moles of C atoms are in 1 mol of sucrose ($C_{12}H_{22}O_{11}$)?
(b) How many C atoms are in 2 mol of sucrose?

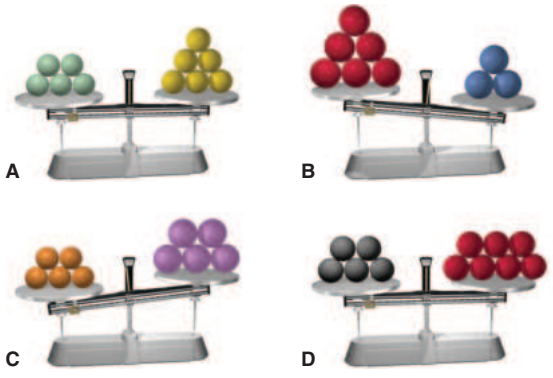
3.3 Why might the expression "1 mol of chlorine" be confusing? What change would remove any uncertainty? For what other elements might a similar confusion exist? Why?

3.4 How is the molecular mass of a compound the same as the molar mass, and how is it different?

3.5 What advantage is there to using a counting unit (the mole) for amount of substance rather than a mass unit?

3.6 You need to calculate the number of P_4 molecules that can form from 2.5 g of $Ca_3(PO_4)_2$. Draw a road map for solving this and write a Plan, without doing any calculations.

3.7 Each of the following balances weighs the indicated numbers of atoms of two elements:



For each balance, which element—left, right, or neither,
(a) Has the higher molar mass?
(b) Has more atoms per gram?
(c) Has fewer atoms per gram?
(d) Has more atoms per mole?

Skill-Building Exercises (grouped in similar pairs)

3.8 Calculate the molar mass of each of the following:
(a) $Sr(OH)_2$ (b) N_2O_3 (c) $NaClO_3$ (d) Cr_2O_3

3.9 Calculate the molar mass of each of the following:
(a) $(NH_4)_3PO_4$ (b) CH_2Cl_2 (c) $CuSO_4 \cdot 5H_2O$ (d) BrF_3

3.10 Calculate the molar mass of each of the following:
(a) SnO (b) BaF_2 (c) $Al_2(SO_4)_3$ (d) $MnCl_2$

3.11 Calculate the molar mass of each of the following:
(a) N_2O_4 (b) C_4H_9OH (c) $MgSO_4 \cdot 7H_2O$ (d) $Ca(C_2H_3O_2)_2$

3.12 Calculate each of the following quantities:
(a) Mass (g) of 0.346 mol of Zn
(b) Number of F atoms in 2.62 mol of F_2
(c) Number of Ca atoms in 28.5 g of Ca

3.13 Calculate each of the following quantities:
(a) Amount (mol) of Mn atoms in 62.0 mg of Mn
(b) Amount (mol) for 1.36×10^{22} atoms of Cu
(c) Mass (g) of 8.05×10^{24} Li atoms

3.14 Calculate each of the following quantities:
(a) Mass (g) of 0.68 mol of $KMnO_4$
(b) Amount (mol) of O atoms in 8.18 g of $Ba(NO_3)_2$
(c) Number of O atoms in 7.3×10^{-3} g of $CaSO_4 \cdot 2H_2O$

3.15 Calculate each of the following quantities:
(a) Mass (kg) of 4.6×10^{21} molecules of NO_2
(b) Amount (mol) of Cl atoms in 0.0615 g of $C_2H_4Cl_2$
(c) Number of H^- ions in 5.82 g of SrH_2

3.16 Calculate each of the following quantities:
(a) Mass (g) of 6.44×10^{-2} mol of $MnSO_4$
(b) Amount (mol) of compound in 15.8 kg of $Fe(ClO_4)_3$
(c) Number of N atoms in 92.6 mg of NH_4NO_2

3.17 Calculate each of the following quantities:
(a) Total number of ions in 38.1 g of SrF_2
(b) Mass (kg) of 3.58 mol of $CuCl_2 \cdot 2H_2O$
(c) Mass (mg) of 2.88×10^{22} formula units of $Bi(NO_3)_3 \cdot 5H_2O$

3.18 Calculate each of the following quantities:
(a) Mass (g) of 8.35 mol of copper(I) carbonate
(b) Mass (g) of 4.04×10^{20} molecules of dinitrogen pentoxide
(c) Amount (mol) and number of formula units in 78.9 g of sodium perchlorate
(d) Number of sodium ions, perchlorate ions, chlorine atoms, and oxygen atoms in the mass of compound in part (c)

3.19 Calculate each of the following quantities:
(a) Mass (g) of 8.42 mol of chromium(III) sulfate decahydrate
(b) Mass (g) of 1.83×10^{24} molecules of dichlorine heptoxide
(c) Amount (mol) and number of formula units in 6.2 g of lithium sulfate
(d) Number of lithium ions, sulfate ions, sulfur atoms, and oxygen atoms in the mass of compound in part (c)

3.20 Calculate each of the following:
(a) Mass % of H in ammonium bicarbonate
(b) Mass % of O in sodium dihydrogen phosphate heptahydrate

3.21 Calculate each of the following:
(a) Mass % of I in strontium periodate
(b) Mass % of Mn in potassium permanganate

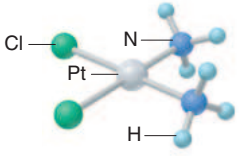
3.22 Calculate each of the following:
(a) Mass fraction of C in cesium acetate
(b) Mass fraction of O in uranyl sulfate trihydrate (the uranyl ion is UO_2^{2+})

3.23 Calculate each of the following:
(a) Mass fraction of Cl in calcium chlorate
(b) Mass fraction of N in dinitrogen trioxide

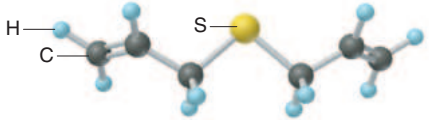
Problems in Context

3.24 Oxygen is required for the metabolic combustion of foods. Calculate the number of atoms in 38.0 g of oxygen gas, the amount absorbed from the lungs in about 15 min when a person is at rest.

3.25 Cisplatin *(right)*, or Platinol, is used in the treatment of certain cancers. Calculate (a) the amount (mol) of compound in 285.3 g of cisplatin; (b) the number of hydrogen atoms in 0.98 mol of cisplatin.



3.26 Allyl sulfide *(below)* gives garlic its characteristic odor. Calculate (a) the mass (g) of 2.63 mol of allyl sulfide; (b) the number of carbon atoms in 35.7 g of allyl sulfide.



3.27 Iron reacts slowly with oxygen and water to form a compound commonly called rust ($Fe_2O_3\cdot4H_2O$). For 45.2 kg of rust, calculate (a) moles of compound; (b) moles of Fe_2O_3; (c) grams of Fe.

3.28 Propane is widely used in liquid form as a fuel for barbecue grills and camp stoves. For 85.5 g of propane, calculate (a) moles of compound; (b) grams of carbon.

3.29 The effectiveness of a nitrogen fertilizer is determined mainly by its mass % N. Rank the following fertilizers, most effective first: potassium nitrate; ammonium nitrate; ammonium sulfate; urea, $CO(NH_2)_2$.

3.30 The mineral galena is composed of lead(II) sulfide and has an average density of 7.46 g/cm^3. (a) How many moles of lead(II) sulfide are in 1.00 ft^3 of galena? (b) How many lead atoms are in 1.00 dm^3 of galena?

3.31 Hemoglobin, a protein in red blood cells, carries O_2 from the lungs to the body's cells. Iron (as ferrous ion, Fe^{2+}) makes up 0.33 mass % of hemoglobin. If the molar mass of hemoglobin is 6.8×10^4 g/mol, how many Fe^{2+} ions are in one molecule?

Determining the Formula of an Unknown Compound

(Sample Problems 3.8 to 3.11)

Concept Review Questions

3.32 What is the difference between an empirical formula and a molecular formula? Can they ever be the same?

3.33 List three ways compositional data may be given in a problem that involves finding an empirical formula.

3.34 Which of the following sets of information allows you to obtain the molecular formula of a covalent compound? In each case that allows it, explain how you would proceed (draw a road map and write a Plan for a solution).
(a) Number of moles of each type of atom in a given sample of the compound
(b) Mass % of each element and the total number of atoms in a molecule of the compound
(c) Mass % of each element and the number of atoms of one element in a molecule of the compound
(d) Empirical formula and mass % of each element
(e) Structural formula

3.35 Is $MgCl_2$ an empirical or a molecular formula for magnesium chloride? Explain.

Skill-Building Exercises (grouped in similar pairs)

3.36 What is the empirical formula and empirical formula mass for each of the following compounds?
(a) C_2H_4 (b) $C_2H_6O_2$ (c) N_2O_5
(d) $Ba_3(PO_4)_2$ (e) Te_4I_{16}

3.37 What is the empirical formula and empirical formula mass for each of the following compounds?
(a) C_4H_8 (b) $C_3H_6O_3$ (c) P_4O_{10}
(d) $Ga_2(SO_4)_3$ (e) Al_2Br_6

3.38 Give the name, empirical formula, and molar mass of the compound depicted in Figure P3.38.

3.39 Give the name, empirical formula, and molar mass of the compound depicted in Figure P3.39.

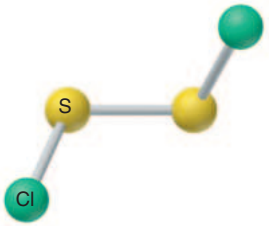


Figure P3.38

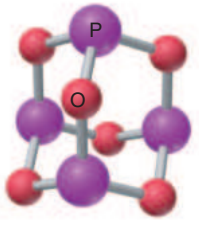

Figure P3.39

3.40 What is the molecular formula of each compound?
(a) Empirical formula CH_2 ($\mathcal{M}$ = 42.08 g/mol)
(b) Empirical formula NH_2 ($\mathcal{M}$ = 32.05 g/mol)
(c) Empirical formula NO_2 ($\mathcal{M}$ = 92.02 g/mol)
(d) Empirical formula CHN ($\mathcal{M}$ = 135.14 g/mol)

3.41 What is the molecular formula of each compound?
(a) Empirical formula CH ($\mathcal{M}$ = 78.11 g/mol)
(b) Empirical formula $C_3H_6O_2$ ($\mathcal{M}$ = 74.08 g/mol)
(c) Empirical formula HgCl ($\mathcal{M}$ = 472.1 g/mol)
(d) Empirical formula $C_7H_4O_2$ ($\mathcal{M}$ = 240.20 g/mol)

3.42 Find the empirical formula of the following compounds: (a) 0.063 mol of chlorine atoms combined with 0.22 mol of oxygen atoms; (b) 2.45 g of silicon combined with 12.4 g of chlorine; (c) 27.3 mass % carbon and 72.7 mass % oxygen

3.43 Find the empirical formula of the following compounds: (a) 0.039 mol of iron atoms combined with 0.052 mol of oxygen atoms; (b) 0.903 g of phosphorus combined with 6.99 g of bromine; (c) A hydrocarbon with 79.9 mass % carbon

3.44 An oxide of nitrogen contains 30.45 mass % N. (a) What is the empirical formula of the oxide? (b) If the molar mass is 90±5 g/mol, what is the molecular formula?

3.45 A chloride of silicon contains 79.1 mass % Cl. (a) What is the empirical formula of the chloride? (b) If the molar mass is 269 g/mol, what is the molecular formula?

3.46 A sample of 0.600 mol of a metal M reacts completely with excess fluorine to form 46.8 g of MF_2.
(a) How many moles of F are in the sample of MF_2 that forms?
(b) How many grams of M are in this sample of MF_2?
(c) What element is represented by the symbol M?

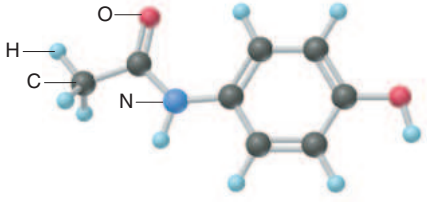
3.47 A 0.370-mol sample of a metal oxide (M_2O_3) weighs 55.4 g.
(a) How many moles of O are in the sample?
(b) How many grams of M are in the sample?
(c) What element is represented by the symbol M?

Problems in Context

3.48 Nicotine is a poisonous, addictive compound found in tobacco. A sample of nicotine contains 6.16 mmol of C, 8.56 mmol of H, and 1.23 mmol of N [1 mmol (1 millimole) = 10^{-3} mol]. What is the empirical formula of nicotine?

3.49 Cortisol ($\mathcal{M}$ = 362.47 g/mol) is a steroid hormone involved in protein synthesis. Medically, it has a major use in reducing inflammation from rheumatoid arthritis. Cortisol is 69.6% C, 8.34% H, and 22.1% O by mass. What is its molecular formula?

3.50 Acetaminophen *(below)* is a popular nonaspirin pain reliever. What is the mass % of each element in acetaminophen?



3.51 Menthol ($\mathcal{M}$ = 156.3 g/mol), the strong-smelling substance in many cough drops, is a compound of carbon, hydrogen, and oxygen. When 0.1595 g of menthol was burned in a combustion apparatus, 0.449 g of CO_2 and 0.184 g of H_2O formed. What is menthol's molecular formula?

Writing and Balancing Chemical Equations

(Sample Problems 3.12 and 3.13)

Concept Review Questions

3.52 What three types of information does a balanced chemical equation provide? How?

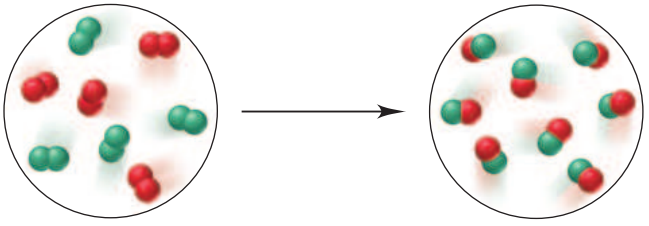
3.53 How does a balanced chemical equation apply the law of conservation of mass?

3.54 In the process of balancing the equation

$$Al + Cl_2 \longrightarrow AlCl_3$$

Student I writes: $Al + Cl_2 \longrightarrow AlCl_2$
Student II writes: $Al + Cl_2 + Cl \longrightarrow AlCl_3$
Student III writes: $2Al + 3Cl_2 \longrightarrow 2AlCl_3$
Is the approach of Student I valid? Student II? Student III? Explain.

3.55 The scenes below represent a chemical reaction between elements A *(red)* and B *(green):*



Which best represents the balanced equation for the reaction?
(a) $2A + 2B \longrightarrow A_2 + B_2$ (b) $A_2 + B_2 \longrightarrow 2AB$
(c) $B_2 + 2AB \longrightarrow 2B_2 + A_2$ (d) $4A_2 + 4B_2 \longrightarrow 8AB$

Skill-Building Exercises (grouped in similar pairs)

3.56 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:
(a) $__Cu(s) + __S_8(s) \longrightarrow __Cu_2S(s)$
(b) $__P_4O_{10}(s) + __H_2O(l) \longrightarrow __H_3PO_4(l)$
(c) $__B_2O_3(s) + __NaOH(aq) \longrightarrow __Na_3BO_3(aq) + __H_2O(l)$
(d) $__CH_3NH_2(g) + __O_2(g) \longrightarrow __CO_2(g) + __H_2O(g) + __N_2(g)$

3.57 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:
(a) $__Cu(NO_3)_2(aq) + __KOH(aq) \longrightarrow __Cu(OH)_2(s) + __KNO_3(aq)$
(b) $__BCl_3(g) + __H_2O(l) \longrightarrow __H_3BO_3(s) + __HCl(g)$
(c) $__CaSiO_3(s) + __HF(g) \longrightarrow __SiF_4(g) + __CaF_2(s) + __H_2O(l)$
(d) $__(CN)_2(g) + __H_2O(l) \longrightarrow __H_2C_2O_4(aq) + __NH_3(g)$

3.58 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:
(a) $__SO_2(g) + __O_2(g) \longrightarrow __SO_3(g)$
(b) $__Sc_2O_3(s) + __H_2O(l) \longrightarrow __Sc(OH)_3(s)$
(c) $__H_3PO_4(aq) + __NaOH(aq) \longrightarrow __Na_2HPO_4(aq) + __H_2O(l)$
(d) $__C_6H_{10}O_5(s) + __O_2(g) \longrightarrow __CO_2(g) + __H_2O(g)$

3.59 Write balanced equations for each of the following by inserting the correct coefficients in the blanks:
(a) $__As_4S_6(s) + __O_2(g) \longrightarrow __As_4O_6(s) + __SO_2(g)$
(b) $__Ca_3(PO_4)_2(s) + __SiO_2(s) + __C(s) \longrightarrow __P_4(g) + __CaSiO_3(l) + __CO(g)$
(c) $__Fe(s) + __H_2O(g) \longrightarrow __Fe_3O_4(s) + __H_2(g)$
(d) $__S_2Cl_2(l) + __NH_3(g) \longrightarrow __S_4N_4(s) + __S_8(s) + __NH_4Cl(s)$

3.60 Convert the following into balanced equations:
(a) When gallium metal is heated in oxygen gas, it melts and forms solid gallium(III) oxide.
(b) Liquid hexane burns in oxygen gas to form carbon dioxide gas and water vapor.

(c) When solutions of calcium chloride and sodium phosphate are mixed, solid calcium phosphate forms and sodium chloride remains in solution.

3.61 Convert the following into balanced equations:
(a) When lead(II) nitrate solution is added to potassium iodide solution, solid lead(II) iodide forms and potassium nitrate solution remains.
(b) Liquid disilicon hexachloride reacts with water to form solid silicon dioxide, hydrogen chloride gas, and hydrogen gas.
(c) When nitrogen dioxide is bubbled into water, a solution of nitric acid forms and gaseous nitrogen monoxide is released.

Problem in Context

3.62 Loss of atmospheric ozone has led to an ozone "hole" over Antarctica. The loss occurs in part through three consecutive steps:
(1) Chlorine atoms react with ozone (O_3) to form chlorine monoxide and molecular oxygen.
(2) Chlorine monoxide forms ClOOCl.
(3) ClOOCl absorbs sunlight and breaks into chlorine atoms and molecular oxygen.
(a) Write a balanced equation for each step.
(b) Write an overall balanced equation for the sequence.

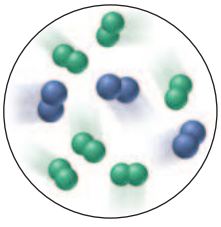
Calculating Quantities of Reactant and Product

(Sample Problems 3.14 to 3.21)

Concept Review Questions

3.63 What does the term *stoichiometrically equivalent molar ratio* mean, and how is it applied in solving problems?

3.64 The scene below represents a mixture of A_2 and B_2 before they react to form AB_3.



(a) What is the limiting reactant?
(b) How many molecules of product can form?

3.65 Percent yields are generally calculated from masses. Would the result be the same if amounts (mol) were used instead? Why?

Skill-Building Exercises (grouped in similar pairs)

3.66 Reactants A and B form product C. Draw a road map and write a Plan to find the mass (g) of C when 25 g of A reacts with excess B.

3.67 Reactants D and E form product F. Draw a road map and write a Plan to find the mass (g) of F when 27 g of D reacts with 31 g of E.

3.68 Chlorine gas can be made in the laboratory by the reaction of hydrochloric acid and manganese(IV) oxide:

$$4HCl(aq) + MnO_2(s) \longrightarrow MnCl_2(aq) + 2H_2O(g) + Cl_2(g)$$

When 1.82 mol of HCl reacts with excess MnO_2, how many (a) moles of Cl_2 and (b) grams of Cl_2 form?

3.69 Bismuth oxide reacts with carbon to form bismuth metal:

$$Bi_2O_3(s) + 3C(s) \longrightarrow 2Bi(s) + 3CO(g)$$

When 283 g of Bi_2O_3 reacts with excess carbon, how many (a) moles of Bi_2O_3 react and (b) moles of Bi form?

3.70 Potassium nitrate decomposes on heating, producing potassium oxide and gaseous nitrogen and oxygen:

$$4KNO_3(s) \longrightarrow 2K_2O(s) + 2N_2(g) + 5O_2(g)$$

To produce 56.6 kg of oxygen, how many (a) moles of KNO_3 and (b) grams of KNO_3 must be heated?

3.71 Chromium(III) oxide reacts with hydrogen sulfide (H_2S) gas to form chromium(III) sulfide and water:

$$Cr_2O_3(s) + 3H_2S(g) \longrightarrow Cr_2S_3(s) + 3H_2O(l)$$

To produce 421 g of Cr_2S_3, how many (a) moles of Cr_2O_3 and (b) grams of Cr_2O_3 are required?

3.72 Calculate the mass (g) of each product formed when 43.82 g of diborane (B_2H_6) reacts with excess water:

$$B_2H_6(g) + H_2O(l) \longrightarrow H_3BO_3(s) + H_2(g) \text{ [unbalanced]}$$

3.73 Calculate the mass (g) of each product formed when 174 g of silver sulfide reacts with excess hydrochloric acid:

$$Ag_2S(s) + HCl(aq) \longrightarrow AgCl(s) + H_2S(g) \text{ [unbalanced]}$$

3.74 Elemental phosphorus occurs as tetratomic molecules, P_4. What mass (g) of chlorine gas is needed to react completely with 455 g of phosphorus to form phosphorus pentachloride?

3.75 Elemental sulfur occurs as octatomic molecules, S_8. What mass (g) of fluorine gas is needed to react completely with 17.8 g of sulfur to form sulfur hexafluoride?

3.76 Solid iodine trichloride is prepared in two steps: first, a reaction between solid iodine and gaseous chlorine to form solid iodine monochloride; then, treatment with more chlorine.
(a) Write a balanced equation for each step.
(b) Write a balanced equation for the overall reaction.
(c) How many grams of iodine are needed to prepare 2.45 kg of final product?

3.77 Lead can be prepared from galena [lead(II) sulfide] by first roasting the galena in oxygen gas to form lead(II) oxide and sulfur dioxide. Heating the metal oxide with more galena forms the molten metal and more sulfur dioxide.
(a) Write a balanced equation for each step.
(b) Write an overall balanced equation for the process.
(c) How many metric tons of sulfur dioxide form for every metric ton of lead obtained?

3.78 Many metals react with oxygen gas to form the metal oxide. For example, calcium reacts as follows:

$$2Ca(s) + O_2(g) \longrightarrow 2CaO(s)$$

You wish to calculate the mass (g) of calcium oxide that can be prepared from 4.20 g of Ca and 2.80 g of O_2.
(a) What amount (mol) of CaO can be produced from the given mass of Ca?
(b) What amount (mol) of CaO can be produced from the given mass of O_2?
(c) Which is the limiting reactant?
(d) How many grams of CaO can be produced?

3.79 Metal hydrides react with water to form hydrogen gas and the metal hydroxide. For example,

$$SrH_2(s) + 2H_2O(l) \longrightarrow Sr(OH)_2(s) + 2H_2(g)$$

You wish to calculate the mass (g) of hydrogen gas that can be prepared from 5.70 g of SrH_2 and 4.75 g of H_2O.

(a) What amount (mol) of H_2 can be produced from the given mass of SrH_2?
(b) What amount (mol) of H_2 can be produced from the given mass of H_2O?
(c) Which is the limiting reactant?
(d) How many grams of H_2 can be produced?

3.80 Calculate the maximum numbers of moles and grams of iodic acid (HIO_3) that can form when 635 g of iodine trichloride reacts with 118.5 g of water:

$$ICl_3 + H_2O \longrightarrow ICl + HIO_3 + HCl \text{ [unbalanced]}$$

How many grams of the excess reactant remains?

3.81 Calculate the maximum numbers of moles and grams of H_2S that can form when 158 g of aluminum sulfide reacts with 131 g of water:

$$Al_2S_3 + H_2O \longrightarrow Al(OH)_3 + H_2S \text{ [unbalanced]}$$

How many grams of the excess reactant remain?

3.82 When 0.100 mol of carbon is burned in a closed vessel with 8.00 g of oxygen, how many grams of carbon dioxide can form? Which reactant is in excess, and how many grams of it remain after the reaction?

3.83 A mixture of 0.0375 g of hydrogen and 0.0185 mol of oxygen in a closed container is sparked to initiate a reaction. How many grams of water can form? Which reactant is in excess, and how many grams of it remain after the reaction?

3.84 Aluminum nitrite and ammonium chloride react to form aluminum chloride, nitrogen, and water. How many grams of each substance are present after 72.5 g of aluminum nitrite and 58.6 g of ammonium chloride react completely?

3.85 Calcium nitrate and ammonium fluoride react to form calcium fluoride, dinitrogen monoxide, and water vapor. How many grams of each substance are present after 16.8 g of calcium nitrate and 17.50 g of ammonium fluoride react completely?

3.86 Two successive reactions, A ⟶ B and B ⟶ C, have yields of 73% and 68%, respectively. What is the overall percent yield for conversion of A to C?

3.87 Two successive reactions, D ⟶ E and E ⟶ F, have yields of 48% and 73%, respectively. What is the overall percent yield for conversion of D to F?

3.88 What is the percent yield of a reaction in which 45.5 g of tungsten(VI) oxide (WO_3) reacts with excess hydrogen gas to produce metallic tungsten and 9.60 mL of water (d = 1.00 g/mL)?

3.89 What is the percent yield of a reaction in which 200. g of phosphorus trichloride reacts with excess water to form 128 g of HCl and aqueous phosphorous acid (H_3PO_3)?

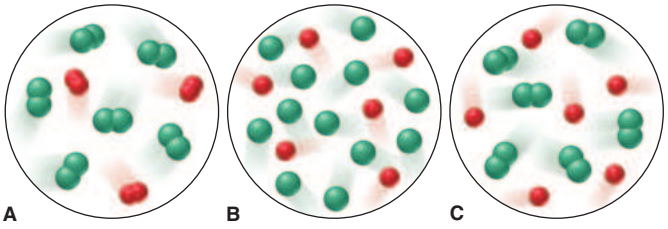
3.90 When 20.5 g of methane and 45.0 g of chlorine gas undergo a reaction that has a 75.0% yield, what mass (g) of chloromethane (CH_3Cl) forms? Hydrogen chloride also forms.

3.91 When 56.6 g of calcium and 30.5 g of nitrogen gas undergo a reaction that has a 93.0% yield, what mass (g) of calcium nitride forms?

Problems in Context

3.92 Cyanogen, $(CN)_2$, has been observed in the atmosphere of Titan, Saturn's largest moon, and in the gases of interstellar nebulas. On Earth, it is used as a welding gas and a fumigant. In its reaction with fluorine gas, carbon tetrafluoride and nitrogen trifluoride gases are produced. What mass (g) of carbon tetrafluoride forms when 60.0 g of each reactant is used?

3.93 Gaseous dichlorine monoxide decomposes readily to chlorine *(green)* and oxygen *(red)* gases.
(a) Which scene best depicts the product mixture after the decomposition?



(b) Write the balanced equation for the decomposition.
(c) If each oxygen atom represents 0.050 mol, how many molecules of dichlorine monoxide were present before the decomposition?

3.94 An intermediate step in the production of nitric acid involves the reaction of ammonia with oxygen gas to form nitrogen monoxide and water. How many grams of nitrogen monoxide can form in the reaction of 485 g of ammonia with 792 g of oxygen?

3.95 Butane gas is compressed and used as a liquid fuel in disposable cigarette lighters and lightweight camping stoves. Suppose a lighter contains 5.50 mL of butane (d = 0.579 g/mL).
(a) How many grams of oxygen are needed to burn the butane completely?
(b) How many moles of H_2O form when all the butane burns?
(c) How many total molecules of gas form when the butane burns completely?

3.96 Sodium borohydride ($NaBH_4$) is used industrially in many organic syntheses. One way to prepare it is by reacting sodium hydride with gaseous diborane (B_2H_6). Assuming an 88.5% yield, how many grams of $NaBH_4$ can be prepared by reacting 7.98 g of sodium hydride and 8.16 g of diborane?

Comprehensive Problems

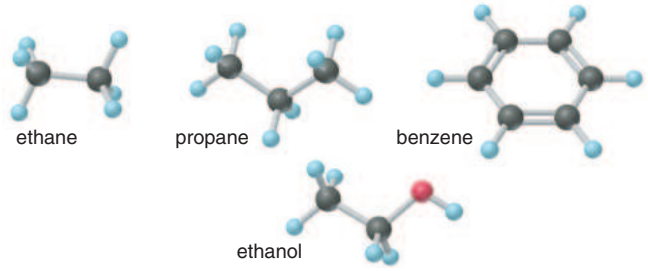
3.97 The mole is defined in terms of the carbon-12 atom. Use the definition to find (a) the mass in grams equal to 1 atomic mass unit; (b) the ratio of the gram to the atomic mass unit.

3.98 The first sulfur-nitrogen compound was prepared in 1835 and has been used to synthesize many others. In the early 1980s, researchers made another such compound that conducts electricity like a metal. Mass spectrometry of the compound shows a molar mass of 184.27 g/mol, and analysis shows it to contain 2.288 g of S for every 1.000 g of N. What is its molecular formula?

3.99 Hydroxyapatite, $Ca_5(PO_4)_3(OH)$, is the main mineral component of dental enamel, dentin, and bone. Coating the compound on metallic implants (such as titanium alloys and stainless steels) helps the body accept the implant. When placed in bone voids, the powder encourages natural bone to grow into the void. Hydroxyapatite is prepared by adding aqueous phosphoric acid to a dilute slurry of calcium hydroxide. (a) Write a balanced equation for this preparation. (b) What mass (g) of hydroxyapatite could form from 100. g of 85% phosphoric acid and 100. g of calcium hydroxide?

3.100 Narceine is a narcotic in opium that crystallizes from solution as a hydrate that contains 10.8 mass % water and has a molar mass of 499.52 g/mol. Determine x in narceine·xH_2O.

3.101 Hydrogen-containing fuels have a "fuel value" based on their mass % H. Rank the following compounds from highest fuel value to lowest: ethane, propane, benzene, ethanol, cetyl palmitate (whale oil, $C_{32}H_{64}O_2$).



3.102 Serotonin ($\mathcal{M}$ = 176 g/mol) transmits nerve impulses between neurons. It contains 68.2% C, 6.86% H, 15.9% N, and 9.08% O by mass. What is its molecular formula?

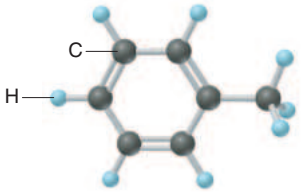
3.103 In 1961, scientists agreed that the atomic mass unit (amu) would be defined as $\frac{1}{12}$ the mass of an atom of ^{12}C. Before then, it was defined as $\frac{1}{16}$ the *average* mass of an atom of naturally occurring oxygen (a mixture of ^{16}O, ^{17}O, and ^{18}O). The current atomic mass of oxygen is 15.9994 amu. (a) Did Avogadro's number change after the definition of an amu changed and, if so, in what direction? (b) Did the definition of the mole change? (c) Did the mass of a mole of a substance change? (d) Before 1961, was Avogadro's number 6.02×10^{23} (to three significant figures), as it is today?

3.104 Convert the following descriptions into balanced equations:
(a) In a gaseous reaction, hydrogen sulfide burns in oxygen to form sulfur dioxide and water vapor.
(b) When crystalline potassium chlorate is heated to just above its melting point, it reacts to form two different crystalline compounds, potassium chloride and potassium perchlorate.
(c) When hydrogen gas is passed over powdered iron(III) oxide, iron metal and water vapor form.
(d) The combustion of gaseous ethane in air forms carbon dioxide and water vapor.
(e) Iron(II) chloride is converted to iron(III) fluoride by treatment with chlorine trifluoride gas. Chlorine gas is also formed.

3.105 Isobutylene is a hydrocarbon used in the manufacture of synthetic rubber. When 0.847 g of isobutylene was subjected to combustion analysis, the gain in mass of the CO_2 absorber was 2.657 g and that of the H_2O absorber was 1.089 g. What is the empirical formula of isobutylene?

3.106 The multistep smelting of ferric oxide to form elemental iron occurs at high temperatures in a blast furnace. In the first step, ferric oxide reacts with carbon monoxide to form Fe_3O_4. This substance reacts with more carbon monoxide to form iron(II) oxide, which reacts with still more carbon monoxide to form molten iron. Carbon dioxide is also produced in each step. (a) Write an overall balanced equation for the iron-smelting process. (b) How many grams of carbon monoxide are required to form 45.0 metric tons of iron from ferric oxide?

3.107 One of the compounds used to increase the octane rating of gasoline is toluene *(right)*. Suppose 20.0 mL of toluene (d = 0.867 g/mL) is consumed when a sample of gasoline burns in air.
(a) How many grams of oxygen are needed for complete combustion of the toluene? (b) How many total moles of gaseous products form? (c) How many molecules of water vapor form?



3.108 During studies of the reaction in Sample Problem 3.20,

$$2N_2H_4(l) + N_2O_4(l) \longrightarrow 3N_2(g) + 4H_2O(g)$$

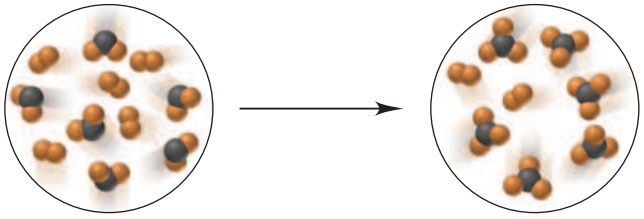
a chemical engineer measured a less-than-expected yield of N_2 and discovered that the following side reaction occurs:

$$N_2H_4(l) + 2N_2O_4(l) \longrightarrow 6NO(g) + 2H_2O(g)$$

In one experiment, 10.0 g of NO formed when 100.0 g of each reactant was used. What is the highest percent yield of N_2 that can be expected?

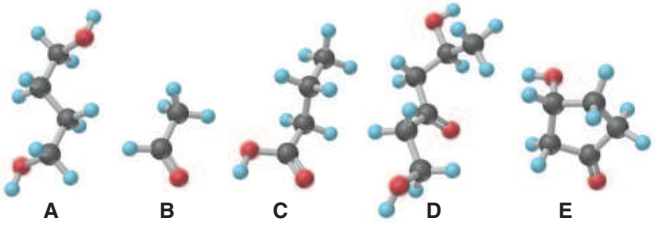
3.109 A 0.652-g sample of a pure strontium halide reacts with excess sulfuric acid. The solid strontium sulfate formed is separated, dried, and found to weigh 0.755 g. What is the formula of the original halide?

3.110 The following scenes represent a chemical reaction between AB_2 and B_2:



(a) Write a balanced equation for the reaction. (b) What is the limiting reactant? (c) How many moles of product can be made from 3.0 mol of B_2 and 5.0 mol of AB_2? (d) How many moles of excess reactant remain after the reaction in part (c)?

3.111 Which of the following models represent compounds having the same empirical formula? What is the empirical formula mass of this common formula?



3.112 The zirconium oxalate $K_2Zr(C_2O_4)_3(H_2C_2O_4)\cdot H_2O$ was synthesized by mixing 1.68 g of $ZrOCl_2\cdot 8H_2O$ with 5.20 g of $H_2C_2O_4\cdot 2H_2O$ and an excess of aqueous KOH. After 2 months, 1.25 g of crystalline product was obtained, along with aqueous KCl and water. Calculate the percent yield.

3.113 Seawater is approximately 4.0% by mass dissolved ions, 85% of which are from NaCl. (a) Find the mass % of NaCl in seawater. (b) Find the mass % of Na^+ ions and of Cl^- ions in seawater.

3.114 Is each of the following statements true or false? Correct any that are false.
(a) A mole of one substance has the same number of atoms as a mole of any other substance.
(b) The theoretical yield for a reaction is based on the balanced chemical equation.
(c) A limiting-reactant problem is being stated when the available quantity of one of the reactants is given in moles.
(d) The empirical and molecular formulas of a compound are always different.

3.115 In each pair, choose the larger of the indicated quantities or state that the samples are equal:
(a) Entities: 0.4 mol of O_3 molecules or 0.4 mol of O atoms
(b) Grams: 0.4 mol of O_3 molecules or 0.4 mol of O atoms
(c) Moles: 4.0 g of N_2O_4 or 3.3 g of SO_2
(d) Grams: 0.6 mol of C_2H_4 or 0.6 mol of F_2
(e) Total ions: 2.3 mol of sodium chlorate or 2.2 mol of magnesium chloride
(f) Molecules: 1.0 g of H_2O or 1.0 g of H_2O_2
(g) Grams: 6.02×10^{23} atoms of ^{235}U or 6.02×10^{23} atoms of ^{238}U

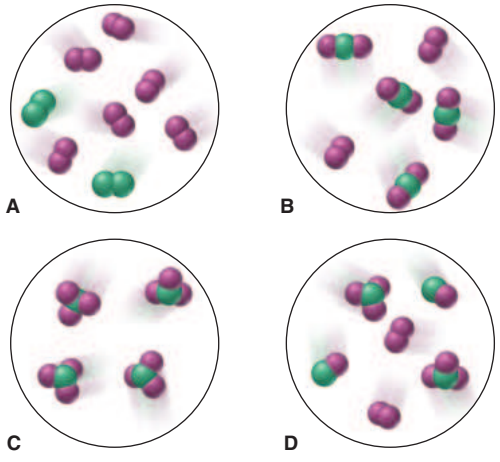
3.116 For the reaction between solid tetraphosphorus trisulfide and oxygen gas to form solid tetraphosphorus decoxide and sulfur dioxide gas, write a balanced equation. Show the equation (see Table 3.4) in terms of (a) molecules, (b) moles, and (c) grams.

3.117 Hydrogen gas is considered a clean fuel because it produces only water vapor when it burns. If the reaction has a 98.8% yield, what mass (g) of hydrogen forms 105 kg of water?

3.118 Solar winds composed of free protons, electrons, and α particles bombard Earth constantly, knocking gas molecules out of the atmosphere. In this way, Earth loses about 3.0 kg of matter per second. It is estimated that the atmosphere will be gone in about 50 billion years. Use this estimate to calculate (a) the mass (kg) of Earth's atmosphere and (b) the amount (mol) of nitrogen, which makes up 75.5 mass % of the atmosphere.

3.119 Calculate each of the following quantities:
(a) Amount (mol) of 0.588 g of ammonium bromide
(b) Number of potassium ions in 88.5 g of potassium nitrate
(c) Mass (g) of 5.85 mol of glycerol ($C_3H_8O_3$)
(d) Volume (L) of 2.85 mol of chloroform ($CHCl_3$; $d = 1.48$ g/mL)
(e) Number of sodium ions in 2.11 mol of sodium carbonate
(f) Number of atoms in 25.0 μg of cadmium
(g) Number of atoms in 0.0015 mol of fluorine gas

3.120 Elements X *(green)* and Y *(purple)* react according to the following equation: $X_2 + 3Y_2 \longrightarrow 2XY_3$. Which molecular scene represents the product of the reaction?



3.121 Hydrocarbon mixtures are used as fuels. (a) How many grams of $CO_2(g)$ are produced by the combustion of 200. g of a mixture that is 25.0% CH_4 and 75.0% C_3H_8 by mass? (b) A 252-g gaseous mixture of CH_4 and C_3H_8 burns in excess O_2, and 748 g of CO_2 gas is collected. What is the mass % of CH_4 in the mixture?

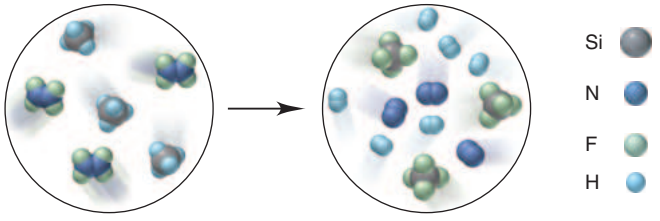
3.122 Nitrogen (N), phosphorus (P), and potassium (K) are the main nutrients in plant fertilizers. By industry convention, the numbers on a label refer to the mass percents of N, P_2O_5, and K_2O, in that order. Calculate the N/P/K ratio of a 30/10/10 fertilizer in terms of moles of each element, and express it as *x*/*y*/1.0.

3.123 What mass percents of ammonium sulfate, ammonium hydrogen phosphate, and potassium chloride would you use to prepare 10/10/10 plant fertilizer (see Problem 3.122)?

3.124 Ferrocene, synthesized in 1951, was the first organic iron compound with Fe—C bonds. An understanding of the structure of ferrocene gave rise to new ideas about chemical bonding and led to the preparation of many useful compounds. In the combustion analysis of ferrocene, which contains only Fe, C, and H, a 0.9437-g sample produced 2.233 g of CO_2 and 0.457 g of H_2O. What is the empirical formula of ferrocene?

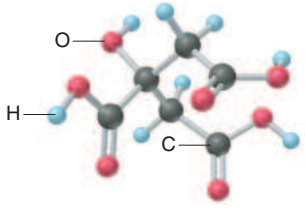
3.125 When carbon-containing compounds are burned in a limited amount of air, some $CO(g)$ as well as $CO_2(g)$ is produced. A gaseous product mixture is 35.0 mass % CO and 65.0 mass % CO_2. What is the mass % of C in the mixture?

3.126 Write a balanced equation for the reaction depicted below:



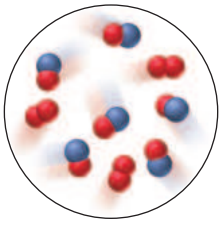
If each reactant molecule represents 1.25×10^{-2} mol and the reaction yield is 87%, how many grams of Si-containing product form?

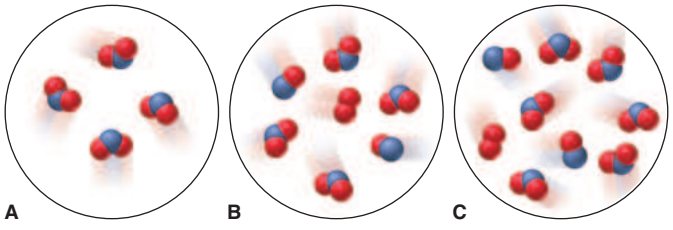
3.127 Citric acid *(right)* is concentrated in citrus fruits and plays a central metabolic role in nearly every animal and plant cell. (a) What are the molar mass and formula of citric acid? (b) How many moles of citric acid are in 1.50 qt of lemon juice ($d = 1.09$ g/mL) that is 6.82% citric acid by mass?



3.128 Various nitrogen oxides, as well as sulfur oxides, contribute to acidic rainfall through complex reaction sequences. Nitrogen and oxygen combine during the high-temperature combustion of fuels in air to form nitrogen monoxide gas, which reacts with more oxygen to form nitrogen dioxide gas. In contact with water vapor, nitrogen dioxide forms aqueous nitric acid and more nitrogen monoxide. (a) Write balanced equations for these reactions. (b) Use the equations to write one overall balanced equation that does *not* include nitrogen monoxide and nitrogen dioxide. (c) How many metric tons (t) of nitric acid form when 1350 t of atmospheric nitrogen is consumed (1 t = 1000 kg)?

3.129 Nitrogen monoxide reacts with elemental oxygen to form nitrogen dioxide. The scene at right represents an initial mixture of reactants. If the reaction has a 66% yield, which of the scenes below (A, B, or C) best represents the final product mixture?



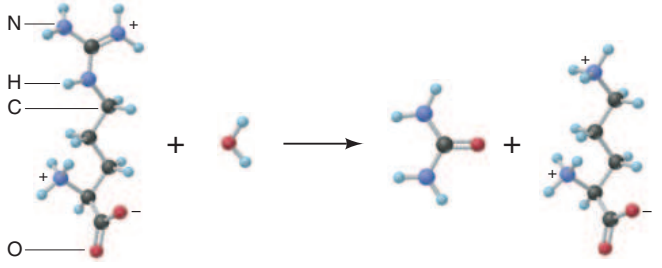


3.130 Fluorine is so reactive that it forms compounds with several of the noble gases.
(a) When 0.327 g of platinum is heated in fluorine, 0.519 g of a dark red, volatile solid forms. What is its empirical formula?
(b) When 0.265 g of this red solid reacts with excess xenon gas, 0.378 g of an orange-yellow solid forms. What is the empirical formula of this compound, the first to contain a noble gas?
(c) Fluorides of xenon can be formed by direct reaction of the elements at high pressure and temperature. Under conditions that produce only the tetra- and hexafluorides, 1.85×10^{-4} mol of xenon reacted with 5.00×10^{-4} mol of fluorine, and 9.00×10^{-6} mol of xenon was found in excess. What are the mass percents of each xenon fluoride in the product mixture?

3.131 Hemoglobin is 6.0% heme ($C_{34}H_{32}FeN_4O_4$) by mass. To remove the heme, hemoglobin is treated with acetic acid and NaCl, which forms hemin ($C_{34}H_{32}N_4O_4FeCl$). A blood sample from a crime scene contains 0.65 g of hemoglobin. (a) How many grams of heme are in the sample? (b) How many moles of heme? (c) How many grams of Fe? (d) How many grams of hemin could be formed for a forensic chemist to measure?

3.132 Manganese is a key component of extremely hard steel. The element occurs naturally in many oxides. A 542.3-g sample of a manganese oxide has an Mn/O ratio of 1.00/1.42 and consists of braunite (Mn_2O_3) and manganosite (MnO). (a) How many grams of braunite and of manganosite are in the ore? (b) What is the Mn^{3+}/Mn^{2+} ratio in the ore?

3.133 The human body excretes nitrogen in the form of urea, NH_2CONH_2. The key step in its biochemical formation is the reaction of water with arginine to produce urea and ornithine:



(a) What is the mass % of nitrogen in urea, in arginine, and in ornithine? (b) How many grams of nitrogen can be excreted as urea when 135.2 g of ornithine is produced?

3.134 Aspirin (acetylsalicylic acid, $C_9H_8O_4$) is made by reacting salicylic acid ($C_7H_6O_3$) with acetic anhydride [$(CH_3CO)_2O$]:

$$C_7H_6O_3(s) + (CH_3CO)_2O(l) \longrightarrow C_9H_8O_4(s) + CH_3COOH(l)$$

In one preparation, 3.077 g of salicylic acid and 5.50 mL of acetic anhydride react to form 3.281 g of aspirin. (a) Which is the limiting reactant (d of acetic anhydride = 1.080 g/mL)? (b) What is the percent yield of this reaction? (c) What is the percent atom economy of this reaction?

3.135 The rocket fuel hydrazine (N_2H_4) is made by the three-step Raschig process, which has the following overall equation:

$$NaOCl(aq) + 2NH_3(aq) \longrightarrow N_2H_4(aq) + NaCl(aq) + H_2O(l)$$

What is the percent atom economy of this process?

3.136 Lead(II) chromate ($PbCrO_4$) is used as the yellow pigment for marking traffic lanes but is banned from house paint because of the risk of lead poisoning. It is produced from chromite ($FeCr_2O_4$), an ore of chromium:

$$4FeCr_2O_4(s) + 8K_2CO_3(aq) + 7O_2(g) \longrightarrow 2Fe_2O_3(s) + 8K_2CrO_4(aq) + 8CO_2(g)$$

Lead(II) ion then replaces the K^+ ion. If a yellow paint is to have 0.511% $PbCrO_4$ by mass, how many grams of chromite are needed per kilogram of paint?

3.137 Ethanol (CH_3CH_2OH), the intoxicant in alcoholic beverages, is also used to make other organic compounds. In concentrated sulfuric acid, ethanol forms diethyl ether and water:

$$2CH_3CH_2OH(l) \longrightarrow CH_3CH_2OCH_2CH_3(l) + H_2O(g)$$

In a side reaction, some ethanol forms ethylene and water:

$$CH_3CH_2OH(l) \longrightarrow CH_2CH_2(g) + H_2O(g)$$

(a) If 50.0 g of ethanol yields 35.9 g of diethyl ether, what is the percent yield of diethyl ether? (b) If 45.0% of the ethanol that did not produce the ether reacts by the side reaction, what mass (g) of ethylene is produced?

3.138 When powdered zinc is heated with sulfur, a violent reaction occurs, and zinc sulfide forms:

$$Zn(s) + S_8(s) \longrightarrow ZnS(s) \text{ [unbalanced]}$$

Some of the reactants also combine with oxygen in air to form zinc oxide and sulfur dioxide. When 83.2 g of Zn reacts with 52.4 g of S_8, 104.4 g of ZnS forms.
(a) What is the percent yield of ZnS?
(b) If all the remaining reactants combine with oxygen, how many grams of each of the two oxides form?

3.139 Cocaine ($C_{17}H_{21}O_4N$) is a natural substance found in coca leaves, which have been used for centuries as a local anesthetic and stimulant. Illegal cocaine arrives in the United States either as the pure compound or as the hydrochloride salt ($C_{17}H_{21}O_4NHCl$). At 25°C, the salt is very soluble in water (2.50 kg/L), but cocaine is much less so (1.70 g/L).
(a) What is the maximum mass (g) of the salt that can dissolve in 50.0 mL of water?
(b) If this solution is treated with NaOH, the salt is converted to cocaine. How much more water (L) is needed to dissolve it?

3.140 High-temperature superconducting oxides hold great promise in the utility, transportation, and computer industries.
(a) One superconductor is $La_{2-x}Sr_xCuO_4$. Calculate the molar masses of this oxide when $x = 0$, $x = 1$, and $x = 0.163$.
(b) Another common superconducting oxide is made by heating a mixture of barium carbonate, copper(II) oxide, and yttrium(III) oxide, followed by further heating in O_2:

$$4BaCO_3(s) + 6CuO(s) + Y_2O_3(s) \longrightarrow 2YBa_2Cu_3O_{6.5}(s) + 4CO_2(g)$$

$$2YBa_2Cu_3O_{6.5}(s) + \tfrac{1}{2}O_2(g) \longrightarrow 2YBa_2Cu_3O_7(s)$$

When equal masses of the three reactants are heated, which reactant is limiting?
(c) After the product in part (b) is removed, what is the mass % of each reactant in the remaining solid mixture?

4 Three Major Classes of Chemical Reactions

4.1 Solution Concentration and the Role of Water as a Solvent
- Polar Nature of Water
- Ionic Compounds in Water
- Covalent Compounds in Water
- Expressing Concentration in Terms of Molarity
- Amount-Mass-Number Conversions Involving Solutions
- Preparing and Diluting Molar Solutions

4.2 Writing Equations for Aqueous Ionic Reactions

4.3 Precipitation Reactions
- The Key Event: Formation of a Solid
- Predicting Whether a Precipitate Will Form
- Stoichiometry of Precipitation Reactions

4.4 Acid-Base Reactions
- The Key Event: Formation of Water
- Proton Transfer in Acid-Base Reactions
- Stoichiometry of Acid-Base Reactions: Acid-Base Titrations

4.5 Oxidation-Reduction (Redox) Reactions
- The Key Event: Movement of Electrons
- Redox Terminology
- Oxidation Numbers
- Stoichiometry of Redox Reactions: Redox Titrations

4.6 Elements in Redox Reactions
- Combination Reactions
- Decomposition Reactions
- Displacement Reactions and Activity Series
- Combustion Reactions

4.7 The Reversibility of Reactions and the Equilibrium State

Concepts and Skills to Review Before You Study This Chapter

- names and formulas of compounds (Section 2.8)
- nature of ionic and covalent bonding (Section 2.7)
- amount-mass-number conversions (Section 3.1)
- balancing chemical equations (Section 3.3)
- calculating quantities of reactants and products (Section 3.4)

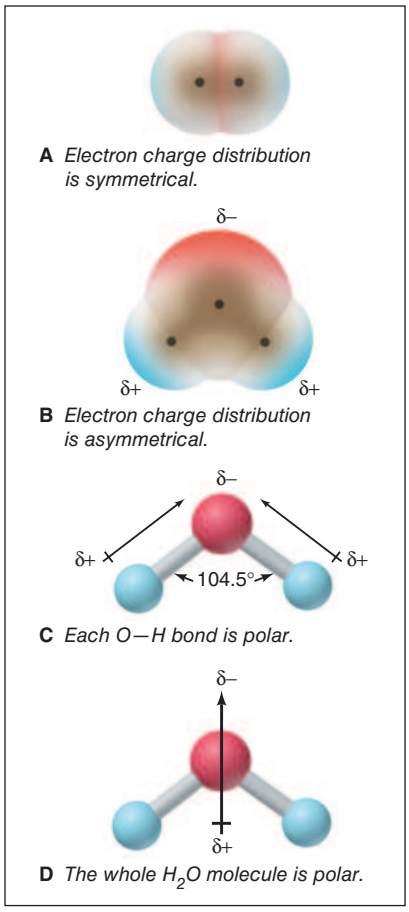
Artists did not have an affordable, stable blue pigment until 1704, when a paint maker accidentally produced Prussian blue in his laboratory. The pigment quickly became extremely popular due to its deep color and because it faded in light much less than other blue pigments; it has since been used by countless artists, including van Gogh and Picasso. This first modern synthetic pigment is produced by a simple reaction occurring in water and is just one of a myriad of products formed by aqueous reactions. In nature, aqueous reactions occur unceasingly in the gigantic containers we know as oceans. And, in every cell of your body, thousands of reactions taking place right now enable you to function. With millions of reactions occurring in and around you, it would be impossible to describe them all. Fortunately, it isn't necessary because when we survey even a small percentage of reactions, especially those in aqueous solution, a few major classes emerge.

IN THIS CHAPTER . . . *We examine the underlying nature of three classes of reactions and the complex part that water plays in aqueous chemistry.*

- We visualize the molecular structure of water to learn its role as solvent, how it interacts with ionic and covalent compounds, and the nature of electrolytes.
- We discuss molarity as a way to express the concentration of an ionic or covalent compound in solution.
- We write ionic equations that represent the species in solution and the actual change that occurs when ionic compounds dissolve and react in water.
- We describe precipitation reactions and learn how to predict when they will occur.
- We see how acids and bases act as electrolytes and how they neutralize each other. We view acid-base reactions as proton-transfer processes and discuss how to quantify these reactions through titration.
- We examine oxidation-reduction (redox) reactions in the formation of ionic and covalent substances. We learn how to determine oxidation numbers and use them to determine oxidizing and reducing agents and how to quantify these reactions through titration. We describe several important types of redox reactions, one of which is used to predict the relative reactivity of metals.
- An introduction to the reversible nature of all chemical change and the nature of equilibrium previews coverage of this central topic in later chapters.

4.1 SOLUTION CONCENTRATION AND THE ROLE OF WATER AS A SOLVENT

In Chapter 2, we defined a solution as a homogeneous mixture with a uniform composition. A solution consists of a smaller quantity of one substance, the **solute,** dissolved in a larger quantity of another, the **solvent;** in an aqueous solution, water serves as the solvent. For any reaction in solution, the solvent plays a key role that depends on its chemical nature. Some solvents passively disperse the substances into individual molecules. But water is much more active, interacting strongly with the substances and even reacting with them in some cases. Let's focus on how the water molecule interacts with both ionic and covalent solutes.



A *Electron charge distribution is symmetrical.*

B *Electron charge distribution is asymmetrical.*

C *Each O—H bond is polar.*

D *The whole H_2O molecule is polar.*

Figure 4.1 **Electron distribution in molecules of H_2 and H_2O.**

The Polar Nature of Water

On the atomic scale, water's great solvent power arises from the *uneven distribution of electron charge* and its *bent molecular shape,* which create a *polar molecule:*

1. *Uneven charge distribution*. Recall from Section 2.7 that the electrons in a covalent bond are shared between the atoms. In a bond between identical atoms—as in H_2, Cl_2, O_2—the sharing is equal and electron charge is distributed evenly between the two nuclei (symmetrical shading in the space-filling model of Figure 4.1A). In covalent bonds between different atoms, the sharing is uneven because one atom attracts the electron pair more strongly than the other atom does.

For example, in each O—H bond of water, the shared electrons are closer to the O atom because an O atom attracts electrons more strongly than an H atom does. (We'll discuss the reasons in Chapter 9.) This uneven charge distribution creates a *polar bond,* one with partially charged "poles." In Figure 4.1B, the asymmetrical shading shows this distribution, and the δ symbol indicates a partial charge. The O end is partially negative, represented by red shading and δ−, and the H end is partially positive, represented by blue shading and δ+. In the ball-and-stick model of Figure 4.1C, the *polar arrow* points to the negative pole, and the tail, shaped like a plus sign, marks the positive pole.

2. *Bent molecular shape*. The sequence of the H—O—H atoms in water is not linear: the water molecule is bent with a bond angle of 104.5° (Figure 4.1C).

3. *Molecular polarity*. The combination of polar bonds and bent shape makes water a **polar molecule:** the region near the O atom is partially negative, and the region between the H atoms is partially positive (Figure 4.1D).

Ionic Compounds in Water

In this subsection, we consider two closely related aspects of aqueous solutions of ionic compounds—how they occur and how they behave. We also use a compound's formula to calculate the amount (mol) of each ion in solution.

How Ionic Compounds Dissolve: Replacement of Charge Attractions In an ionic solid, oppositely charged ions are held together by electrostatic attractions (see Figure 1.3C and Section 2.7). Water separates the ions by *replacing these attractions with others between several water molecules and each ion.* Picture a granule of a soluble ionic compound in water: the negative ends of some water molecules are attracted to the cations, and the positive ends of other water molecules are attracted to the anions (Figure 4.2). Dissolution occurs because the *attractions between each type of ion*

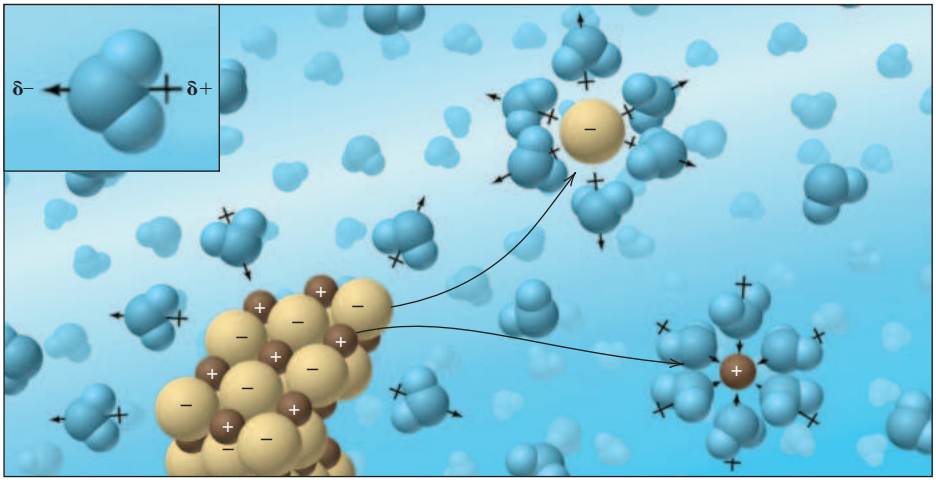


Figure 4.2 **An ionic compound dissolving in water.** The inset shows the polar arrow and partial charges (not shown in the rest of the scene) of each water molecule.

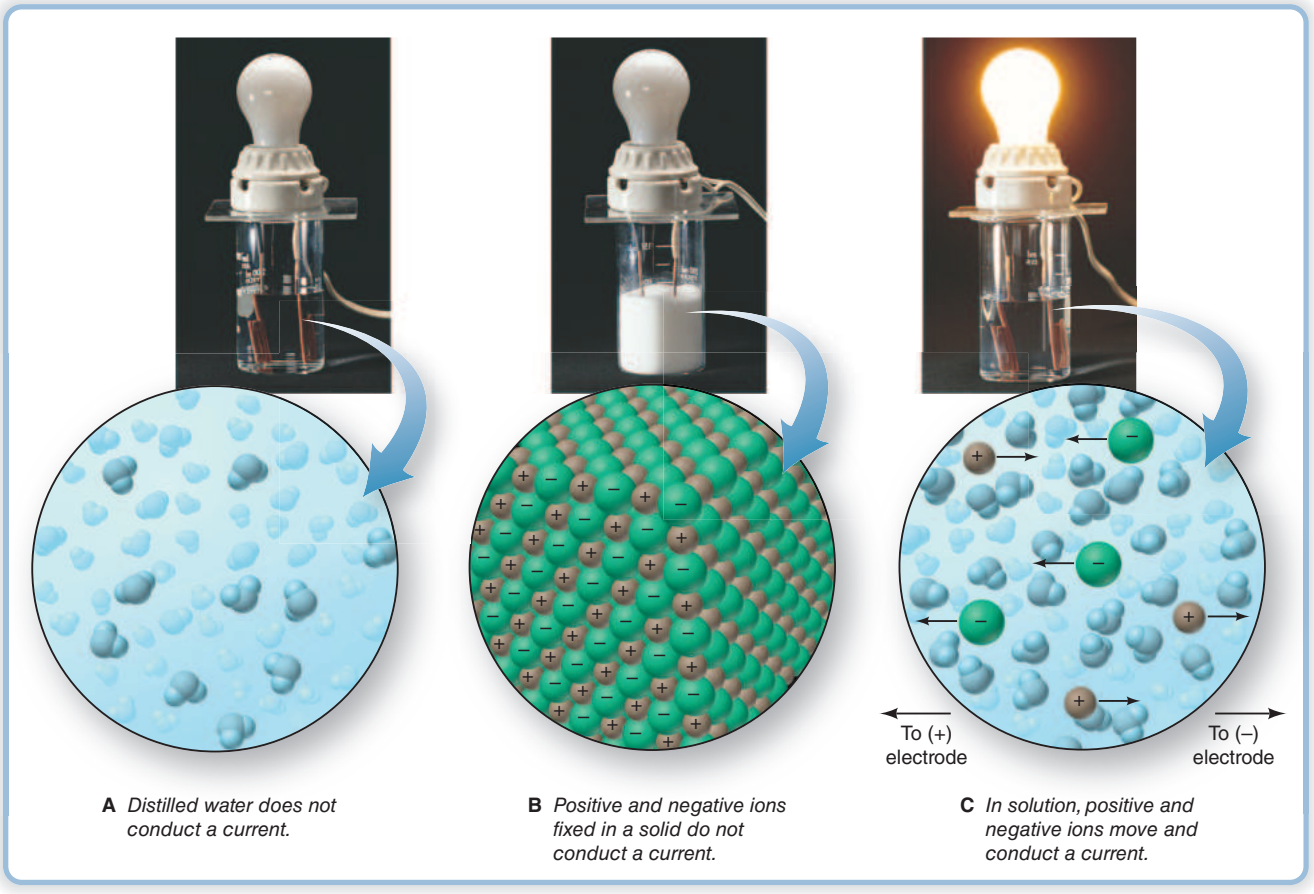
and several water molecules outweigh the attractions between the ions. Gradually, all the ions separate (dissociate), become **solvated**—surrounded closely by solvent molecules—and then move randomly in the solution.

For an ionic compound that doesn't dissolve in water, the attraction between ions is greater than the attraction between the ions and water. Actually, these so-called insoluble substances *do* dissolve to a very small extent, usually several orders of magnitude less than so-called soluble substances. For example, NaCl (a "soluble" compound) is over 4×10^4 times more soluble than AgCl (an "insoluble" compound):

$$\text{Solubility of NaCl in } H_2O \text{ at } 20°C = 365 \text{ g/L}$$
$$\text{Solubility of AgCl in } H_2O \text{ at } 20°C = 0.009 \text{ g/L}$$

In Chapter 13, you'll see that dissolving involves more than a contest between the relative energies of attraction of ions for each other or for water. It is also favored by the greater freedom of motion the ions have when they leave the solid and disperse randomly through the solution.

How Ionic Solutions Behave: Electrolytes and Electrical Conductivity When an ionic compound dissolves, the solution's *electrical conductivity,* the flow of electric current, increases dramatically. When electrodes are immersed in distilled water (Figure 4.3A) or pushed into an ionic solid (Figure 4.3B), no current flows, as shown by the unlit bulb. But in an aqueous solution of the compound, a large current flows, as shown by the lit bulb (Figure 4.3C). Current flow implies the *movement of charged particles:* when the ionic compound dissolves, the separate solvated ions move toward the electrode of opposite charge. A substance that conducts a current when dissolved in water is an **electrolyte.** Soluble ionic compounds are *strong* electrolytes because they dissociate completely and conduct a large current.



A *Distilled water does not conduct a current.*

B *Positive and negative ions fixed in a solid do not conduct a current.*

C *In solution, positive and negative ions move and conduct a current.*

Figure 4.3 **The electrical conductivity of ionic solutions.**

Calculating the Number of Moles of Ions in Solution *From the formula of the soluble ionic compound, we know the number of moles of each ion in solution.* For example, the equations for dissolving KBr and $CaBr_2$ in water to form solvated ions are

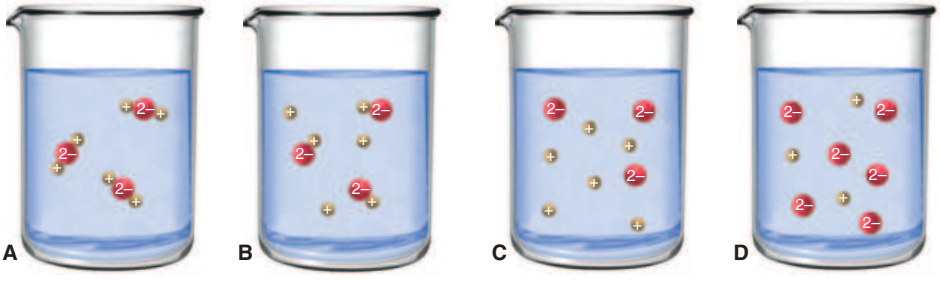
$$KBr(s) \xrightarrow{H_2O} K^+(aq) + Br^-(aq)$$

$$CaBr_2(s) \xrightarrow{H_2O} Ca^{2+}(aq) + 2Br^-(aq)$$

("H_2O" above the arrows means that water is the solvent, not a reactant.) Note that 1 mol of KBr dissociates into 2 mol of ions—1 mol of K^+ and 1 mol of Br^-—and 1 mol of $CaBr_2$ dissociates into 3 mol of ions—1 mol of Ca^{2+} and 2 mol of Br^-. Sample Problems 4.1 and 4.2 apply these ideas, first with molecular scenes and then in calculations.

SAMPLE PROBLEM 4.1 Using Molecular Scenes to Depict an Ionic Compound in Aqueous Solution

Problem The beakers contain aqueous solutions of the strong electrolyte potassium sulfate.
(a) Which beaker best represents the compound in solution (water molecules are not shown)?
(b) If each particle represents 0.1 mol, what is the total number of particles in solution?



Plan **(a)** We determine the formula and write an equation for 1 mol of compound dissociating into ions. Potassium sulfate is a strong electrolyte, so it dissociates completely, but, in general, *polyatomic ions remain intact in solution*. **(b)** We count the number of separate particles, and then multiply by 0.1 mol and by Avogadro's number.

Solution **(a)** The formula is K_2SO_4, so the equation is

$$K_2SO_4(s) \xrightarrow{H_2O} 2K^+(aq) + SO_4^{2-}(aq)$$

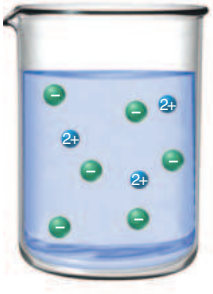
There are two separate 1+ particles for every 2− particle, so beaker C is best.
(b) There are 9 particles, so the total amount (mol) of particles is 0.9 mol, and we have

$$\text{No. of particles} = 0.9 \cancel{\text{mol}} \times \frac{6.022\times10^{23} \text{ particles}}{1 \cancel{\text{mol}}} = 5.420\times10^{23} \text{ particles}$$

Check Rounding to check the math in (b) gives $0.9 \times 6 = 5.4$, so the answer seems correct. The number of particles is an exact number since we actually counted them; thus, the answer can have as many significant figures as in Avogadro's number.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*



4.1A **(a)** Which strong electrolyte is dissolved in water (water molecules not shown) in the beaker at left: LiBr, Cs_2CO_3, or $BaCl_2$? **(b)** If each particle represents 0.05 mol, what mass (g) of compound was dissolved?

4.1B **(a)** Make a drawing similar to that in Follow-up Problem 4.1A that shows two formula units of the strong electrolyte sodium phosphate dissolved in water (without showing any water molecules). **(b)** When 0.40 mol of sodium phosphate is dissolved in water, how many moles of ions result?

SOME SIMILAR PROBLEMS 4.5 and 4.6

SAMPLE PROBLEM 4.2 Determining Amount (mol) of Ions in Solution

Problem What amount (mol) of each ion is in each solution?
(a) 5.0 mol of ammonium sulfate dissolved in water
(b) 78.5 g of cesium bromide dissolved in water
(c) 7.42×10^{22} formula units of copper(II) nitrate dissolved in water

Plan We write an equation that shows 1 mol of compound dissociating into ions. **(a)** We multiply the number of moles of ions by 5.0. **(b)** We first convert grams to moles. **(c)** We first convert formula units to moles.

Solution **(a)** $(NH_4)_2SO_4(s) \xrightarrow{H_2O} 2NH_4^+(aq) + SO_4^{2-}(aq)\, SO_4^{\,2}$
Calculating amount (mol) of NH_4^+ ions:

$$\text{Amount (mol) of } NH_4^+ = 5.0 \text{ mol } (NH_4)_2SO_4 \times \frac{2 \text{ mol } NH_4^+}{1 \text{ mol } (NH_4)_2SO_4} = 10. \text{ mol } NH_4^+$$

The formula shows 1 mol of SO_4^{2-} per mole of $(NH_4)_2SO_4$, so 5.0 mol of SO_4^{2-} is also present.

(b) $CsBr(s) \xrightarrow{H_2O} Cs^+(aq) + Br^-(aq)$
Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of CsBr} = 78.5 \text{ g CsBr} \times \frac{1 \text{ mol CsBr}}{212.8 \text{ g CsBr}} = 0.369 \text{ mol CsBr}$$

Thus, 0.369 mol of Cs^+ and 0.369 mol of Br^- are present.

(c) $Cu(NO_3)_2(s) \xrightarrow{H_2O} Cu^{2+}(aq) + 2NO_3^-(aq)$
Converting from formula units to amount (mol):

$$\text{Amount (mol) of } Cu(NO_3)_2 = 7.42\times10^{22} \text{ formula units } Cu(NO_3)_2 \times \frac{1 \text{ mol } Cu(NO_3)_2}{6.022\times10^{23} \text{ formula units } Cu(NO_3)_2} = 0.123 \text{ mol } Cu(NO_3)_2$$

$$\text{Amount (mol) of } NO_3^- = 0.123 \text{ mol } Cu(NO_3)_2 \times \frac{2 \text{ mol } NO_3^-}{1 \text{ mol } Cu(NO_3)_2} = 0.246 \text{ mol } NO_3^-$$

0.123 mol of Cu^{2+} is also present.

Check Round off to check the math and see if the relative numbers of moles of ions are consistent with the formula. For instance, in (a), 10. mol NH_4^+/5.0 mol SO_4^{2-} = 2 NH_4^+/1 SO_4^{2-}, or $(NH_4)_2SO_4$.

FOLLOW-UP PROBLEMS

4.2A What amount (mol) of each ion is in each solution?
(a) 2 mol of potassium perchlorate dissolved in water
(b) 354 g of magnesium acetate dissolved in water
(c) 1.88×10^{24} formula units of ammonium chromate dissolved in water

4.2B What amount (mol) of each ion is in each solution?
(a) 4 mol of lithium carbonate dissolved in water
(b) 112 g of iron(III) sulfate dissolved in water
(c) 8.09×10^{22} formula units of aluminum nitrate dissolved in water

SOME SIMILAR PROBLEMS 4.18–4.21

Covalent Compounds in Water

Water dissolves many covalent (molecular) compounds also. Table sugar (sucrose, $C_{12}H_{22}O_{11}$), beverage (grain) alcohol (ethanol, CH_3CH_2OH), and automobile antifreeze (ethylene glycol, $HOCH_2CH_2OH$) are some familiar examples. All contain their own

polar bonds, which interact with the bonds of water. However, most soluble covalent substances *do not* separate into ions, but remain intact molecules. For example,

$$HOCH_2CH_2OH(l) \xrightarrow{H_2O} HOCH_2CH_2OH(aq)$$

As a result, their aqueous solutions do not conduct an electric current, and these substances are **nonelectrolytes.** (As you'll see shortly, however, a small group of H-containing molecules that act as acids in aqueous solution *do* dissociate into ions.) Many other covalent substances, such as benzene (C_6H_6) and octane (C_8H_{18}), do not contain polar bonds, and these substances do not dissolve appreciably in water.

Expressing Concentration in Terms of Molarity

When working quantitatively with any solution, it is essential to know the **concentration**—*the quantity of solute dissolved in a given quantity of solution (or of solvent).*

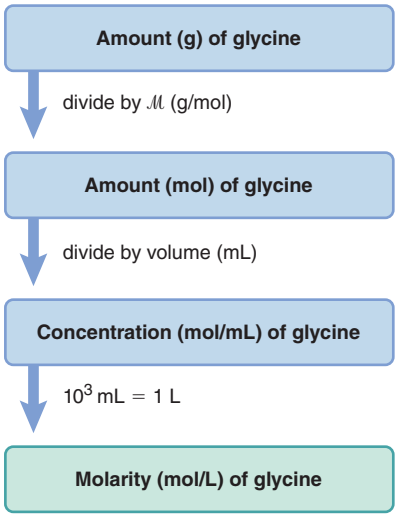
Concentration is an *intensive* property (like density or temperature; Section 1.4) and thus is independent of the solution volume: a 50-L tank of a solution has the *same concentration* (solute quantity/solution quantity) as a 50-mL beaker of the solution. **Molarity (*M*)** is the most common unit of concentration (Chapter 13 covers others). It expresses the concentration in units of *moles of solute per liter of solution:*

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of solution}} \quad \text{or} \quad M = \frac{\text{mol solute}}{\text{L soln}} \tag{4.1}$$

SAMPLE PROBLEM 4.3 Calculating the Molarity of a Solution

Problem Glycine ($C_2H_5NO_2$) has the simplest structure of the 20 amino acids that make up proteins. What is the molarity of a solution that contains 53.7 g of glycine dissolved in 495 mL of solution?

Road Map



Plan The molarity is the number of moles of solute in each liter of solution. We convert the mass (g) of glycine (75.1 g) to amount (mol) by dividing by its molar mass. We divide that number of moles by the volume (495 mL) and convert the volume to liters to find the molarity (see the road map).

Solution Finding the amount (mol) of glycine:

$$\text{Amount (mol) of glycine} = 53.7 \text{ g glycine} \times \frac{1 \text{ mol glycine}}{75.07 \text{ g glycine}} = 0.715 \text{ mol glycine}$$

Dividing by the volume and converting the volume units to obtain molarity:

$$\text{Molarity} = \frac{0.715 \text{ mol glycine}}{495 \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} = 1.44 \, M \text{ glycine}$$

Check A quick look at the math shows about 0.7 mol of glycine in about 0.5 L of solution, so the concentration should be about 1.4 mol/L, or 1.4 *M*.

FOLLOW-UP PROBLEMS

4.3A Calculate the molarity of the solution made when 6.97 g of KI is dissolved in enough water to give a total volume of 100. mL.

4.3B Calculate the molarity of a solution that contains 175 mg of sodium nitrate in a total volume of 15.0 mL.

SOME SIMILAR PROBLEMS 4.22(b), 4.23(c), 4.24(b), and 4.25(a)

Amount-Mass-Number Conversions Involving Solutions

Like many intensive properties, molarity can be used as a *conversion factor* between volume (L) of solution and amount (mol) of solute:

$$\frac{\text{mol solute}}{\text{L solution}} \quad \text{or} \quad \frac{\text{L solution}}{\text{mol solute}}$$

From moles of solute, we can find the mass or the number of entities of solute (Figure 4.4), as applied in Sample Problems 4.4 and 4.5.

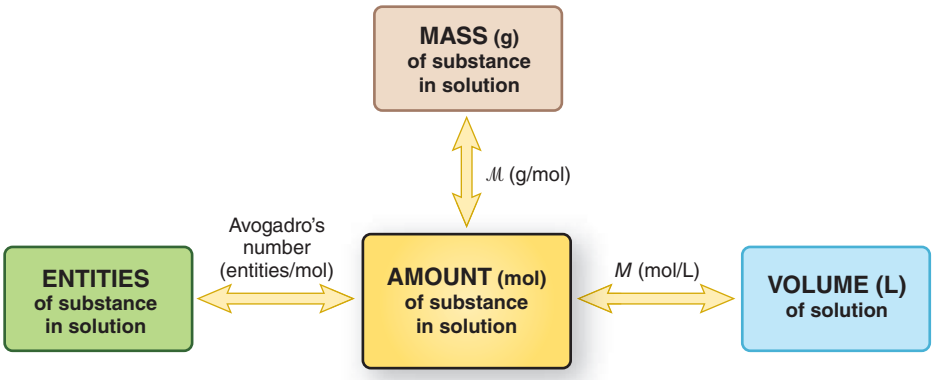


Figure 4.4 Summary of amount-mass-number relationships in solution. The amount (mol) of a substance in solution is related to the volume (L) of solution through the molarity (*M*; mol/L). As always, convert the given quantity to amount (mol) first.

SAMPLE PROBLEM 4.4 Calculating Mass of Solute in a Given Volume of Solution

Problem Biochemists often study reactions in solutions containing phosphate ion, which is commonly found in cells. How many grams of solute are in 1.75 L of 0.460 *M* sodium hydrogen phosphate?

Plan We need the mass (g) of solute, so we multiply the known solution volume (1.75 L) by the known molarity (0.460 *M*) to find the amount (mol) of solute and convert it to mass (g) using the solute's molar mass (see the road map).

Solution Calculating amount (mol) of solute in solution:

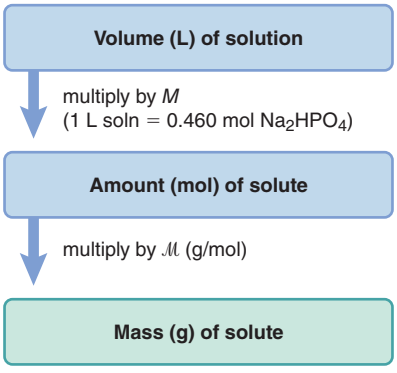
$$\text{Amount (mol) of } Na_2HPO_4 = 1.75 \text{ L soln} \times \frac{0.460 \text{ mol } Na_2HPO_4}{1 \text{ L soln}} = 0.805 \text{ mol } Na_2HPO_4$$

Converting from amount (mol) of solute to mass (g):

$$\text{Mass (g) } Na_2HPO_4 = 0.805 \text{ mol } Na_2HPO_4 \times \frac{141.96 \text{ g } Na_2HPO_4}{1 \text{ mol } Na_2HPO_4} = 114 \text{ g } Na_2HPO_4$$

Check The answer seems to be correct: ~1.8 L of 0.5 mol/L solution contains 0.9 mol, and 150 g/mol × 0.9 mol = 135 g, which is close to 114 g of solute.

Road Map



FOLLOW-UP PROBLEMS

4.4A In biochemistry laboratories, solutions of sucrose (table sugar, $C_{12}H_{22}O_{11}$) are used in high-speed centrifuges to separate the parts of a biological cell. How many liters of 3.30 *M* sucrose contain 135 g of solute? Include a road map that shows how you planned the solution.

4.4B A chemist adds 40.5 mL of a 0.128 *M* solution of sulfuric acid to a reaction mixture. How many moles of sulfuric acid are being added? Include a road map that shows how you planned the solution.

SOME SIMILAR PROBLEMS 4.22(a), 4.22(c), 4.23(a), 4.24(a), 4.25(b), and 4.25(c)

SAMPLE PROBLEM 4.5 Determining Amount (mol) of Ions in a Solution

Problem What amount (mol) of each ion is in 35 mL of 0.84 *M* zinc chloride?

Plan We write an equation that shows 1 mol of compound dissociating into ions. We convert molarity and volume to moles of zinc chloride and use the dissociation equation to convert moles of compound to moles of ions.

Solution $ZnCl_2(aq) \longrightarrow Zn^{2+}(aq) + 2Cl^-(aq)$

Converting from volume (mL) and molarity (mol/L) to amount (mol) of compound:

$$\text{Amount (mol) of } ZnCl_2 = 35 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{0.84 \text{ mol } ZnCl_2}{1 \text{ L}} = 2.9\times10^{-2} \text{ mol } ZnCl_2$$

$$\text{Amount (mol) of } Cl^- = 2.9\times10^{-2} \text{ mol } ZnCl_2 \times \frac{2 \text{ mol } Cl^-}{1 \text{ mol } ZnCl_2} = 5.8\times10^{-2} \text{ mol } Cl^-$$

2.9×10^{-2} mol of Zn^{2+} is also present.

Check The relative numbers of moles of ions are consistent with the formula for zinc chloride: 0.029 mol Zn^{2+}/0.058 mol Cl^- = 1 Zn^{2+}/2 Cl^-, or $ZnCl_2$.

FOLLOW-UP PROBLEMS

4.5A What amount (mol) of each ion is in 1.32 L of 0.55 *M* sodium phosphate?

4.5B What is the molarity of aluminum ion in a solution that contains 1.25 mol of aluminum sulfate in 875 mL?

SOME SIMILAR PROBLEMS 4.23(b), 4.24(c), 4.26, 4.27

Preparing and Diluting Molar Solutions

Notice that the volume term in the denominator of the molarity expression in Equation 4.1 is the *solution* volume, **not** the *solvent* volume. This means that you *cannot* dissolve 1 mol of solute in 1 L of solvent to make a 1 *M* solution. Because the solute volume adds to the solvent volume, the total volume (solute + solvent) would be *more* than 1 L, so the concentration would be *less* than 1 *M*.

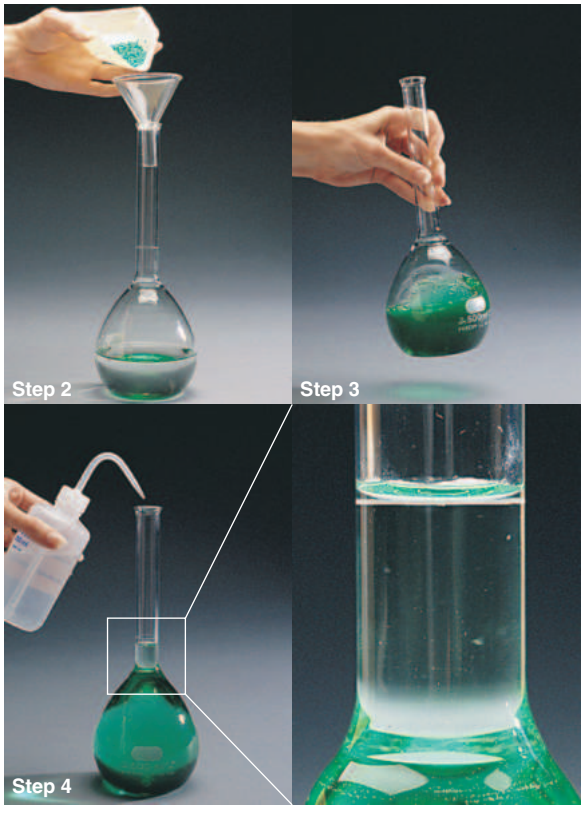


Figure 4.5 Laboratory preparation of molar solutions.

Preparing a Solution Correctly preparing a solution of a solid solute requires four steps. Let's prepare 0.500 L of 0.350 *M* nickel(II) nitrate hexahydrate [$Ni(NO_3)_2 \cdot 6H_2O$]:

1. *Weigh the solid.* Calculate the mass of solid needed by converting from volume (L) to amount (mol) and then to mass (g):

$$\text{Mass (g) of solute} = 0.500 \text{ L soln} \times \frac{0.350 \text{ mol } Ni(NO_3)_2 \cdot 6H_2O}{1 \text{ L soln}} \times \frac{290.82 \text{ g } Ni(NO_3)_2 \cdot 6H_2O}{1 \text{ mol } Ni(NO_3)_2 \cdot 6H_2O} = 50.9 \text{ g } Ni(NO_3)_2 \cdot 6H_2O$$

2. *Transfer the solid.* We need 0.500 L of solution, so we choose a 500-mL volumetric flask (a flask with a fixed volume indicated by a mark on the neck), add enough distilled water to fully dissolve the solute (usually about half the final volume, or 250 mL of distilled water in this case), and transfer the solute. Wash down any solid clinging to the neck with some solvent.
3. *Dissolve the solid.* Swirl the flask until all the solute is dissolved. If necessary, wait until the solution is at room temperature. (As we discuss in Chapter 13, the solution process may be accompanied by heating or cooling.)
4. *Add solvent to the final volume.* Add distilled water to bring the solution volume to the line on the flask neck; cover and mix thoroughly again.

Figure 4.5 shows the last three steps.

Diluting a Solution A concentrated solution (higher molarity) is converted to a dilute solution (lower molarity) by adding solvent, which means the solution volume increases but the amount (mol) of solute stays the same. As a result, the dilute solution contains *fewer solute particles per unit volume* and, thus, has a lower concentration than the concentrated solution (Figure 4.6). Chemists often prepare a concentrated solution *(stock solution)* and store it and dilute it as needed.

Solving Dilution Problems To solve dilution problems, we use the fact that the amount (mol) of solute does not change during the dilution process. Therefore, once we calculate the amount of solute needed to make a particular volume of a dilute solution, we can then calculate the volume of concentrated solution that contains that

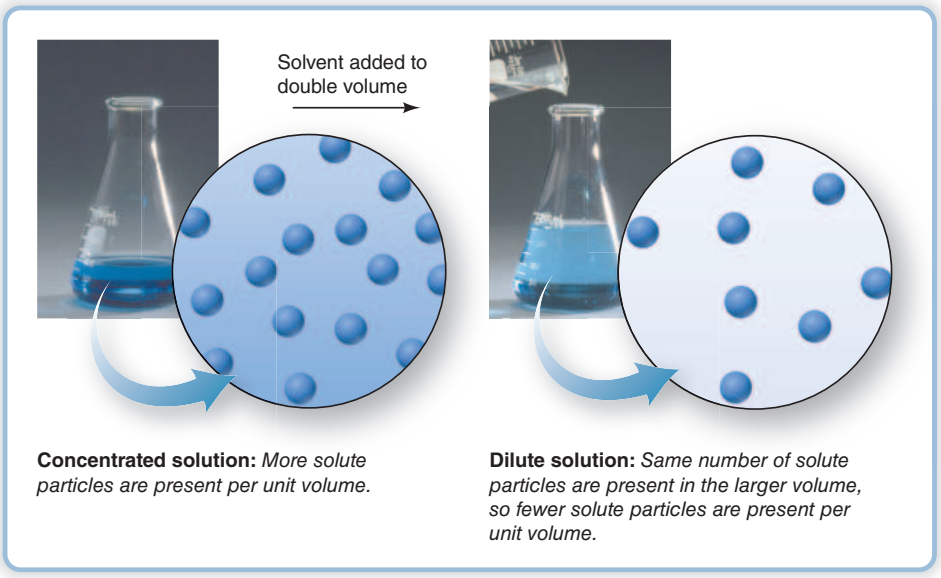

Figure 4.6 Converting a concentrated solution to a dilute solution.

amount of solute. This two-part calculation can be combined into one step in the following relationship:

$$M_{dil} \times V_{dil} = \text{amount (mol)} = M_{conc} \times V_{conc} \qquad (4.2)$$

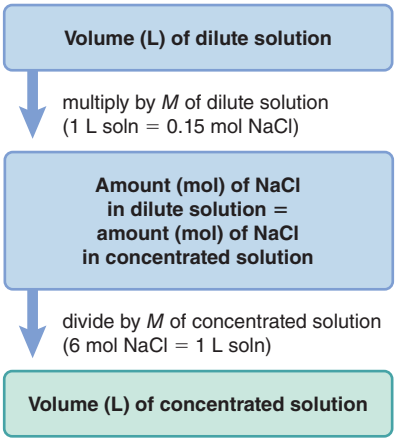
where M and V are the molarity and volume of the *dil*ute (subscript "dil") and *conc*entrated (subscript "conc") solutions. In Sample Problem 4.6, we first use the two-part calculation, followed by the one-step relationship.

SAMPLE PROBLEM 4.6 Preparing a Dilute Solution from a Concentrated Solution

Problem Isotonic saline is 0.15 M aqueous NaCl. It simulates the total concentration of ions in many cellular fluids, and its uses range from cleaning contact lenses to washing red blood cells. How would you prepare 0.80 L of isotonic saline from a 6.0 M stock solution?

Plan To dilute a concentrated solution, we add only solvent, so the *moles of solute are the same in both solutions.* First, we will use a two-part calculation. We know the volume (0.80 L) and molarity (0.15 M) of the dilute (dil) NaCl solution needed, so we find the amount (mol) of NaCl it contains. Then, we find the volume (L) of concentrated (conc; 6.0 M) NaCl solution that contains the same amount (mol) (see the road map). Then we will confirm the answer by using Equation 4.2. Once the final volume is calculated, we add solvent *up to* the final volume.

Road Map



Solution

Two-part calculation: Finding amount (mol) of solute in dilute solution:

$$\text{Amount (mol) of NaCl in dil soln} = 0.80 \text{ L soln} \times \frac{0.15 \text{ mol NaCl}}{1 \text{ L soln}}$$

$$= 0.12 \text{ mol NaCl}$$

Finding amount (mol) of solute in concentrated solution: Because we add only solvent to dilute the solution,

$$\text{Amount (mol) of NaCl in dil soln} = \text{amount (mol) of NaCl in conc soln}$$

$$= 0.12 \text{ mol NaCl}$$

Finding the volume (L) of concentrated solution that contains 0.12 mol of NaCl:

$$\text{Volume (L) of conc NaCl soln} = 0.12 \text{ mol NaCl} \times \frac{1 \text{ L soln}}{6.0 \text{ mol NaCl}}$$

$$= 0.020 \text{ L soln}$$

To confirm, we use Equation 4.2, $M_{dil} \times V_{dil} = M_{conc} \times V_{conc}$, with $M_{dil} = 0.15\ M$, $V_{dil} = 0.80$ L, $M_{conc} = 6.0\ M$, and V_{conc} = unknown:

$$V_{conc} = \frac{M_{dil} \times V_{dil}}{M_{conc}} = \frac{0.15\ M \times 0.80\ \text{L}}{6.0\ M}$$
$$= 0.020\ \text{L soln}$$

To prepare 0.80 L of dilute solution, place 0.020 L of 6.0 *M* NaCl in a 1.0-L graduated cylinder, add distilled water (~780 mL) to the 0.80-L mark, and stir thoroughly.

Check The answer seems reasonable because a small volume of concentrated solution is used to prepare a large volume of dilute solution. Also, the ratio of volumes (0.020 L/0.80 L) is the same as the ratio of concentrations (0.15 *M*/6.0 *M*).

FOLLOW-UP PROBLEMS

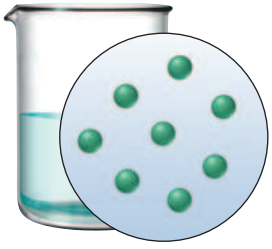
4.6A A chemist dilutes 60.0 mL of 4.50 *M* potassium permanganate to make a 1.25 *M* solution. What is the final volume of the diluted solution?

4.6B A chemical engineer dilutes a stock solution of sulfuric acid by adding 25.0 m^3 of 7.50 *M* acid to enough water to make 500. m^3. What is the concentration of sulfuric acid in the diluted solution, in g/mL?

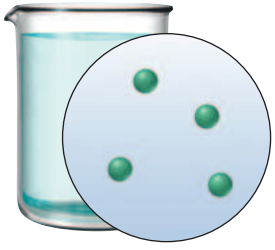
SOME SIMILAR PROBLEMS 4.28 and 4.29

In the next sample problem, we use a variation of Equation 4.2, with molecular scenes showing numbers of particles, to visualize changes in concentration.

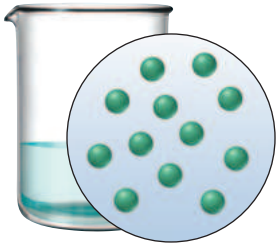
SAMPLE PROBLEM 4.7 Visualizing Changes in Concentration



(a)



(b)



Problem The top circle at left represents a unit volume of a solution. Draw a circle representing a unit volume of the solution after each of these changes:
(a) For every 1 mL of solution, 1 mL of solvent is added.
(b) One-third of the solvent is boiled off.

Plan Given the starting solution, we have to find the number of solute particles in a unit volume after each change. The number of particles per unit volume, *N*, is directly related to the number of moles per unit volume, *M*, so we can use a relationship similar to Equation 4.2 to find the number of particles. **(a)** The volume increases, so the final solution is more dilute—fewer particles per unit volume. **(b)** Some solvent is lost, so the final solution is more concentrated—more particles per unit volume.

Solution **(a)** Finding the number of particles in the dilute solution, N_{dil}:

$$N_{dil} \times V_{dil} = N_{conc} \times V_{conc}$$

thus,
$$N_{dil} = N_{conc} \times \frac{V_{conc}}{V_{dil}} = 8\ \text{particles} \times \frac{1\ \text{mL}}{2\ \text{mL}} = 4\ \text{particles}$$

(b) Finding the number of particles in the concentrated solution, N_{conc}:

$$N_{dil} \times V_{dil} = N_{conc} \times V_{conc}$$

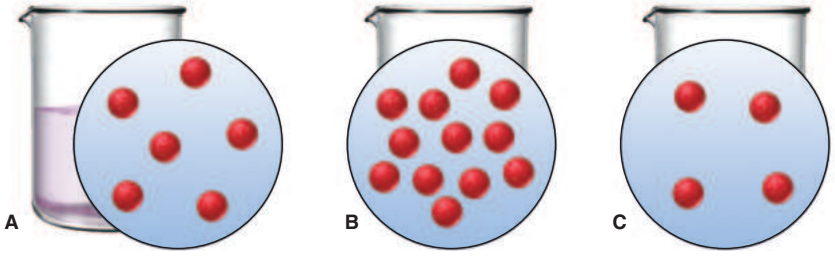
thus,
$$N_{conc} = N_{dil} \times \frac{V_{dil}}{V_{conc}} = 8\ \text{particles} \times \frac{1\ \text{mL}}{\frac{2}{3}\ \text{mL}} = 12\ \text{particles}$$

Check In (a), the volume is doubled (from 1 mL to 2 mL), so the number of particles should be halved; $\frac{1}{2}$ of 8 is 4. In (b), the volume is $\frac{2}{3}$ of the original, so the number of particles should be $\frac{3}{2}$ of the original; $\frac{3}{2}$ of 8 is 12.

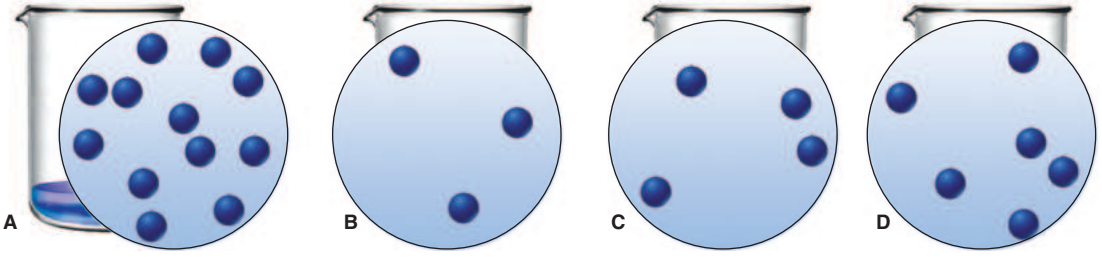
Comment In (b), we assumed that only solvent boils off. This is true with nonvolatile solutes, such as ionic compounds, but in Chapter 13, we'll encounter solutions in which both solvent *and* solute are volatile.

FOLLOW-UP PROBLEMS

4.7A The circle labeled A represents a unit volume of a solution. Explain the changes that must be made to A to obtain the unit volumes in B and C.



4.7B Circle A represents a unit volume of 100. mL of a solution. Which circle (B, C, or D) best represents the unit volume after 300. mL of solvent has been added?



SOME SIMILAR PROBLEMS 4.10 and 4.12

Summary of Section 4.1

- Because of polar bonds and a bent shape, the water molecule is polar, and water dissolves many ionic and covalent compounds.
- When an ionic compound dissolves, the attraction between each ion and water replaces the attraction between ions. Soluble ionic compounds are electrolytes because the ions are free to move and, thus, the solution conducts electricity.
- The formula of a soluble ionic compound shows the number of moles of each ion in solution per mole of compound dissolved.
- Water dissolves many covalent substances that contain polar bonds. These compounds are nonelectrolytes because the molecules remain intact, and, thus, the solution does not conduct electricity.
- The concentration of a solute in a solution can be expressed by molarity which is the number of moles of solute dissolved in 1 liter of solution. A more concentrated solution (higher molarity) is converted to a more dilute solution (lower molarity) by adding solvent.
- Molarity can be used as a conversion factor between volume of solution and amount (mol) of solute, from which you can find mass of solute.

4.2 WRITING EQUATIONS FOR AQUEOUS IONIC REACTIONS

Chemists use three types of equations to represent aqueous ionic reactions. Let's examine a reaction to see what each type shows. When solutions of silver nitrate and sodium chromate are mixed, brick-red, solid silver chromate (Ag_2CrO_4) forms.

Figure 4.7 depicts the reaction at the macroscopic level *(photos)*, the atomic level *(blow-up circles)*, and the symbolic level with the three types of equations (reacting ions are in red type):

- The **molecular equation** *(top)* reveals the least about the species that are actually in solution because *it shows all the reactants and products as if they were intact, undissociated compounds.* Only the designation for solid, (*s*), tells us that a change has occurred:

$$2AgNO_3(aq) + Na_2CrO_4(aq) \longrightarrow Ag_2CrO_4(s) + 2NaNO_3(aq)$$

- The **total ionic equation** *(middle)* is much more accurate because *it shows all the soluble ionic substances as they actually exist in solution, where they are dissociated into ions.* The $Ag_2CrO_4(s)$ stands out as the only undissociated substance:

$$2Ag^+(aq) + 2NO_3^-(aq) + 2Na^+(aq) + CrO_4^{2-}(aq) \longrightarrow Ag_2CrO_4(s) + 2Na^+(aq) + 2NO_3^-(aq)$$

The charges also balance: four positive and four negative for a net zero charge on the left side, and two positive and two negative for a net zero charge on the right.

Notice that $Na^+(aq)$ and $NO_3^-(aq)$ appear unchanged on both sides of the equation. These are called **spectator ions** (shown with pale colors in the atomic-level scenes). They are not involved in the actual chemical change but are present only as part of the reactants; that is, we can't add an Ag^+ ion without also adding an anion, in this case, the NO_3^- ion.

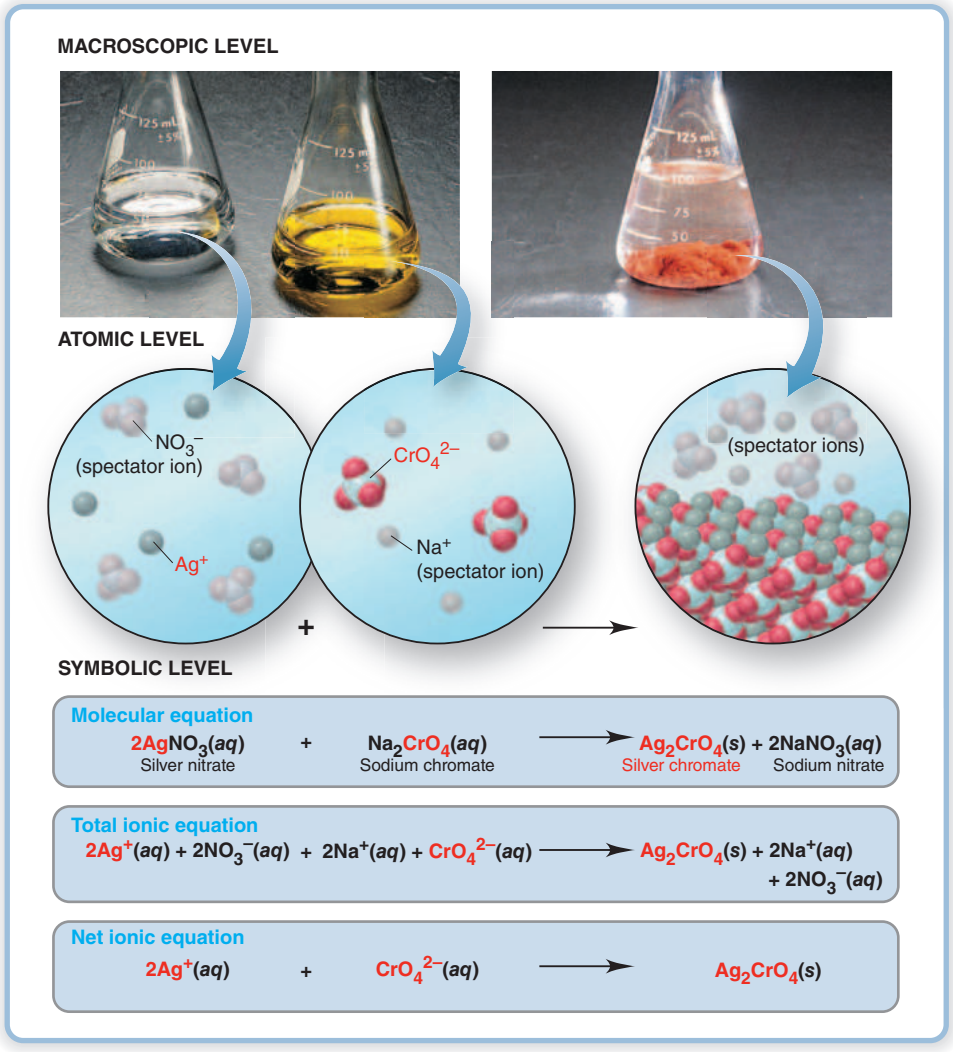


Figure 4.7 An aqueous ionic reaction and the three types of equations.

- The **net ionic equation** *(bottom)* is very useful because *it eliminates the spectator ions and shows only the actual chemical change:*

$$2Ag^+(aq) + CrO_4^{2-}(aq) \longrightarrow Ag_2CrO_4(s)$$

The formation of solid silver chromate from silver ions and chromate ions *is* the only change. To make that point clearly, suppose we had mixed solutions of potassium chromate, $K_2CrO_4(aq)$, and silver acetate, $AgC_2H_3O_2(aq)$, instead of sodium chromate and silver nitrate. The three ionic equations would be

Molecular: $2AgC_2H_3O_2(aq) + K_2CrO_4(aq) \longrightarrow Ag_2CrO_4(s) + 2KC_2H_3O_2(aq)$

Total ionic: $2Ag^+(aq) + 2C_2H_3O_2^-(aq) + 2K^+(aq) + CrO_4^{2-}(aq) \longrightarrow Ag_2CrO_4(s) + 2K^+(aq) + 2C_2H_3O_2^-(aq)$

Net ionic: $2Ag^+(aq) + CrO_4^{2-}(aq) \longrightarrow Ag_2CrO_4(s)$

Thus, the same change would have occurred, and only the spectator ions would differ—$K^+(aq)$ and $C_2H_3O_2^-(aq)$ instead of $Na^+(aq)$ and $NO_3^-(aq)$.

Next, we'll apply these types of equations to three important classes of chemical reactions—precipitation, acid-base, and oxidation-reduction.

Summary of Section 4.2

- A molecular equation shows all substances intact and undissociated into ions.
- A total ionic equation shows all soluble ionic compounds as separate, solvated ions. Spectator ions appear unchanged on both sides of the equation.
- A net ionic equation eliminates the spectator ions and, thus, shows only the actual chemical change.

4.3 PRECIPITATION REACTIONS

Precipitation reactions occur commonly in both nature and commerce. Coral reefs and some gems and minerals form, in part, through this process. And the chemical industry employs precipitation methods to make several important inorganic compounds.

The Key Event: Formation of a Solid from Dissolved Ions

In a **precipitation reaction,** two soluble ionic compounds react to form an insoluble product, a **precipitate.** The reaction you saw between silver nitrate and sodium chromate is one example. Precipitates form for the same reason that some ionic compounds don't dissolve: the electrostatic attraction between the ions outweighs the tendency of the ions to remain solvated and move throughout the solution. When the two solutions are mixed, the ions collide and stay together, and a solid product "comes out of solution." Thus, the key event in a precipitation reaction is *the formation of an insoluble product through the net removal of ions from solution.* Figure 4.8 *(on the next page)* shows the process for calcium fluoride.

Predicting Whether a Precipitate Will Form

To predict whether a precipitate will form when we mix two aqueous ionic solutions, we refer to the short list of solubility rules in Table 4.1 *(on page 153).* Let's see how to apply these rules. When sodium iodide and potassium nitrate are each dissolved in water, their solutions consist of solvated, dispersed ions:

$$NaI(s) \xrightarrow{H_2O} Na^+(aq) + I^-(aq)$$

$$KNO_3(s) \xrightarrow{H_2O} K^+(aq) + NO_3^-(aq)$$

Three steps help us predict if a precipitate forms:

1. *Note the ions in the reactants.* The reactant ions are

$$Na^+(aq) + I^-(aq) + K^+(aq) + NO_3^-(aq) \longrightarrow ?$$

2. *Consider all possible cation-anion combinations.* In addition to NaI and KNO_3, which we know are soluble, the other cation-anion combinations are $NaNO_3$ and KI.

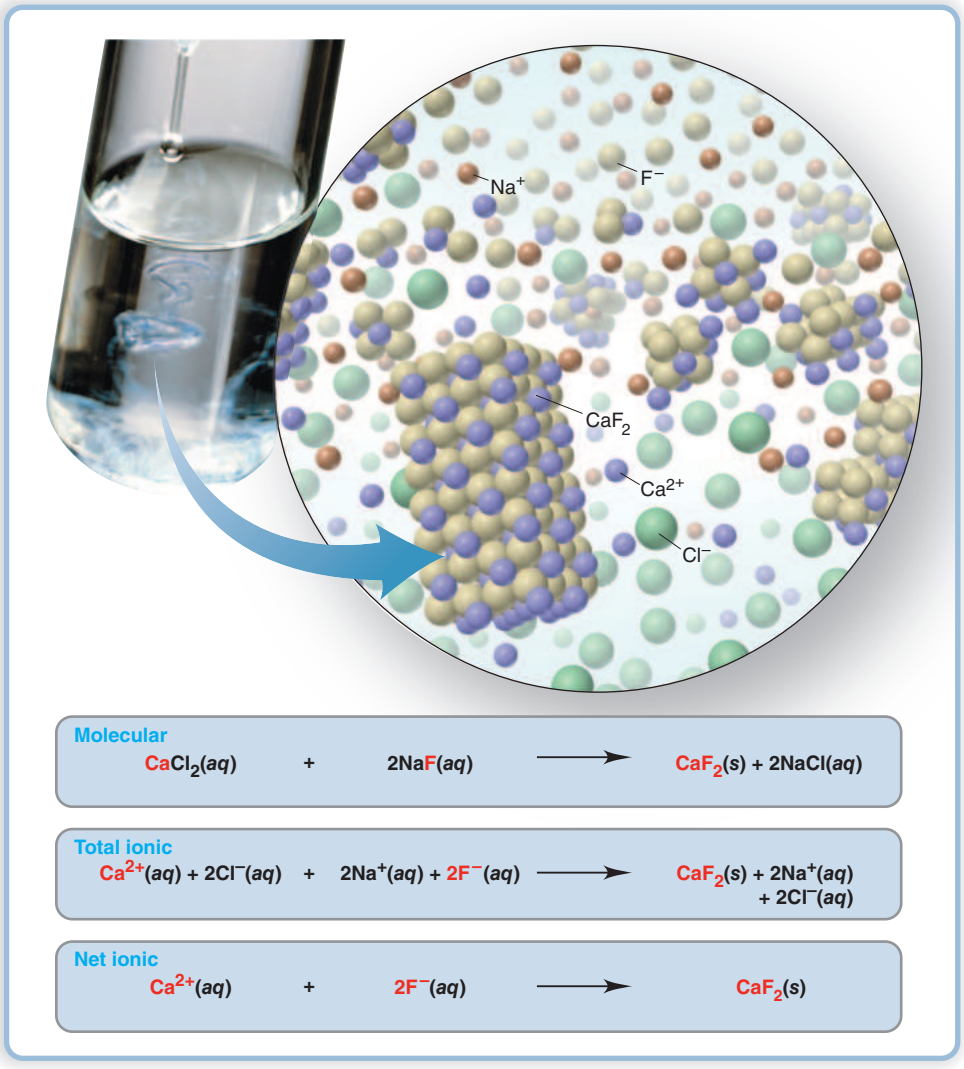

Figure 4.8 The precipitation of calcium fluoride. When aqueous solutions of NaF (from pipet) and $CaCl_2$ (in test tube) react, solid CaF_2 forms (water molecules are omitted for clarity).

3. *Decide whether any combination is insoluble.* According to Table 4.1, all compounds of Group lA(l) ions and all nitrate compounds are soluble. No reaction occurs because all the cation-anion combinations—NaI, KNO_3, $NaNO_3$, and KI—are soluble:

$$Na^+(aq) + I^-(aq) + K^+(aq) + NO_3^-(aq) \longrightarrow Na^+(aq) + NO_3^-(aq) + K^+(aq) + I^-(aq)$$

All the ions are spectator ions, so when we eliminate them, we have no net ionic equation.

Now, what happens if we substitute a solution of lead(II) nitrate, $Pb(NO_3)_2$, for the KNO_3 solution? The reactant ions are Na^+, I^-, Pb^{2+}, and NO_3^-. In addition to the two soluble reactants, NaI and $Pb(NO_3)_2$, the other two possible cation-anion combinations are $NaNO_3$ and PbI_2. According to Table 4.1, $NaNO_3$ is soluble, but PbI_2 is *not*. The total ionic equation shows the reaction that occurs as Pb^{2+} and I^- ions collide and form a precipitate:

$$2Na^+(aq) + 2I^-(aq) + Pb^{2+}(aq) + 2NO_3^-(aq) \longrightarrow 2Na^+(aq) + 2NO_3^-(aq) + PbI_2(s)$$

And the net ionic equation confirms it:

$$Pb^{2+}(aq) + 2I^-(aq) \longrightarrow PbI_2(s)$$

Table 4.1 Solubility Rules for Ionic Compounds in Water

Soluble Ionic Compounds	Insoluble Exceptions
All common compounds of Group 1A(1) ions (Li^+, Na^+, K^+, etc.)	None
All common compounds of ammonium ion (NH_4^+)	None
All common nitrates (NO_3^-), acetates (CH_3COO^- or $C_2H_3O_2^-$), and perchlorates (ClO_4^-)	None
All common chlorides (Cl^-), bromides (Br^-), and iodides (I^-)	Chlorides, bromides, and iodides of Ag^+, Pb^{2+}, Cu^+, and Hg_2^{2+}
All common fluorides (F^-)	PbF_2 and fluorides of Group 2A(2)
All common sulfates (SO_4^{2-})	$CaSO_4$, $SrSO_4$, $BaSO_4$, Ag_2SO_4, $PbSO_4$
Insoluble Ionic Compounds	**Soluble Exceptions**
All common metal hydroxides	Group 1A(1) hydroxides and $Ca(OH)_2$, $Sr(OH)_2$, and $Ba(OH)_2$
All common carbonates (CO_3^{2-}) and phosphates (PO_4^{3-})	Carbonates and phosphates of Group 1A(1) and NH_4^+
All common sulfides	Sulfides of Group 1A(1), Group 2A(2), and NH_4^+

A Type of Metathesis Reaction The molecular equation for the reaction between $Pb(NO_3)_2$ and NaI shows *the ions exchanging partners* (Figure 4.9):

$$2NaI(aq) + Pb(NO_3)_2(aq) \longrightarrow PbI_2(s) + 2NaNO_3(aq)$$

Such reactions are called *double-displacement reactions,* or **metathesis** (pronounced *meh-TA-thuh-sis*) **reactions.** Some that involve precipitation are important in industry, including the preparation of silver bromide used in black-and-white film:

$$AgNO_3(aq) + KBr(aq) \longrightarrow AgBr(s) + KNO_3(aq)$$

The reactions that form Ag_2CrO_4 (Figure 4.7) and CaF_2 (Figure 4.8) are also examples of metathesis reactions, as are acid–base reactions (Section 4.4). Sample Problems 4.8 and 4.9 provide practice in predicting if a precipitate forms.

$2NaI(aq) + Pb(NO_3)_2(aq) \longrightarrow PbI_2(s) + 2NaNO_3(aq)$

Figure 4.9 The precipitation of PbI_2, a metathesis reaction.

SAMPLE PROBLEM 4.8 Predicting Whether a Precipitation Reaction Occurs; Writing Ionic Equations

Problem Does a reaction occur when each of these pairs of solutions is mixed? If so, write balanced molecular, total ionic, and net ionic equations, and identify the spectator ions.

(a) Potassium fluoride(aq) + strontium nitrate(aq) ⟶

(b) Ammonium perchlorate(aq) + sodium bromide(aq) ⟶

Plan We note the reactant ions, write the cation-anion combinations, and refer to Table 4.1 to see if any are insoluble. For the molecular equation, we predict the products and write them all as intact compounds. For the total ionic equation, we write the soluble compounds as separate ions. For the net ionic equation, we eliminate the spectator ions.

Solution **(a)** In addition to the reactants, the two other ion combinations are strontium fluoride and potassium nitrate. Table 4.1 shows that strontium fluoride is insoluble, so a reaction *does* occur. Writing the molecular equation:

$$2KF(aq) + Sr(NO_3)_2(aq) \longrightarrow SrF_2(s) + 2KNO_3(aq)$$

Writing the total ionic equation:

$$2K^+(aq) + 2F^-(aq) + Sr^{2+}(aq) + 2NO_3^-(aq) \longrightarrow SrF_2(s) + 2K^+(aq) + 2NO_3^-(aq)$$

Writing the net ionic equation:

$$Sr^{2+}(aq) + 2F^-(aq) \longrightarrow SrF_2(s)$$

The spectator ions are K^+ and NO_3^-.

(b) The other ion combinations are ammonium bromide and sodium perchlorate. Table 4.1 shows that ammonium, sodium, and perchlorate compounds are soluble, and all bromides are soluble except those of Ag^+, Pb^{2+}, Cu^+, and Hg_2^{2+}. Therefore, ***no*** reaction occurs. The compounds remain as solvated ions.

FOLLOW-UP PROBLEMS

4.8A Predict whether a reaction occurs, and if so, write balanced total and net ionic equations:

(a) Iron(III) chloride(aq) + cesium phosphate(aq) ⟶

(b) Sodium hydroxide(aq) + cadmium nitrate(aq) ⟶

(c) Magnesium bromide(aq) + potassium acetate(aq) ⟶

4.8B Predict whether a reaction occurs, and if so, write balanced total and net ionic equations:

(a) Silver nitrate(aq) + barium chloride(aq) ⟶

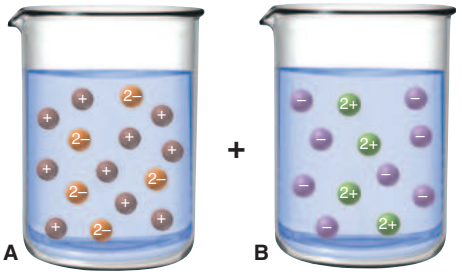
(b) Ammonium carbonate(aq) + potassium sulfide(aq) ⟶

(c) Nickel(II) sulfate(aq) + lead(II) nitrate(aq) ⟶

SOME SIMILAR PROBLEMS 4.41–4.46

SAMPLE PROBLEM 4.9 Using Molecular Depictions in Precipitation Reactions

Problem The molecular views below depict reactant solutions for a precipitation reaction (with ions shown as colored spheres and water omitted for clarity):



(a) Which compound is dissolved in beaker A: KCl, Na_2SO_4, $MgBr_2$, or Ag_2SO_4?

(b) Which compound is dissolved in beaker B: NH_4NO_3, $MgSO_4$, $Ba(NO_3)_2$, or CaF_2?

(c) Name the precipitate and the spectator ions when solutions A and B are mixed, and write balanced molecular, total ionic, and net ionic equations for any reaction.

(d) If each particle represents 0.010 mol of ions, what is the maximum mass (g) of precipitate that can form (assuming complete reaction)?

Plan **(a)** and **(b)** From the depictions, we note the charge and number of each kind of ion and use Table 4.1 to determine the ion combinations that are soluble. **(c)** Once we know the combinations, Table 4.1 tells which two ions form the solid, so the other two are spectator ions. **(d)** This part is a limiting-reactant problem because the amounts of two species are involved. We count the number of each kind of ion that forms the solid. We multiply the number of each reactant ion by 0.010 mol and calculate the amount (mol) of product that forms from each. Whichever ion forms less is limiting, so we use the molar mass of the precipitate to find mass (g).

Solution **(a)** In solution A, there are two 1+ particles for each 2− particle. Therefore, the dissolved compound cannot be KCl or $MgBr_2$. Of the remaining two choices, Ag_2SO_4 is insoluble, so the dissolved compound must be Na_2SO_4.

(b) In solution B, there are two 1− particles for each 2+ particle. Therefore, the dissolved compound cannot be NH_4NO_3 or $MgSO_4$. Of the remaining two choices, CaF_2 is insoluble, so the dissolved compound must be $Ba(NO_3)_2$.

(c) Of the two possible ion combinations, $BaSO_4$ and $NaNO_3$, $BaSO_4$ is insoluble, so Na^+ and NO_3^- are spectator ions.

Molecular: $Ba(NO_3)_2(aq) + Na_2SO_4(aq) \longrightarrow BaSO_4(s) + 2NaNO_3(aq)$

Total ionic: $Ba^{2+}(aq) + 2NO_3^-(aq) + 2Na^+(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s) + 2NO_3^-(aq) + 2Na^+(aq)$

Net ionic: $Ba^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s)$

(d) Finding the ion that is the limiting reactant:

For Ba^{2+}:

$$\text{Amount (mol) of } BaSO_4 = 4\ \cancel{Ba^{2+}\ \text{particles}} \times \frac{0.010\ \cancel{\text{mol } Ba^{2+}\ \text{ions}}}{1\ \cancel{Ba^{2+}\ \text{particle}}} \times \frac{1\ \text{mol } BaSO_4}{1\ \cancel{\text{mol } Ba^{2+}\ \text{ions}}}$$

$$= 0.040\ \text{mol } BaSO_4$$

For SO_4^{2-}:

$$\text{Amount (mol) of } BaSO_4 = 5 \text{ } \cancel{SO_4^{2-} \text{ particles}} \times \frac{0.010 \text{ } \cancel{\text{mol } SO_4^{2-} \text{ ions}}}{1 \text{ } \cancel{SO_4^{2-} \text{ particle}}} \times \frac{1 \text{ mol } BaSO_4}{1 \text{ } \cancel{\text{mol } SO_4^{2-} \text{ ions}}}$$

$$= 0.050 \text{ mol } BaSO_4$$

Therefore, Ba^{2+} ion is the limiting reactant.
Calculating the mass (g) of product ($\mathcal{M}$ of $BaSO_4$ = 233.4 g/mol):

$$\text{Mass (g) of } BaSO_4 = 0.040 \text{ } \cancel{\text{mol } BaSO_4} \times \frac{233.4 \text{ g } BaSO_4}{1 \text{ } \cancel{\text{mol } BaSO_4}} = \boxed{9.3 \text{ g } BaSO_4}$$

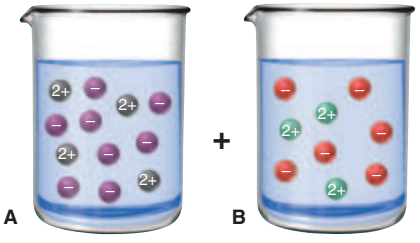
Check Counting the number of Ba^{2+} ions allows a more direct calculation for a check: four Ba^{2+} particles means the maximum mass of $BaSO_4$ that can form is

$$\text{Mass (g) of } BaSO_4 = 4 \text{ } \cancel{Ba^{2+} \text{ particles}} \times \frac{0.010 \text{ } \cancel{\text{mol } Ba^{2+} \text{ ions}}}{1 \text{ } \cancel{Ba^{2+} \text{ particle}}} \times \frac{1 \text{ } \cancel{\text{mol } BaSO_4}}{1 \text{ } \cancel{\text{mol } Ba^{2+} \text{ ions}}} \times \frac{233.4 \text{ g } BaSO_4}{1 \text{ } \cancel{\text{mol}}}$$

$$= 9.3 \text{ g } BaSO_4$$

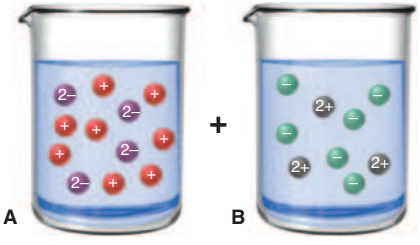
FOLLOW-UP PROBLEMS

4.9A Molecular views of the reactant solutions for a precipitation reaction are shown below (with ions represented as spheres and water molecules omitted):



(a) Which compound is dissolved in beaker A: $Zn(NO_3)_2$, KCl, Na_2SO_4, or $PbCl_2$?
(b) Which compound is dissolved in beaker B: $(NH_4)_2SO_4$, $Cd(OH)_2$, $Ba(OH)_2$, or KNO_3?
(c) Name the precipitate and the spectator ions when solutions A and B are mixed, and write balanced molecular, total ionic, and net ionic equations for the reaction.
(d) If each particle represents 0.050 mol of ions, what is the maximum mass (g) of precipitate that can form (assuming complete reaction)?

4.9B Molecular views of the reactant solutions for a precipitation reaction are shown below (with ions represented as spheres and water molecules omitted):



(a) Which compound is dissolved in beaker A: Li_2CO_3, NH_4Cl, Ag_2SO_4, or FeS?
(b) Which compound is dissolved in beaker B: $Ni(OH)_2$, $AgNO_3$, $CaCl_2$, or $BaSO_4$?
(c) Name the precipitate and the spectator ions when solutions A and B are mixed, and write balanced molecular, total ionic, and net ionic equations for the reaction.
(d) If each particle represents 0.20 mol of ions, what is the maximum mass (g) of precipitate that can form (assuming complete reaction)?

SOME SIMILAR PROBLEMS 4.51 and 4.52

Stoichiometry of Precipitation Reactions

In Chapter 3, we saw that the amounts (mol) of reactants and products in a reaction are stoichiometrically equivalent to each other and that the molar ratios between them can be used as conversion factors to calculate the amount of one substance that reacts

with, produces, or is formed from a specific amount of another substance. Solving stoichiometry problems for any reaction that takes place in solution, such as a precipitation reaction, requires the additional step of converting the volume of reactant or product in solution to amount (mol):

1. Balance the equation.
2. Find the amount (mol) of one substance using its molar mass (for a pure substance) or the volume and molarity (for a substance in solution).
3. Relate that amount to the stoichiometrically equivalent amount of another substance.
4. Convert to the desired units.

Figure 4.10 summarizes the possible relationships among quantities of substances in a reaction occurring in solution. Sample Problems 4.10 and 4.11 apply these relationships to precipitation reactions, and we'll also use them for the other classes of reactions.

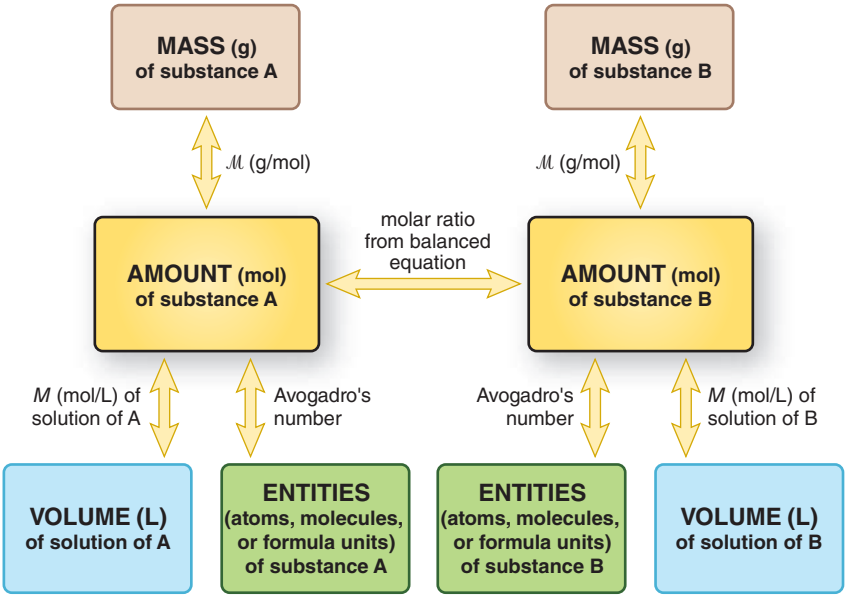


Figure 4.10 Summary of amount-mass-number relationships for a chemical reaction in solution.

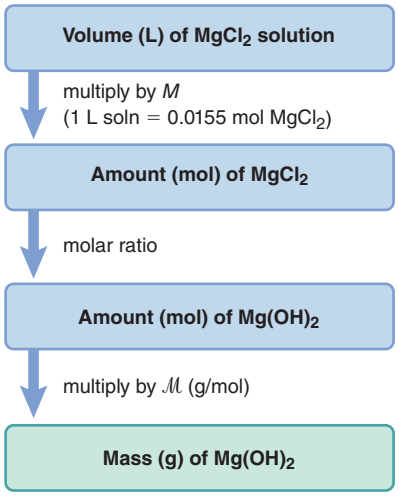
SAMPLE PROBLEM 4.10 Calculating Amounts of Reactants and Products in a Precipitation Reaction

Problem Magnesium is the second most abundant metal in seawater, after sodium. The first step in its industrial extraction involves the reaction of the magnesium ion with calcium hydroxide to precipitate magnesium hydroxide. What mass of magnesium hydroxide is formed when 0.180 L of 0.0155 *M* magnesium chloride reacts with excess calcium hydroxide?

Plan We are given the molarity (0.0155 *M*) and the volume (0.180 L) of magnesium chloride solution that reacts with excess calcium hydroxide, and we must find the mass of precipitate. After writing the balanced equation, we find the amount (mol) of magnesium chloride from its molarity and volume and use the molar ratio to find the amount (mol) of magnesium hydroxide that is produced. Finally, we use the molar mass to convert from amount (mol) to mass (g) of magnesium hydroxide (see the road map).

Road Map



Solution Writing the balanced equation:

$$MgCl_2(aq) + Ca(OH)_2(aq) \longrightarrow Mg(OH)_2(s) + CaCl_2(aq)$$

Finding the amount (mol) of $MgCl_2$:

$$\text{Amount (mol) of } MgCl_2 = 0.180 \text{ L } \cancel{MgCl_2} \times \frac{0.0155 \text{ mol } MgCl_2}{1 \text{ L } \cancel{MgCl_2}} = 0.00279 \text{ mol } MgCl_2$$

Using the molar ratio to convert amount (mol) of $MgCl_2$ to amount (mol) of $Mg(OH)_2$:

$$\text{Amount (mol) of } Mg(OH)_2 = 0.00279 \text{ } \cancel{\text{mol } MgCl_2} \times \frac{1 \text{ mol } Mg(OH)_2}{1 \text{ } \cancel{\text{mol } MgCl_2}}$$

$$= 0.00279 \text{ mol } Mg(OH)_2$$

Converting from amount (mol) of $Mg(OH)_2$ to mass (g):

$$\text{Mass (g) of } Mg(OH)_2 = 0.00279 \text{ mol } Mg(OH)_2 \times \frac{58.33 \text{ g } Mg(OH)_2}{1 \text{ mol } Mg(OH)_2} = 0.163 \text{ g } Mg(OH)_2$$

Check The answer seems reasonable; rounding to check the math shows that we have (0.2 L) × (0.02 *M*) = 0.004 mol of $MgCl_2$; due to the 1/1 molar ratio, 0.004 mol of $Mg(OH)_2$ is produced.

FOLLOW-UP PROBLEMS

4.10A It is desirable to remove calcium ion from hard water to prevent the formation of precipitates known as *boiler scale* that reduce heating efficiency. The calcium ion is reacted with sodium phosphate to form solid calcium phosphate, which is easier to remove than boiler scale. What volume of 0.260 *M* sodium phosphate is needed to react completely with 0.300 L of 0.175 *M* calcium chloride?

4.10B To lift fingerprints from a crime scene, a solution of silver nitrate is sprayed on a surface to react with the sodium chloride left behind by perspiration. What is the molarity of a silver nitrate solution if 45.0 mL of it reacts with excess sodium chloride to produce 0.148 g of precipitate?

SOME SIMILAR PROBLEMS 4.47, 4.48, 4.53, and 4.54

Except for the additional step of finding amounts (mol) in solution, limiting-reactant problems for precipitation reactions in solution are handled just like other such problems.

SAMPLE PROBLEM 4.11 Solving a Limiting-Reactant Problem for a Precipitation Reaction

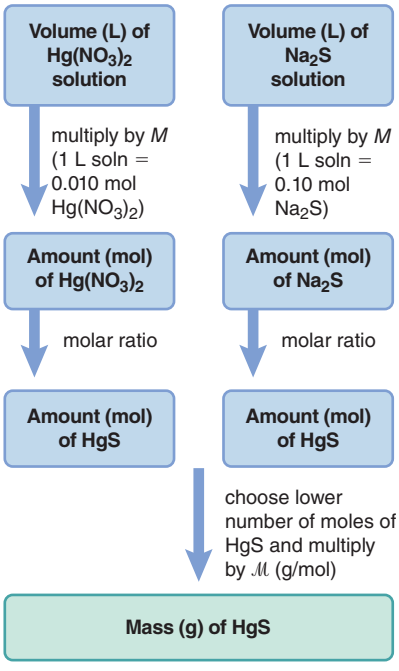
Problem Mercury and its compounds have uses from fillings for teeth (as a mixture with silver, copper, and tin) to the production of chlorine. Because of their toxicity, however, soluble mercury compounds, such as mercury(II) nitrate, must be removed from industrial wastewater. One removal method reacts the wastewater with sodium sulfide solution to produce solid mercury(II) sulfide and sodium nitrate solution. In a laboratory simulation, 0.050 L of 0.010 *M* mercury(II) nitrate reacts with 0.020 L of 0.10 *M* sodium sulfide.

(a) How many grams of mercury(II) sulfide form?

(b) Write a reaction table for this process.

Plan This is a limiting-reactant problem because *the quantities of two reactants are given.* After balancing the equation, we determine the limiting reactant. From the molarity and volume of each solution, we calculate the amount (mol) of each reactant. Then, we use the molar ratio to find the amount of product (HgS) that each reactant forms. The limiting reactant forms fewer moles of HgS, which we convert to mass (g) of HgS using its molar mass (see the road map). We use the amount of HgS formed from the limiting reactant in a reaction table (see Section 3.4).

Road Map



Solution **(a)** Writing the balanced equation:

$$Hg(NO_3)_2(aq) + Na_2S(aq) \longrightarrow HgS(s) + 2NaNO_3(aq)$$

Finding the amount (mol) of HgS formed from $Hg(NO_3)_2$: Combining the steps gives

$$\text{Amount (mol) of HgS} = 0.050 \text{ L soln} \times \frac{0.010 \text{ mol } Hg(NO_3)_2}{1 \text{ L soln}} \times \frac{1 \text{ mol HgS}}{1 \text{ mol } Hg(NO_3)_2}$$

$$= \mathbf{5.0 \times 10^{-4} \text{ mol HgS}}$$

Finding the amount (mol) of HgS from Na_2S: Combining the steps gives

$$\text{Amount (mol) of HgS} = 0.020 \text{ L soln} \times \frac{0.10 \text{ mol } Na_2S}{1 \text{ L soln}} \times \frac{1 \text{ mol HgS}}{1 \text{ mol } Na_2S}$$

$$= \mathbf{2.0 \times 10^{-3} \text{ mol HgS}}$$

$Hg(NO_3)_2$ is the limiting reactant because it forms fewer moles of HgS.

Converting the amount (mol) of HgS formed from $Hg(NO_3)_2$ to mass (g):

$$\text{Mass (g) of HgS} = 5.0 \times 10^{-4} \text{ mol HgS} \times \frac{232.7 \text{ g HgS}}{1 \text{ mol HgS}} = 0.12 \text{ g HgS}$$

(b) With $Hg(NO_3)_2$ as the limiting reactant, the reaction table is

Amount (mol)	$Hg(NO_3)_2(aq)$	+	$Na_2S(aq)$	⟶	$HgS(s)$	+	$2NaNO_3(aq)$
Initial	5.0×10^{-4}		2.0×10^{-3}		0		0
Change	-5.0×10^{-4}		-5.0×10^{-4}		$+5.0\times10^{-4}$		$+1.0\times10^{-3}$
Final	0		1.5×10^{-3}		5.0×10^{-4}		1.0×10^{-3}

A large excess of Na_2S remains after the reaction. Note that the amount of $NaNO_3$ formed is twice the amount of $Hg(NO_3)_2$ consumed, as the balanced equation shows.

Check As a check on our choice of the limiting reactant, let's use the alternative method in Sample Problem 3.20 (see Comment, pp. 121–122).

Finding amount (mol) of reactants given:

$$\text{Amount (mol) of } Hg(NO_3)_2 = 0.050 \text{ L soln} \times \frac{0.010 \text{ mol } Hg(NO_3)_2}{1 \text{ L soln}}$$

$$= 5.0\times10^{-4} \text{ mol } Hg(NO_3)_2$$

$$\text{Amount (mol) of } Na_2S = 0.020 \text{ L soln} \times \frac{0.10 \text{ mol } Na_2S}{1 \text{ L soln}}$$

$$= 2.0\times10^{-3} \text{ mol } Na_2S$$

The molar ratio of the reactants is 1 $Hg(NO_3)_2$/1 Na_2S. Therefore, $Hg(NO_3)_2$ is limiting because there is less of it than we would need to react with all of the available Na_2S.

FOLLOW-UP PROBLEMS

4.11A Despite the toxicity of lead, many of its compounds are still used to make pigments. **(a)** When 268 mL of 1.50 *M* lead(II) acetate reacts with 130. mL of 3.40 *M* sodium chloride, how many grams of solid lead(II) chloride can form? **(b)** Using the abbreviation "Ac" for the acetate ion, write a reaction table for the process.

4.11B Iron(III) hydroxide has been used to adsorb arsenic and heavy metals from contaminated soil and water. Solid iron(III) hydroxide is produced by reacting aqueous solutions of iron(III) chloride and sodium hydroxide. **(a)** What mass of iron(III) hydroxide is formed when 155 mL of 0.250 *M* iron(III) chloride reacts with 215 mL of 0.300 *M* sodium hydroxide? **(b)** Write a reaction table for this process.

SOME SIMILAR PROBLEMS 4.49, 4.50, and 4.56

Summary of Section 4.3

- In a precipitation reaction, an insoluble ionic compound forms when solutions of two soluble ones are mixed. The electrostatic attraction between certain pairs of solvated ions is strong enough to overcome the attraction of each ion for water.
- Based on a set of solubility rules, we can predict the formation of a precipitate by noting which of all possible cation-anion combinations is insoluble.
- When chemical changes such as precipitation reactions occur in solution, amounts of reactants and products are given in terms of concentration and volume.
- By using molarity as a conversion factor, we can apply the principles of stoichiometry to precipitation reactions in solution.

4.4 ACID-BASE REACTIONS

Aqueous acid-base reactions occur in processes as diverse as the metabolic action of proteins and carbohydrates, the industrial production of fertilizer, and the revitalization of lakes damaged by acid rain.

These reactions involve water as reactant or product, in addition to its common role as solvent. Of course, an **acid-base reaction** (also called a **neutralization reaction**) occurs when an acid reacts with a base, but the definitions of these terms and the scope

of this reaction class have changed over the years. For our purposes at this point, we'll use definitions that apply to substances found commonly in the lab:

- *An **acid** is a substance that produces H^+ ions when dissolved in water.*

$$HX \xrightarrow{H_2O} H^+(aq) + X^-(aq)$$

- *A **base** is a substance that produces OH^- ions when dissolved in water.*

$$MOH \xrightarrow{H_2O} M^+(aq) + OH^-(aq)$$

(Other definitions are presented later in this section and in Chapter 18.)

Acids and the Solvated Proton *Acidic solutions arise when certain covalent H-containing molecules dissociate into ions in water.* In every case, these molecules contain a *polar bond to H* in which the other atom pulls much more strongly on the electron pair. A good example is HBr. The Br end of the H—Br bond is partially negative, and the H end is partially positive. When hydrogen bromide gas dissolves in water, the poles of H_2O molecules are attracted to the oppositely charged poles of the HBr. The bond breaks, with H becoming the solvated cation $H^+(aq)$ and Br becoming the solvated anion $Br^-(aq)$:

$$HBr(g) \xrightarrow{H_2O} H^+(aq) + Br^-(aq)$$

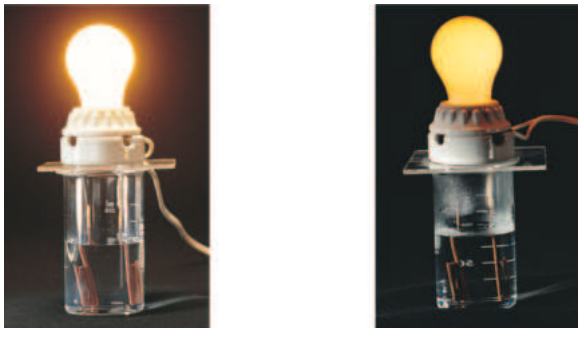
The solvated H^+ ion is a very unusual species. The H atom is a proton surrounded by an electron, so H^+ is just a proton. With a full positive charge concentrated in such a tiny volume, H^+ attracts the negative pole of water molecules so strongly that it forms a covalent bond to one of them. We can show this interaction by writing the solvated H^+ ion as an H_3O^+ ion (hydronium ion) that also is solvated:

$$HBr(g) + H_2O(l) \longrightarrow H_3O^+(aq) + Br^-(aq)$$

The hydronium ion, which we write as H_3O^+ [or $(H_2O)H^+$], associates with other water molecules to give species such as $H_5O_2^+$ [or $(H_2O)_2H^+$], $H_7O_3^+$ [or $(H_2O)_3H^+$], $H_9O_4^+$ [or $(H_2O)_4H^+$], and so forth. Figure 4.11 shows $H_7O_3^+$, an H_3O^+ ion associated *(dotted lines)* with two H_2O molecules. As a general notation for these various species, we write $H^+(aq)$, but later in this chapter and in much of the text, we'll use $H_3O^+(aq)$.

Acids and Bases as Electrolytes Acids and bases are categorized in terms of their "strength," the degree to which they dissociate into ions in water (Table 4.2):

- *Strong acids and strong bases dissociate completely into ions.* Therefore, like soluble ionic compounds, they are *strong* electrolytes and conduct a large current, as shown by the brightly lit bulb (Figure 4.12A).



A Strong acid (or base) = strong electrolyte

B Weak acid (or base) = weak electrolyte

Figure 4.12 Acids and bases as electrolytes.

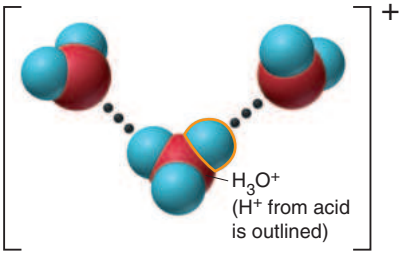


Figure 4.11 The H^+ ion as a solvated hydronium ion.

Table 4.2 Strong and Weak Acids and Bases

Acids

Strong
Hydrochloric acid, HCl
Hydrobromic acid, HBr
Hydriodic acid, HI
Nitric acid, HNO_3
Sulfuric acid, H_2SO_4
Perchloric acid, $HClO_4$

Weak (a few of many examples)
Hydrofluoric acid, HF
Phosphoric acid, H_3PO_4
Acetic acid, CH_3COOH (or $HC_2H_3O_2$)

Bases

Strong
Group 1A(1) hydroxides:
Lithium hydroxide, LiOH
Sodium hydroxide, NaOH
Potassium hydroxide, KOH
Rubidium hydroxide, RbOH
Cesium hydroxide, CsOH

Heavy Group 2A(2) hydroxides:
Calcium hydroxide, $Ca(OH)_2$
Strontium hydroxide, $Sr(OH)_2$
Barium hydroxide, $Ba(OH)_2$

Weak (one of many examples)
Ammonia, NH_3

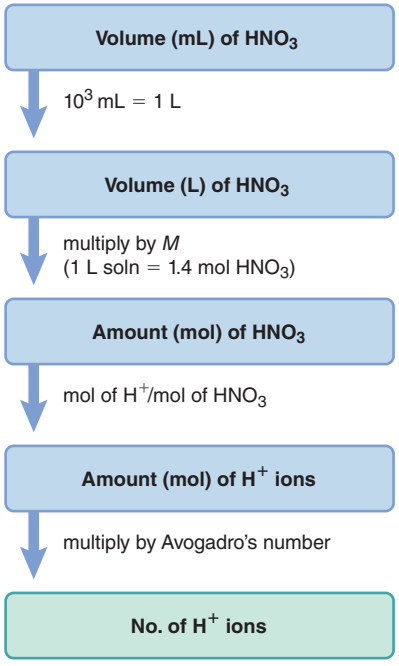
- *Weak acids and weak bases dissociate very little into ions.* Most of their molecules remain intact. Therefore, they are *weak* electrolytes, which means they conduct a small current (Figure 4.12B; see previous page).

Because a strong acid (or strong base) dissociates completely, we can find the molarity of H^+ (or OH^-) and the amount (mol) or number of each ion in solution. (You'll see how to determine these quantities for weak acids in Chapter 18.)

SAMPLE PROBLEM 4.12 Determining the Number of H^+ (or OH^-) Ions in Solution

Problem Nitric acid is a major chemical in the fertilizer and explosives industries. How many $H^+(aq)$ ions are in 25.3 mL of 1.4 *M* nitric acid?

Road Map



Plan We know the volume (25.3 mL) and molarity (1.4 *M*) of nitric acid, and we need the number of $H^+(aq)$. We convert from mL to L and multiply by the molarity to find the amount (mol) of acid. Table 4.2 shows that nitric acid is a strong acid, so it dissociates completely. With the formula, we write a dissociation equation, which shows the amount (mol) of H^+ ions per mole of acid. We multiply that amount by Avogadro's number to find the number of $H^+(aq)$ ions (see the road map).

Solution Finding the amount (mol) of nitric acid:

$$\text{Amount (mol) of } HNO_3 = 25.3 \cancel{\text{mL}} \times \frac{1 \cancel{\text{L}}}{1000 \cancel{\text{mL}}} \times \frac{1.4 \text{ mol}}{1 \cancel{\text{L}}} = 0.035 \text{ mol}$$

Nitric acid is HNO_3, so we have:

$$HNO_3(l) \xrightarrow{H_2O} H^+(aq) + NO_3^-(aq)$$

Finding the number of H^+ ions:

$$\text{No. of } H^+ \text{ ions} = 0.035 \cancel{\text{mol HNO}_3} \times \frac{1 \cancel{\text{mol H}^+}}{1 \cancel{\text{mol HNO}_3}} \times \frac{6.022 \times 10^{23} \text{ H}^+ \text{ ions}}{1 \cancel{\text{mol H}^+}}$$

$$= 2.1 \times 10^{22} \text{ H}^+ \text{ ions}$$

Check The number of moles seems correct: 0.025 L × 1.4 mol/L = 0.035 mol, and multiplying by 6×10^{23} ions/mol gives 2×10^{22} ions.

FOLLOW-UP PROBLEMS

4.12A How many $OH^-(aq)$ ions are present in 451 mL of 1.20 *M* potassium hydroxide?

4.12B How many $H^+(aq)$ ions are present in 65.5 mL of 0.722 *M* hydrochloric acid?

SOME SIMILAR PROBLEMS 4.63 and 4.64

Structural Features of Acids and Bases A key structural feature appears in common laboratory acids and bases:

- *Acids.* Strong acids, such as HNO_3 and H_2SO_4, and weak acids, such as HF and H_3PO_4, have one or more H atoms as part of their structure, which are either completely released (strong) or partially released (weak) as protons in water.
- *Bases.* Strong bases have either OH^- (e.g., NaOH) or O^{2-} (e.g., K_2O) as part of their structure. The oxide ion is not stable in water and reacts to form OH^- ion:

$$O^{2-}(s) + H_2O(l) \longrightarrow 2OH^-(aq) \quad \text{so} \quad K_2O(s) + H_2O(l) \longrightarrow 2K^+(aq) + 2OH^-(aq)$$

Weak bases, such as ammonia, do not contain OH^- ions, but, as you'll see in later chapters, they all have an electron pair on N. Weak bases produce OH^- ions in a reaction that occurs to a small extent in water:

$$NH_3(g) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

(The reaction arrow in the preceding equation indicates that the reaction proceeds in both directions; we'll discuss this important idea further in Section 4.7.)

The Key Event: Formation of H_2O from H^+ and OH^-

To see the key event in acid-base reactions, we'll write the three types of aqueous ionic equations (with color) and focus on the reaction between the strong acid HCl and the strong base $Ba(OH)_2$:

- The molecular equation is

$$2HCl(aq) + Ba(OH)_2(aq) \longrightarrow BaCl_2(aq) + 2H_2O(l)$$

- HCl and $Ba(OH)_2$ dissociate completely, so the total ionic equation is

$$2H^+(aq) + 2Cl^-(aq) + Ba^{2+}(aq) + 2OH^-(aq) \longrightarrow Ba^{2+}(aq) + 2Cl^-(aq) + 2H_2O(l)$$

- In the net ionic equation, we eliminate the spectator ions, $Ba^{2+}(aq)$ and $Cl^-(aq)$:

$$2H^+(aq) + 2OH^-(aq) \longrightarrow 2H_2O(l) \quad \text{or} \quad H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$$

Thus, *the key event in aqueous reactions between a strong acid and a strong base is that an H^+ ion from the acid and an OH^- ion from the base form a water molecule.* Only the spectator ions differ from one strong acid–strong base reaction to another.

Like precipitation reactions, acid-base reactions occur through *the electrostatic attraction of ions and their removal from solution as the product.* In this case, rather than an insoluble ionic solid, the product is H_2O, which consists almost entirely of undissociated molecules. Actually, water molecules dissociate *very* slightly (which, as you'll see in Chapter 18, is very important), but the formation of water in an acid-base reaction results in an enormous net removal of H^+ and OH^- ions.

The molecular and total ionic equations above show that if you evaporate the water, the spectator ions remain: the ionic compound that results from the reaction of an acid and a base is called a **salt,** which in this case is barium chloride. Thus, in an aqueous neutralization reaction, *an acid and a base form a salt solution and water:*

$$\underset{\text{acid}}{HX(aq)} + \underset{\text{base}}{MOH(aq)} \longrightarrow \underset{\text{salt}}{MX(aq)} + \underset{\text{water}}{H_2O(l)}$$

Note that *the cation of the salt comes from the base and the anion from the acid.*

Like precipitation reactions, *acid-base reactions are metathesis (double-displacement) reactions.* The reaction of aluminum hydroxide, the active ingredient in some antacids, with HCl, the major component of stomach acid, is another example:

$$3HCl(aq) + Al(OH)_3(s) \longrightarrow AlCl_3(aq) + 3H_2O(l)$$

SAMPLE PROBLEM 4.13 Writing Ionic Equations for Acid-Base Reactions

Problem Write balanced molecular, total ionic, and net ionic equations for each of the following acid-base reactions and identify the spectator ions:
(a) Hydrochloric acid(aq) + potassium hydroxide(aq) ⟶
(b) Strontium hydroxide(aq) + perchloric acid(aq) ⟶
(c) Barium hydroxide(aq) + sulfuric acid(aq) ⟶

Plan All are strong acids and bases (see Table 4.2), so the actual reaction is between H^+ and OH^-. The products are H_2O and a salt solution of spectator ions. In (c), we note that the salt ($BaSO_4$) is insoluble (see Table 4.1), so there are no spectator ions.

Solution **(a)** Writing the molecular equation:

$$HCl(aq) + KOH(aq) \longrightarrow KCl(aq) + H_2O(l)$$

Writing the total ionic equation:

$$H^+(aq) + Cl^-(aq) + K^+(aq) + OH^-(aq) \longrightarrow K^+(aq) + Cl^-(aq) + H_2O(l)$$

Writing the net ionic equation:

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$$

$K^+(aq)$ and $Cl^-(aq)$ are the spectator ions.

(b) Writing the molecular equation:

$$Sr(OH)_2(aq) + 2HClO_4(aq) \longrightarrow Sr(ClO_4)_2(aq) + 2H_2O(l)$$

Writing the total ionic equation:

$$Sr^{2+}(aq) + 2OH^-(aq) + 2H^+(aq) + 2ClO_4^-(aq) \longrightarrow Sr^{2+}(aq) + 2ClO_4^-(aq) + 2H_2O(l)$$

Writing the net ionic equation:

$$2OH^-(aq) + 2H^+(aq) \longrightarrow 2H_2O(l) \quad \text{or} \quad OH^-(aq) + H^+(aq) \longrightarrow H_2O(l)$$

$Sr^{2+}(aq)$ and $ClO_4^-(aq)$ are the spectator ions.

(c) Writing the molecular equation:

$$Ba(OH)_2(aq) + H_2SO_4(aq) \longrightarrow BaSO_4(s) + 2H_2O(l)$$

Writing the total ionic equation:

$$Ba^{2+}(aq) + 2OH^-(aq) + 2H^+(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s) + 2H_2O(l)$$

This is a neutralization *and* a precipitation reaction, so the net ionic equation is the same as the total ionic. There are no spectator ions.

FOLLOW-UP PROBLEMS

4.13A Write balanced molecular, total ionic, and net ionic equations for the reaction between aqueous solutions of calcium hydroxide and nitric acid.

4.13B Write balanced molecular, total ionic, and net ionic equations for the reaction between aqueous solutions of hydriodic acid and lithium hydroxide.

SOME SIMILAR PROBLEMS 4.65(a) and 4.66(a)

Proton Transfer in Acid-Base Reactions

When we take a closer look (with color) at the reaction between a strong acid and strong base, as well as several related reactions, a unifying pattern appears. Let's examine three types of reaction to gain insight about this pattern.

Reaction Between a Strong Acid and a Strong Base When HCl gas dissolves in water, the H^+ ion ends up bonded to a water molecule. Thus, hydrochloric acid actually consists of solvated H_3O^+ and Cl^- ions:

$$HCl(g) + H_2O(l) \longrightarrow H_3O^+(aq) + Cl^-(aq)$$

If we add NaOH solution, the total ionic equation shows that H_3O^+ *transfers a proton* to OH^- (leaving a water molecule written as H_2O, and forming a water molecule written as HOH):

$$[H_3O^+(aq) + Cl^-(aq)] + [Na^+(aq) + OH^-(aq)] \longrightarrow H_2O(l) + Cl^-(aq) + Na^+(aq) + HOH(l)$$

(H^+ transfer)

Without the spectator ions, the net ionic equation shows more clearly the *transfer of a proton* from H_3O^+ to OH^-:

$$H_3O^+(aq) + OH^-(aq) \longrightarrow H_2O(l) + HOH(l) \quad [\text{or } 2H_2O(l)]$$

(H^+ transfer)

This equation is identical to the one we saw earlier (see p. 161),

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$$

with the additional H_2O molecule left over from the H_3O^+. Figure 4.13 shows this process on the atomic level and also shows that, if the water is evaporated, the spectator ions, Cl^- and Na^+, crystallize as the salt NaCl.

Thus, *an acid-base reaction is a proton-transfer process.* In the early 20th century, the chemists Johannes Brønsted and Thomas Lowry stated:

- *An acid is a molecule (or ion) that donates a proton.*
- *A base is a molecule (or ion) that accepts a proton.*

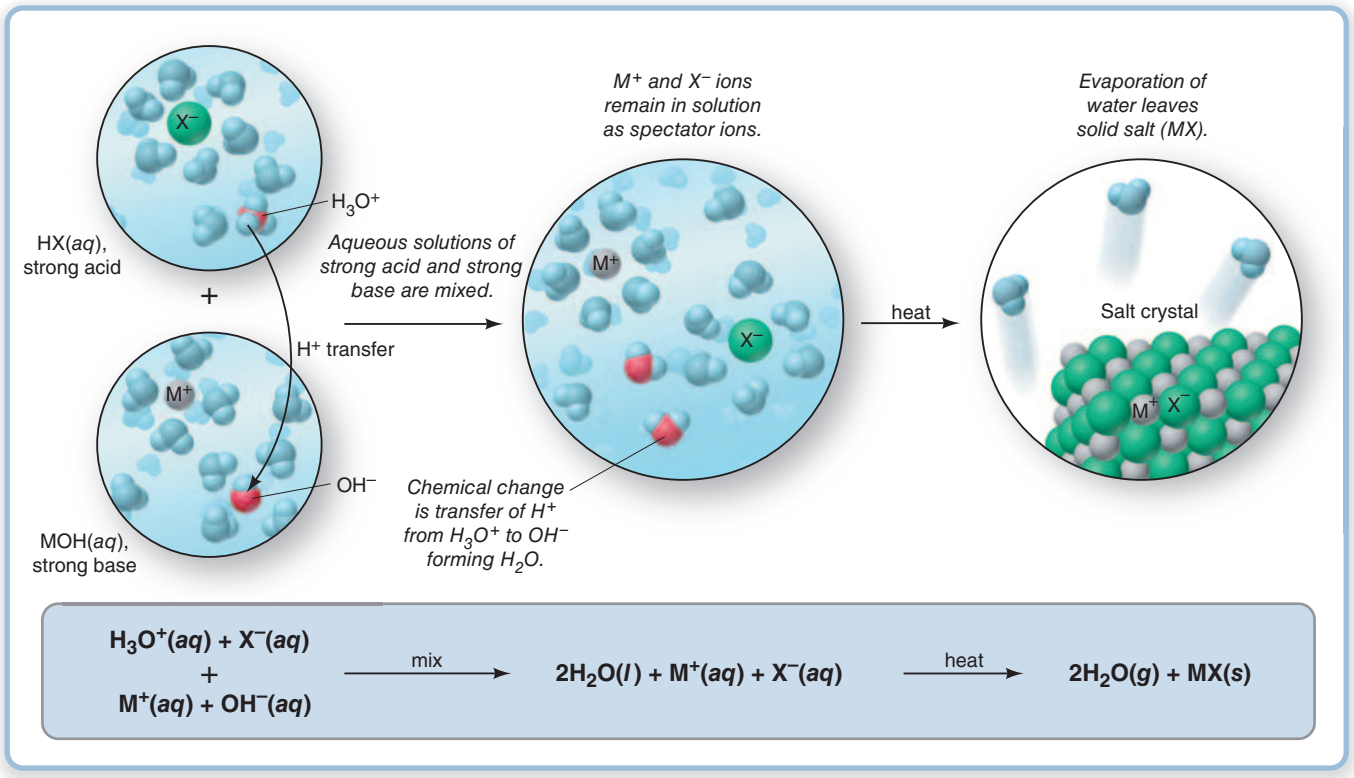


Figure 4.13 An aqueous strong acid–strong base reaction as a proton-transfer process.

Therefore, in an aqueous reaction between strong acid and strong base, *H_3O^+ ion acts as the acid and donates a proton to OH^- ion, which acts as the base and accepts it.* (We discuss the Brønsted-Lowry concept thoroughly in Chapter 18.)

Gas-Forming Reactions: Acids with Carbonates (or Sulfites) When an ionic carbonate, such as K_2CO_3, is treated with an acid, such as HCl, one of the products is carbon dioxide, as the molecular equation shows:

$$2HCl(aq) + K_2CO_3(aq) \longrightarrow 2KCl(aq) + [H_2CO_3(aq)]$$
$$[H_2CO_3(aq)] \longrightarrow H_2O(l) + CO_2(g)$$

Square brackets around a species, in this case H_2CO_3, mean it is very unstable: H_2CO_3 decomposes immediately into water and carbon dioxide. Combining these two equations (see Sample Problem 3.17, p. 116) cancels $[H_2CO_3]$ and gives the overall equation:

$$2HCl(aq) + K_2CO_3(aq) \longrightarrow 2KCl(aq) + H_2O(l) + CO_2(g)$$

Writing the total ionic equation with H_3O^+ ions from the HCl shows the actual species in solution and the key event in a gas-forming reaction, *removal of ions from solution through formation of both a gas **and** water:*

$$2H_3O^+(aq) + 2Cl^-(aq) + 2K^+(aq) + CO_3^{2-}(aq) \longrightarrow$$
$$2Cl^-(aq) + 2K^+(aq) + CO_2(g) + H_2O(l) + 2H_2O(l) \quad [\text{or } 3H_2O(l)]$$

Writing the net ionic equation, with the intermediate formation of H_2CO_3, eliminates the spectator ions, Cl^- and K^+, and makes it easier to see that *proton transfer* takes place as each of the two H_3O^+ ions transfers one proton to the carbonate ion:

$$2H_3O^+(aq) + CO_3^{2-}(aq) \longrightarrow [H_2CO_3(aq)] + 2H_2O(l) \longrightarrow$$
$$CO_2(g) + H_2O(l) + 2H_2O(l) \quad [\text{or } 3H_2O(l)]$$

($2H^+$ transfer)

In essence, this is an acid-base reaction with carbonate ion accepting the protons and, thus, acting as the base.

Ionic sulfites react similarly to form water and gaseous SO_2; the net ionic equation, in which SO_3^{2-} acts as the base and forms the unstable H_2SO_3, is

$$2H_3O^+(aq) + SO_3^{2-}(aq) \longrightarrow [H_2SO_3(aq)] + 2H_2O(l) \longrightarrow SO_2(g) + H_2O(l) + 2H_2O(l) \quad [\text{or } 3H_2O(l)]$$

($2H^+$ transfer)

Reactions Between Weak Acids and Strong Bases As in the reaction between a strong acid and a strong base, a proton-transfer process also occurs when a weak acid reacts with a strong base, but the total ionic equation is written differently.

For example, when solutions of the weak acid acetic acid (CH_3COOH, Table 4.2) and the strong base sodium hydroxide are mixed, the molecular equation is

$$CH_3COOH(aq) + NaOH(aq) \longrightarrow CH_3COONa(aq) + H_2O(l)$$

Since acetic acid is weak and, thus, dissociates very little, it appears on the left side of the total ionic equation as an *undissociated, intact molecule* instead of as ions:

$$CH_3COOH(aq) + Na^+(aq) + OH^-(aq) \longrightarrow CH_3COO^-(aq) + Na^+(aq) + H_2O(l)$$

The net ionic equation reveals that proton transfer occurs directly from the weak acid rather than from H_3O^+ (as is the case with a strong acid):

$$CH_3COOH(aq) + OH^-(aq) \longrightarrow CH_3COO^-(aq) + H_2O(l)$$

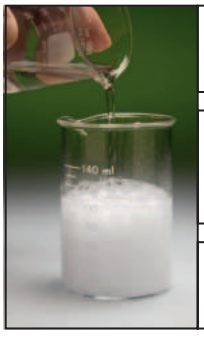
(H^+ transfer)

There is only one spectator ion, $Na^+(aq)$. Table 4.3 compares the reactions of strong and weak acids with a strong base.

Table 4.3 Reactions of Strong and Weak Acids with a Strong Base

	Strong Acid and Strong Base	Weak Acid and Strong Base
Molecular equation	$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$	$CH_3COOH(aq) + NaOH(aq) \longrightarrow CH_3COONa(aq) + H_2O(l)$
Total ionic equation	$H_3O^+(aq) + Cl^-(aq) + Na^+(aq) + OH^-(aq) \longrightarrow H_2O(l) + Na^+(aq) + Cl^-(aq) + H_2O(l)$	$CH_3COOH(aq) + Na^+(aq) + OH^-(aq) \longrightarrow CH_3COO^-(aq) + Na^+(aq) + H_2O(l)$
Net ionic equation	$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$	$CH_3COOH(aq) + OH^-(aq) \longrightarrow CH_3COO^-(aq) + H_2O(l)$

Weak acids also react with carbonates to form CO_2, but as we have seen, the weak acid is written as an intact molecule, instead of as ions, because it dissociates very little in solution. Figure 4.14 shows the reaction between vinegar (a 5% solution of acetic acid) and baking soda (sodium hydrogen carbonate) solution. In fact, when stomach acid (mostly HCl) builds up, your duodenum releases the hormone secretin, which stimulates your pancreas to release HCO_3^- ions that react with the excess acid in an analogous reaction.



Molecular equation

$$NaHCO_3(aq) + CH_3COOH(aq) \longrightarrow CH_3COONa(aq) + CO_2(g) + H_2O(l)$$

Total ionic equation

$$Na^+(aq) + HCO_3^-(aq) + CH_3COOH(aq) \longrightarrow CH_3COO^-(aq) + Na^+(aq) + CO_2(g) + H_2O(l)$$

Net ionic equation

$$HCO_3^-(aq) + CH_3COOH(aq) \longrightarrow CH_3COO^-(aq) + CO_2(g) + H_2O(l)$$

Figure 4.14 A gas-forming reaction with a weak acid. Note that the two ionic equations include acetic acid because it does *not* dissociate appreciably into ions.

SAMPLE PROBLEM 4.14 Writing Proton-Transfer Equations for Acid-Base Reactions

Problem Write balanced total and net ionic equations for the following reactions and use curved arrows to show how the proton transfer occurs. For (a), give the name and formula of the salt present when the water evaporates. For (b), note that propanoic acid (CH_3CH_2COOH) is a weak acid and identify the spectator ion(s).
(a) Hydriodic acid(aq) + calcium hydroxide(aq) ⟶
(b) Potassium hydroxide(aq) + propanoic acid(aq) ⟶

Plan **(a)** The reactants are a strong acid and a strong base (Table 4.2), so the acidic species is H_3O^+, which transfers a proton to the OH^- from the base. The products are H_2O and a solution of spectator ions that becomes a solid salt when the water evaporates.
(b) Since the acid is weak, it occurs as intact molecules in solution and transfers its proton to the OH^- from the base. The only spectator ion is the cation of the base.

Solution **(a)** Writing the total ionic equation:

$$2H_3O^+(aq) + 2I^-(aq) + Ca^{2+}(aq) + 2OH^-(aq) \longrightarrow 2I^-(aq) + Ca^{2+}(aq) + 4H_2O(l)$$

Writing the net ionic equation:

$$2H_3O^+(aq) + 2OH^-(aq) \longrightarrow 4H_2O(l) \quad \text{or} \quad H_3O^+(aq) + OH^-(aq) \longrightarrow 2H_2O(l)$$

$I^-(aq)$ and $Ca^{2+}(aq)$ are spectator ions, so the salt is calcium iodide, CaI_2.
(b) Writing the total ionic equation:

$$K^+(aq) + OH^-(aq) + CH_3CH_2COOH(aq) \longrightarrow K^+(aq) + H_2O(l) + CH_3CH_2COO^-(aq)$$

Writing the net ionic equation:

$$OH^-(aq) + CH_3CH_2COOH(aq) \longrightarrow H_2O(l) + CH_3CH_2COO^-(aq)$$

$K^+(aq)$ is the only spectator ion.

FOLLOW-UP PROBLEMS

4.14A Write balanced total and net ionic equations for the reaction between aqueous solutions of nitrous acid and strontium hydroxide. Use a curved arrow in the net ionic equation to show the proton transfer. Give the name and formula of the salt that is present when the water evaporates, and identify the spectator ion(s).

4.14B Write balanced total and net ionic equations for the reaction between aqueous solutions of calcium hydrogen carbonate and hydrobromic acid. Use a curved arrow in the net ionic equation to show the proton transfer. Give the name and formula of the salt that is present when the water evaporates.

SOME SIMILAR PROBLEMS 4.65(b), 4.66(b), 4.67, and 4.68

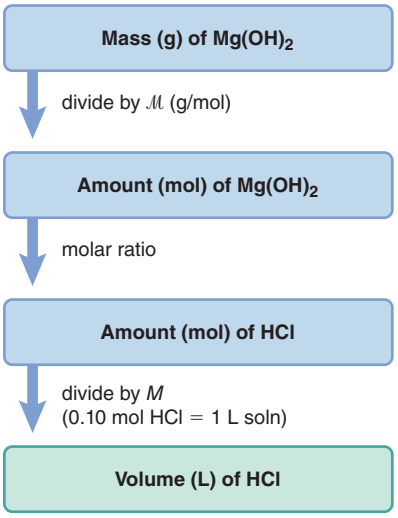
Stoichiometry of Acid-Base Reactions: Acid-Base Titrations

As we saw for precipitation reactions, the molar ratios in an acid-base reaction can also be combined with concentration and volume information to quantify the reactants and products involved in the reaction. Sample Problem 4.15 demonstrates this type of calculation.

SAMPLE PROBLEM 4.15 Calculating the Amounts of Reactants and Products in an Acid-Base Reaction

Problem Specialized cells in the stomach release HCl to aid digestion. If they release too much, the excess can be neutralized with a base in the form of an antacid. Magnesium hydroxide is a common active ingredient in antacids. As a government chemist testing commercial antacids, you use 0.10 *M* HCl to simulate the acid concentration in the stomach. How many liters of this "stomach acid" will react with a tablet containing 0.10 g of magnesium hydroxide?

Road Map



Plan We are given the mass (0.10 g) of magnesium hydroxide, $Mg(OH)_2$, that reacts with the acid. We also know the acid concentration (0.10 *M*) and must find the acid volume. After writing the balanced equation, we convert the mass (g) of $Mg(OH)_2$ to amount (mol) and use the molar ratio to find the amount (mol) of HCl that reacts with it. Then, we use the molarity of HCl to find the volume (L) that contains this amount (see the road map).

Solution Writing the balanced equation:

$$Mg(OH)_2(s) + 2HCl(aq) \longrightarrow MgCl_2(aq) + 2H_2O(l)$$

Converting from mass (g) of $Mg(OH)_2$ to amount (mol):

$$\text{Amount (mol) of } Mg(OH)_2 = 0.10 \text{ g } \cancel{Mg(OH)_2} \times \frac{1 \text{ mol } Mg(OH)_2}{58.33 \text{ g } \cancel{Mg(OH)_2}}$$

$$= 1.7\times10^{-3} \text{ mol } Mg(OH)_2$$

Converting from amount (mol) of $Mg(OH)_2$ to amount (mol) of HCl:

$$\text{Amount (mol) of HCl} = 1.7\times10^{-3} \text{ } \cancel{\text{mol } Mg(OH)_2} \times \frac{2 \text{ mol HCl}}{1 \text{ } \cancel{\text{mol } Mg(OH)_2}}$$

$$= 3.4\times10^{-3} \text{ mol HCl}$$

Converting from amount (mol) of HCl to volume (L):

$$\text{Volume (L) of HCl} = 3.4\times10^{-3} \text{ } \cancel{\text{mol HCl}} \times \frac{1 \text{ L}}{0.10 \text{ } \cancel{\text{mol HCl}}}$$

$$= 3.4\times10^{-2} \text{ L}$$

Check The size of the answer seems reasonable: a small volume of dilute acid (0.034 L of 0.10 *M*) reacts with a small amount of antacid (0.0017 mol).

FOLLOW-UP PROBLEMS

4.15A Another active ingredient in some antacids is aluminum hydroxide. What mass of aluminum hydroxide is needed to react with the volume of 0.10 *M* HCl calculated in Sample Problem 4.15?

4.15B The active ingredient in an aspirin tablet is acetylsalicylic acid, $HC_9H_7O_4$, which is mixed with inert binding agents and fillers. An aspirin tablet dissolved in water requires 14.10 mL of 0.128 *M* NaOH for complete reaction of the acetylsalicylic acid. What mass of acetylsalicylic acid is in the tablet? (*Hint:* Only one proton in aspirin reacts with the base.)

SOME SIMILAR PROBLEMS 4.69, 4.70, 4.76, and 4.77

Quantifying Acid-Base Reactions by Titration

Acid-base reactions are studied quantitatively in a laboratory procedure called a *titration*. In any **titration,** *the known concentration of one solution is used to determine the unknown concentration of another.* In a typical acid-base titration, a *standardized* solution of base, one whose concentration is *known,* is added to a solution of acid whose concentration is *unknown (or vice versa).*

Figure 4.15A shows the laboratory setup for an acid-base titration with a known volume of acid and a few drops of indicator in a flask. An *acid-base indicator* is a substance whose color is different in acid than in base; the indicator used in the figure is phenolphthalein, which is pink in base and colorless in acid. (We examine indicators in Chapters 18 and 19.) Base is added from a buret, and the OH^- ions react with the H^+ ions. As the titration nears its end (Figure 4.15B), the drop of added base creates a temporary excess of OH^-, causing some indicator molecules to change to the basic color; they return to the acidic color when the flask is swirled. There are two key stages in the titration:

- The **equivalence point** occurs when *the amount (mol) of H^+ ions in the original volume of acid has reacted with the same amount (mol) of OH^- ions from the buret:*

  Amount (mol) of H^+ (originally in flask) = amount (mol) of OH^- (added from buret)

- The **end point** occurs when a tiny excess of OH^- ions changes the indicator permanently to its basic color (Figure 4.15C).

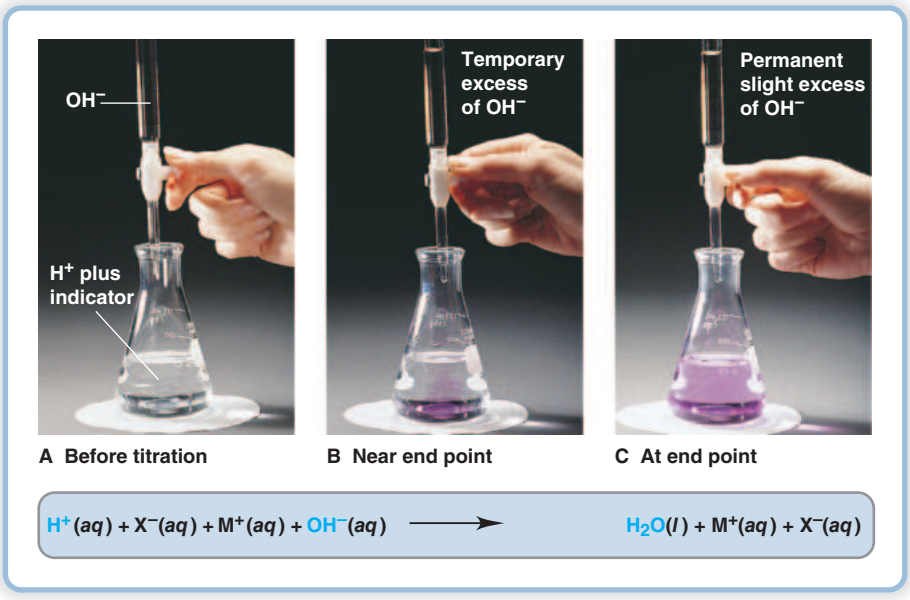


Figure 4.15 An acid-base titration.

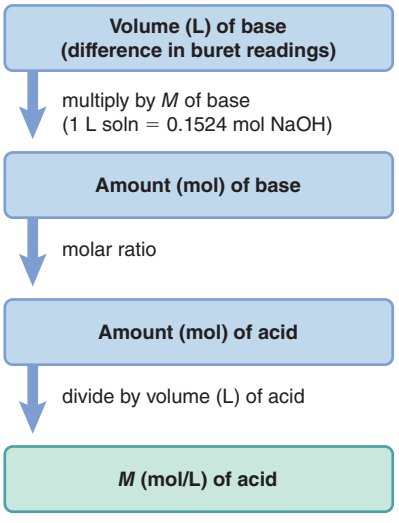
In calculations, such as in Sample Problem 4.16, we assume that this tiny excess of OH^- ions is insignificant and that *the amount of base needed to reach the end point is the same as the amount needed to reach the equivalence point.*

SAMPLE PROBLEM 4.16 Finding the Concentration of an Acid from a Titration

Problem To standardize an HCl solution, you put 50.00 mL of it in a flask with a few drops of indicator and put 0.1524 *M* NaOH in a buret. The buret reads 0.55 mL at the start and 33.87 mL at the end point. Find the molarity of the HCl solution.

Plan We have to find the molarity of the acid from the volume of acid (50.00 mL), the initial (0.55 mL) and final (33.87 mL) volumes of base, and the molarity of the base (0.1524 *M*). First, we balance the equation. The volume of added base is the difference in buret readings, and we use the base's molarity to calculate the amount (mol) of base. Then, we use the molar ratio from the balanced equation to find the amount (mol) of acid originally present and divide by the acid's original volume to find the molarity (see the road map).

Road Map



Solution Writing the balanced equation:

$$NaOH(aq) + HCl(aq) \longrightarrow NaCl(aq) + H_2O(l)$$

Finding the volume (L) of NaOH solution added:

$$\text{Volume (L) of solution} = (33.87 \cancel{\text{mL}} \text{ soln} - 0.55 \cancel{\text{mL}} \text{ soln}) \times \frac{1 \text{ L}}{1000 \cancel{\text{mL}}}$$

$$= 0.03332 \text{ L soln}$$

Finding the amount (mol) of NaOH added:

$$\text{Amount (mol) of NaOH} = 0.03332 \cancel{\text{L soln}} \times \frac{0.1524 \text{ mol NaOH}}{1 \cancel{\text{L soln}}}$$

$$= 5.078 \times 10^{-3} \text{ mol NaOH}$$

Finding the amount (mol) of HCl originally present: Since the molar ratio is 1/1,

$$\text{Amount (mol) of HCl} = 5.078 \times 10^{-3} \cancel{\text{mol NaOH}} \times \frac{1 \text{ mol HCl}}{1 \cancel{\text{mol NaOH}}} = 5.078 \times 10^{-3} \text{ mol HCl}$$

Calculating the molarity of HCl:

$$\text{Molarity of HCl} = \frac{5.078 \times 10^{-3} \text{ mol HCl}}{50.00 \cancel{\text{mL}}} \times \frac{1000 \cancel{\text{mL}}}{1 \text{ L}} = 0.1016 \, M \text{ HCl}$$

Check The answer makes sense: a large volume of less concentrated acid neutralized a small volume of more concentrated base. With rounding, the numbers of moles of H^+ and OH^- are about equal: 50 mL × 0.1 *M* H^+ = 0.005 mol = 33 mL × 0.15 *M* OH^-.

FOLLOW-UP PROBLEMS

4.16A What volume of 0.1292 *M* $Ba(OH)_2$ would neutralize 50.00 mL of the HCl solution standardized in Sample Problem 4.16?

4.16B Calculate the molarity of a solution of KOH if 18.15 mL of it is required for the titration of a 20.00-mL sample of a 0.2452 *M* H_2SO_4 solution.

SOME SIMILAR PROBLEMS 4.71 and 4.72

Summary of Section 4.4

- In an acid-base (neutralization) reaction between an acid (an H^+-yielding substance) and a base (an OH^--yielding substance), H^+ and OH^- ions form H_2O.
- Strong acids and bases dissociate completely in water (strong electrolytes); weak acids and bases dissociate slightly (weak electrolytes).
- An acid-base reaction involves the transfer of a proton from an acid (a species that donates an H^+) to a base (a species that accepts an H^+).
- A gas-forming acid-base reaction occurs when an acid transfers a proton to a carbonate (or sulfite), forming water and a gas that leaves the reaction mixture.
- Since weak acids dissociate very little, ionic equations show a weak acid as an intact molecule transferring its proton to the base.
- Molarity can be used as a conversion factor to solve stoichiometric problems involving acid-base reactions.
- In a titration, the known concentration of one solution is used to determine the concentration of the other.

4.5 OXIDATION-REDUCTION (REDOX) REACTIONS

Oxidation-reduction (redox) reactions include the formation of a compound from its elements (and the reverse process), all combustion processes, the generation of electricity in batteries, the production of cellular energy, and many others. In fact, redox reactions are so widespread that many do not occur in solution at all. In this section, we examine the key event in the redox process, discuss important terminology, see how to determine whether a reaction involves a redox process, and learn how to quantify redox reactions. (The redox reactions in this section can be balanced by methods you learned in Chapter 3; you'll learn how to balance more complex ones when we discuss electrochemistry in Chapter 21.)

The Key Event: Movement of Electrons Between Reactants

The key chemical event in an **oxidation-reduction** (or **redox**) **reaction** is the *net movement of electrons from one reactant to another*. The movement occurs from the reactant (or atom in the reactant) with *less* attraction for electrons to the reactant (or atom) with *more* attraction for electrons.

This process occurs in the formation of both ionic and covalent compounds:

- *Ionic compounds: transfer of electrons.* In the reaction that forms MgO from its elements (see Figure 3.7, p. 109), the balanced equation is

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$$

Figure 4.16A shows that each Mg atom loses two electrons and each O atom gains them. This loss and gain is a ***transfer*** *of electrons* away from each Mg atom to each O atom. The resulting Mg^{2+} and O^{2-} ions aggregate into an ionic solid.

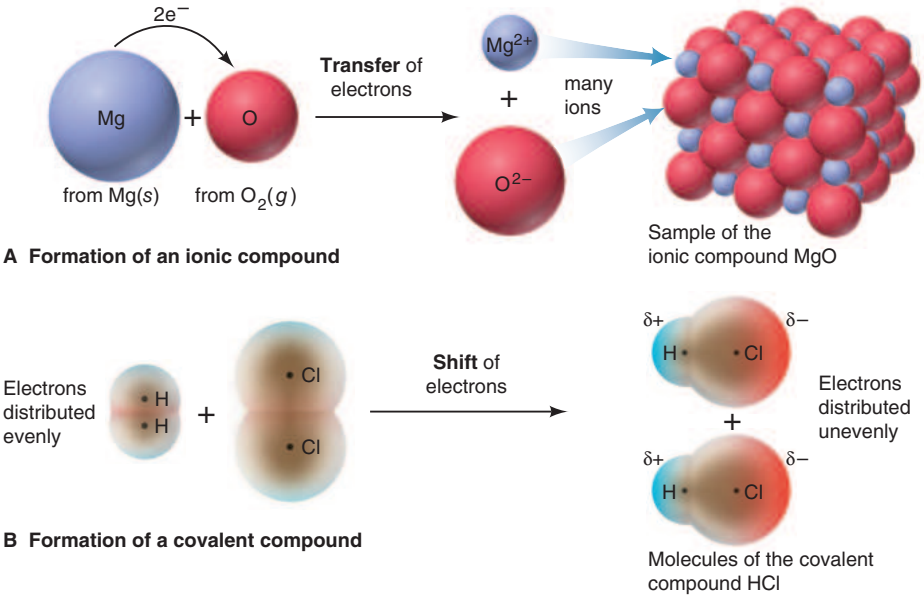


Figure 4.16 The redox process in the formation of (A) ionic and (B) covalent compounds from their elements.

- *Covalent compounds: shift of electrons.* During the formation of a covalent compound from its elements, there is more of a ***shift*** *of electrons* than a full transfer. Thus, *ions do not form.* Consider the formation of HCl gas:

$$H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$$

To see the electron movement, we'll compare the electron distribution in reactant and product. As Figure 4.16B shows, in H_2 and Cl_2, the electrons are shared equally between the atoms *(symmetrical shading)*. Because the Cl atom attracts electrons more than the H atom, in HCl, the electrons are shared unequally *(asymmetrical shading).* Electrons shift away from H and toward Cl, so the Cl atom has more negative charge (*red* and $\delta-$) than it had in Cl_2, and the H atom has less negative charge (*blue* and $\delta+$) than it had in H_2.

Some Essential Redox Terminology

Certain key terms describe the process and explain the name of this reaction class:

- **Oxidation** is the *loss* of electrons.
- **Reduction** is the *gain* of electrons.

During the formation of MgO, Mg undergoes oxidation (loss of electrons), and O_2 undergoes reduction (gain of electrons). The loss and gain are simultaneous, but we can imagine them occurring separately:

$$\text{Oxidation (electron loss by Mg):} \quad Mg \longrightarrow Mg^{2+} + 2e^-$$
$$\text{Reduction (electron gain by } O_2\text{):} \quad \tfrac{1}{2}O_2 + 2e^- \longrightarrow O^{2-}$$

(Throughout this discussion, blue type indicates oxidation, and red type reduction.)

- The **oxidizing agent** is the species doing the oxidizing (causing the electron loss).
- The **reducing agent** is the species doing the reducing (causing the electron gain).

One reactant acts on the other, with a give-and-take of electrons. During the reaction that forms MgO, *O_2 oxidizes Mg* by taking the electrons that Mg gives up, so O_2 is the oxidizing agent; *Mg reduces O_2* by providing the electrons that O_2 takes, so Mg is the reducing agent.

This means that

- *The oxidizing agent is reduced:* it takes electrons (and, thus, gains them).
- *The reducing agent is oxidized:* it gives up electrons (and, thus, loses them).

In the formation of HCl, *Cl_2 oxidizes H_2* (H loses some electron charge and Cl gains it), which is the same as saying that *H_2 reduces Cl_2*. The reducing agent, H_2, is oxidized, and the oxidizing agent, Cl_2, is reduced.

Using Oxidation Numbers to Monitor Electron Charge

Chemists have devised a "bookkeeping" system to monitor which atom loses electron charge and which atom gains it: each atom in a molecule (or formula unit) is assigned an **oxidation number (O.N.),** or *oxidation state,* which is the charge the atom would have *if* electrons were transferred completely, not shared.

Each element in a binary *ionic* compound has a full charge because the atom transferred its electron(s), and so the atom's oxidation number equals the ionic charge. But, each element in a *covalent* compound (or in a polyatomic ion) has a partial charge because the electrons shifted away from one atom and toward the other. For these cases, we determine oxidation number by a set of rules (Table 4.4; you'll learn the atomic basis of the rules in Chapters 8 and 9).

An O.N. has the sign *before* the number (e.g., +2), whereas an ionic charge has the sign *after* the number (e.g., 2+). Also, unlike a unitary ionic charge, as in Na^+ or Cl^-, an O.N. of +1 or −1 retains the numeral. For example, we don't write the sodium ion as Na^{1+}, but the O.N. of the Na^+ ion is +1, not +.

Table 4.4 Rules for Assigning an Oxidation Number (O.N.)

General Rules

1. For an atom in its elemental form (Na, O_2, Cl_2, etc.): O.N. = 0
2. For a monatomic ion: O.N. = ion charge (with the sign *before* the numeral)
3. The sum of O.N. values for the atoms in a molecule or formula unit of a compound equals zero. The sum of O.N. values for the atoms in a polyatomic ion equals the ion's charge.

Rules for Specific Atoms or Periodic Table Groups

1. For Group 1A(1):	O.N. = +1 in all compounds
2. For Group 2A(2):	O.N. = +2 in all compounds
3. For hydrogen:	O.N. = +1 in combination with nonmetals
	O.N. = −1 in combination with metals and boron
4. For fluorine:	O.N. = −1 in all compounds
5. For oxygen:	O.N. = −1 in peroxides
	O.N. = −2 in all other compounds (except with F)
6. For Group 7A(17):	O.N. = −1 in combination with metals, nonmetals (except O), and other halogens lower in the group

SAMPLE PROBLEM 4.17 Determining the Oxidation Number of Each Element in a Compound (or Ion)

Problem Determine the oxidation number (O.N.) of each element in these species:
(a) Zinc chloride **(b)** Sulfur trioxide **(c)** Nitric acid **(d)** Dichromate ion

Plan We determine the formulas and consult Table 4.4, including the general rules that the O.N. values for a compound add up to zero and those for a polyatomic ion add up to the ion's charge.

Solution **(a)** $ZnCl_2$. The sum of O.N.s must equal zero. The O.N. of the Zn^{2+} ion is +2, so the O.N. of each Cl^- ion is −1, for a total of −2.
(b) SO_3. The O.N. of each oxygen is −2, for a total of −6. The O.N.s must add up to zero, so the O.N. of S is +6.
(c) HNO_3. The O.N. of H is +1, so the O.N.s of the atoms in NO_3^- must add up to −1 to equal the charge of the polyatomic ion and give zero for the compound. The O.N. of each O is −2, for a total of −6. Therefore, the O.N. of N is +5.
(d) $Cr_2O_7^{2-}$. The O.N. of each O is −2, so the total for seven O atoms is −14. Therefore, each Cr must have an O.N. of +6 in order for the sum of the O.N.s to equal the charge of the ion: +12 + (−14) = −2.

FOLLOW-UP PROBLEMS

4.17A Determine the O.N. of each element in the following:
(a) Scandium oxide (Sc_2O_3) **(b)** Gallium chloride ($GaCl_3$)
(c) Hydrogen phosphate ion **(d)** Iodine trifluoride

4.17B Determine the O.N. of each element in the following:
(a) Potassium carbonate **(b)** Ammonium ion
(c) Calcium phosphide (Ca_3P_2) **(d)** Sulfur tetrachloride
SOME SIMILAR PROBLEMS 4.84–4.91

Using O.N.s to Identify Redox Reactions and Oxidizing and Reducing Agents

A redox reaction is defined as one in which the oxidation numbers of the species change. By assigning an oxidation number to each atom, we can see which species was oxidized and which reduced and, thus, which is the oxidizing agent and which the reducing agent:

- If an atom has a higher (more positive or less negative) O.N. in the product than it had in the reactant, the reactant that contains that atom was oxidized (lost electrons) and is the reducing agent. Thus, *oxidation is shown by an increase in O.N.*
- If an atom has a lower (more negative or less positive) O.N. in the product than it had in the reactant, the reactant that contains that atom was reduced (gained electrons) and is the oxidizing agent. Thus, *reduction is shown by a decrease in O.N.*

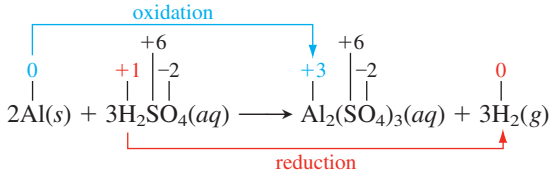
Sample Problem 4.18 introduces the *tie-line,* a useful device for keeping track of changes in oxidation numbers.

SAMPLE PROBLEM 4.18 Identifying Redox Reactions and Oxidizing and Reducing Agents

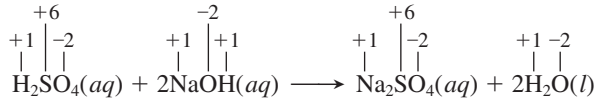
Problem Use oxidation numbers to decide which of the following are redox reactions. For each redox reaction, identify the oxidizing agent and the reducing agent:
(a) $2Al(s) + 3H_2SO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 3H_2(g)$
(b) $H_2SO_4(aq) + 2NaOH(aq) \longrightarrow Na_2SO_4(aq) + 2H_2O(l)$
(c) $PbO(s) + CO(g) \longrightarrow Pb(s) + CO_2(g)$

Plan To determine whether a reaction is an oxidation-reduction process, we use Table 4.4 to assign each atom an O.N. and then note whether it changes as the reactants become products. If the O.N. of an atom changes during the reaction, we draw a tie-line from the atom on the left side to the one on the right and label the change. For those reactions that are redox reactions, a reactant is the reducing agent if it contains an atom that is oxidized (O.N. *increases* from left to right in the equation). A reactant is the oxidizing agent if it contains an atom that is reduced (O.N. *decreases*).

Solution **(a)** Assigning oxidation numbers and marking the changes:

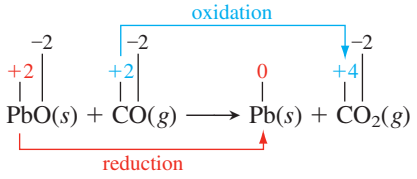


In this case, the O.N.s of Al and H change, so this is a redox reaction. The O.N. of Al changes from 0 to +3 (Al loses electrons), so Al is oxidized; Al is the reducing agent. The O.N. of H decreases from +1 to 0 (H gains electrons), so H^+ is reduced; H_2SO_4 is the oxidizing agent.
(b) Assigning oxidation numbers:



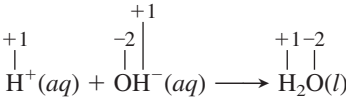
Because each atom in the products has the same O.N. that it had in the reactants, we conclude that this is *not* a redox reaction.

(c) Assigning oxidation numbers and marking the changes:



In this case, the O.N.s of Pb and C change, so this is a redox reaction. The O.N. of Pb decreases from +2 to 0, so Pb is reduced; PbO is the oxidizing agent. The O.N. of C increases from +2 to +4, so CO is oxidized; CO is the reducing agent. In general, when a substance (such as CO) changes to one with more O atoms (such as CO_2), it is oxidized; and when a substance (such as PbO) changes to one with fewer O atoms (such as Pb), it is reduced.

Comment The reaction in part (b) is an acid-base reaction in which H_2SO_4 transfers two H^+ ions to two OH^- ions to form two H_2O molecules. In the net ionic equation,



we see that the O.N.s remain the same on both sides. Therefore, *an acid-base reaction is **not** a redox reaction.*

FOLLOW-UP PROBLEMS

4.18A Use oxidation numbers to decide which of the following are redox reactions. For all redox reactions, identify the oxidizing agent and the reducing agent:

(a) $NCl_3(l) + 3H_2O(l) \longrightarrow NH_3(aq) + 3HOCl(aq)$

(b) $AgNO_3(aq) + NH_4I(aq) \longrightarrow AgI(s) + NH_4NO_3(aq)$

(c) $2H_2S(g) + 3O_2(g) \longrightarrow 2SO_2(g) + 2H_2O(g)$

4.18B Use oxidation numbers to decide which of the following are redox reactions. For all redox reactions, identify the oxidizing agent and the reducing agent:

(a) $SiO_2(s) + 4HF(g) \longrightarrow SiF_4(g) + 2H_2O(l)$

(b) $2C_2H_6(g) + 7O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(g)$

(c) $5CO(g) + I_2O_5(s) \longrightarrow 5CO_2(g) + I_2(s)$

SOME SIMILAR PROBLEMS 4.92–4.95

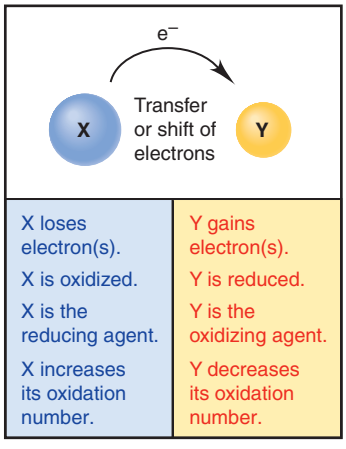


Figure 4.17 **A summary of terminology for redox reactions.**

Be sure to remember that *transferred electrons are never free because the reducing agent loses electrons and the oxidizing agent gains them **simultaneously.*** In other words, a complete reaction *cannot* be "an oxidation" *or* "a reduction"; it must be an oxidation-reduction. Figure 4.17 summarizes redox terminology.

Stoichiometry of Redox Reactions: Redox Titrations

Just as for precipitation and acid-base reactions, stoichiometry is important for redox reactions; a special application of stoichiometry that we focus on here is redox titration. In an acid-base titration, a known concentration of a base is used to find an unknown concentration of an acid (or vice versa). Similarly, in a redox titration, a known concentration of oxidizing agent is used to find an unknown concentration of reducing agent (or vice versa). This kind of titration has many applications, from measuring the iron content in drinking water to quantifying vitamin C in fruits and vegetables.

The permanganate ion, MnO_4^-, is a common oxidizing agent because it is deep purple, and so also serves as an indicator. In Figure 4.18, MnO_4^- is used to determine oxalate ion ($C_2O_4^{2-}$) concentration. As long as $C_2O_4^{2-}$ is present, it reduces the added MnO_4^- to faint pink (nearly colorless) Mn^{2+} (Figure 4.18, *left*). When all the $C_2O_4^{2-}$ has been oxidized, the next drop of MnO_4^- turns the solution light purple (Figure 4.18, *right*). This color change indicates the *end point,* which we assume is the same as the *equivalence point,* the point at which the electrons lost by the oxidized

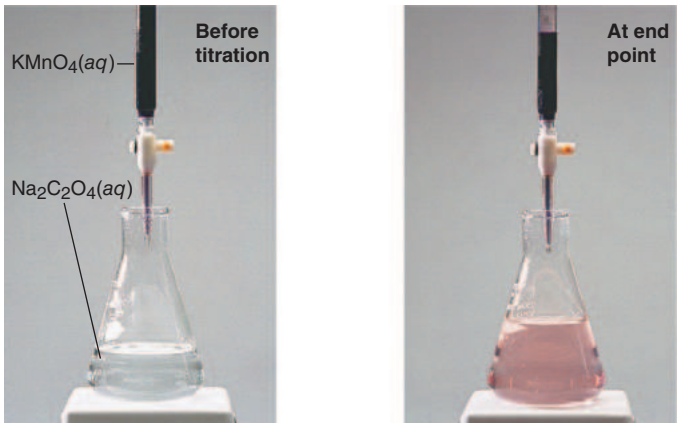

Figure 4.18 The redox titration of $C_2O_4^{2-}$ with MnO_4^-.

Net ionic equation:

$$\overset{+7}{2MnO_4^-}(aq) + \overset{+3}{5C_2O_4^{2-}}(aq) + 16H^+(aq) \longrightarrow \overset{+2}{2Mn^{2+}}(aq) + \overset{+4}{10CO_2}(g) + 8H_2O(l)$$

species ($C_2O_4^{2-}$) equal the electrons gained by the reduced species (MnO_4^-). We can calculate the $C_2O_4^{2-}$ concentration from the known volume of $Na_2C_2O_4$ solution and the known volume and concentration of $KMnO_4$ solution.

SAMPLE PROBLEM 4.19 Finding the Amount of Reducing Agent by Titration

Problem Calcium ion (Ca^{2+}) is necessary for the clotting of blood and many other physiological processes. To measure the Ca^{2+} concentration in 1.00 mL of human blood, $Na_2C_2O_4$ solution is added, which precipitates the Ca^{2+} as CaC_2O_4. This solid is dissolved in dilute H_2SO_4 to release $C_2O_4^{2-}$, and 2.05 mL of 4.88×10^{-4} *M* $KMnO_4$ is required to reach the end point. The balanced equation is

$$2KMnO_4(aq) + 5CaC_2O_4(s) + 8H_2SO_4(aq) \longrightarrow 2MnSO_4(aq) + K_2SO_4(aq) + 5CaSO_4(s) + 10CO_2(g) + 8H_2O(l)$$

Calculate the amount (mol) of Ca^{2+} in 1.00 mL of blood.

Plan We have to find the amount (mol) of Ca^{2+} from the volume (2.05 mL) and concentration (4.88×10^{-4} *M*) of $KMnO_4$ used to oxidize the CaC_2O_4 precipitated from 1.00 mL of blood. We find the amount (mol) of $KMnO_4$ needed to reach the end point and use the molar ratio to find the amount (mol) of CaC_2O_4. Then we use the chemical formula, which shows 1 mol of Ca^{2+} for every mol of CaC_2O_4 (see the road map).

Solution Converting volume (mL) and concentration (*M*) to amount (mol) of $KMnO_4$:

$$\text{Amount (mol) of } KMnO_4 = 2.05 \text{ mL soln} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{4.88\times10^{-4} \text{ mol } KMnO_4}{1 \text{ L soln}}$$
$$= 1.00\times10^{-6} \text{ mol } KMnO_4$$

Using the molar ratio to convert amount (mol) of $KMnO_4$ to amount (mol) of CaC_2O_4:

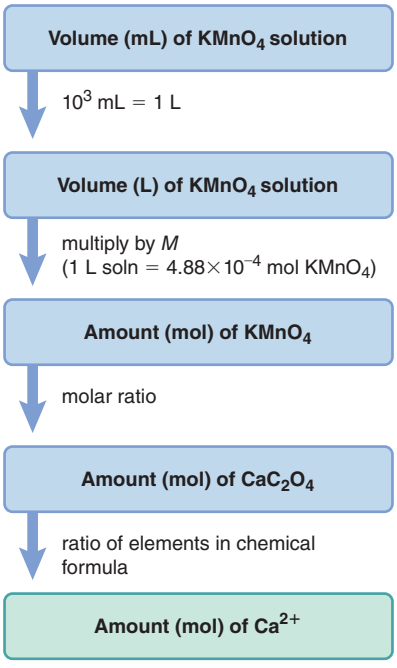
$$\text{Amount (mol) of } CaC_2O_4 = 1.00\times10^{-6} \text{ mol } KMnO_4 \times \frac{5 \text{ mol } CaC_2O_4}{2 \text{ mol } KMnO_4}$$
$$= 2.50\times10^{-6} \text{ mol } CaC_2O_4$$

Finding the amount (mol) of Ca^{2+}:

$$\text{Amount (mol) of } Ca^{2+} = 2.50\times10^{-6} \text{ mol } CaC_2O_4 \times \frac{1 \text{ mol } Ca^{2+}}{1 \text{ mol } CaC_2O_4} = 2.50\times10^{-6} \text{ mol } Ca^{2+}$$

Check A very small volume of dilute $KMnO_4$ is needed, so 10^{-6} mol of $KMnO_4$ seems reasonable. The molar ratio of CaC_2O_4 to $KMnO_4$ is 5/2, which gives 2.5×10^{-6} mol of CaC_2O_4 and thus 2.5×10^{-6} mol of Ca^{2+}.

Road Map



Comment **1.** When blood is donated, the receiving bag contains $Na_2C_2O_4$ solution, which precipitates the Ca^{2+} ion to prevent clotting.
2. Normal Ca^{2+} concentration in human adult blood is 9.0 to 11.5 mg Ca^{2+}/100 mL. If we multiply the amount of Ca^{2+} in 1 mL by 100 and then multiply by the molar mass of Ca (40.08 g/mol), we get 1.0×10^{-2} g, or 10.0 mg Ca^{2+} in 100 mL:

$$\text{Mass (mg) of } Ca^{2+} = \frac{2.50\times10^{-6}\ \cancel{\text{mol } Ca^{2+}}}{1\ \cancel{\text{mL}}} \times 100\ \cancel{\text{mL}} \times \frac{40.08\ \cancel{\text{g}}\ Ca^{2+}}{1\ \cancel{\text{mol } Ca^{2+}}} \times \frac{1000\text{ mg}}{1\ \cancel{\text{g}}}$$

$$= 10.0\text{ mg } Ca^{2+}$$

FOLLOW-UP PROBLEMS

4.19A When 2.50 mL of low-fat milk is treated with sodium oxalate and the precipitate dissolved in H_2SO_4, 6.53 mL of 4.56×10^{-3} *M* $KMnO_4$ is required to reach the end point. **(a)** Calculate the molarity of Ca^{2+} in the milk sample. **(b)** What is the concentration of Ca^{2+} in g/L? Is this value consistent with the typical value for milk of about 1.2 g Ca^{2+}/L?

4.19B The amount of iron in an iron ore is determined by converting the Fe to $FeSO_4$, followed by titration with a solution of $K_2Cr_2O_7$. The balanced equation is

$$6FeSO_4(aq) + K_2Cr_2O_7(aq) + 7H_2SO_4(aq) \longrightarrow$$
$$3Fe_2(SO_4)_3(aq) + Cr_2(SO_4)_3(aq) + 7H_2O(l) + K_2SO_4(aq)$$

(a) What is the molarity of Fe^{2+} if 21.85 mL of 0.250 *M* $K_2Cr_2O_7$ is required for the titration of 30.0 mL of $FeSO_4$ solution? **(b)** If the original sample of iron ore had a mass of 2.58 g, what is the mass percent of iron in the ore?

SOME SIMILAR PROBLEMS 4.96 and 4.97

Summary of Section 4.5

- When one reactant has a greater attraction for electrons than another, there is a net movement of electrons, and a redox reaction takes place. Electron gain (reduction) and electron loss (oxidation) occur simultaneously.
- Assigning oxidation numbers to all atoms in a reaction is a method for identifying a redox reaction. The species that is oxidized (contains an atom that increases in oxidation number) is the reducing agent; the species that is reduced (contains an atom that decreases in oxidation number) is the oxidizing agent.
- A redox titration determines the concentration of an oxidizing agent from the known concentration of the reducing agent (or vice versa).

4.6 ELEMENTS IN REDOX REACTIONS

In many redox reactions, such as those in Sample Problem 4.18, *atoms occur as an element on one side of an equation and as part of a compound on the other.** One way to classify these is by comparing the *numbers* of reactants and products. With that approach, we have three types—*combination, decomposition,* and *displacement;* one other type involving elements is *combustion*. In this section, we survey each type with several examples.

Combination Redox Reactions

In a combination redox reaction, two or more reactants, at least one of which is an element, form a compound:

$$X + Y \longrightarrow Z$$

*Many other redox reactions, however, do *not* involve elements (see Sample Problem 4.19).

Combining Two Elements Two elements may react to form binary ionic or covalent compounds. Here are some important examples:

1. *Metal and nonmetal form an ionic compound.* Figure 4.19 shows a typical example, the reaction between the alkali metal potassium and the halogen chlorine, on the macroscopic, atomic, and symbolic levels. Note the change in oxidation numbers in the balanced equation: K is oxidized, so it is the reducing agent; Cl_2 is reduced, so it is the oxidizing agent. In fact, whenever a binary ionic compound forms from its elements, *the metal is the reducing agent and the nonmetal is the oxidizing agent*.

Aluminum reacts with O_2, as does nearly every metal, to form an ionic oxide:

$$\overset{0}{4Al(s)} + \overset{0}{3O_2(g)} \longrightarrow \overset{+3\ -2}{2Al_2O_3(s)}$$

The Al_2O_3 layer on the surface of an aluminum pot prevents oxygen from reacting with the next layer of Al atoms, thus protecting the metal from further oxidation.

2. *Two nonmetals form a covalent compound.* In one of thousands of examples, ammonia forms from nitrogen and hydrogen in a reaction that occurs in industry on an enormous scale:

$$\overset{0}{N_2(g)} + \overset{0}{3H_2(g)} \longrightarrow \overset{-3\ +1}{2NH_3(g)}$$

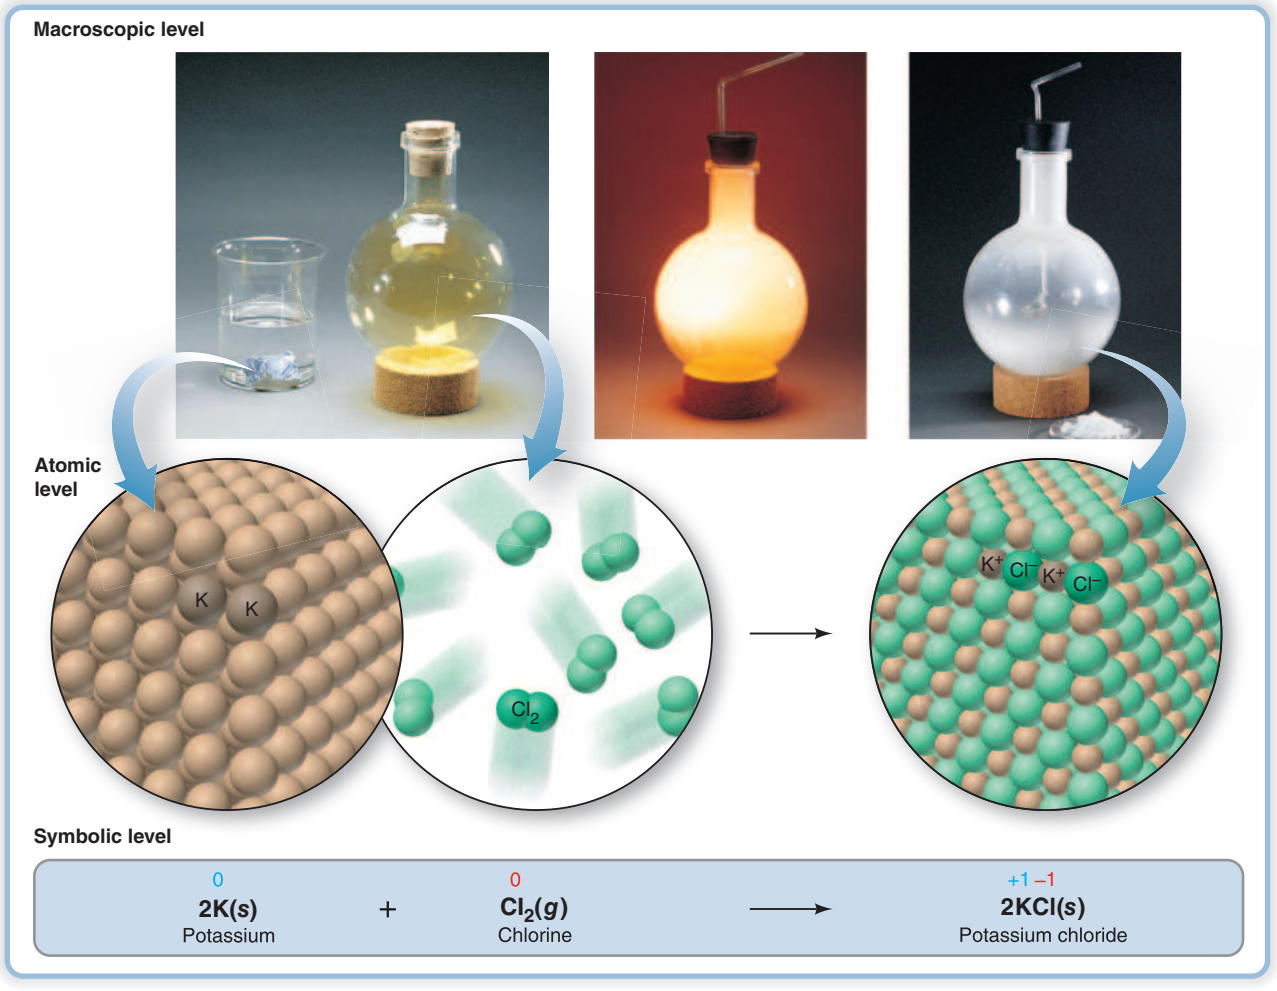


Figure 4.19 Combining elements to form an ionic compound: potassium metal and chlorine gas form solid potassium chloride. Darker atoms in the atomic view indicate the stoichiometry.

Halogens react with many other nonmetals, as in the formation of phosphorus trichloride, a reactant in the production of pesticides and other organic compounds:

$$\overset{0}{P_4}(s) + 6\overset{0}{Cl_2}(g) \longrightarrow 4\overset{+3}{\overset{-1}{PCl_3}}(l)$$

Nearly every nonmetal reacts with O_2 to form a covalent oxide, as when nitrogen monoxide forms from the nitrogen and oxygen in air at the very high temperatures created by lightning and in a car's engine:

$$\overset{0}{N_2}(g) + \overset{0}{O_2}(g) \longrightarrow 2\overset{+2}{\overset{-2}{NO}}(g)$$

Combining a Compound and an Element Many binary covalent compounds react with nonmetals to form larger compounds. Many nonmetal oxides react with additional O_2 to form "higher" oxides (those with more O atoms in each molecule). For example,

$$2\overset{+2}{\overset{-2}{NO}}(g) + \overset{0}{O_2}(g) \longrightarrow 2\overset{+4}{\overset{-2}{NO_2}}(g)$$

Similarly, many nonmetal halides combine with additional halogen to form "higher" halides:

$$\overset{+3}{\overset{-1}{PCl_3}}(l) + \overset{0}{Cl_2}(g) \longrightarrow \overset{+5}{\overset{-1}{PCl_5}}(s)$$

Decomposition Redox Reactions

In a *decomposition redox reaction,* a compound forms two or more products, at least one of which is an element:

$$Z \longrightarrow X + Y$$

In any decomposition reaction, the reactant absorbs enough energy for one or more bonds to break. The energy can take several forms, but the most important are decomposition by heat (thermal) and by electricity (electrolytic). The products are either elements or elements and smaller compounds.

Thermal Decomposition When the energy absorbed is heat, the reaction is called a *thermal decomposition*. (A Greek delta, Δ, above the yield arrow indicates strong heating is required.) Many metal oxides, chlorates, and perchlorates release oxygen when strongly heated. Heating potassium chlorate is a method for forming small amounts of oxygen in the laboratory; the same reaction occurs in some explosives and fireworks:

$$2\overset{+1}{K}\overset{+5}{Cl}\overset{-2}{O_3}(s) \xrightarrow{\Delta} 2\overset{+1}{K}\overset{-1}{Cl}(s) + 3\overset{0}{O_2}(g)$$

The decomposition of mercury(II) oxide, used by Lavoisier in his classic experiments, is shown in Figure 4.20. Notice that, in these cases, the lone reactant is the oxidizing *and* the reducing agent. For example, in the reactant HgO, the O^{2-} ion reduces the Hg^{2+} ion, and at the same time, Hg^{2+} oxidizes O^{2-}.

Electrolytic Decomposition In the process of electrolysis, a compound absorbs electrical energy and decomposes into its elements. In the early 19th century, the observation of the electrolysis of water was crucial for establishing atomic masses:

$$2\overset{+1}{H}\overset{-2}{O}(l) \xrightarrow{\text{electricity}} 2\overset{0}{H_2}(g) + \overset{0}{O_2}(g)$$

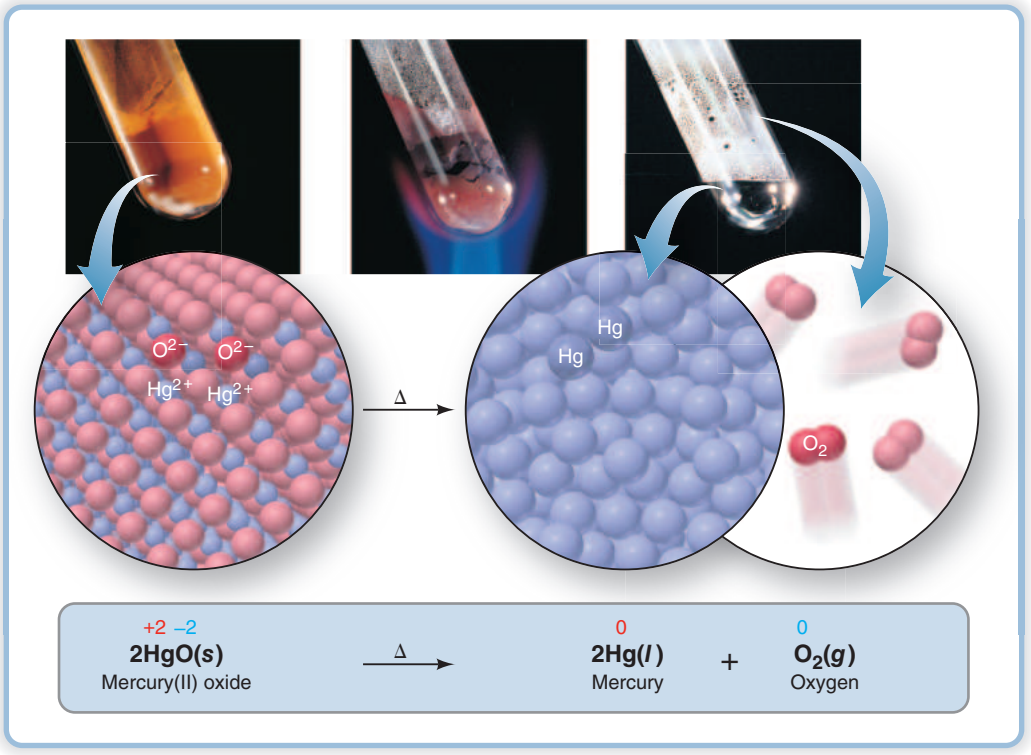

Figure 4.20 Decomposition of the compound mercury(II) oxide to its elements.

Many active metals, such as sodium, magnesium, and calcium, are produced industrially by electrolysis of their molten halides:

$$\overset{+2\ -1}{MgCl_2(l)} \xrightarrow{\text{electricity}} \overset{0}{Mg(l)} + \overset{0}{Cl_2(g)}$$

(We examine the details of electrolysis in Chapter 21 and its role in the industrial recovery of several elements in Chapter 22.)

Displacement Redox Reactions and Activity Series

In any *displacement reaction,* the number of substances on the two sides of the equation remains the same, but atoms (or ions) exchange places. There are two types of displacement reactions:

1. In *double*-displacement (metathesis) reactions, such as precipitation and acid-base reactions (Sections 4.3 and 4.4), atoms (or ions) of two *compounds* exchange places; these reactions are *not* redox processes:

$$AB + CD \longrightarrow AD + CB$$

2. In *single*-displacement reactions, one of the substances is an *element;* therefore, *all single-displacement reactions* ***are*** *redox processes:*

$$X + YZ \longrightarrow XZ + Y$$

In solution, single-displacement reactions occur when an atom of one element displaces the ion of another: if the displacement involves metals, the atom *reduces* the ion; if it involves nonmetals (specifically halogens), the atom *oxidizes* the ion. In two *activity series*—one for metals and one for halogens—the elements are ranked in order of their ability to displace hydrogen (for metals) and one another.

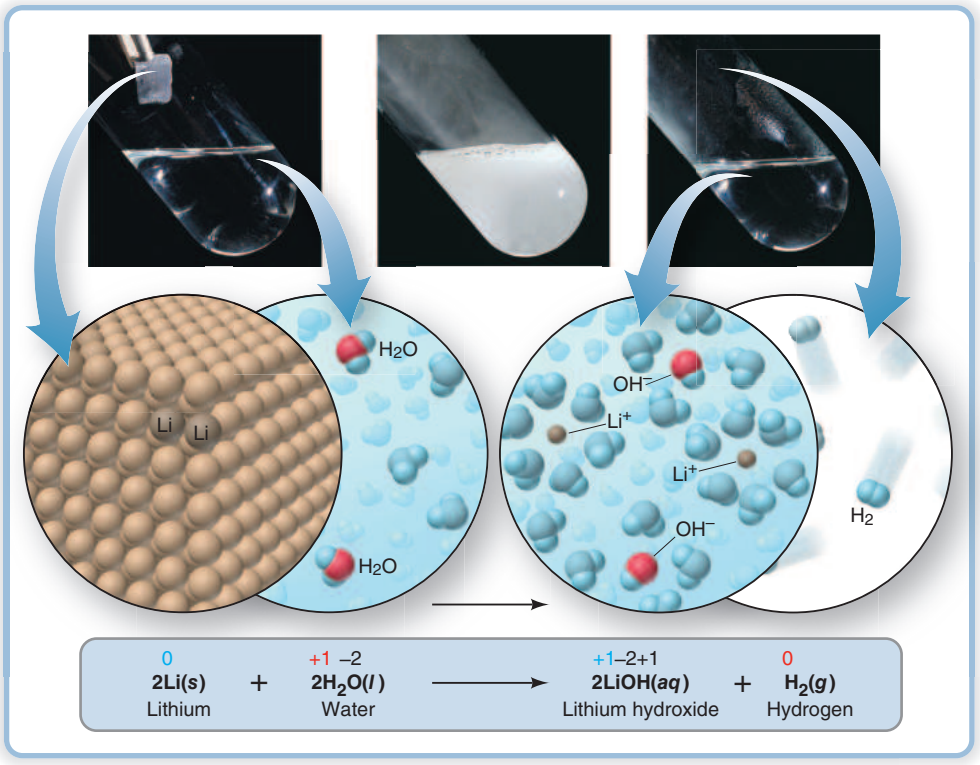

Figure 4.21 The active metal lithium displaces hydrogen from water. Only water molecules involved in the reaction are red and blue.

The Activity Series of the Metals Metals are ranked by their ability to displace H_2 from various sources and another metal from solution. In all displacements of H_2, the metal is the reducing agent (O.N. increases), and water or acid is the oxidizing agent (O.N. of H decreases). The activity series of the metals is based on these facts:

- *The most reactive metals displace H_2 from liquid water.* Group 1A(1) metals and Ca, Sr, and Ba from Group 2A(2) displace H_2 from water (Figure 4.21).
- *Slightly less reactive metals displace H_2 from steam.* Heat supplied by steam is needed for less reactive metals such as Al and Zn to displace H_2:

$$\overset{0}{2Al(s)} + \overset{+1\,-2}{6H_2O(g)} \xrightarrow{\Delta} \overset{+3\,-2\;\;+1}{2Al(OH)_3(s)} + \overset{0}{3H_2(g)}$$

- *Still less reactive metals displace H_2 from acids.* The higher concentration of H^+ in acid solutions is needed for even less reactive metals such as Ni and Sn to displace H_2 (Figure 4.22). For nickel, the net ionic equation is

$$\overset{0}{Ni(s)} + \overset{+1}{2H^+(aq)} \longrightarrow \overset{+2}{Ni^{2+}(aq)} + \overset{0}{H_2(g)}$$

- *The least reactive metals cannot displace H_2 from any source.* Fortunately, precious metals, such as silver, gold, and platinum, do *not* react with water or acid.
- *An atom of one metal displaces the ion of another.* Comparisons of metal reactivity show, for example, that Zn metal displaces Cu^{2+} ion from aqueous $CuSO_4$:

$$\overset{+2}{Cu^{2+}(aq)} + \overset{+6\;\;-2}{SO_4^{2-}(aq)} + \overset{0}{Zn(s)} \longrightarrow \overset{0}{Cu(s)} + \overset{+2}{Zn^{2+}(aq)} + \overset{+6\;\;-2}{SO_4^{2-}(aq)}$$

And Figure 4.23 shows that Cu metal displaces silver (Ag^+) ion from solution; therefore, zinc is more reactive than copper, which is more reactive than silver.

Figure 4.22 The displacement of H_2 from acid by nickel.

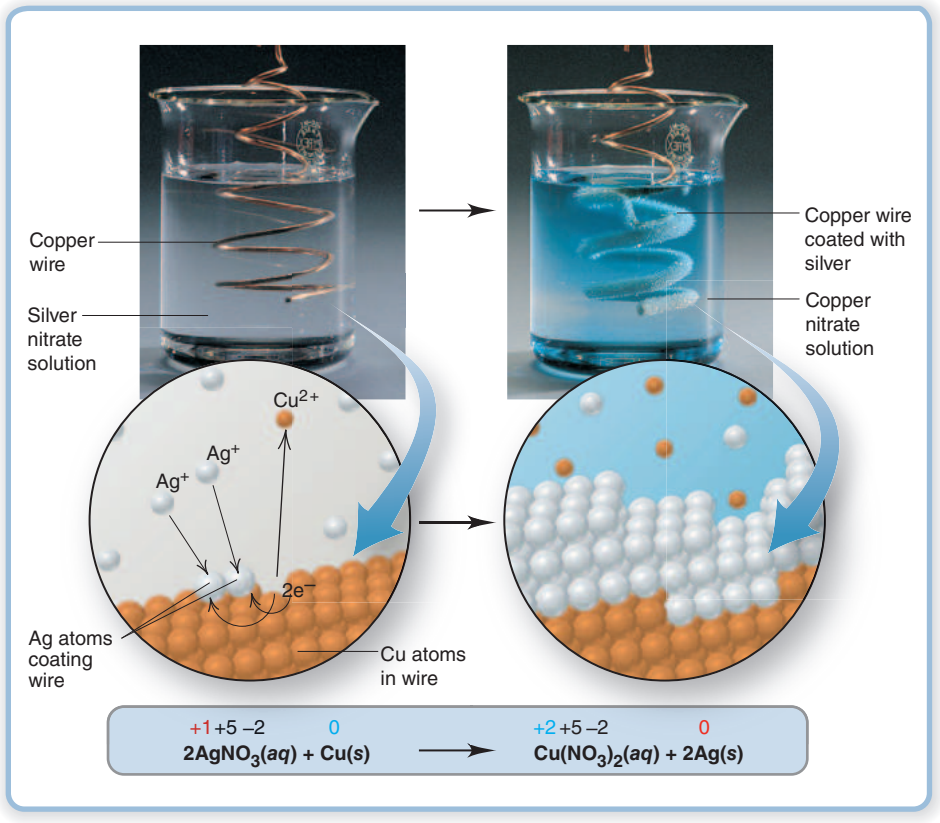

Figure 4.23 A more reactive metal (Cu) displacing the ion of a less reactive metal (Ag^+) from solution.

Many such reactions form the basis of the **activity series of the metals.** Note these two points from Figure 4.24:

- Elements higher on the list are stronger reducing agents than elements lower down; in other words, any metal can reduce the ions of metals below it.
- From higher to lower, a metal can displace H_2 (reduce H^+) from water, steam, acid, or not at all.

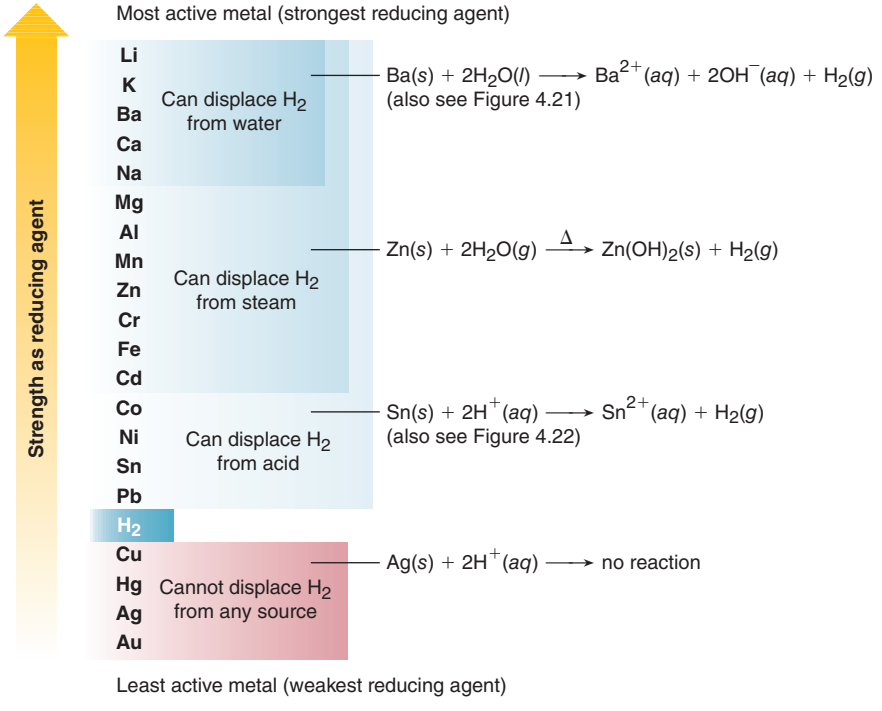

Figure 4.24 The activity series of the metals.

The Activity Series of the Halogens Reactivity of the elements decreases down Group 7A(17), so we have

$$F_2 > Cl_2 > Br_2 > I_2$$

A halogen higher in the group is a stronger oxidizing agent than one lower down. Thus, elemental chlorine can oxidize bromide ions *(below)* or iodide ions from solution, and elemental bromine can oxidize iodide ions:

$$\overset{-1}{2Br^-}(aq) + \overset{0}{Cl_2}(aq) \longrightarrow \overset{0}{Br_2}(aq) + \overset{-1}{2Cl^-}(aq)$$

Combustion Reactions

Combustion is the process of combining with oxygen, most commonly with the release of heat and the production of light, as in a flame. Combustion reactions are not usually classified by the number of reactants and products, but *all of these reactions are redox processes* because elemental oxygen is a reactant:

$$\overset{+2}{\overset{-2}{2CO}}(g) + \overset{0}{O_2}(g) \longrightarrow \overset{+4}{\overset{-2}{2CO_2}}(g)$$

The combustion reactions that we commonly use to produce energy involve coal, petroleum, gasoline, natural gas, or wood as a reactant. These mixtures consist of substances with many C—C and C—H bonds, which break during the reaction, and each C and H atom combines with oxygen to form CO_2 and H_2O. The combustion of butane is typical:

$$2C_4H_{10}(g) + 13O_2(g) \longrightarrow 8CO_2(g) + 10H_2O(g)$$

Biological *respiration* is a multistep combustion process that occurs within our cells when we "burn" foodstuffs, such as glucose, for energy:

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g) + \text{energy}$$

SAMPLE PROBLEM 4.20 Identifying the Type of Redox Reaction

Problem Classify each of these redox reactions as a combination, decomposition, or displacement reaction, write a balanced molecular equation for each, as well as total and net ionic equations for part (c), and identify the oxidizing and reducing agents:

(a) Magnesium(s) + nitrogen(g) ⟶ magnesium nitride(s)
(b) Hydrogen peroxide(l) ⟶ water + oxygen gas
(c) Aluminum(s) + lead(II) nitrate(aq) ⟶ aluminum nitrate(aq) + lead(s)

Plan To decide on reaction type, recall that combination reactions have fewer products than reactants, decomposition reactions have more products than reactants, and displacement reactions have the same number of reactants and products. The oxidation number (O.N.) becomes more positive for the reducing agent and less positive for the oxidizing agent.

Solution **(a)** Combination: two substances form one. This reaction occurs, along with formation of magnesium oxide, when magnesium burns in air, which is mostly N_2:

$$\overset{0}{3Mg}(s) + \overset{0}{N_2}(g) \longrightarrow \overset{+2\ -3}{Mg_3N_2}(s)$$

Mg is the reducing agent; N_2 is the oxidizing agent.

(b) Decomposition: one substance forms two. Because hydrogen peroxide is very unstable and breaks down from heat, light, or just shaking, this reaction occurs within every bottle of this common household antiseptic:

$$\overset{+1\ -1}{\overset{-1}{2H_2O_2}}(l) \longrightarrow \overset{+1\ -2}{2H_2O}(l) + \overset{0}{O_2}(g)$$

H_2O_2 is both the oxidizing *and* the reducing agent. The O.N. of O in peroxides is −1. It is shown in blue *and* red because it both increases to 0 in O_2 and decreases to −2 in H_2O.

(c) Displacement: two substances form two others. As Figure 4.24 shows, Al is more active than Pb and, thus, displaces it from aqueous solution:

$$\overset{0}{2Al(s)} + \overset{+2\,+5\,-2}{3Pb(NO_3)_2(aq)} \longrightarrow \overset{+3\,+5\,-2}{2Al(NO_3)_3(aq)} + \overset{0}{3Pb(s)}$$

Al is the reducing agent; $Pb(NO_3)_2$ is the oxidizing agent.

The total ionic equation is

$$2Al(s) + 3Pb^{2+}(aq) + 6NO_3^-(aq) \longrightarrow 2Al^{3+}(aq) + 6NO_3^-(aq) + 3Pb(s)$$

The net ionic equation is

$$2Al(s) + 3Pb^{2+}(aq) \longrightarrow 2Al^{3+}(aq) + 3Pb(s)$$

FOLLOW-UP PROBLEMS

4.20A Classify each of the following redox reactions as a combination, decomposition, or displacement reaction, write a balanced molecular equation for each, as well as total and net ionic equations for parts (b) and (c), and identify the oxidizing and reducing agents:

(a) $S_8(s) + F_2(g) \longrightarrow SF_4(g)$

(b) $CsI(aq) + Cl_2(aq) \longrightarrow CsCl(aq) + I_2(aq)$

(c) $Ni(NO_3)_2(aq) + Cr(s) \longrightarrow Ni(s) + Cr(NO_3)_3(aq)$

4.20B Classify each of the following redox reactions as a combination, decomposition, or displacement reaction, write a balanced molecular equation for each, as well as total and net ionic equations for part (a), and identify the oxidizing and reducing agents:

(a) $Co(s) + HCl(aq) \longrightarrow CoCl_2(aq) + H_2(g)$

(b) $CO(g) + O_2(g) \longrightarrow CO_2(g)$

(c) $N_2O_5(s) \longrightarrow NO_2(g) + O_2(g)$

SOME SIMILAR PROBLEMS 4.103–4.106

Summary of Section 4.6

- A reaction that has an element as reactant or product is a redox reaction.
- In combination redox reactions, elements combine to form a compound, or a compound and an element combine.
- In decomposition redox reactions, a compound breaks down by absorption of heat or electricity into elements or into a different compound and an element.
- In displacement redox reactions, one element displaces the ion of another from solution.
- Activity series rank elements in order of ability to displace each other. A more reactive metal can displace (reduce) hydrogen ion or the ion of a less reactive metal from solution. A more reactive halogen can displace (oxidize) the ion of a less reactive halogen from solution.
- Combustion releases heat through a redox reaction of a substance with O_2.

4.7 THE REVERSIBILITY OF REACTIONS AND THE EQUILIBRIUM STATE

So far, we have viewed reactions as transformations of reactants into products that proceed until they are complete, that is, until the limiting reactant is used up. However, many reactions stop before this happens because two opposing reactions are taking place simultaneously: the forward (left-to-right) reaction continues, but the reverse (right-to-left) reaction occurs just as fast (at the same rate). At this point, *no further changes appear in the amounts of reactants or products,* and the reaction mixture has reached **dynamic equilibrium.** On the macroscopic level, the reaction is *static,* but it is *dynamic* on the molecular level.

Reversibility of Calcium Carbonate Decomposition In principle, *every reaction is reversible and will reach dynamic equilibrium if all the reactants and products are present*. Consider the reversible breakdown and formation of calcium carbonate. When heated, it breaks down to calcium oxide and carbon dioxide:

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g) \text{ [breakdown]}$$

And it forms when calcium oxide and carbon dioxide react:

$$CaO(s) + CO_2(g) \longrightarrow CaCO_3(s) \text{ [formation]}$$

Let's study this process with two experiments:

1. We place $CaCO_3$ in an *open* steel container and heat it to approximately 900°C (Figure 4.25A). The $CaCO_3$ starts breaking down to CaO and CO_2, and the CO_2 escapes from the open container. The reaction goes to completion because the reverse reaction (formation) cannot occur in the absence of CO_2.

2. We perform the same experiment in a *closed* container (Figure 4.25B). The breakdown (forward reaction) starts as before, but soon the CaO and CO_2 start reacting with each other (formation). Gradually, with time, as the amounts of CaO and CO_2 increase, the formation reaction speeds up. Eventually, the reverse reaction (formation) occurs as fast as the forward reaction (breakdown), and the amounts of $CaCO_3$, CaO, and CO_2 no longer change: the system has reached a state of equilibrium. We indicate this condition with a pair of arrows pointing in opposite directions:

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

In contrast to the reaction in the open container, equilibrium *is* reached because *all the substances remain in contact with each other.*

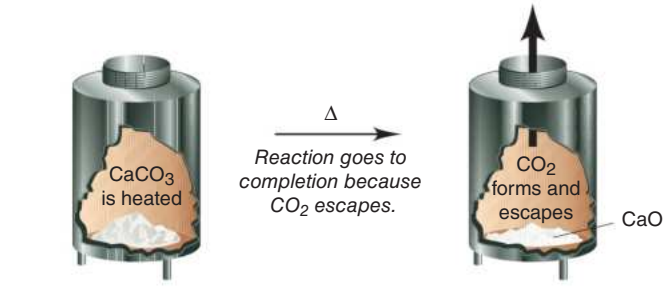

Figure 4.25 The equilibrium state.

Some Other Types of Reversible Reactions Reaction reversibility applies to other systems as well:

1. *Weak acids in water.* Weak acids dissociate very little into ions in water because the dissociation becomes balanced by a reassociation of H_3O^+ with the anion to re-form the weak acid and water. For example, when acetic acid dissolves, some CH_3COOH molecules transfer a proton to H_2O and form H_3O^+ and CH_3COO^- ions. As more ions form, the ions react with each other more often to re-form acetic acid and water:

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3COO^-(aq)$$

In fact, in 0.1 *M* CH_3COOH at 25°C, only about 1.3% of acid molecules are dissociated! Each weak acid dissociates to its own extent. For example, under the same conditions, propionic acid (CH_3CH_2COOH) is 1.1% dissociated, and hydrofluoric acid (HF) is 8.6% dissociated.

2. *Weak bases in water.* Similarly, the weak base ammonia reacts with water to form NH_4^+ and OH^- ions. As more ions form, they interact more often to re-form ammonia and water, and the rates of the forward and reverse reactions soon balance:

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

The weak base methylamine (CH_3NH_2) reacts with water to a greater extent than ammonia does before reaching equilibrium, and the weak base aniline ($C_6H_5NH_2$) reacts to a lesser extent.

3. *Gas-forming reactions.* Acids react with carbonates (see page 163):

$$2HCl(aq) + K_2CO_3(aq) \longrightarrow 2KCl(aq) + H_2O(l) + CO_2(g)$$

This type of reaction goes to completion in an open container because the CO_2 escapes. But, if the container is closed to keep the CO_2 present, the reverse reaction takes place and the mixture reaches equilibrium.

4. *Other acid-base and precipitation reactions.* These processes seem to "go to completion" because the ions become tied up in the product, either as water (acid-base) or as an insoluble solid (precipitation), and are not available to re-form reactants. In truth, though, water and ionic precipitates do dissociate to an extremely small extent, so these reactions also reach equilibrium, but the final reaction mixture consists of *almost* all product.

Thus, some reactions proceed very little before reaching equilibrium, others proceed almost to completion, and still others reach equilibrium with significant amounts of both reactants *and* products present. In Chapter 20, we'll examine the factors that determine to what extent a reaction proceeds.

Dynamic equilibrium occurs in many natural systems, from the cycling of water in the environment to the nuclear processes occurring in stars. We examine equilibrium in chemical and physical systems in Chapters 12, 13, and 17 through 21.

Summary of Section 4.7

- Every reaction is reversible if all the substances involved are present.
- As the amounts of products increase, the reactants begin to re-form. When the reverse reaction occurs as rapidly as the forward reaction, the amounts of the substances no longer change, and the reaction mixture has reached dynamic equilibrium.
- Weak acids and bases reach equilibrium in water with a very small proportion of their molecules dissociated.
- An aqueous ionic reaction "goes to completion" because a product is removed (as a gas) or because products are formed that react very slightly in a reverse reaction (usually water or a precipitate).

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. Why water is a polar molecule and how it dissociates ionic compounds into ions (§4.1)
2. The differing nature of the species present when ionic and covalent compounds dissolve in water (§4.1)
3. The distinctions among strong electrolytes, weak electrolytes, and nonelectrolytes (§4.1, §4.4)
4. The meanings of concentration and molarity (§4.1)
5. The effect of dilution on the concentration of a solute (§4.1)
6. The three types of equations that specify the species and the chemical change in an aqueous ionic reaction (§4.2)
7. The key event in three classes of aqueous ionic reactions (§4.3–§4.5)
8. How to decide whether a precipitation reaction occurs (§4.3)
9. The distinction between strong and weak aqueous acids and bases (§4.4)
10. How acid-base reactions are proton transfers; how carbonates (and sulfites) act as bases in gas-forming reactions (§4.4)
11. The distinction between a transfer and a shift of electrons in the formation of ionic and covalent compounds (§4.5)
12. The relation between change in oxidation number and identity of oxidizing and reducing agents (§4.5)
13. The presence of elements in combination, decomposition, and displacement redox reactions; the meaning of an activity series (§4.6)
14. The balance between forward and reverse reactions in dynamic equilibrium; why some acids and bases are weak (§4.7)

Master These Skills

1. Using molecular scenes to depict a soluble ionic compound in water (SP 4.1)
2. Using the formula of a compound to find the number of moles of ions in solution (SP 4.2)
3. Calculating molarity and mass of solute in solution (SPs 4.3–4.5)
4. Preparing a dilute solution from a concentrated one (SP 4.6)
5. Using molecular scenes to understand changes in concentration (SP 4.7)
6. Predicting whether a precipitation reaction occurs (SP 4.8)
7. Using molecular views to understand precipitation reactions (SP 4.9)
8. Using molar ratios to convert between amounts of reactants and products for reactions in solution (SPs 4.10, 4.11, 4.15)
9. Determining the number of H^+ (or OH^-) ions in an aqueous acid (or base) solution (SP 4.12)
10. Writing ionic equations to describe precipitation and acid-base reactions (SPs 4.8, 4.9, 4.13)
11. Writing acid-base equations as proton transfers (SP 4.14)
12. Calculating an unknown concentration from an acid-base or redox titration (SPs 4.16, 4.19)
13. Determining the oxidation number of any element in a compound (SP 4.17)
14. Identifying redox reactions and oxidizing and reducing agents from changes in O.N.s (SP 4.18)
15. Predicting the products of a single-displacement reaction based on an activity series (§4.6)
16. Distinguishing among combination, decomposition, and displacement redox reactions (SP 4.20)

Key Equations and Relationships

Page numbers appear in parentheses.

4.1 Defining molarity (144):

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of solution}} \quad \text{or} \quad M = \frac{\text{mol solute}}{\text{L soln}}$$

4.2 Diluting a concentrated solution (147):

$$M_{dil} \times V_{dil} = \text{amount (mol)} = M_{conc} \times V_{conc}$$

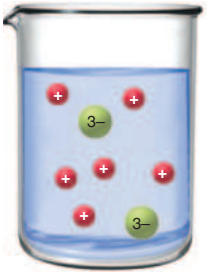
BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

4.1A (a) The compound is $BaCl_2$.

(b) Mass (g) of $BaCl_2 = 9\ \cancel{\text{particles}} \times \dfrac{0.05\ \cancel{\text{mol particles}}}{1\ \cancel{\text{particle}}} \times \dfrac{1\ \cancel{\text{mol BaCl}_2}}{3\ \cancel{\text{mol particles}}} \times \dfrac{208.2\ \text{g BaCl}_2}{1\ \cancel{\text{mol BaCl}_2}}$

$= 31.2\ \text{g BaCl}_2$

4.1B (a)



(b) Amount (mol) of ions $= 0.40\ \cancel{\text{mol Na}_3\text{PO}_4} \times \dfrac{4\ \text{mol ions}}{1\ \cancel{\text{mol Na}_3\text{PO}_4}}$

$= 1.6\ \text{mol ions}$

4.2A (a) $KClO_4(s) \xrightarrow{H_2O} K^+(aq) + ClO_4^-(aq)$;
2 mol of K^+ and 2 mol of ClO_4^-

(b) $Mg(C_2H_3O_2)_2(s) \xrightarrow{H_2O} Mg^{2+}(aq) + 2C_2H_3O_2^-(aq)$;
2.49 mol of Mg^{2+} and 4.97 mol of $C_2H_3O_2^-$

(c) $(NH_4)_2CrO_4(s) \xrightarrow{H_2O} 2NH_4^+(aq) + CrO_4^{2-}(aq)$;
6.24 mol of NH_4^+ and 3.12 mol of CrO_4^{2-}

4.2B (a) $Li_2CO_3(s) \xrightarrow{H_2O} 2Li^+(aq) + CO_3^{2-}(aq)$;
8 mol of Li^+ and 4 mol of CO_3^{2-}

(b) $Fe_2(SO_4)_3(s) \xrightarrow{H_2O} 2Fe^{3+}(aq) + 3SO_4^{2-}(aq)$;
0.560 mol of Fe^{3+} and 0.840 mol of SO_4^{2-}

(c) $Al(NO_3)_3(s) \xrightarrow{H_2O} Al^{3+}(aq) + 3NO_3^-(aq)$;
0.134 mol of Al^{3+} and 0.403 mol of NO_3^-

4.3A Amount (mol) of KI $= 6.97\ \cancel{\text{g KI}} \times \dfrac{1\ \text{mol KI}}{166.0\ \cancel{\text{g KI}}}$

$= 0.0420\ \text{mol KI}$

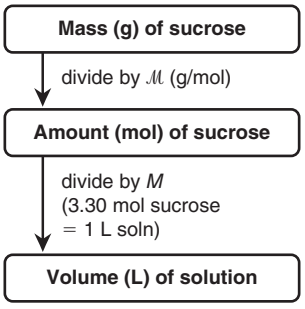
$M = \dfrac{0.0420\ \text{mol KI}}{100.\ \cancel{\text{mL soln}}} \times \dfrac{1000\ \cancel{\text{mL}}}{1\ \text{L}} = 0.420\ M$

4.3B Amount (mol) of $NaNO_3 = 175\ \cancel{\text{mg NaNO}_3} \times \dfrac{1\ \cancel{\text{g}}}{1000\ \cancel{\text{mg}}} \times \dfrac{1\ \text{mol NaNO}_3}{85.00\ \cancel{\text{g NaNO}_3}}$

$= 2.06\times10^{-3}\ \text{mol NaNO}_3$

$M = \dfrac{2.06\times10^{-3}\ \text{mol NaNO}_3}{15.0\ \cancel{\text{mL soln}}} \times \dfrac{1000\ \cancel{\text{mL}}}{1\ \text{L}} = 0.137\ M$

4.4A

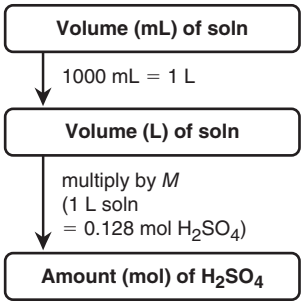


Volume (L) of sucrose soln

$= 135\ \cancel{\text{g sucrose}} \times \dfrac{1\ \cancel{\text{mol sucrose}}}{342.30\ \cancel{\text{g sucrose}}} \times \dfrac{1\ \text{L soln}}{3.30\ \cancel{\text{mol sucrose}}}$

$= 0.120\ \text{L soln}$

4.4B



Amount (mol) of $H_2SO_4 = 40.5\ \cancel{\text{mL soln}} \times \dfrac{1\ \cancel{\text{L}}}{1000\ \cancel{\text{mL}}} \times \dfrac{0.128\ \text{mol H}_2\text{SO}_4}{1\ \cancel{\text{L soln}}}$

$= 5.18\times10^{-3}\ \text{mol H}_2\text{SO}_4$

4.5A $Na_3PO_4(aq) \longrightarrow 3Na^+(aq) + PO_4^{3-}(aq)$;
Amount (mol) of Na_3PO_4

$= 1.32\ \cancel{\text{L}} \times \dfrac{0.55\ \cancel{\text{mol Na}_3\text{PO}_4}}{1\ \cancel{\text{L}}} \times \dfrac{3\ \text{mol Na}^+}{1\ \cancel{\text{mol Na}_3\text{PO}_4}}$

$= 2.2\ \text{mol Na}^+$

Similarly, there are 0.73 mol PO_4^{3-}.

4.5B $Al_2(SO_4)_3(aq) \longrightarrow 2Al^{3+}(aq) + 3SO_4^{2-}(aq)$
Amount (mol) of Al^{3+}

$= 1.25\ \cancel{\text{mol Al}_2(\text{SO}_4)_3} \times \dfrac{2\ \text{mol Al}^{3+}}{1\ \cancel{\text{mol Al}_2(\text{SO}_4)_3}} = 2.50\ \text{mol Al}^{3+}$

$M = \dfrac{2.50\ \text{mol Al}^{3+}}{0.875\ \text{L}} = 2.86\ M$

4.6A $V_{dil} = \dfrac{4.50\ \cancel{M} \times 60.0\ \text{mL}}{1.25\ \cancel{M}} = 216\ \text{mL}$

4.6B M of diluted $H_2SO_4 = \dfrac{7.50\ M \times 25.0\ \cancel{\text{m}^3}}{500.\ \cancel{\text{m}^3}}$

$= 0.375\ M\ \text{H}_2\text{SO}_4$

Mass (g) of H_2SO_4/mL soln $= \dfrac{0.375\ \cancel{\text{mol H}_2\text{SO}_4}}{1\ \cancel{\text{L soln}}} \times \dfrac{1\ \cancel{\text{L}}}{1000\ \text{mL}} \times \dfrac{98.08\ \text{g H}_2\text{SO}_4}{1\ \cancel{\text{mol H}_2\text{SO}_4}}$

$= 3.68\times10^{-2}\ \text{g/mL soln}$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

4.7A To obtain B, the total volume of solution A was reduced by half:

$$V_{conc} = V_{dil} \times \frac{N_{dil}}{N_{conc}} = 1.0\ mL \times \frac{6\ \cancel{particles}}{12\ \cancel{particles}} = 0.50\ mL$$

To obtain C, $\frac{1}{2}$ of a unit volume of solvent was added to the unit volume of A:

$$V_{dil} = V_{conc} \times \frac{N_{conc}}{N_{dil}} = 1.0\ mL \times \frac{6\ \cancel{particles}}{4\ \cancel{particles}} = 1.5\ mL$$

4.7B $$N_{dil} = N_{conc} \times \frac{V_{conc}}{V_{dil}} = 12\ particles \times \frac{100.\ \cancel{mL}}{400.\ \cancel{mL}}$$
$$= 3\ particles$$

Circle B is the best representation of the unit volume.

4.8A (a) $Fe^{3+}(aq) + 3Cl^-(aq) + 3Cs^+(aq) + PO_4^{3-}(aq) \longrightarrow FePO_4(s) + 3Cl^-(aq) + 3Cs^+(aq)$

$Fe^{3+}(aq) + PO_4^{3-}(aq) \longrightarrow FePO_4(s)$

(b) $2Na^+(aq) + 2OH^-(aq) + Cd^{2+}(aq) + 2NO_3^-(aq) \longrightarrow 2Na^+(aq) + 2NO_3^-(aq) + Cd(OH)_2(s)$

$2OH^-(aq) + Cd^{2+}(aq) \longrightarrow Cd(OH)_2(s)$

(c) No reaction occurs.

4.8B (a) $2Ag^+(aq) + 2NO_3^-(aq) + Ba^{2+}(aq) + 2Cl^-(aq) \longrightarrow 2AgCl(s) + 2NO_3^-(aq) + Ba^{2+}(aq)$

$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$

(b) No reaction occurs.

(c) $Ni^{2+}(aq) + SO_4^{2-}(aq) + Pb^{2+}(aq) + 2NO_3^-(aq) \longrightarrow Ni^{2+}(aq) + 2NO_3^-(aq) + PbSO_4(s)$

$SO_4^{2-}(aq) + Pb^{2+}(aq) \longrightarrow PbSO_4(s)$

4.9A (a) Beaker A contains a solution of $Zn(NO_3)_2$.
(b) Beaker B contains a solution of $Ba(OH)_2$.
(c) The precipitate is zinc hydroxide, and the spectator ions are Ba^{2+} and NO_3^-.

Molecular: $Zn(NO_3)_2(aq) + Ba(OH)_2(aq) \longrightarrow Zn(OH)_2(s) + Ba(NO_3)_2(aq)$

Total ionic:

$Zn^{2+}(aq) + 2NO_3^-(aq) + Ba^{2+}(aq) + 2OH^-(aq) \longrightarrow Zn(OH)_2(s) + Ba^{2+}(aq) + 2NO_3^-(aq)$

Net ionic: $Zn^{2+}(aq) + 2OH^-(aq) \longrightarrow Zn(OH)_2(s)$

(d) The OH^- ion is limiting.

$$\text{Mass (g) of } Zn(OH)_2 = 6\ \cancel{OH^-\ particles} \times \frac{0.050\ \cancel{mol\ OH^-\ ions}}{1\ \cancel{OH^-\ particle}} \times \frac{1\ \cancel{mol\ Zn(OH)_2}}{2\ \cancel{mol\ OH^-\ ions}} \times \frac{99.40\ g\ Zn(OH)_2}{1\ \cancel{mol\ Zn(OH)_2}}$$
$$= 15\ g\ Zn(OH)_2$$

4.9B (a) Beaker A contains a solution of Li_2CO_3.
(b) Beaker B contains a solution of $CaCl_2$.
(c) The precipitate is $CaCO_3$, and the spectator ions are Li^+ and Cl^-.

Molecular: $Li_2CO_3(aq) + CaCl_2(aq) \longrightarrow 2LiCl(aq) + CaCO_3(s)$

Total ionic:

$2Li^+(aq) + CO_3^{2-}(aq) + Ca^{2+}(aq) + 2Cl^-(aq) \longrightarrow 2Li^+(aq) + 2Cl^-(aq) + CaCO_3(s)$

Net ionic: $Ca^{2+}(aq) + CO_3^{2-}(aq) \longrightarrow CaCO_3(s)$

(d) The Ca^{2+} ion is limiting.

$$\text{Mass (g) of } CaCO_3 = 3\ \cancel{Ca^{2+}\ particles} \times \frac{0.20\ \cancel{mol\ Ca^{2+}\ ions}}{1\ \cancel{Ca^{2+}\ particle}} \times \frac{1\ \cancel{mol\ CaCO_3}}{1\ \cancel{mol\ Ca^{2+}\ ions}} \times \frac{100.09\ g\ CaCO_3}{1\ \cancel{mol\ CaCO_3}}$$
$$= 60.\ g\ CaCO_3$$

4.10A $3CaCl_2(aq) + 2Na_3PO_4(aq) \longrightarrow Ca_3(PO_4)_2(s) + 6NaCl(aq)$

$$\text{Volume (L) of } Na_3PO_4 = 0.300\ \cancel{L\ CaCl_2\ soln} \times \frac{0.175\ \cancel{mol\ CaCl_2}}{1\ \cancel{L\ CaCl_2\ soln}} \times \frac{2\ \cancel{mol\ Na_3PO_4}}{3\ \cancel{mol\ CaCl_2}} \times \frac{1\ L\ Na_3PO_4\ solution}{0.260\ \cancel{mol\ Na_3PO_4}}$$
$$= 0.135\ L\ soln$$

4.10B $AgNO_3(aq) + NaCl(aq) \longrightarrow AgCl(s) + NaNO_3(aq)$

$$\text{Amount (mol) of } AgNO_3 = 0.148\ \cancel{g\ AgCl} \times \frac{1\ \cancel{mol\ AgCl}}{143.4\ \cancel{g\ AgCl}} \times \frac{1\ mol\ AgNO_3}{1\ \cancel{mol\ AgCl}}$$
$$= 0.00103\ mol\ AgNO_3$$

$$\text{Molarity of } AgNO_3 = \frac{0.00103\ mol\ AgNO_3}{45.0\ \cancel{mL}} \times \frac{10^3\ \cancel{mL}}{1\ L}$$
$$= 0.0229\ M$$

4.11A (a) For $Pb(C_2H_3O_2)_2$:

$$\text{Amount (mol) of } Pb(C_2H_3O_2)_2 = 0.268\ \cancel{L} \times \frac{1.50\ mol\ Pb(C_2H_3O_2)_2}{1\ \cancel{L}}$$
$$= 0.402\ mol\ Pb(C_2H_3O_2)_2$$

$$\text{Amount (mol) of } PbCl_2 = 0.402\ \cancel{mol\ Pb(C_2H_3O_2)_2} \times \frac{1\ mol\ PbCl_2}{1\ \cancel{mol\ Pb(C_2H_3O_2)_2}}$$
$$= 0.402\ mol\ PbCl_2$$

$$\text{For NaCl: Amount (mol) of NaCl} = 0.130\ \cancel{L} \times \frac{3.40\ mol\ NaCl}{1\ \cancel{L}}$$
$$= 0.442\ mol\ NaCl$$

$$\text{Amount (mol) of } PbCl_2 = 0.442\ \cancel{mol\ NaCl} \times \frac{1\ mol\ PbCl_2}{2\ \cancel{mol\ NaCl}}$$
$$= 0.221\ mol\ PbCl_2$$

Thus, NaCl is the limiting reactant.

$$\text{Mass (g) of } PbCl_2 = 0.22\ \cancel{mol\ PbCl_2} \times \frac{278.1\ g\ PbCl_2}{1\ \cancel{mol\ PbCl_2}}$$
$$= 61.5\ g\ PbCl_2$$

(b) Using "Ac" for acetate ion and with NaCl limiting:

Amount (mol)	$Pb(Ac)_2$	+ 2NaCl	⟶	$PbCl_2$	+ 2NaAc
Initial	0.402	0.442		0	0
Change	−0.221	−0.442		+0.221	+0.442
Final	0.181	0		0.221	0.442

4.11B (a) $FeCl_3(aq) + 3NaOH(aq) \longrightarrow Fe(OH)_3(s) + 3NaCl(aq)$

For $FeCl_3$:

$$\text{Amount (mol) of } FeCl_3 = 0.155 \cancel{\text{ L FeCl}_3} \times \frac{0.250 \text{ mol } FeCl_3}{1 \cancel{\text{ L FeCl}_3}}$$
$$= 0.0388 \text{ mol } FeCl_3$$

$$\text{Amount (mol) of } Fe(OH)_3 = 0.0388 \cancel{\text{ mol FeCl}_3} \times \frac{1 \text{ mol } Fe(OH)_3}{1 \cancel{\text{ mol FeCl}_3}} = 0.0388 \text{ mol } Fe(OH)_3$$

For NaOH:

$$\text{Amount (mol) of NaOH} = 0.215 \cancel{\text{ L NaOH}} \times \frac{0.300 \text{ mol NaOH}}{1 \cancel{\text{ L NaOH}}}$$
$$= 0.0645 \text{ mol NaOH}$$

$$\text{Amount (mol) of } Fe(OH)_3 = 0.0645 \cancel{\text{ mol NaOH}} \times \frac{1 \text{ mol } Fe(OH)_3}{3 \cancel{\text{ mol NaOH}}} = 0.0215 \text{ mol } Fe(OH)_3$$

Thus, NaOH is the limiting reactant.

$$\text{Mass (g) of } Fe(OH)_3 = 0.0215 \cancel{\text{ mol Fe(OH)}_3} \times \frac{106.87 \text{ } Fe(OH)_3}{1 \cancel{\text{ mol Fe(OH)}_3}} = 2.30 \text{ g } Fe(OH)_3$$

(b)

Amount (mol)	$FeCl_3$	+ 3NaOH	⟶	$Fe(OH)_3$	+ 3NaCl
Initial	0.0388	0.0645		0	0
Change	−0.0215	−0.0645		+0.0215	+0.0645
Final	0.0173	0		0.0215	0.0645

4.12A $$\text{No. of } OH^- \text{ ions} = 451 \cancel{\text{ mL}} \times \frac{1 \cancel{\text{ L}}}{10^3 \cancel{\text{ mL}}} \times \frac{1.20 \cancel{\text{ mol KOH}}}{1 \cancel{\text{ L soln}}} \times \frac{1 \text{ mol } OH^-}{1 \cancel{\text{ mol KOH}}} \times \frac{6.022\times10^{23} \text{ } OH^- \text{ ions}}{1 \text{ mol } OH^-}$$
$$= 3.26\times10^{23} \text{ } OH^- \text{ ions}$$

4.12B $$\text{No. of } H^+ \text{ ions} = 65.5 \cancel{\text{ mL}} \times \frac{1 \cancel{\text{ L}}}{10^3 \cancel{\text{ mL}}} \times \frac{0.722 \cancel{\text{ mol HCl}}}{1 \cancel{\text{ L soln}}} \times \frac{1 \text{ mol } H^+}{1 \cancel{\text{ mol HCl}}} \times \frac{6.022\times10^{23} \text{ } H^+ \text{ ions}}{1 \text{ mol } H^+}$$
$$= 2.85\times10^{22} \text{ } H^+ \text{ ions}$$

4.13A $Ca(OH)_2(aq) + 2HNO_3(aq) \longrightarrow Ca(NO_3)_2(aq) + 2H_2O(l)$

$Ca^{2+}(aq) + 2OH^-(aq) + 2H^+(aq) + 2NO_3^-(aq) \longrightarrow Ca^{2+}(aq) + 2NO_3^-(aq) + 2H_2O(l)$

$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$

4.13B $HI(aq) + LiOH(aq) \longrightarrow LiI(aq) + H_2O(l)$

$H^+(aq) + I^-(aq) + Li^+(aq) + OH^-(aq) \longrightarrow Li^+(aq) + I^-(aq) + H_2O(l)$

$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$

4.14A $2HNO_2(aq) + Sr^{2+}(aq) + 2OH^-(aq) \longrightarrow 2NO_2^-(aq) + Sr^{2+}(aq) + 2H_2O(l)$

$HNO_2(aq) + OH^-(aq) \longrightarrow NO_2^-(aq) + H_2O(l)$

The salt is strontium nitrite, $Sr(NO_2)_2$, and Sr^{2+} is the spectator ion.

4.14B $2H_3O^+(aq) + 2Br^-(aq) + Ca^{2+}(aq) + 2HCO_3^-(aq) \longrightarrow 2CO_2(g) + 4H_2O(l) + 2Br^-(aq) + Ca^{2+}(aq)$

or $H_3O^+(aq) + HCO_3^-(aq) \longrightarrow CO_2(g) + 2H_2O(l)$

The salt is calcium bromide, $CaBr_2$.

4.15A $Al(OH)_3(s) + 3HCl(aq) \longrightarrow AlCl_3(aq) + 3H_2O(l)$

$$\text{Mass (g) of } Al(OH)_3 = 3.4\times10^{-2} \cancel{\text{ L HCl}} \text{ soln} \times \frac{0.10 \cancel{\text{ mol HCl}}}{1 \cancel{\text{ L soln}}} \times \frac{1 \cancel{\text{ mol Al(OH)}_3}}{3 \cancel{\text{ mol HCl}}} \times \frac{78.00 \text{ g } Al(OH)_3}{1 \cancel{\text{ mol Al(OH)}_3}}$$
$$= 0.088 \text{ g } Al(OH)_3$$

4.15B $HC_9H_7O_4(aq) + NaOH(aq) \longrightarrow NaC_9H_7O_4(aq) + H_2O(l)$

$$\text{Mass (g) of } HC_9H_7O_4 = 14.10 \cancel{\text{ mL NaOH}} \text{ soln} \times \frac{1 \cancel{\text{ L}}}{10^3 \cancel{\text{ mL}}} \times \frac{0.128 \cancel{\text{ mol NaOH}}}{1 \cancel{\text{ L soln}}} \times \frac{1 \cancel{\text{ mol } HC_9H_7O_4}}{1 \cancel{\text{ mol NaOH}}} \times \frac{180.15 \text{ g } HC_9H_7O_4}{1 \cancel{\text{ mol } HC_9H_7O_4}}$$
$$= 0.325 \text{ g } HC_9H_7O_4$$

4.16A $Ba(OH)_2(aq) + 2HCl(aq) \longrightarrow BaCl_2(aq) + 2H_2O(l)$

$$\text{Volume (L) of soln} = 50.00 \cancel{\text{ mL HCl soln}} \times \frac{1 \text{ L}}{10^3 \cancel{\text{ mL}}} \times \frac{0.1016 \cancel{\text{ mol HCl}}}{1 \cancel{\text{ L soln}}} \times \frac{1 \cancel{\text{ mol Ba(OH)}_2}}{2 \cancel{\text{ mol HCl}}} \times \frac{1 \cancel{\text{ L soln}}}{0.1292 \cancel{\text{ mol Ba(OH)}_2}}$$
$$= 0.01966 \text{ L}$$

4.16B $2KOH(aq) + H_2SO_4(aq) \longrightarrow K_2SO_4(aq) + 2H_2O(l)$

$$\text{Amount (mol) of KOH} = 20.00 \cancel{\text{ mL } H_2SO_4 \text{ soln}} \times \frac{1 \cancel{\text{ L}}}{10^3 \cancel{\text{ mL}}} \times \frac{0.2452 \cancel{\text{ mol } H_2SO_4}}{1 \cancel{\text{ L soln}}} \times \frac{2 \text{ mol KOH}}{1 \cancel{\text{ mol } H_2SO_4}}$$
$$= 0.009808 \text{ mol KOH}$$

$$\text{Molarity of KOH} = \frac{0.009808 \text{ mol KOH}}{18.15 \cancel{\text{ mL}}} \times \frac{10^3 \cancel{\text{ mL}}}{1 \text{ L}}$$
$$= 0.5404 \text{ } M$$

4.17A (a) O.N. of Sc = +3; O.N. of O = −2
(b) O.N. of Ga = +3; O.N. of Cl = −1
(c) O.N. of H = +1; O.N. of P = +5; O.N. of O = −2
(d) O.N. of I = +3; O.N. of F = −1

4.17B (a) O.N. of K = +1; O.N. of C = +4; O.N. of O = −2
(b) O.N. of N = −3; O.N. of H = +1
(c) O.N. of Ca = +2; O.N. of P = −3
(d) O.N. of S = +4; O.N. of Cl = −1

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

4.18A O.N. decreased: *reduction*

(a) $\overset{+3}{N}\overset{-1}{Cl_3}(l) + \overset{+1}{3H_2}\overset{-2}{O}(l) \longrightarrow \overset{-3}{N}\overset{+1}{H_3}(aq) + \overset{+1}{3H}\overset{-2}{O}\overset{+1}{Cl}(aq)$

O.N. increased: *oxidation*

Redox; O.N. of N decreases, and O.N. of Cl increases. NCl_3 is both the reducing and the oxidizing agent.

(b) $\overset{+1}{Ag}\overset{+5}{N}\overset{-2}{O_3}(aq) + \overset{+1}{N}\overset{-3}{H_4}\overset{-1}{I}(aq) \longrightarrow \overset{+1}{Ag}\overset{-1}{I}(s) + \overset{+1}{N}\overset{-3}{H_4}\overset{+5}{N}\overset{-2}{O_3}(aq)$

Not redox; no changes in O.N. values.

O.N. decreased: *reduction*

(c) $\overset{+1}{2H_2}\overset{-2}{S}(g) + \overset{0}{3O_2}(g) \longrightarrow \overset{+4}{2S}\overset{-2}{O_2}(g) + \overset{+1}{2H_2}\overset{-2}{O}(g)$

O.N. increased: *oxidation*

Redox; O.N. of S increases, and O.N. of O decreases. H_2S is the reducing agent; O_2 is the oxidizing agent.

4.18B (a) $\overset{+4}{Si}\overset{-2}{O_2}(s) + \overset{+1}{4H}\overset{-1}{F}(g) \longrightarrow \overset{+4}{Si}\overset{-1}{F_4}(g) + \overset{+1}{2H_2}\overset{-2}{O}(l)$

Not redox; no changes in O.N. values.

O.N. increased: *oxidation*

(b) $\overset{-3}{2C_2}\overset{+1}{H_6}(g) + \overset{0}{7O_2}(g) \longrightarrow \overset{+4}{4C}\overset{-2}{O_2}(g) + \overset{+1}{6H_2}\overset{-2}{O}(g)$

O.N. decreased: *reduction*

Redox; O.N. of O decreases, and O.N. of C increases. C_2H_6 is the reducing agent; O_2 is the oxidizing agent.

O.N. increased: *oxidation*

(c) $\overset{+2}{5C}\overset{-2}{O}(g) + \overset{+5}{I_2}\overset{-2}{O_5}(s) \longrightarrow \overset{+4}{5C}\overset{-2}{O_2}(g) + \overset{0}{I_2}(s)$

O.N. decreased: *reduction*

Redox; O.N. of I decreases, and O.N. of C increases. CO is the reducing agent; I_2O_5 is the oxidizing agent.

4.19A (a) Amount (mol) of Ca^{2+}

$$= 6.53 \text{ mL soln} \times \frac{1 \text{ L}}{10^3 \text{ mL}} \times \frac{4.56\times10^{-3} \text{ mol } KMnO_4}{1 \text{ L soln}} \times \frac{5 \text{ mol } CaC_2O_4}{2 \text{ mol } KMnO_4} \times \frac{1 \text{ mol } Ca^{2+}}{1 \text{ mol } CaC_2O_4}$$

$$= 7.44\times10^{-5} \text{ mol } Ca^{2+}$$

$$\text{Molarity of } Ca^{2+} = \frac{7.44\times10^{-5} \text{ mol } Ca^{2+}}{2.50 \text{ mL milk}} \times \frac{10^3 \text{ mL}}{1 \text{ L}}$$

$$= 2.98\times10^{-2} \, M \, Ca^{2+}$$

$$\text{(b) Conc. of } Ca^{2+} \text{ (g/L)} = \frac{2.98\times10^{-2} \text{ mol } Ca^{2+}}{1 \text{ L}} \times \frac{40.08 \text{ g } Ca^{2+}}{1 \text{ mol } Ca^{2+}} = \frac{1.19 \text{ g } Ca^{2+}}{1 \text{ L}}$$

Yes, the calculated value is close to the typical value.

4.19B (a) Amount (mol) of Fe^{2+}

$$= 21.85 \text{ mL soln} \times \frac{1 \text{ L}}{10^3 \text{ mL}} \times \frac{0.250 \text{ mol } K_2Cr_2O_7}{1 \text{ L soln}} \times \frac{6 \text{ mol } FeSO_4}{1 \text{ mol } K_2Cr_2O_7} \times \frac{1 \text{ mol } Fe^{2+}}{1 \text{ mol } FeSO_4}$$

$$= 0.0328 \text{ mol } Fe^{2+}$$

$$\text{Molarity of } Fe^{2+} = \frac{0.0328 \text{ mol } Fe^{2+}}{30.0 \text{ mL soln}} \times \frac{10^3 \text{ mL}}{1 \text{ L}}$$

$$= 1.09 \, M \, Fe^{2+}$$

$$\text{(b) Mass (g) of Fe} = 0.0328 \text{ mol } Fe^{2+} \times \frac{1 \text{ mol Fe}}{1 \text{ mol } Fe^{2+}} \times \frac{55.85 \text{ g Fe}}{1 \text{ mol Fe}}$$

$$= 1.83 \text{ g Fe}$$

$$\text{Mass \% of Fe} = \frac{1.83 \text{ g Fe}}{2.58 \text{ g ore}} \times 100 = 70.9\%$$

4.20A (a) Combination: $S_8(s) + 16F_2(g) \longrightarrow 8SF_4(g)$

S_8 is the reducing agent; F_2 is the oxidizing agent.

(b) Displacement:

$2CsI(aq) + Cl_2(aq) \longrightarrow 2CsCl(aq) + I_2(aq)$

$2Cs^+(aq) + 2I^-(aq) + Cl_2(aq) \longrightarrow 2Cs^+(aq) + 2Cl^-(aq) + I_2(aq)$

$2I^-(aq) + Cl_2(aq) \longrightarrow 2Cl^-(aq) + I_2(aq)$

Cl_2 is the oxidizing agent; CsI is the reducing agent.

(c) Displacement:

$3Ni(NO_3)_2(aq) + 2Cr(s) \longrightarrow 3Ni(s) + 2Cr(NO_3)_3(aq)$

$3Ni^{2+}(aq) + 6NO_3^-(aq) + 2Cr(s) \longrightarrow 3Ni(s) + 2Cr^{3+}(aq) + 6NO_3^-(aq)$

$3Ni^{2+}(aq) + 2Cr(s) \longrightarrow 3Ni(s) + 2Cr^{3+}(aq)$

Cr is the reducing agent; $Ni(NO_3)_2$ is the oxidizing agent.

4.20B (a) Displacement: $Co(s) + 2HCl(aq) \longrightarrow CoCl_2(aq) + H_2(g)$

$Co(s) + 2H^+(aq) + 2Cl^-(aq) \longrightarrow Co^{2+}(aq) + 2Cl^-(aq) + H_2(g)$

$Co(s) + 2H^+(aq) \longrightarrow Co^{2+}(aq) + H_2(g)$

Co is the reducing agent; HCl is the oxidizing agent.

(b) Combination: $2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$

CO is the reducing agent; O_2 is the oxidizing agent.

(c) Decomposition: $2N_2O_5(s) \longrightarrow 4NO_2(g) + O_2(g)$

N_2O_5 is both the oxidizing and the reducing agent.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Solution Concentration and the Role of Water as a Solvent

(Sample Problems 4.1 to 4.7)

Concept Review Questions

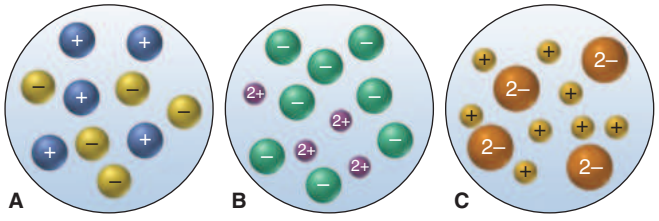
4.1 What two factors cause water to be polar?

4.2 What types of substances are most likely to be soluble in water?

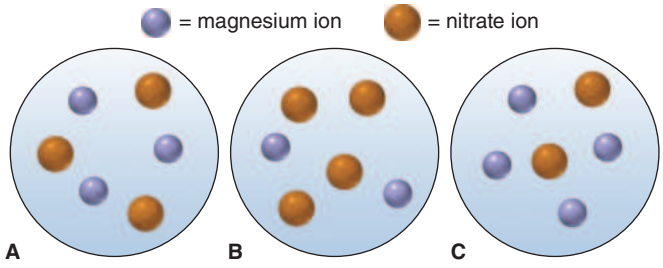
4.3 What must be present in an aqueous solution for it to conduct an electric current? What general classes of compounds form solutions that conduct?

4.4 What occurs on the molecular level when an ionic compound dissolves in water?

4.5 Which of the following scenes best represents how the ions occur in an aqueous solution of: (a) $CaCl_2$; (b) Li_2SO_4; (c) NH_4Br?



4.6 Which of the following scenes best represents a volume from a solution of magnesium nitrate?

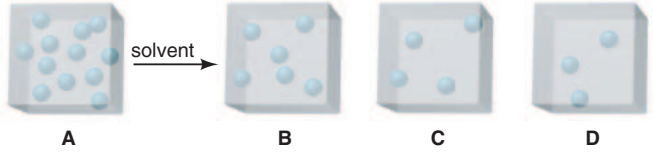


4.7 Why are some ionic compounds soluble in water and others are not?

4.8 Why are some covalent compounds soluble in water and others are not?

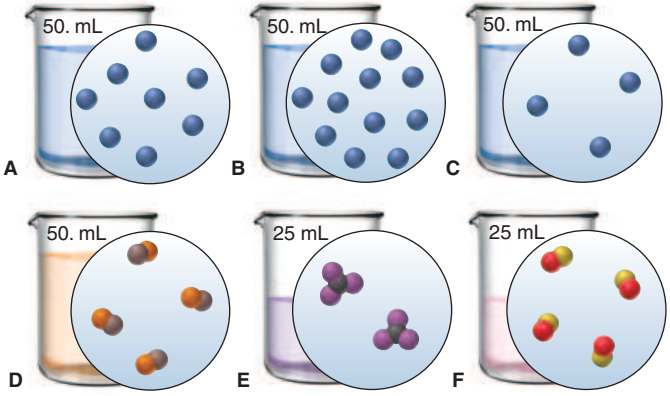
4.9 Some covalent compounds dissociate into ions in water. What atom do these compounds have in their structures? What type of solution do they form? Name three examples of such a solution.

4.10 Box A represents one unit volume of solution A. Which box—B, C, or D—represents one unit volume after adding enough solvent to solution A to (a) triple its volume; (b) double its volume; (c) quadruple its volume?



4.11 A mathematical equation useful for dilution calculations is $M_{dil} \times V_{dil} = M_{conc} \times V_{conc}$. (a) What does each symbol mean, and why does the equation work? (b) Given the volume and molarity of a $CaCl_2$ solution, how do you determine the amount (mol) and the mass (g) of solute?

4.12 Six different aqueous solutions (with solvent molecules omitted for clarity) are represented in the beakers below, and their total volumes are noted.



(a) Which solution has the highest molarity? (b) Which solutions have the same molarity? (c) If you mix solutions A and C, does the resulting solution have a higher, a lower, or the same molarity as solution B? (d) After 50. mL of water is added to solution D, is its molarity higher, lower, or the same as the molarity of solution F after 75 mL is added to it? (e) How much solvent must be evaporated from solution E for it to have the same molarity as solution A?

4.13 Are the following instructions for diluting a 10.0 *M* solution to a 1.00 *M* solution correct: "Take 100.0 mL of the 10.0 *M* solution and add 900.0 mL water"? Explain.

Skill-Building Exercises (grouped in similar pairs)

4.14 Is each of the following very soluble in water? Explain.
(a) Benzene, C_6H_6 (b) Sodium hydroxide
(c) Ethanol, CH_3CH_2OH (d) Potassium acetate

4.15 Is each of the following very soluble in water? Explain.
(a) Lithium nitrate (b) Glycine, H_2NCH_2COOH
(c) Pentane (d) Ethylene glycol, $HOCH_2CH_2OH$

4.16 Does an aqueous solution of each of the following conduct an electric current? Explain.
(a) Cesium bromide (b) Hydrogen iodide

4.17 Does an aqueous solution of each of the following conduct an electric current? Explain.
(a) Potassium sulfate (b) Sucrose, $C_{12}H_{22}O_{11}$

4.18 How many total moles of ions are released when each of the following dissolves in water?
(a) 0.32 mol of NH_4Cl (b) 25.4 g of $Ba(OH)_2 \cdot 8H_2O$
(c) 3.55×10^{19} formula units of LiCl

4.19 How many total moles of ions are released when each of the following dissolves in water?
(a) 0.805 mol of Rb_2SO_4 (b) 3.85×10^{-3} g of $Ca(NO_3)_2$
(c) 4.03×10^{19} formula units of $Sr(HCO_3)_2$

4.20 How many total moles of ions are released when each of the following dissolves in water?
(a) 0.75 mol of K_3PO_4 (b) 6.88×10^{-3} g of $NiBr_2\cdot3H_2O$
(c) 2.23×10^{22} formula units of $FeCl_3$

4.21 How many total moles of ions are released when each of the following dissolves in water?
(a) 0.734 mol of Na_2HPO_4 (b) 3.86 g of $CuSO_4\cdot5H_2O$
(c) 8.66×10^{20} formula units of $NiCl_2$

4.22 Calculate each of the following quantities:
(a) Mass (g) of solute in 185.8 mL of 0.267 *M* calcium acetate
(b) Molarity of 500. mL of solution containing 21.1 g of potassium iodide
(c) Amount (mol) of solute in 145.6 L of 0.850 *M* sodium cyanide

4.23 Calculate each of the following quantities:
(a) Volume (mL) of 2.26 *M* potassium hydroxide that contains 8.42 g of solute
(b) Number of Cu^{2+} ions in 52 L of 2.3 *M* copper(II) chloride
(c) Molarity of 275 mL of solution containing 135 mmol of glucose

4.24 Calculate each of the following quantities:
(a) Mass (g) of solute needed to make 475 mL of 5.62×10^{-2} *M* potassium sulfate
(b) Molarity of a solution that contains 7.25 mg of calcium chloride in each milliliter
(c) Number of Mg^{2+} ions in each milliliter of 0.184 *M* magnesium bromide

4.25 Calculate each of the following quantities:
(a) Molarity of the solution resulting from dissolving 46.0 g of silver nitrate in enough water to give a final volume of 335 mL
(b) Volume (L) of 0.385 *M* manganese(II) sulfate that contains 63.0 g of solute
(c) Volume (mL) of 6.44×10^{-2} *M* adenosine triphosphate (ATP) that contains 1.68 mmol of ATP

4.26 How many moles and how many ions of each type are present in each of the following?
(a) 130. mL of 0.45 *M* aluminum chloride
(b) 9.80 mL of a solution containing 2.59 g lithium sulfate/L
(c) 245 mL of a solution containing 3.68×10^{22} formula units of potassium bromide per liter

4.27 How many moles and how many ions of each type are present in each of the following?
(a) 88 mL of 1.75 *M* magnesium chloride
(b) 321 mL of a solution containing 0.22 g aluminum sulfate/L
(c) 1.65 L of a solution containing 8.83×10^{21} formula units of cesium nitrate per liter

4.28 Calculate each of the following quantities:
(a) Molarity of a solution prepared by diluting 37.00 mL of 0.250 *M* potassium chloride to 150.00 mL
(b) Molarity of a solution prepared by diluting 25.71 mL of 0.0706 *M* ammonium sulfate to 500.00 mL
(c) Molarity of sodium ion in a solution made by mixing 3.58 mL of 0.348 *M* sodium chloride with 500. mL of 6.81×10^{-2} *M* sodium sulfate (assume volumes are additive)

4.29 Calculate each of the following quantities:
(a) Volume (L) of 2.050 *M* copper(II) nitrate that must be diluted with water to prepare 750.0 mL of a 0.8543 *M* solution
(b) Volume (L) of 1.63 *M* calcium chloride that must be diluted with water to prepare 350. mL of a 2.86×10^{-2} *M* chloride ion solution
(c) Final volume (L) of a 0.700 *M* solution prepared by diluting 18.0 mL of 0.155 *M* lithium carbonate with water

4.30 A sample of concentrated nitric acid has a density of 1.41 g/mL and contains 70.0% HNO_3 by mass.
(a) What mass (g) of HNO_3 is present per liter of solution?
(b) What is the molarity of the solution?

4.31 Concentrated sulfuric acid (18.3 *M*) has a density of 1.84 g/mL.
(a) How many moles of H_2SO_4 are in each milliliter of solution?
(b) What is the mass % of H_2SO_4 in the solution?

Problems in Context

4.32 Ordinary household bleach is an aqueous solution of sodium hypochlorite. What is the molarity of a bleach solution that contains 20.5 g of sodium hypochlorite in 375 mL?

4.33 Muriatic acid, an industrial grade of concentrated HCl, is used to clean masonry and cement. Its concentration is 11.7 *M*. (a) Write instructions for diluting the concentrated acid to make 3.0 gallons of 3.5 *M* acid for routine use (1 gal = 4 qt; 1 qt = 0.946 L). (b) How many milliliters of the muriatic acid solution contain 9.66 g of HCl?

4.34 To study a marine organism, a biologist prepares a 1.00-kg sample to simulate the ion concentrations in seawater. She mixes 26.5 g of NaCl, 2.40 g of $MgCl_2$, 3.35 g of $MgSO_4$, 1.20 g of $CaCl_2$, 1.05 g of KCl, 0.315 g of $NaHCO_3$, and 0.098 g of NaBr in distilled water. (a) If the density of the solution is 1.025 g/cm^3, what is the molarity of each ion? (b) What is the total molarity of alkali metal ions? (c) What is the total molarity of alkaline earth metal ions? (d) What is the total molarity of anions?

4.35 Water "softeners" remove metal ions such as Ca^{2+} and Fe^{3+} by replacing them with enough Na^+ ions to maintain the same number of positive charges in the solution. If 1.0×10^3 L of "hard" water is 0.015 *M* Ca^{2+} and 0.0010 *M* Fe^{3+}, how many moles of Na^+ are needed to replace these ions?

Writing Equations for Aqueous Ionic Reactions

Concept Review Questions

4.36 Which ions do not appear in a net ionic equation? Why?

4.37 Write two sets of equations (both molecular and total ionic) with different reactants that have the same net ionic equation as the following equation:

$$Ba(NO_3)_2(aq) + Na_2CO_3(aq) \longrightarrow BaCO_3(s) + 2NaNO_3(aq)$$

Precipitation Reactions

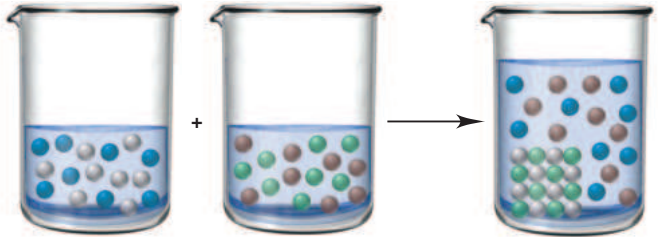
(Sample Problems 4.8 to 4.11)

Concept Review Questions

4.38 Why do some pairs of ions precipitate and others do not?

4.39 Use Table 4.1 to determine which of the following combinations leads to a precipitation reaction. How can you identify the spectator ions in the reaction?
(a) Calcium nitrate(*aq*) + sodium chloride(*aq*) ⟶
(b) Potassium chloride(*aq*) + lead(II) nitrate(*aq*) ⟶

4.40 The beakers represent the aqueous reaction of $AgNO_3$ and NaCl. Silver ions are gray. What colors are used to represent NO_3^-, Na^+, and Cl^-? Write molecular, total ionic, and net ionic equations for the reaction.



Skill-Building Exercises (grouped in similar pairs)

4.41 Complete the following precipitation reactions with balanced molecular, total ionic, and net ionic equations:
(a) $Hg_2(NO_3)_2(aq) + KI(aq) \longrightarrow$
(b) $FeSO_4(aq) + Sr(OH)_2(aq) \longrightarrow$

4.42 Complete the following precipitation reactions with balanced molecular, total ionic, and net ionic equations:
(a) $CaCl_2(aq) + Cs_3PO_4(aq) \longrightarrow$
(b) $Na_2S(aq) + ZnSO_4(aq) \longrightarrow$

4.43 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations:
(a) Sodium nitrate + copper(II) sulfate
(b) Ammonium bromide + silver nitrate

4.44 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations:
(a) Potassium carbonate + barium hydroxide
(b) Aluminum nitrate + sodium phosphate

4.45 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations.
(a) Potassium chloride + iron(III) nitrate
(b) Ammonium sulfate + barium chloride

4.46 When each of the following pairs of aqueous solutions is mixed, does a precipitation reaction occur? If so, write balanced molecular, total ionic, and net ionic equations:
(a) Sodium sulfide + nickel(II) sulfate
(b) Lead(II) nitrate + potassium bromide

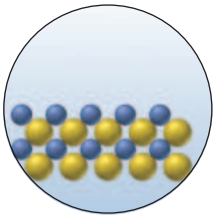
4.47 If 38.5 mL of lead(II) nitrate solution reacts completely with excess sodium iodide solution to yield 0.628 g of precipitate, what is the molarity of lead(II) ion in the original solution?

4.48 If 25.0 mL of silver nitrate solution reacts with excess potassium chloride solution to yield 0.842 g of precipitate, what is the molarity of silver ion in the original solution?

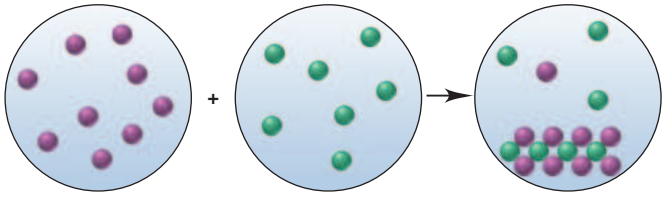
4.49 How many grams of barium sulfate form when 35.0 mL of 0.160 *M* barium chloride reacts with 58.0 mL of 0.065 *M* sodium sulfate?

4.50 How many grams of iron(III) sulfide form when 62.0 mL of 0.135 *M* iron(III) chloride reacts with 45.0 mL of 0.285 *M* calcium sulfide?

4.51 With ions shown as spheres and solvent molecules omitted for clarity, the circle *(right)* illustrates the solid formed when a solution containing K^+, Mg^{2+}, Ag^+, or Pb^{2+} *(blue)* is mixed with one containing ClO_4^-, NO_3^-, or SO_4^{2-} *(yellow)*. (a) Identify the solid. (b) Write a balanced net ionic equation for the reaction. (c) If each sphere represents 5.0×10^{-4} mol of ion, what mass of product forms?



4.52 The precipitation reaction between 25.0 mL of a solution containing a cation *(purple)* and 35.0 mL of a solution containing an anion *(green)* is depicted below (with ions shown as spheres and solvent molecules omitted for clarity).



(a) Given the following choices of reactants, write balanced total ionic and net ionic equations that best represent the reaction:
(1) $KNO_3(aq) + CuCl_2(aq) \longrightarrow$
(2) $NaClO_4(aq) + CaCl_2(aq) \longrightarrow$
(3) $Li_2SO_4(aq) + AgNO_3(aq) \longrightarrow$
(4) $NH_4Br(aq) + Pb(CH_3COO)_2(aq) \longrightarrow$
(b) If each sphere represents 2.5×10^{-3} mol of ion, find the total number of ions present.
(c) What is the mass of solid formed?

4.53 A 1.50-g sample of an unknown alkali-metal carbonate was dissolved in water, and 31.10 mL of 0.350 *M* $CaCl_2$ was required to precipitate all the carbonate ions as $CaCO_3$. Give the name and formula of the unknown compound.

4.54 A 0.750-g sample of a compound that might be iron(II) chloride, nickel(II) chloride, or zinc chloride is dissolved in water, and 22.40 mL of 0.515 *M* $AgNO_3$ is required to completely precipitate all the chloride ion as AgCl. Name the compound, and write its formula.

Problems in Context

4.55 The mass percent of Cl^- in a seawater sample is determined by titrating 25.00 mL of seawater with $AgNO_3$ solution, causing a precipitation reaction. An indicator is used to detect the end point, which occurs when free Ag^+ ion is present in solution after all the Cl^- has reacted. If 53.63 mL of 0.2970 *M* $AgNO_3$ is required to reach the end point, what is the mass percent of Cl^- in the seawater (*d* of seawater = 1.024 g/mL)?

4.56 Aluminum sulfate, known as *cake alum,* has a wide range of uses, from dyeing leather and cloth to purifying sewage. In aqueous solution, it reacts with base to form a white precipitate. (a) Write balanced total and net ionic equations for its reaction with aqueous NaOH. (b) What mass of precipitate forms when 185.5 mL of 0.533 *M* NaOH is added to 627 mL of a solution that contains 15.8 g of aluminum sulfate per liter?

Acid-Base Reactions

(Sample Problems 4.12 to 4.16)

Concept Review Questions

4.57 Is the total ionic equation the same as the net ionic equation when $Sr(OH)_2(aq)$ and $H_2SO_4(aq)$ react? Explain.

4.58 Write a general equation for a neutralization reaction.

4.59 (a) Name three common strong acids. (b) Name three common strong bases. (c) What is a characteristic behavior of a strong acid or a strong base?

4.60 (a) Name three common weak acids. (b) Name one common weak base. (c) What is the major difference between a weak acid and a strong acid or between a weak base and a strong base, and what experiment would you perform to observe it?

4.61 Do either of the following reactions go to completion? If so, what factor(s) cause(s) each to do so?

(a) $MgSO_3(s) + 2HCl(aq) \longrightarrow MgCl_2(aq) + SO_2(g) + H_2O(l)$

(b) $3Ba(OH)_2(aq) + 2H_3PO_4(aq) \longrightarrow Ba_3(PO_4)_2(s) + 6H_2O(l)$

4.62 (a) The net ionic equation for the aqueous neutralization reaction between acetic acid and sodium hydroxide is different from that for the reaction between hydrochloric acid and sodium hydroxide. Explain by writing balanced net ionic equations. (b) For a solution of acetic acid in water, list the major species in decreasing order of concentration.

Skill-Building Exercises (grouped in similar pairs)

4.63 How many moles of H^+ ions are present in the following aqueous solutions?

(a) 1.40 L of 0.25 *M* perchloric acid

(b) 6.8 mL of 0.92 *M* nitric acid

(c) 2.6 L of 0.085 *M* hydrochloric acid

4.64 How many moles of H^+ ions are present in the following aqueous solutions?

(a) 1.4 mL of 0.75 *M* hydrobromic acid

(b) 2.47 mL of 1.98 *M* hydriodic acid

(c) 395 mL of 0.270 *M* nitric acid

4.65 Complete the following acid-base reactions with balanced molecular, total ionic, and net ionic equations:

(a) Potassium hydroxide(aq) + hydrobromic acid$(aq) \longrightarrow$

(b) Ammonia(aq) + hydrochloric acid$(aq) \longrightarrow$

4.66 Complete the following acid-base reactions with balanced molecular, total ionic, and net ionic equations:

(a) Cesium hydroxide(aq) + nitric acid$(aq) \longrightarrow$

(b) Calcium hydroxide(aq) + acetic acid$(aq) \longrightarrow$

4.67 Limestone (calcium carbonate) is insoluble in water but dissolves when a hydrochloric acid solution is added. Write balanced total ionic and net ionic equations, showing hydrochloric acid as it actually exists in water and the reaction as a proton-transfer process.

4.68 Zinc hydroxide is insoluble in water but dissolves when a nitric acid solution is added. Why? Write balanced total ionic and net ionic equations, showing nitric acid as it actually exists in water and the reaction as a proton-transfer process.

4.69 How many milliliters of 0.383 *M* HCl are needed to react with 16.2 g of $CaCO_3$?

$$2HCl(aq) + CaCO_3(s) \longrightarrow CaCl_2(aq) + CO_2(g) + H_2O(l)$$

4.70 How many grams of NaH_2PO_4 are needed to react with 43.74 mL of 0.285 *M* NaOH?

$$NaH_2PO_4(s) + 2NaOH(aq) \longrightarrow Na_3PO_4(aq) + 2H_2O(l)$$

4.71 If 25.98 mL of 0.1180 *M* KOH solution reacts with 52.50 mL of CH_3COOH solution, what is the molarity of the acid solution?

4.72 If 26.25 mL of 0.1850 *M* NaOH solution reacts with 25.00 mL of H_2SO_4, what is the molarity of the acid solution?

Problems in Context

4.73 An auto mechanic spills 88 mL of 2.6 *M* H_2SO_4 solution from an auto battery. How many milliliters of 1.6 *M* $NaHCO_3$ must be poured on the spill to react completely with the sulfuric acid?

4.74 Sodium hydroxide is used extensively in acid-base titrations because it is a strong, inexpensive base. A sodium hydroxide solution was standardized by titrating 25.00 mL of 0.1528 *M* standard hydrochloric acid. The initial buret reading of the sodium hydroxide was 2.24 mL, and the final reading was 39.21 mL. What was the molarity of the base solution?

4.75 An unknown amount of acid can often be determined by adding an excess of base and then "back-titrating" the excess. A 0.3471-g sample of a mixture of oxalic acid, which has two ionizable protons, and benzoic acid, which has one, is treated with 100.0 mL of 0.1000 *M* NaOH. The excess NaOH is titrated with 20.00 mL of 0.2000 *M* HCl. Find the mass % of benzoic acid.

4.76 One of the first steps in the enrichment of uranium for use in nuclear power plants involves a displacement reaction between UO_2 and aqueous HF:

$$UO_2(s) + HF(aq) \longrightarrow UF_4(s) + H_2O(l) \text{ [unbalanced]}$$

How many liters of 2.40 *M* HF will react with 2.15 kg of UO_2?

4.77 A mixture of bases can sometimes be the active ingredient in antacid tablets. If 0.4826 g of a mixture of $Al(OH)_3$ and $Mg(OH)_2$ is neutralized with 17.30 mL of 1.000 *M* HNO_3, what is the mass % of $Al(OH)_3$ in the mixture?

Oxidation-Reduction (Redox) Reactions

(Sample Problems 4.17 to 4.19)

Concept Review Questions

4.78 Describe how to determine the oxidation number of sulfur in (a) H_2S and (b) SO_3^{2-}.

4.79 Is the following a redox reaction? Explain.

$$NH_3(aq) + HCl(aq) \longrightarrow NH_4Cl(aq)$$

4.80 Explain why an oxidizing agent undergoes reduction.

4.81 Why must every redox reaction involve an oxidizing agent and a reducing agent?

4.82 In which of the following equations does sulfuric acid act as an oxidizing agent? In which does it act as an acid? Explain.

(a) $4H^+(aq) + SO_4^{2-}(aq) + 2NaI(s) \longrightarrow 2Na^+(aq) + I_2(s) + SO_2(g) + 2H_2O(l)$

(b) $BaF_2(s) + 2H^+(aq) + SO_4^{2-}(aq) \longrightarrow 2HF(aq) + BaSO_4(s)$

4.83 Identify the oxidizing agent and the reducing agent in the following reaction, and explain your answer:

$$8NH_3(g) + 6NO_2(g) \longrightarrow 7N_2(g) + 12H_2O(l)$$

Skill-Building Exercises (grouped in similar pairs)

4.84 Give the oxidation number of carbon in the following:

(a) CF_2Cl_2 (b) $Na_2C_2O_4$ (c) HCO_3^- (d) C_2H_6

4.85 Give the oxidation number of bromine in the following:
(a) KBr (b) BrF_3 (c) $HBrO_3$ (d) CBr_4

4.86 Give the oxidation number of nitrogen in the following:
(a) NH_2OH (b) N_2F_4 (c) NH_4^+ (d) HNO_2

4.87 Give the oxidation number of sulfur in the following:
(a) $SOCl_2$ (b) H_2S_2 (c) H_2SO_3 (d) Na_2S

4.88 Give the oxidation number of arsenic in the following:
(a) AsH_3 (b) $H_2AsO_4^-$ (c) $AsCl_3$

4.89 Give the oxidation number of phosphorus in the following:
(a) $H_2P_2O_7^{2-}$ (b) PH_4^+ (c) PCl_5

4.90 Give the oxidation number of manganese in the following:
(a) MnO_4^{2-} (b) Mn_2O_3 (c) $KMnO_4$

4.91 Give the oxidation number of chromium in the following:
(a) CrO_3 (b) $Cr_2O_7^{2-}$ (c) $Cr_2(SO_4)_3$

4.92 Identify the oxidizing and reducing agents in the following:
(a) $5H_2C_2O_4(aq) + 2MnO_4^-(aq) + 6H^+(aq) \longrightarrow 2Mn^{2+}(aq) + 10CO_2(g) + 8H_2O(l)$
(b) $3Cu(s) + 8H^+(aq) + 2NO_3^-(aq) \longrightarrow 3Cu^{2+}(aq) + 2NO(g) + 4H_2O(l)$

4.93 Identify the oxidizing and reducing agents in the following:
(a) $Sn(s) + 2H^+(aq) \longrightarrow Sn^{2+}(aq) + H_2(g)$
(b) $2H^+(aq) + H_2O_2(aq) + 2Fe^{2+}(aq) \longrightarrow 2Fe^{3+}(aq) + 2H_2O(l)$

4.94 Identify the oxidizing and reducing agents in the following:
(a) $8H^+(aq) + 6Cl^-(aq) + Sn(s) + 4NO_3^-(aq) \longrightarrow SnCl_6^{2-}(aq) + 4NO_2(g) + 4H_2O(l)$
(b) $2MnO_4^-(aq) + 10Cl^-(aq) + 16H^+(aq) \longrightarrow 5Cl_2(g) + 2Mn^{2+}(aq) + 8H_2O(l)$

4.95 Identify the oxidizing and reducing agents in the following:
(a) $8H^+(aq) + Cr_2O_7^{2-}(aq) + 3SO_3^{2-}(aq) \longrightarrow 2Cr^{3+}(aq) + 3SO_4^{2-}(aq) + 4H_2O(l)$
(b) $NO_3^-(aq) + 4Zn(s) + 7OH^-(aq) + 6H_2O(l) \longrightarrow 4Zn(OH)_4^{2-}(aq) + NH_3(aq)$

Problems in Context

4.96 The active agent in many hair bleaches is hydrogen peroxide. The amount of H_2O_2 in 14.8 g of hair bleach was determined by titration with a standard potassium permanganate solution:

$$2MnO_4^-(aq) + 5H_2O_2(aq) + 6H^+(aq) \longrightarrow 5O_2(g) + 2Mn^{2+}(aq) + 8H_2O(l)$$

(a) How many moles of MnO_4^- were required for the titration if 43.2 mL of 0.105 *M* $KMnO_4$ was needed to reach the end point?
(b) How many moles of H_2O_2 were present in the 14.8-g sample of bleach?
(c) How many grams of H_2O_2 were in the sample?
(d) What is the mass percent of H_2O_2 in the sample?
(e) What is the reducing agent in the redox reaction?

4.97 A person's blood alcohol (C_2H_5OH) level can be determined by titrating a sample of blood plasma with a potassium dichromate solution. The balanced equation is

$$16H^+(aq) + 2Cr_2O_7^{2-}(aq) + C_2H_5OH(aq) \longrightarrow 4Cr^{3+}(aq) + 2CO_2(g) + 11H_2O(l)$$

If 35.46 mL of 0.05961 *M* $Cr_2O_7^{2-}$ is required to titrate 28.00 g of plasma, what is the mass percent of alcohol in the blood?

Elements in Redox Reactions

(Sample Problem 4.20)

Concept Review Questions

4.98 Which type of redox reaction leads to each of the following?
(a) An increase in the number of substances
(b) A decrease in the number of substances
(c) No change in the number of substances

4.99 Why do decomposition redox reactions typically have compounds as reactants, whereas combination redox and displacement redox reactions have one or more elements?

4.100 Which of the types of reactions discussed in Section 4.6 commonly produce more than one compound?

4.101 Are all combustion reactions redox reactions? Explain.

4.102 Give one example of a combination reaction that is a redox reaction and another that is not a redox reaction.

Skill-Building Exercises (grouped in similar pairs)

4.103 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:
(a) $Ca(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq) + H_2(g)$
(b) $NaNO_3(s) \longrightarrow NaNO_2(s) + O_2(g)$
(c) $C_2H_2(g) + H_2(g) \longrightarrow C_2H_6(g)$

4.104 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:
(a) $HI(g) \longrightarrow H_2(g) + I_2(g)$
(b) $Zn(s) + AgNO_3(aq) \longrightarrow Zn(NO_3)_2(aq) + Ag(s)$
(c) $NO(g) + O_2(g) \longrightarrow N_2O_4(l)$

4.105 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:
(a) $Sb(s) + Cl_2(g) \longrightarrow SbCl_3(s)$
(b) $AsH_3(g) \longrightarrow As(s) + H_2(g)$
(c) $Zn(s) + Fe(NO_3)_2(aq) \longrightarrow Zn(NO_3)_2(aq) + Fe(s)$

4.106 Balance each of the following redox reactions and classify it as a combination, decomposition, or displacement reaction:
(a) $Mg(s) + H_2O(g) \longrightarrow Mg(OH)_2(s) + H_2(g)$
(b) $Cr(NO_3)_3(aq) + Al(s) \longrightarrow Al(NO_3)_3(aq) + Cr(s)$
(c) $PF_3(g) + F_2(g) \longrightarrow PF_5(g)$

4.107 Predict the product(s) and write a balanced equation for each of the following redox reactions:
(a) $Sr(s) + Br_2(l) \longrightarrow$
(b) $Ag_2O(s) \xrightarrow{\Delta}$
(c) $Mn(s) + Cu(NO_3)_2(aq) \longrightarrow$

4.108 Predict the product(s) and write a balanced equation for each of the following redox reactions:
(a) $Mg(s) + HCl(aq) \longrightarrow$
(b) $LiCl(l) \xrightarrow{\text{electricity}}$
(c) $SnCl_2(aq) + Co(s) \longrightarrow$

4.109 Predict the product(s) and write a balanced equation for each of the following redox reactions:
(a) $N_2(g) + H_2(g) \longrightarrow$
(b) $NaClO_3(s) \xrightarrow{\Delta}$
(c) $Ba(s) + H_2O(l) \longrightarrow$

4.110 Predict the product(s) and write a balanced equation for each of the following redox reactions:
(a) $Fe(s) + HClO_4(aq) \longrightarrow$
(b) $S_8(s) + O_2(g) \longrightarrow$
(c) $BaCl_2(l) \xrightarrow{\text{electricity}}$

4.111 Predict the product(s) and write a balanced equation for each of the following redox reactions:
(a) Cesium + iodine ⟶
(b) Aluminum + aqueous manganese(II) sulfate ⟶
(c) Sulfur dioxide + oxygen ⟶
(d) Butane + oxygen ⟶
(e) Write a balanced net ionic equation for (b).

4.112 Predict the product(s) and write a balanced equation for each of the following redox reactions:
(a) Pentane (C_5H_{12}) + oxygen ⟶
(b) Phosphorus trichloride + chlorine ⟶
(c) Zinc + hydrobromic acid ⟶
(d) Aqueous potassium iodide + bromine ⟶
(e) Write a balanced net ionic equation for (d).

4.113 How many grams of O_2 can be prepared from the thermal decomposition of 4.27 kg of HgO? Name and calculate the mass (in kg) of the other product.

4.114 How many grams of chlorine gas can be produced from the electrolytic decomposition of 874 g of calcium chloride? Name and calculate the mass (in g) of the other product.

4.115 In a combination reaction, 1.62 g of lithium is mixed with 6.50 g of oxygen.
(a) Which reactant is present in excess?
(b) How many moles of product are formed?
(c) After reaction, how many grams of each reactant and product are present?

4.116 In a combination reaction, 2.22 g of magnesium is heated with 3.75 g of nitrogen.
(a) Which reactant is present in excess?
(b) How many moles of product are formed?
(c) After reaction, how many grams of each reactant and product are present?

4.117 A mixture of $KClO_3$ and KCl with a mass of 0.950 g was heated to produce O_2. After heating, the mass of residue was 0.700 g. Assuming all the $KClO_3$ decomposed to KCl and O_2, calculate the mass percent of $KClO_3$ in the original mixture.

4.118 A mixture of $CaCO_3$ and CaO weighing 0.693 g was heated to produce gaseous CO_2. After heating, the remaining solid weighed 0.508 g. Assuming all the $CaCO_3$ broke down to CaO and CO_2, calculate the mass percent of $CaCO_3$ in the original mixture.

Problems in Context

4.119 Before arc welding was developed, a displacement reaction involving aluminum and iron(III) oxide was commonly used to produce molten iron (the thermite process). This reaction was used, for example, to connect sections of iron rails for train tracks. Calculate the mass of molten iron produced when 1.50 kg of aluminum reacts with 25.0 mol of iron(III) oxide.

4.120 Iron reacts rapidly with chlorine gas to form a reddish brown, ionic compound (A), which contains iron in the higher of its two common oxidation states. Strong heating decomposes compound A to compound B, another ionic compound, which contains iron in the lower of its two oxidation states. When compound A is formed by the reaction of 50.6 g of Fe and 83.8 g of Cl_2 and then heated, how much compound B forms?

4.121 A sample of impure magnesium was analyzed by allowing it to react with excess HCl solution. After 1.32 g of the impure metal was treated with 0.100 L of 0.750 *M* HCl, 0.0125 mol of HCl remained. Assuming the impurities do not react, what is the mass % of Mg in the sample?

The Reversibility of Reactions and the Equilibrium State

Concept Review Questions

4.122 Why is the equilibrium state called "dynamic"?

4.123 In a decomposition reaction involving a gaseous product, what must be done for the reaction to reach equilibrium?

4.124 Describe what happens on the molecular level when acetic acid dissolves in water.

4.125 When either a mixture of NO and Br_2 or pure nitrosyl bromide (NOBr) is placed in a reaction vessel, the product mixture contains NO, Br_2, and NOBr. Explain.

Problem in Context

4.126 Ammonia is produced by the millions of tons annually for use as a fertilizer. It is commonly made from N_2 and H_2 by the Haber process. Because the reaction reaches equilibrium before going completely to product, the stoichiometric amount of ammonia is not obtained. At a particular temperature and pressure, 10.0 g of H_2 reacts with 20.0 g of N_2 to form ammonia. When equilibrium is reached, 15.0 g of NH_3 has formed. (a) Calculate the percent yield. (b) How many moles of N_2 and H_2 are present at equilibrium?

Comprehensive Problems

4.127 Nutritional biochemists have known for decades that acidic foods cooked in cast-iron cookware can supply significant amounts of dietary iron (ferrous ion). (a) Write a balanced net ionic equation, with oxidation numbers, that supports this fact. (b) Measurements show an increase from 3.3 mg of iron to 49 mg of iron per $\frac{1}{2}$-cup (125-g) serving during the slow preparation of tomato sauce in a cast-iron pot. How many ferrous ions are present in a 26-oz (737-g) jar of the tomato sauce?

4.128 Limestone ($CaCO_3$) is used to remove acidic pollutants from smokestack flue gases. It is heated to form lime (CaO), which reacts with sulfur dioxide to form calcium sulfite. Assuming a 70.% yield in the overall reaction, what mass of limestone is required to remove all the sulfur dioxide formed by the combustion of 8.5×10^4 kg of coal that is 0.33 mass % sulfur?

4.129 The brewing industry uses yeast to convert glucose to ethanol. The baking industry uses the carbon dioxide produced in the same reaction to make bread rise:

$$C_6H_{12}O_6(s) \xrightarrow{\text{yeast}} 2C_2H_5OH(l) + 2CO_2(g)$$

How many grams of ethanol can be produced from 100. g of glucose? What volume of CO_2 is produced? (Assume 1 mol of gas occupies 22.4 L at the conditions used.)

4.130 A chemical engineer determines the mass percent of iron in an ore sample by converting the Fe to Fe^{2+} in acid and then titrating the Fe^{2+} with MnO_4^-. A 1.1081-g sample was dissolved in acid and then titrated with 39.32 mL of 0.03190 *M* $KMnO_4$. The balanced equation is

$$8H^+(aq) + 5Fe^{2+}(aq) + MnO_4^-(aq) \longrightarrow 5Fe^{3+}(aq) + Mn^{2+}(aq) + 4H_2O(l)$$

Calculate the mass percent of iron in the ore.

4.131 Mixtures of $CaCl_2$ and NaCl are used to melt ice on roads. A dissolved 1.9348-g sample of such a mixture was analyzed by using excess $Na_2C_2O_4$ to precipitate the Ca^{2+} as CaC_2O_4. The CaC_2O_4 was dissolved in sulfuric acid, and the resulting $H_2C_2O_4$ was titrated with 37.68 mL of 0.1019 *M* $KMnO_4$ solution.
(a) Write the balanced net ionic equation for the precipitation reaction.
(b) Write the balanced net ionic equation for the titration reaction. (See Sample Problem 4.19.)
(c) What is the oxidizing agent?
(d) What is the reducing agent?
(e) Calculate the mass percent of $CaCl_2$ in the original sample.

4.132 You are given solutions of HCl and NaOH and must determine their concentrations. You use 27.5 mL of NaOH to titrate 100. mL of HCl and 18.4 mL of NaOH to titrate 50.0 mL of 0.0782 *M* H_2SO_4. Find the unknown concentrations.

4.133 The flask *(right)* represents the products of the titration of 25 mL of sulfuric acid with 25 mL of sodium hydroxide.
(a) Write balanced molecular, total ionic, and net ionic equations for the reaction.
(b) If each orange sphere represents 0.010 mol of sulfate ion, how many moles of acid and of base reacted?
(c) What are the molarities of the acid and the base?

4.134 To find the mass percent of dolomite [$CaMg(CO_3)_2$] in a soil sample, a geochemist titrates 13.86 g of soil with 33.56 mL of 0.2516 *M* HCl. What is the mass percent of dolomite in the soil?

4.135 On a lab exam, you have to find the concentrations of the monoprotic (one proton per molecule) acids HA and HB. You are given 43.5 mL of HA solution in one flask. A second flask contains 37.2 mL of HA, and you add enough HB solution to it to reach a final volume of 50.0 mL. You titrate the first HA solution with 87.3 mL of 0.0906 *M* NaOH and the mixture of HA and HB in the second flask with 96.4 mL of the NaOH solution. Calculate the molarity of the HA and HB solutions.

4.136 Nitric acid, a major industrial and laboratory acid, is produced commercially by the multistep Ostwald process, which begins with the oxidation of ammonia:

Step 1. $4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(l)$
Step 2. $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$
Step 3. $3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(l) + NO(g)$

(a) What are the oxidizing and reducing agents in each step?
(b) Assuming 100% yield in each step, what mass (in kg) of ammonia must be used to produce 3.0×10^4 kg of HNO_3?

4.137 Various data can be used to find the composition of an alloy (a metallic mixture). Show that calculating the mass % of Mg in a magnesium-aluminum alloy (d = 2.40 g/cm^3) using each of the following pieces of data gives the same answer (within rounding): (a) a sample of the alloy has a mass of 0.263 g (d of Mg = 1.74 g/cm^3; d of Al = 2.70 g/cm^3); (b) an identical sample reacting with excess aqueous HCl forms 1.38×10^{-2} mol of H_2; (c) an identical sample reacting with excess O_2 forms 0.483 g of oxide.

4.138 In 1995, Mario Molina, Paul Crutzen, and F. Sherwood Rowland shared the Nobel Prize in chemistry for their work on atmospheric chemistry. One reaction sequence they proposed for the role of chlorine in the decomposition of stratospheric ozone (we'll see another sequence in Chapter 16) is

(1) $Cl(g) + O_3(g) \longrightarrow ClO(g) + O_2(g)$
(2) $ClO(g) + ClO(g) \longrightarrow Cl_2O_2(g)$
(3) $Cl_2O_2(g) \xrightarrow{\text{light}} 2Cl(g) + O_2(g)$

Over the tropics, O atoms are more common in the stratosphere:

(4) $ClO(g) + O(g) \longrightarrow Cl(g) + O_2(g)$

(a) Which, if any, of these are oxidation-reduction reactions?
(b) Write an overall equation combining reactions 1–3.

4.139 Sodium peroxide (Na_2O_2) is often used in self-contained breathing devices, such as those used in fire emergencies, because it reacts with exhaled CO_2 to form Na_2CO_3 and O_2. How many liters of respired air can react with 80.0 g of Na_2O_2 if each liter of respired air contains 0.0720 g of CO_2?

4.140 A student forgets to weigh a mixture of sodium bromide dihydrate and magnesium bromide hexahydrate. Upon strong heating, the sample loses 252.1 mg of water. The mixture of anhydrous salts reacts with excess $AgNO_3$ solution to form 6.00×10^{-3} mol of solid AgBr. Find the mass % of each compound in the original mixture.

4.141 A typical formulation for window glass is 75% SiO_2, 15% Na_2O, and 10.% CaO by mass. What masses of sand (SiO_2), sodium carbonate, and calcium carbonate must be combined to produce 1.00 kg of glass after carbon dioxide is driven off by thermal decomposition of the carbonates?

4.142 The quantity of dissolved oxygen (DO) in natural waters is an essential parameter for monitoring survival of most aquatic life. DO is affected by temperature and the amount of organic waste. An earlier method for determining DO involved a two-step process:

1. The water sample is treated with KI,

$$O_2(aq) + 4KI(aq) + 2H_2SO_4(aq) \longrightarrow 2I_2(aq) + 2H_2O(l) + 2K_2SO_4(aq)$$

2. The I_2 is titrated with sodium thiosulfate,

$$I_2(aq) + 2Na_2S_2O_3(aq) \longrightarrow Na_2S_4O_6(aq) + 2NaI(aq)$$

A 50.0-mL water sample is treated with KI, and then 15.75 mL of 0.0105 *M* $Na_2S_2O_3$ is required to reach the end point.
(a) Which substance is oxidized in step 1, and which is reduced in step 2?
(b) What mass (g) of O_2 is dissolved in the water sample?

4.143 Physicians who specialize in sports medicine routinely treat athletes and dancers. Ethyl chloride, a local anesthetic commonly used for simple injuries, is the product of the combination of ethylene with hydrogen chloride:

$$C_2H_4(g) + HCl(g) \longrightarrow C_2H_5Cl(g)$$

If 0.100 kg of C_2H_4 and 0.100 kg of HCl react: (a) How many molecules of gas (reactants plus products) are present when the reaction is complete? (b) How many moles of gas are present when half the product forms?

4.144 Thyroxine ($C_{15}H_{11}I_4NO_4$) is a hormone synthesized by the thyroid gland and used to control many metabolic functions in the body. A physiologist determines the mass percent of thyroxine in a thyroid extract by igniting 0.4332 g of extract with sodium carbonate, which converts the iodine to iodide. The iodide is dissolved in water, and bromine and hydrochloric acid are added, which convert the iodide to iodate.
(a) How many moles of iodate form per mole of thyroxine?
(b) Excess bromine is boiled off and more iodide is added, which reacts as shown in the following equation:

$$IO_3^-(aq) + 6H^+(aq) + 5I^-(aq) \longrightarrow 3I_2(aq) + 3H_2O(l)$$

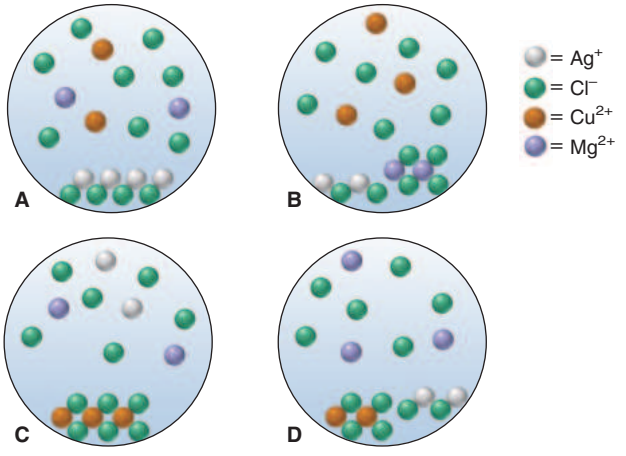
How many moles of iodine are produced per mole of thyroxine? (*Hint:* Be sure to balance the charges as well as the atoms.) What are the oxidizing and reducing agents in the reaction?
(c) The iodine reacts completely with 17.23 mL of 0.1000 *M* thiosulfate as shown in the following *unbalanced* equation:

$$I_2(aq) + S_2O_3^{2-}(aq) \longrightarrow I^-(aq) + S_4O_6^{2-}(aq)$$

What is the mass percent of thyroxine in the thyroid extract?

4.145 Over time, as their free fatty acid (FFA) content increases, edible fats and oils become rancid. To measure rancidity, the fat or oil is dissolved in ethanol, and any FFA present is titrated with KOH dissolved in ethanol. In a series of tests on olive oil, a stock solution of 0.050 *M* ethanolic KOH was prepared at 25°C, stored at 0°C, and then placed in a 100-mL buret to titrate oleic acid [an FFA with formula $CH_3(CH_2)_7CH{=}CH(CH_2)_7COOH$] in the oil. Each of four 10.00-g samples of oil took several minutes to titrate: the first required 19.60 mL, the second 19.80 mL, and the third and fourth 20.00 mL of the ethanolic KOH.
(a) What is the apparent acidity of each sample, in terms of mass % of oleic acid? (*Note:* As the ethanolic KOH warms in the buret, its volume increases by a factor of 0.00104/°C.)
(b) Is the variation in acidity a random or systematic error? Explain.
(c) What is the actual acidity? How would you demonstrate this?

4.146 A chemist mixes solid AgCl, $CuCl_2$, and $MgCl_2$ in enough water to give a final volume of 50.0 mL.
(a) With ions shown as spheres and solvent molecules omitted for clarity, which scene best represents the resulting mixture?



(b) If each sphere represents 5.0×10^{-3} mol of ions, what is the total concentration of *dissolved* (separated) ions?
(c) What is the total mass of solid?

4.147 Calcium dihydrogen phosphate, $Ca(H_2PO_4)_2$, and sodium hydrogen carbonate, $NaHCO_3$, are ingredients of baking powder that react to produce CO_2, which causes dough or batter to rise:

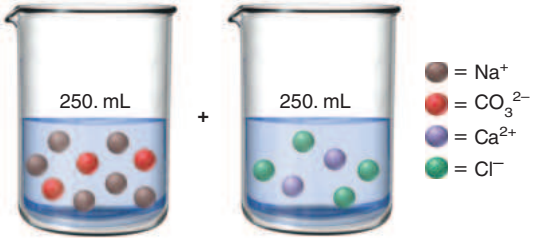
$$Ca(H_2PO_4)_2(s) + NaHCO_3(s) \longrightarrow CO_2(g) + H_2O(g) + CaHPO_4(s) + Na_2HPO_4(s) \quad \text{[unbalanced]}$$

If the baking powder contains 31% $NaHCO_3$ and 35% $Ca(H_2PO_4)_2$ by mass:
(a) How many moles of CO_2 are produced from 1.00 g of baking powder?
(b) If 1 mol of CO_2 occupies 37.0 L at 350°F (a typical baking temperature), what volume of CO_2 is produced from 1.00 g of baking powder?

4.148 In a titration of HNO_3, you add a few drops of phenolphthalein indicator to 50.00 mL of acid in a flask. You quickly add 20.00 mL of 0.0502 *M* NaOH but overshoot the end point, and the solution turns deep pink. Instead of starting over, you add 30.00 mL of the acid, and the solution turns colorless. Then, it takes 3.22 mL of the NaOH to reach the end point.
(a) What is the concentration of the HNO_3 solution?
(b) How many moles of NaOH were in excess after the first addition?

4.149 The active compound in Pepto-Bismol contains C, H, O, and Bi.
(a) When 0.22105 g of it was burned in excess O_2, 0.1422 g of bismuth(III) oxide, 0.1880 g of carbon dioxide, and 0.02750 g of water were formed. What is the empirical formula of this compound?
(b) Given a molar mass of 1086 g/mol, determine the molecular formula.
(c) Complete and balance the acid-base reaction between bismuth(III) hydroxide and salicylic acid ($HC_7H_5O_3$), which is used to form this compound.
(d) A dose of Pepto-Bismol contains 0.600 mg of active ingredient. If the yield of the reaction in part (c) is 88.0%, what mass (in mg) of bismuth(III) hydroxide is required to prepare one dose?

4.150 Two aqueous solutions contain the ions indicated below.



(a) Write balanced molecular, total ionic, and net ionic equations for the reaction that occurs when the solutions are mixed.
(b) If each sphere represents 0.050 mol of ion, what mass (in g) of precipitate forms, assuming 100% yield?
(c) What is the concentration of each ion in solution after reaction?

4.151 In 1997 and 2009, at United Nations conferences on climate change, many nations agreed to expand their research efforts to develop renewable sources of carbon-based fuels. For more than a quarter century, Brazil has been engaged in a program to replace gasoline with ethanol derived from the root crop manioc (cassava).
(a) Write separate balanced equations for the complete combustion of ethanol (C_2H_5OH) and of gasoline (represented by the formula C_8H_{18}).
(b) What mass of oxygen is required to burn completely 1.00 L of a mixture that is 90.0% gasoline (d = 0.742 g/mL) and 10.0% ethanol (d = 0.789 g/mL) by volume?
(c) If 1.00 mol of O_2 occupies 22.4 L, what volume of O_2 is needed to burn 1.00 L of the mixture?
(d) Air is 20.9% O_2 by volume. What volume of air is needed to burn 1.00 L of the mixture?

4.152 In a car engine, gasoline (represented by C_8H_{18}) does not burn completely, and some CO, a toxic pollutant, forms along with CO_2 and H_2O. If 5.0% of the gasoline forms CO:
(a) What is the ratio of CO_2 to CO molecules in the exhaust?
(b) What is the mass ratio of CO_2 to CO?

(c) What percentage of the gasoline must form CO for the mass ratio of CO_2 to CO to be exactly 1/1?

4.153 The amount of ascorbic acid (vitamin C; $C_6H_8O_6$) in tablets is determined by reaction with bromine and then titration of the hydrobromic acid with standard base:

$$C_6H_8O_6(aq) + Br_2(aq) \longrightarrow C_6H_6O_6(aq) + 2HBr(aq)$$
$$HBr(aq) + NaOH(aq) \longrightarrow NaBr(aq) + H_2O(l)$$

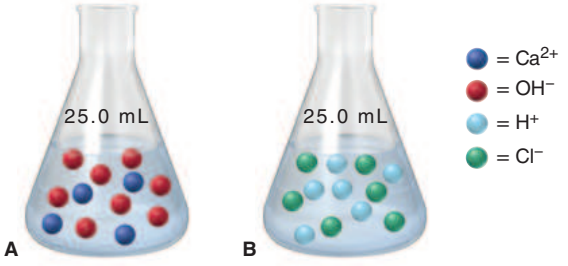
A certain tablet is advertised as containing 500 mg of vitamin C. One tablet was dissolved in water and reacted with Br_2. The solution was then titrated with 43.20 mL of 0.1350 *M* NaOH. Did the tablet contain the advertised quantity of vitamin C?

4.154 In the process of *salting-in,* protein solubility in a dilute salt solution is increased by adding more salt. Because the protein solubility depends on the total ion concentration as well as the ion charge, salts containing doubly charged ions are often more effective than those containing singly charged ions.
(a) How many grams of $MgCl_2$ must dissolve to equal the ion concentration of 12.4 g of NaCl?
(b) How many grams of CaS must dissolve?
(c) Which of the three salt solutions would dissolve the most protein?

4.155 At liftoff, a space shuttle uses a solid mixture of ammonium perchlorate and aluminum powder to obtain great thrust from the volume change of solid to gas. In the presence of a catalyst, the mixture forms solid aluminum oxide and aluminum trichloride and gaseous water and nitrogen monoxide.
(a) Write a balanced equation for the reaction, and identify the reducing and oxidizing agents.
(b) How many total moles of gas (water vapor and nitrogen monoxide) are produced when 50.0 kg of ammonium perchlorate reacts with a stoichiometric amount of Al?
(c) What is the change in volume from this reaction? (*d* of NH_4ClO_4 = 1.95 g/cc, Al = 2.70 g/cc, Al_2O_3 = 3.97 g/cc, and $AlCl_3$ = 2.44 g/cc; assume 1 mol of gas occupies 22.4 L.)

4.156 A *reaction cycle* for an element is a series of reactions beginning and ending with that element. In the following copper reaction cycle, copper has either a 0 or a +2 oxidation state. Write balanced molecular and net ionic equations for each step.
(1) Copper metal reacts with aqueous bromine to produce a green-blue solution.
(2) Adding aqueous sodium hydroxide forms a blue precipitate.
(3) The precipitate is heated and turns black (water is released).
(4) The black solid dissolves in nitric acid to give a blue solution.
(5) Adding aqueous sodium phosphate forms a green precipitate.
(6) The precipitate forms a blue solution in sulfuric acid.
(7) Copper metal is recovered from the blue solution when zinc metal is added.

4.157 Two 25.0-mL aqueous solutions, labeled A and B, contain the ions indicated:



(a) If each sphere represents 1.0×10^{-3} mol of ion, will the equivalence point have been reached when all of B has been added to A?
(b) What is the molarity of B?
(c) What additional volume (mL) of B must be added to reach the equivalence point?

Concepts and Skills to Review Before You Study This Chapter

- physical states of matter (Section 1.1)
- SI unit conversions (Section 1.4)
- amount-mass-number conversions (Section 3.1)

Air bags have been required in cars sold in the United States ever since 1998, and for good reason: they save lives and prevent injuries. A chemical reaction inflates an air bag with nitrogen gas within 0.00004 seconds (40 μs) after impact—about 10,000 times faster than the blink of an eye (0.4 s)! Air bags work because of one of the properties of gases—the ability to expand and fill a container. Other remarkable properties of gases are at work in the rising of a loaf of bread, the operation of a car engine, and, as we'll discuss later in the chapter, even in the act of breathing. People have been studying the behavior of gases and the other states of matter throughout history; in fact, three of the four "elements" of the ancient Greeks were air (gas), water (liquid), and earth (solid). Yet, despite millennia of observations, many questions remain. In this chapter and its companion, Chapter 12, we examine the physical states and their interrelations. Here, we highlight the gaseous state, the one we understand best.

Gases are everywhere. Our atmosphere is a colorless, odorless mixture of 18 gases, some of which—O_2, N_2, H_2O vapor, and CO_2—take part in life-sustaining cycles of redox reactions throughout the environment. And several other gases, such as chlorine and ammonia, have essential roles in industry. Yet, in this chapter, we put aside the *chemical* behavior unique to any particular gas and focus instead *on the* ***physical*** *behavior common to all gases.*

IN THIS CHAPTER . . . *We explore the physical behavior of gases and the theory that explains it. In the process, we see how scientists use mathematics to model nature.*

- We compare the behaviors of gases, liquids, and solids.
- We discuss laboratory methods for measuring gas pressure.
- We consider laws that describe the behavior of a gas in terms of how its volume changes with a change in (1) pressure, (2) temperature, or (3) amount. We focus on the ideal gas law, which encompasses these three laws, and apply it to solve gas law problems.
- We rearrange the ideal gas law to determine the density and molar mass of an unknown gas, the partial pressure of any gas in a mixture, and the amounts of gaseous reactants and products in a chemical change.
- We see how the kinetic-molecular theory explains the gas laws and accounts for other important behaviors of gas particles.
- We apply key ideas about gas behavior to Earth's atmosphere.
- We find that the behavior of real, not ideal, gases, especially under extreme conditions, requires refinements of the ideal gas law and the kinetic-molecular theory.

5.1 AN OVERVIEW OF THE PHYSICAL STATES OF MATTER

Most substances can exist as a solid, a liquid, or a gas under appropriate conditions of pressure and temperature. In Chapter 1, we used the relative position and motion of the particles of a substance to distinguish how each state fills a container (see Figure 1.1, p. 4):

- A gas adopts the container shape and fills it, because its particles are far apart and move randomly.
- A liquid adopts the container shape to the extent of its volume, because its particles are close together but free to move around each other.
- A solid has a fixed shape regardless of the container shape, because its particles are close together and held rigidly in place.

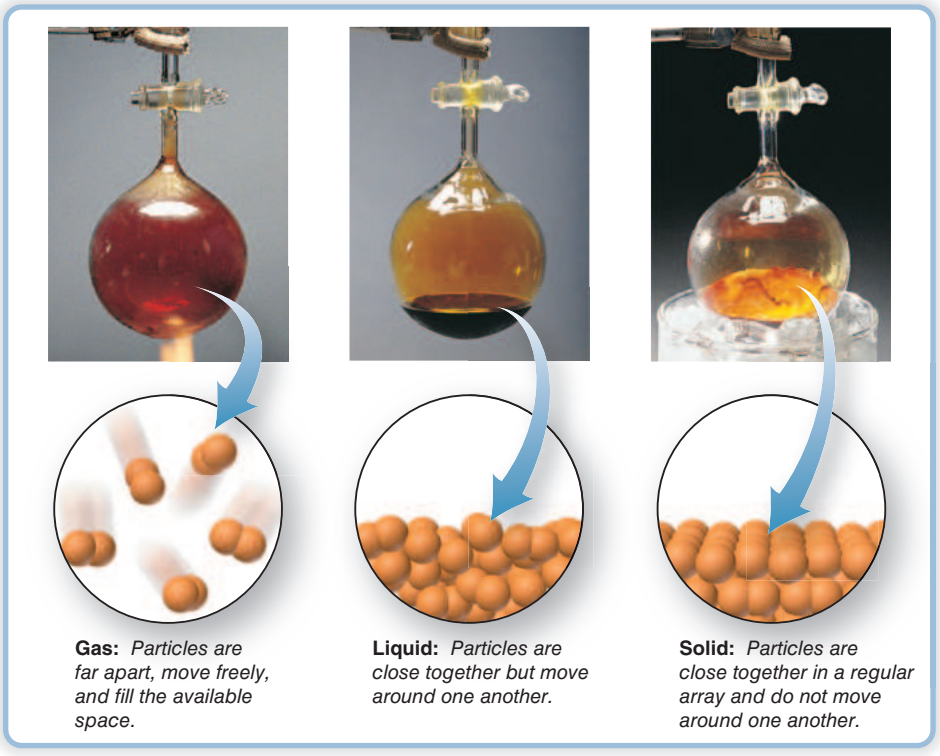

Figure 5.1 The three states of matter. Many pure substances, such as bromine (Br_2), can exist under appropriate conditions of pressure and temperature as a gas, liquid, or solid.

Figure 5.1 focuses on the three states of bromine.

Several other aspects of their behaviors distinguish gases from liquids and solids:

1. *Gas volume changes significantly with pressure.* When a sample of gas is confined to a container of variable volume, such as a cylinder with a piston, *increasing* the force on the piston *decreases* the gas volume. Removing the external force allows the volume to increase again. Gases under pressure can do a lot of work: rapidly expanding compressed air in a jackhammer breaks rock and cement; compressed air in tires lifts the weight of a car. In contrast, the volume of a liquid or a solid does not change significantly under pressure.
2. *Gas volume changes significantly with temperature.* When a sample of gas is heated, it expands; when it is cooled, it shrinks. This volume change is 50 to 100 times greater for gases than for liquids or solids. The expansion that occurs when gases are rapidly heated can have dramatic effects, like lifting a rocket into space, and everyday ones, like popping corn.
3. *Gases flow very freely.* Gases flow much more freely than liquids and solids. This behavior allows gases to be transported more easily through pipes, but it also means they leak more rapidly out of small holes and cracks.
4. *Gases have relatively low densities.* Gas density is usually measured in units of grams per liter (g/L), whereas liquid and solid densities are in grams per milliliter (g/mL), about 1000 times as dense (see Table 1.5, p. 23). For example, at 20°C and normal atmospheric pressure, the density of $O_2(g)$ is 1.3 g/**L,** whereas the density of $H_2O(l)$ is 1.0 g/**mL** and the density of NaCl(*s*) is 2.2 g/**mL.** When a gas cools, its density *increases* because its volume *decreases:* on cooling from 20°C to 0°C, the density of $O_2(g)$ increases from 1.3 to 1.4 g/L.
5. *Gases form a solution in any proportions.* Air is a solution of 18 gases. Two liquids, however, may or may not form a solution: water and ethanol do, but water and gasoline do not. Two solids generally do not form a solution unless they are melted and mixed while liquids, then allowed to solidify (as is done to make the alloy bronze from copper and tin).

Like the way a gas completely fills a container, these macroscopic properties—changing volume with pressure or temperature, great ability to flow, low density, and ability to form solutions—arise because the particles in a gas are much farther apart than those in either a liquid or a solid at ordinary pressures.

Summary of Section 5.1

- The volume of a gas can be altered significantly by changing the applied force or the temperature. Corresponding changes for liquids and solids are *much* smaller.
- Gases flow more freely and have much lower densities than liquids and solids.
- Gases mix in any proportions to form solutions; liquids and solids generally do not.
- Differences in the physical states are due to the greater average distance between particles in a gas than in a liquid or a solid.

5.2 GAS PRESSURE AND ITS MEASUREMENT

Gas particles move randomly within a container with relatively high velocities, colliding frequently with the container's walls. The force of these collisions with the walls, called the *pressure* of the gas, is the reason you can blow up a balloon or pump up a tire. **Pressure (*P*)** is defined as the force exerted per unit of surface area:

$$\text{Pressure} = \frac{\text{force}}{\text{area}}$$

The gases in the atmosphere exert a force (or *weight*) uniformly on *all* surfaces; the resulting pressure is called *atmospheric pressure* and is typically about 14.7 pounds per square inch (lb/in^2; psi) of surface. Thus, a pressure of 14.7 lb/in^2 exists on the outside of your room (or your body), and it equals the pressure on the inside.

What would happen if the inside and outside pressures on a container were *not* equal? Consider the empty can attached to a vacuum pump in Figure 5.2. With the pump off *(left),* the can maintains its shape because the pressure caused by gas particles in the room colliding with the outside walls of the can is equal to the pressure caused by gas particles in the can colliding with the inside walls. When the pump is turned on *(right),* it removes much of the air inside the can; fewer gas particles inside mean fewer collisions with its inside walls, decreasing the internal pressure greatly. The external pressure of the atmosphere then easily crushes the can. Vacuum-filtration flasks and tubing used in chemistry labs have thick walls that withstand the relatively higher external pressure.

Figure 5.2 Effect of atmospheric pressure on a familiar object.

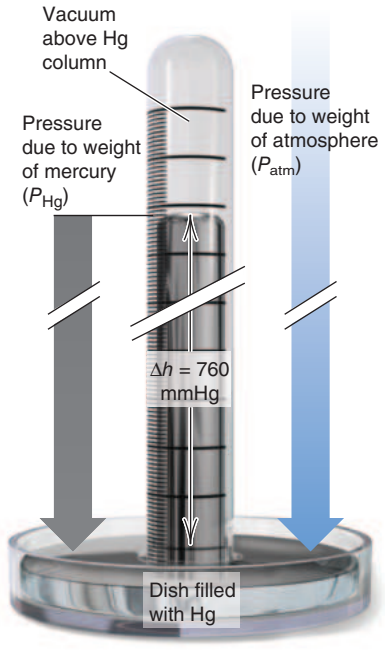

Figure 5.3 A mercury barometer. The pressure of the atmosphere, P_{atm}, balances the pressure of the mercury column, P_{Hg}.

Measuring Gas Pressure: Barometers and Manometers

The **barometer** is used to measure atmospheric pressure. The device is still essentially the same as it was when invented in 1643 by the Italian physicist Evangelista Torricelli: a tube about 1 m long, closed at one end, filled with mercury (atomic symbol, Hg), and inverted into a dish containing more mercury. When the tube is inverted, some of the mercury flows out into the dish, and a vacuum forms above the mercury remaining in the tube (Figure 5.3). At sea level, under ordinary atmospheric conditions, the mercury stops flowing out when the surface of the mercury in the tube is about 760 mm above the surface of the mercury in the dish. At that height, *the column of mercury exerts the same pressure (weight/area) on the mercury surface in the dish as the atmosphere does:* $P_{Hg} = P_{atm}$. Likewise, if you evacuate a closed tube and invert it into a dish of mercury, the atmosphere pushes the mercury up to a height of about 760 mm.

Notice that we did not specify the diameter of the barometer tube. If the mercury in a 1-cm diameter tube rises to a height of 760 mm, the mercury in a 2-cm diameter tube will rise to that height also. The *weight* of mercury is greater in the wider tube, but so is the area; thus, the *pressure,* the *ratio* of weight to area, is the same.

Because the pressure of the mercury column is directly proportional to its height, a unit commonly used for pressure is millimeters of mercury (mmHg). We discuss other units of pressure shortly. *At sea level and 0°C, normal atmospheric pressure is 760 mmHg;* at the top of Mt. Everest (elevation 29,028 ft, or 8848 m), the atmospheric pressure is only about 270 mmHg. Thus, *pressure decreases with altitude:* the column of air above the sea is taller, so it weighs more than the column of air above Mt. Everest.

Laboratory barometers contain mercury because its high density allows a barometer to be a convenient size. If a barometer contained water instead, it would have to be more than 34 ft high, because the pressure of the atmosphere equals the pressure of a column of water about 10,300 mm (almost 34 ft) high. For a given pressure, the ratio of heights (h) of the liquid columns is inversely related to the ratio of the densities (d) of the liquids:

$$\frac{h_{H_2O}}{h_{Hg}} = \frac{d_{Hg}}{d_{H_2O}}$$

Interestingly, several centuries ago, people thought a vacuum had mysterious "suction" powers, and they didn't understand why a suction pump could remove water from a well only to a depth of 34 feet. We know now, as the great 17th-century scientist Galileo explained, that a vacuum does not suck mercury up into a barometer tube, a suction pump does not suck water up from a well, the vacuum pump in Figure 5.2 does not suck in the walls of the crushed can, and the vacuum you create in a straw does not suck the drink into your mouth. Only matter—in this case, the atmospheric gases—can exert a force.

The device used to measure blood pressure is based on a manometer apparatus.

Manometers are devices used to measure the pressure of a gas in an experiment. Figure 5.4 shows two types of manometers. In the *closed-end manometer (left side),* a mercury-filled, curved tube is *closed* at one end and attached to a flask at the other. When the flask is evacuated, the mercury levels in the two arms of the tube are the same because no gas exerts pressure on either mercury surface. When a gas is in the flask, it pushes down the mercury level in the near arm, causing the level to rise in the far arm. The *difference* in column heights (Δh) equals the gas pressure.

The *open-end manometer* (*right side* of Figure 5.4) also consists of a curved tube filled with mercury, but one end of the tube is *open* to the atmosphere and the other is connected to the gas sample. The atmosphere pushes on one mercury surface, and the gas pushes on the other. Again, Δh equals the difference between two pressures. But, when using this type of manometer, we must measure the atmospheric pressure with a barometer and either add or subtract Δh from that value.

Units of Pressure

Pressure results from a force exerted on an area. The SI unit of force is the newton (N): 1 N = 1 kg·m/s^2 (about the weight of an apple). The SI unit of pressure is the **pascal (Pa),** which equals a force of one newton exerted on an area of one square meter:

$$1 \text{ Pa} = 1 \text{ N/m}^2$$

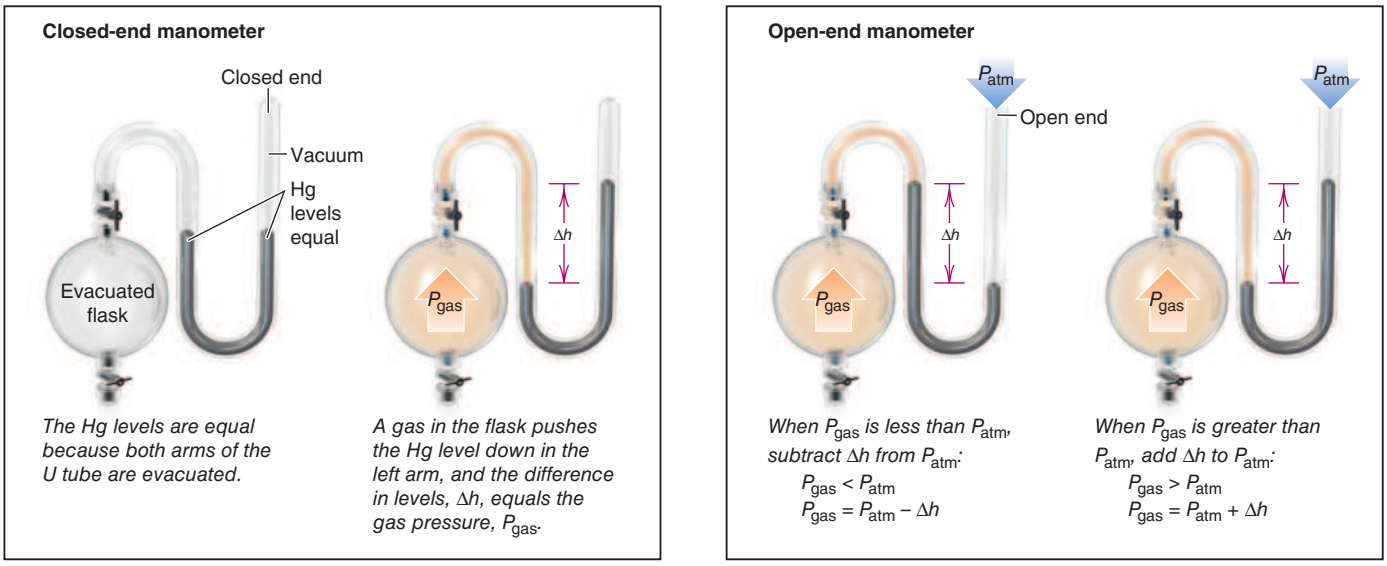

Figure 5.4 Two types of manometer.

A much larger unit is the **standard atmosphere (atm),** the average atmospheric pressure measured at sea level and 0°C. It is defined in terms of the pascal:

$$1 \text{ atm} = 101.325 \text{ kilopascals (kPa)} = 1.01325 \times 10^5 \text{ Pa}$$

Another common unit is the **millimeter of mercury (mmHg),** mentioned earlier; in honor of Torricelli, this unit has been renamed the **torr:**

$$1 \text{ torr} = 1 \text{ mmHg} = \frac{1}{760} \text{ atm} = \frac{101.325}{760} \text{ kPa} = 133.322 \text{ Pa}$$

The *bar* is coming into more common use in chemistry:

$$1 \text{ bar} = 1 \times 10^2 \text{ kPa} = 1 \times 10^5 \text{ Pa}$$

Despite a gradual change to SI units, many chemists still express pressure in torrs and atmospheres, so those units are used in this book, with reference to pascals and bars. Table 5.1 lists some important pressure units with the corresponding values for normal atmospheric pressure.

Table 5.1 Common Units of Pressure

Unit	Normal Atmospheric Pressure at Sea Level and 0°C
pascal (Pa); kilopascal (kPa)	1.01325×10^5 Pa; 101.325 kPa
atmosphere (atm)	1 atm*
millimeters of mercury (mmHg)	760 mmHg*
torr	760 torr*
pounds per square inch (lb/in^2 or psi)	14.7 lb/in^2
bar	1.01325 bar

*These are exact quantities; in calculations, we use as many significant figures as necessary.

SAMPLE PROBLEM 5.1 Converting Units of Pressure

Problem A geochemist heats a limestone ($CaCO_3$) sample and collects the CO_2 released in an evacuated flask attached to a closed-end manometer. After the system comes to room temperature, $\Delta h = 291.4$ mmHg. Calculate the CO_2 pressure in torrs, atmospheres, and kilopascals.

Plan The CO_2 pressure is given in units of mmHg, so we construct conversion factors from Table 5.1 to find the pressure in the other units.

Solution Converting from mmHg to torr:

$$P_{CO_2}\,(\text{torr}) = 291.4\ \cancel{\text{mmHg}} \times \frac{1\ \text{torr}}{1\ \cancel{\text{mmHg}}} = 291.4\ \text{torr}$$

Converting from torr to atm:

$$P_{CO_2}\,(\text{atm}) = 291.4\ \cancel{\text{torr}} \times \frac{1\ \text{atm}}{760\ \cancel{\text{torr}}} = 0.3834\ \text{atm}$$

Converting from atm to kPa:

$$P_{CO_2}\,(\text{kPa}) = 0.3834\ \cancel{\text{atm}} \times \frac{101.325\ \text{kPa}}{1\ \cancel{\text{atm}}} = 38.85\ \text{kPa}$$

Check There are 760 torr in 1 atm, so ~300 torr should be <0.5 atm. There are ~100 kPa in 1 atm, so <0.5 atm should be <50 kPa.

Comment **1.** In the conversion from torr to atm, we retained four significant figures because this unit conversion factor involves *exact* numbers; that is, 760 torr has as many significant figures as the calculation requires (see the footnote on Table 5.1).
2. From here on, except in particularly complex situations, *unit canceling will no longer be shown.*

FOLLOW-UP PROBLEMS

Brief Solutions to ***all*** *Follow-up Problems appear at the end of the chapter.*

5.1A The CO_2 released from another limestone sample is collected in an evacuated flask connected to an open-end manometer. If the barometer reading is 753.6 mmHg and P_{gas} is less than P_{atm}, to give a Δh of 174.0 mmHg, calculate P_{CO_2} in torrs, pascals, and lb/in^2.

5.1B A third sample of limestone is heated, and the CO_2 released is collected in an evacuated flask connected to an open-end manometer. If the atmospheric pressure is 0.9475 atm and P_{gas} is greater than P_{atm}, to give a Δh of 25.8 torr, calculate P_{CO_2} in mmHg, pascals, and lb/in^2.

SOME SIMILAR PROBLEMS 5.10–5.13

Summary of Section 5.2

- Gases exert pressure (force/area) on all surfaces they contact.
- A barometer measures atmospheric pressure based on the height of a mercury column that the atmosphere can support (760 mmHg at sea level and 0°C).
- Closed-end and open-end manometers are used to measure the pressure of a gas sample.
- Pressure units include the atmosphere (atm), torr (identical to mmHg), and pascal (Pa, the SI unit).

5.3 THE GAS LAWS AND THEIR EXPERIMENTAL FOUNDATIONS

The physical behavior of a sample of gas can be described completely by four variables: pressure (P), volume (V), temperature (T), and amount (number of moles, n). The variables are interdependent, which means that *any one of them can be determined by measuring the other three.* Three key relationships exist among the four gas variables—Boyle's, Charles's, and Avogadro's laws. Each of these *gas laws expresses the effect of one variable on another, with the remaining two variables held constant.* Because gas volume is so easy to measure, the laws are expressed as the effect on gas volume of a change in the pressure, temperature, or amount of the gas.

The individual gas laws are special cases of a unifying relationship called the *ideal gas law,* which quantitatively describes the behavior of an **ideal gas,** one that exhibits linear relationships among volume, pressure, temperature, and amount. Although *no ideal gas actually exists,* most simple gases, such as N_2, O_2, H_2, and the noble gases,

behave nearly ideally at ordinary temperatures and pressures. We discuss the ideal gas law after the three individual laws.

The Relationship Between Volume and Pressure: Boyle's Law

Following Torricelli's invention of the barometer, the great 17th-century English chemist Robert Boyle studied the effect of pressure on the volume of a sample of gas.

1. *The experiment.* Figure 5.5 illustrates the setup Boyle might have used in his experiments (parts A and B), the data he might have collected (part C), and graphs of the data (parts D and E). Boyle sealed the shorter leg of a J-shaped glass tube and poured mercury into the longer open leg, thereby trapping some air (the gas in the experiment) in the shorter leg. He calculated the gas volume (V_{gas}) from the height of the trapped air and the diameter of the tube. The total pressure, P_{total}, applied to the trapped gas is the pressure of the atmosphere, P_{atm} (760 mm, measured with a barometer), plus the difference in the heights of the mercury columns (Δh) in the two legs of the J tube, 20 mm (Figure 5.5A); thus, P_{total} is 780 torr. By adding mercury, Boyle increased P_{total}, and the gas volume decreased. In Figure 5.5B, more mercury has been added to the tube, increasing Δh from its original value of 20 mm to 800 mm, so P_{total} doubles to 1560 torr; note that V_{gas} is halved from 20 mL to 10 mL. In this way, by keeping the temperature and amount of gas constant, Boyle was able to measure the effect of the applied pressure on gas volume.

Note the following results in Figure 5.5:

- The product of corresponding P and V values is a constant (part C, rightmost column).
- V is *inversely* proportional to P (part D).
- V is *directly* proportional to $1/P$ (part E), and a plot of V versus $1/P$ is linear. This *linear relationship between two gas variables* is a hallmark of ideal gas behavior.

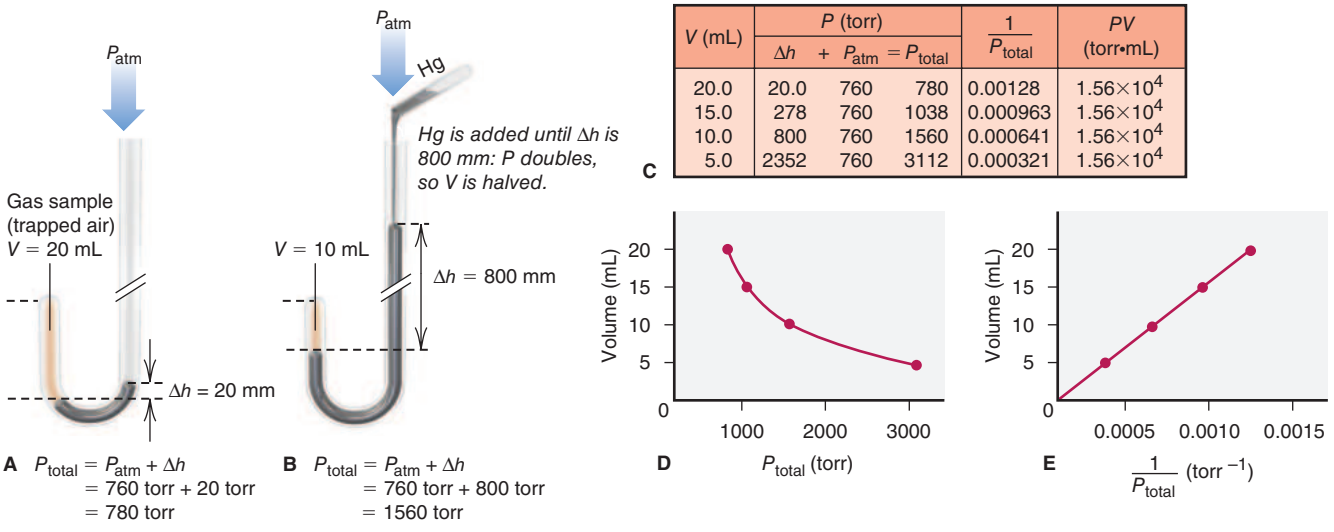
2. *Conclusion and statement of the law.* The generalization of Boyle's observations is known as **Boyle's law:** *at constant temperature, the volume occupied by a fixed amount of gas is* ***inversely*** *proportional to the applied (external) pressure,* or

$$V \propto \frac{1}{P} \qquad [T \text{ and } n \text{ fixed}] \tag{5.1}$$

This relationship can also be expressed as

$$V = \frac{\text{constant}}{P} \qquad \text{or} \qquad PV = \text{constant} \qquad [T \text{ and } n \text{ fixed}]$$

That is, at fixed T and n, $P\uparrow, V\downarrow$ and $P\downarrow, V\uparrow$



V (mL)	P (torr) Δh	+ P_{atm}	= P_{total}	$\frac{1}{P_{total}}$	PV (torr•mL)
20.0	20.0	760	780	0.00128	1.56×10^4
15.0	278	760	1038	0.000963	1.56×10^4
10.0	800	760	1560	0.000641	1.56×10^4
5.0	2352	760	3112	0.000321	1.56×10^4

Figure 5.5 **Boyle's law, the relationship between the volume and pressure of a gas.**

The constant is the same for most simple gases under ordinary conditions. Thus, tripling the external pressure reduces the volume of a gas to a third of its initial value; halving the pressure doubles the volume; and so forth.

The wording of Boyle's law focuses on *external* pressure. But, notice that the mercury level rises as mercury is added, until the pressure of the trapped gas *on* the mercury increases enough to stop its rise. At that point, the pressure exerted *on* the gas equals the pressure exerted *by* the gas (P_{gas}). Thus, in general, at constant temperature, if V_{gas} increases, P_{gas} decreases, and vice versa.

The Relationship Between Volume and Temperature: Charles's Law

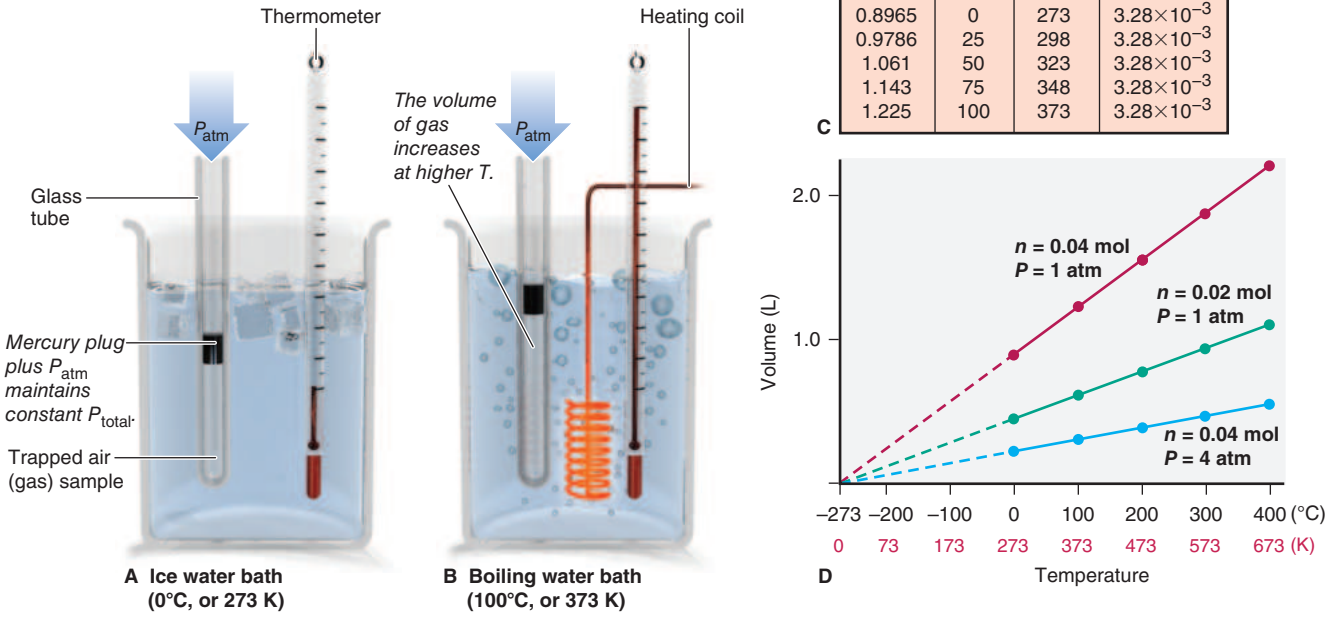
Boyle's work showed that the pressure-volume relationship holds only at constant temperature, but why should that be so? It would take more than a century, until the work of French scientists J. A. C. Charles and J. L. Gay-Lussac, for the relationship between gas volume and temperature to be understood.

1. *The experiment.* Let's examine this relationship by measuring the volume at different temperatures of a fixed amount of a gas under constant pressure. A straight tube, closed at one end, traps a fixed amount of gas (air) under a small mercury plug. The tube is immersed in a water bath that is warmed with a heater or cooled with ice. After each change of temperature, we calculate the gas volume from the length of the gas column and the diameter of the tube. The total pressure exerted on the gas is constant because the mercury plug and the atmospheric pressure do not change (Figure 5.6, parts A and B).

Note the following results in Figure 5.6:

- Typical data (for a 0.04-mol sample of gas at 1 atm) show that dividing the volume of gas by the corresponding Kelvin temperature results in a constant (part C, rightmost column).
- V is *directly* proportional to T in kelvins (red line in part D).
- There is a *linear relationship between V and T.*
- Extrapolating the red line in the graph in part D to lower temperatures (dashed portion) shows that, in theory, the gas occupies zero volume at −273.15°C (the intercept on the temperature axis).
- Plots for a different amount of gas (green line in part D) or for a different gas pressure (blue line) have different slopes, but they converge at −273.15°C.

Figure 5.6 **Charles's law, the relationship between the volume and temperature of a gas.**



V (L)	T (°C)	T (K)	$\frac{V}{T}$ (L/K)
0.8965	0	273	3.28×10^{-3}
0.9786	25	298	3.28×10^{-3}
1.061	50	323	3.28×10^{-3}
1.143	75	348	3.28×10^{-3}
1.225	100	373	3.28×10^{-3}

2. *Conclusion and statement of the law.* Above all, note that *the volume-temperature relationship is linear,* but, unlike volume and pressure, volume and temperature are *directly* proportional. This behavior is incorporated into the modern statement of the volume-temperature relationship, which is known as **Charles's law:** *at constant pressure, the volume occupied by a fixed amount of gas is* ***directly*** *proportional to its absolute (Kelvin) temperature,* or

$$V \propto T \qquad [P \text{ and } n \text{ fixed}] \tag{5.2}$$

This relationship can also be expressed as

$$V = \text{constant} \times T \qquad \text{or} \qquad \frac{V}{T} = \text{constant} \qquad [P \text{ and } n \text{ fixed}]$$

That is, at fixed P and n, $T\uparrow, V\uparrow$ and $T\downarrow, V\downarrow$

If T increases, V increases, and vice versa. As with Boyle's law, the constant is the same for most simple gases under ordinary conditions and for any given P and n.

William Thomson (Lord Kelvin) used the linear relationship between gas volume and temperature to devise the absolute temperature scale (Section 1.4). Absolute zero (0 K or −273.15°C) is the temperature at which an ideal gas would have zero volume. (Absolute zero has never been reached, but physicists have attained 10^{-9} K.) In reality, no sample of matter can have zero volume, and every real gas condenses to a liquid at some temperature higher than 0 K. Nevertheless, the linear dependence of volume on absolute temperature holds for most common gases over a wide temperature range. This dependence of gas volume on the *absolute* temperature adds a practical requirement for chemists (and chemistry students): *the Kelvin scale must be used in gas law calculations.* For instance, if the temperature changes from 200 K to 400 K, the volume of gas doubles. But, if the temperature changes from 200°C to 400°C, the volume increases by a factor of 1.42; that is,

$$\left(\frac{400°\text{C} + 273.15}{200°\text{C} + 273.15}\right) = \frac{673}{473} = 1.42$$

Other Relationships Based on Boyle's and Charles's Laws Two other important relationships arise from Boyle's and Charles's laws:

1. *The pressure-temperature relationship.* Charles's law is expressed as the effect of temperature on gas *volume* at constant pressure. But volume and pressure are interdependent, so a similar relationship can be expressed for the effect of temperature on pressure (sometimes referred to as *Amontons's law*). You can examine this relationship for yourself: measure the pressure in your car or bike tires before and after a long ride and you will find that the air pressure in the tires increases. The air temperature inside the tires also increases from heating due to friction between the tires and the road; a tire's volume can't increase very much, but the increased temperature results in increased pressure. So we observe that, *at constant volume, the pressure exerted by a fixed amount of gas is directly proportional to the absolute temperature:*

$$P \propto T \qquad [V \text{ and } n \text{ fixed}] \tag{5.3}$$

or

$$P = \text{constant} \times T \qquad \text{or} \qquad \frac{P}{T} = \text{constant}$$

That is, at fixed V and n, $T\uparrow, P\uparrow$ and $T\downarrow, P\downarrow$

2. *The combined gas law.* Combining Boyle's and Charles's laws gives the *combined gas law,* which applies to cases when changes in *two* of the three variables (V, P, T) affect the third:

$$\text{Boyle's law: } V \propto \frac{1}{P}\text{; Charles's law: } V \propto T$$

$$\text{Combined gas law: } V \propto \frac{T}{P} \qquad \text{or} \qquad V = \text{constant} \times \frac{T}{P} \qquad \text{or} \qquad \frac{PV}{T} = \text{constant}$$

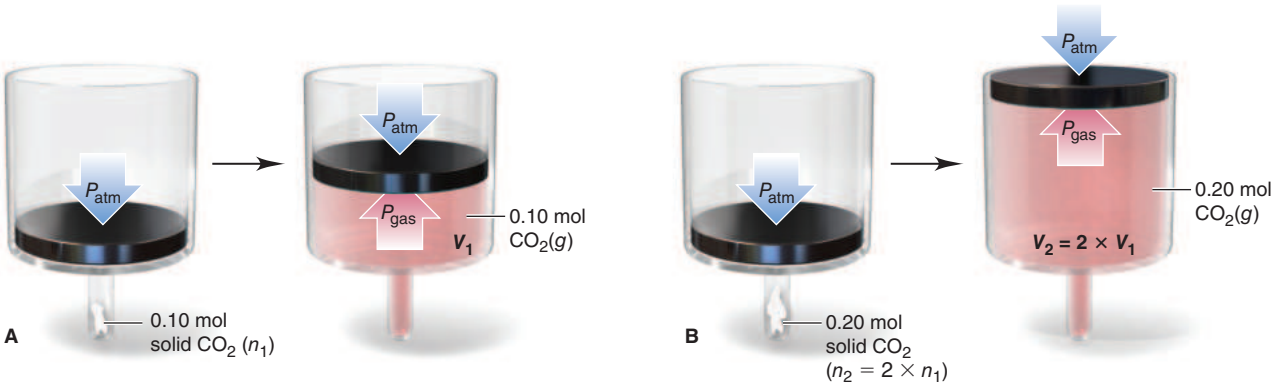


Figure 5.7 Avogadro's law, the relationship between the volume and amount of a gas.

The Relationship Between Volume and Amount: Avogadro's Law

Let's see why both Boyle's and Charles's laws specify a fixed amount of gas.

1. *The experiment.* Figure 5.7 shows an experiment that involves two small test tubes, each fitted to a much larger piston-cylinder assembly. We add 0.10 mol (4.4 g) of dry ice (solid CO_2) to the first tube (A) and 0.20 mol (8.8 g) to the second tube (B). As the solid CO_2 warms to room temperature, it changes to gaseous CO_2, and the volume increases until $P_{gas} = P_{atm}$. At constant temperature, when all the solid has changed to gas, cylinder B has twice the volume of cylinder A.

2. *Conclusion and statement of the law.* Thus, *at fixed temperature and pressure, the volume occupied by a gas is directly proportional to the amount (mol) of gas:*

$$V \propto n \qquad [P \text{ and } T \text{ fixed}] \tag{5.4}$$

That is, as n increases, V increases, and vice versa. This relationship is also expressed as

$$V = \text{constant} \times n \qquad \text{or} \qquad \frac{V}{n} = \text{constant}$$

That is, at fixed P and T, $n\uparrow, V\uparrow$ and $n\downarrow, V\downarrow$

The constant is the same for all simple gases at ordinary temperature and pressure. This relationship is another way of expressing **Avogadro's law,** which states that *at fixed temperature and pressure, equal volumes of* ***any*** *ideal gas contain equal numbers (or moles) of particles.*

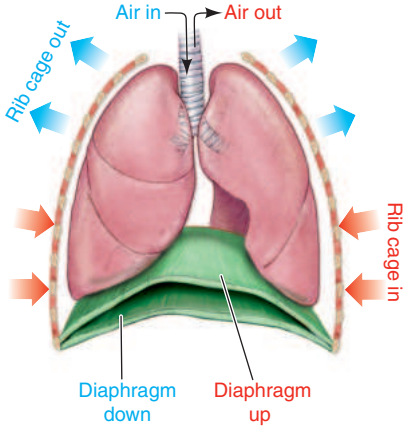

Figure 5.8 The process of breathing applies the gas laws.

Familiar Applications of the Gas Laws The gas laws apply to countless familiar phenomena. In a car engine, a reaction occurs in which fewer moles of gasoline and O_2 form more moles of CO_2 and H_2O vapor, and heat is released. The increase in n (Avogadro's law) and T (Charles's law) increases V, and the piston is pushed back. Dynamite is a solid that forms more moles of hot gases very rapidly when it reacts (Avogadro's and Charles's laws). Dough rises because yeast digests sugar, which creates bubbles of CO_2 (Avogadro's law); the dough expands more as the bread bakes in a hot oven (Charles's law).

No application of the gas laws can be more vital or familiar than breathing (Figure 5.8). When you inhale, muscles move your diaphragm down and your rib cage out *(blue)*. This coordinated movement increases the volume of your lungs, which decreases the air pressure inside them (Boyle's law). The inside pressure is 1–3 torr *less* than atmospheric pressure, so air rushes in. The greater amount of air stretches the elastic tissue of the lungs and expands the volume further (Avogadro's law). The air also expands as it warms from the external temperature to your body temperature (Charles's law). When you exhale, the diaphragm moves up and the rib cage moves

in, so your lung volume decreases *(red)*. The inside pressure becomes 1–3 torr *more* than the outside pressure (Boyle's law), so air rushes out.

Gas Behavior at Standard Conditions

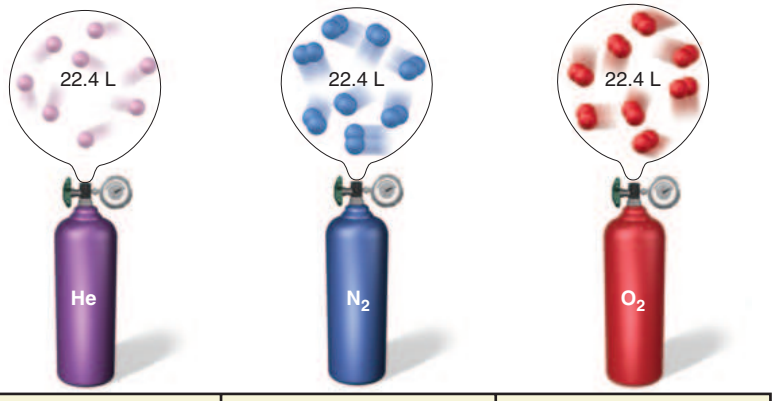
To better understand the factors that influence gas behavior, chemists have assigned a baseline set of *standard conditions* called **standard temperature and pressure (STP):**

$$\text{STP:} \quad 0°\text{C (273.15 K) and 1 atm (760 torr)} \tag{5.5}$$

Under these conditions, the volume of 1 mol of an ideal gas is called the **standard molar volume:**

$$\text{Standard molar volume} = 22.4141 \text{ L or } 22.4 \text{ L [to 3 sf]} \tag{5.6}$$

At STP, helium, nitrogen, oxygen, and other simple gases behave nearly ideally (Figure 5.9). Note that the mass, and thus the density (d), depends on the specific gas, but 1 mol of any of them occupies 22.4 L at STP.



n = 1 mol	n = 1 mol	n = 1 mol
P = 1 atm (760 torr)	P = 1 atm (760 torr)	P = 1 atm (760 torr)
T = 0°C (273 K)	T = 0°C (273 K)	T = 0°C (273 K)
V = 22.4 L	V = 22.4 L	V = 22.4 L
Number of gas particles = 6.022×10^{23}	Number of gas particles = 6.022×10^{23}	Number of gas particles = 6.022×10^{23}
Mass = 4.003 g	Mass = 28.02 g	Mass = 32.00 g
d = 0.179 g/L	d = 1.25 g/L	d = 1.43 g/L

Figure 5.9 Standard molar volume. One mole of an ideal gas occupies 22.4 L at STP (0°C and 1 atm).

Figure 5.10 compares the volumes of some familiar objects with the standard molar volume of an ideal gas.

Figure 5.10 The volumes of 1 mol (22.4 L) of an ideal gas and of some familiar objects: 1 gal of milk (3.79 L), a basketball (7.50 L), and 2.00 L of a carbonated drink.

The Ideal Gas Law

Each of the three gas laws shows how one of the three other gas variables affects gas volume:

- Boyle's law focuses on pressure ($V \propto 1/P$).
- Charles's law focuses on temperature ($V \propto T$).
- Avogadro's law focuses on amount (mol) of gas ($V \propto n$).

By combining these individual effects, we obtain the **ideal gas law** (or *ideal gas equation*):

$$V \propto \frac{nT}{P} \quad \text{or} \quad PV \propto nT \quad \text{or} \quad PV = \text{constant} \times nT \quad \text{or} \quad \frac{PV}{nT} = R$$

where R is a proportionality constant known as the **universal gas constant.** Rearranging gives the most common form of the ideal gas law:

$$PV = nRT \tag{5.7}$$

We obtain a value of R by measuring the volume, temperature, and pressure of a given amount of gas and substituting the values into the ideal gas law. For example, using standard conditions for the gas variables and 1 mol of gas, we have

$$R = \frac{PV}{nT} = \frac{1\text{ atm} \times 22.4141\text{ L}}{1\text{ mol} \times 273.15\text{ K}} = 0.082058\frac{\text{atm·L}}{\text{mol·K}} = 0.0821\frac{\text{atm·L}}{\text{mol·K}}\,[3\text{ sf}] \quad \textbf{(5.8)}$$

This numerical value of R corresponds to P, V, and T expressed *in these units; R has a different numerical value when different units are used*. For example, on p. 229, R has the value 8.314 J/mol·K (J stands for joule, the SI unit of energy).

Figure 5.11 makes a central point: the ideal gas law *becomes* one of the individual gas laws when two of the four variables are kept constant. When initial conditions (subscript 1) change to final conditions (subscript 2), we have

$$P_1V_1 = n_1RT_1 \quad \text{and} \quad P_2V_2 = n_2RT_2$$

Thus, $$\frac{P_1V_1}{n_1T_1} = R \quad \text{and} \quad \frac{P_2V_2}{n_2T_2} = R, \quad \text{so} \quad \frac{P_1V_1}{n_1T_1} = \frac{P_2V_2}{n_2T_2}$$

Notice that if, for example, the two variables P and T remain constant, then $P_1 = P_2$ and $T_1 = T_2$, and we obtain an expression for Avogadro's law:

$$\frac{\cancel{P_1}V_1}{n_1\cancel{T_1}} = \frac{\cancel{P_2}V_2}{n_2\cancel{T_2}} \quad \text{or} \quad \frac{V_1}{n_1} = \frac{V_2}{n_2}$$

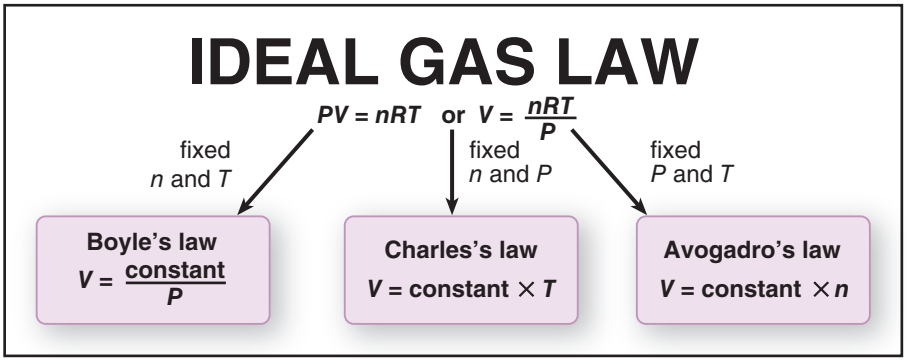


Figure 5.11 The individual gas laws as special cases of the ideal gas law.

As you'll see next, you can use a similar approach to solve gas law problems. Thus, by keeping track of the initial and final values of the gas variables, you avoid the need to memorize the three individual gas laws.

Solving Gas Law Problems

Gas law problems are phrased in many ways but can usually be grouped into two types:

1. *There is a change in one of the four variables which causes a change in another, while the two other variables remain constant.* In this type, the ideal gas law reduces to one of the individual gas laws when you omit the variables that remain constant; you then solve for the new value of the affected variable. Units must be consistent and T must always be in kelvins, but R is not involved. Sample Problems 5.2 to 5.4 are of this type. A variation on this type, shown in Sample Problem 5.5, involves the combined gas law (p. 213) when simultaneous changes in two of the variables cause a change in a third.

2. *One variable is unknown, but the other three are known*, as is R, *and no change occurs.* In this type, exemplified by Sample Problem 5.6, you apply the ideal gas law directly to find the unknown, and the units must conform to those in R.

Solving these problems requires a systematic approach:

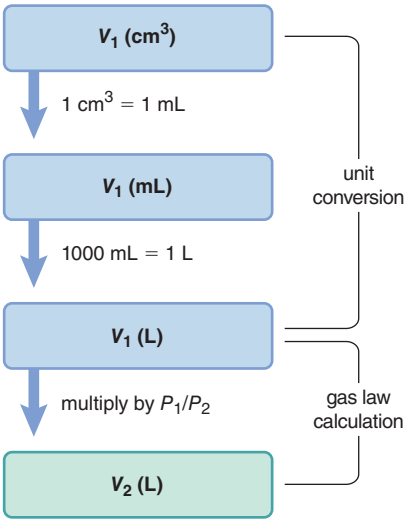
- Summarize the changing gas variables—knowns and unknown—and those held constant.
- Convert units, if necessary.
- Rearrange the ideal gas law to obtain the needed relationship of variables, and solve for the unknown.

SAMPLE PROBLEM 5.2 Applying the Volume-Pressure Relationship

Problem Boyle's apprentice finds that the air trapped in a J tube occupies 24.8 cm^3 at 1.12 atm. By adding mercury to the tube, he increases the pressure on the trapped air to 2.64 atm. Assuming constant temperature, what is the new volume of air (in L)?

Plan We must find the final volume (V_2) in liters, given the initial volume (V_1), initial pressure (P_1), and final pressure (P_2). The temperature and amount of gas are fixed. We convert the units of V_1 from cm^3 to mL and then to L, rearrange the ideal gas law to the appropriate form, and solve for V_2. (Note that the road map has two parts.)

Road Map



Solution Summarizing the gas variables:

$P_1 = 1.12$ atm $\quad P_2 = 2.64$ atm

$V_1 = 24.8\ cm^3$ (convert to L) $\quad V_2$ = unknown $\quad T$ and n remain constant

Converting V_1 from cm^3 to L:

$$V_1 = 24.8\ cm^3 \times \frac{1\ mL}{1\ cm^3} \times \frac{1\ L}{1000\ mL} = 0.0248\ L$$

Rearranging the ideal gas law and solving for V_2: At fixed n and T, we have

$$\frac{P_1V_1}{\cancel{nT}_1} = \frac{P_2V_2}{\cancel{nT}_2} \quad \text{or} \quad P_1V_1 = P_2V_2$$

$$V_2 = V_1 \times \frac{P_1}{P_2} = 0.0248\ L \times \frac{1.12\ atm}{2.64\ atm} = 0.0105\ L$$

Check The relative values of P and V can help us check the math: P more than doubled, so V_2 should be less than $\frac{1}{2}V_1$ ($0.0105/0.0248 < \frac{1}{2}$).

Comment Predicting the direction of the change provides another check on the problem setup: Since P increases, V will decrease; thus, V_2 should be less than V_1. To make $V_2 < V_1$, we must multiply V_1 by a number *less than* 1. This means the ratio of pressures must be *less than* 1, so the larger pressure (P_2) must be in the denominator, or P_1/P_2.

FOLLOW-UP PROBLEMS

5.2A A sample of argon gas occupies 105 mL at 0.871 atm. If the volume of the gas is increased to 352 mL at constant temperature, what is the final pressure of the gas (in kPa)?

5.2B A tank contains 651 L of compressed oxygen gas at a pressure of 122 atm. Assuming the temperature remains constant, what is the volume of the oxygen (in L) at 745 mmHg?

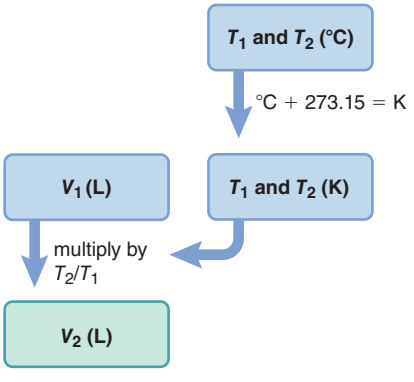
SOME SIMILAR PROBLEMS 5.24 and 5.25

SAMPLE PROBLEM 5.3 Applying the Volume-Temperature and Pressure-Temperature Relationships

Problem A balloon is filled with 1.95 L of air at 25°C and then placed in a car sitting in the sun. What is the volume of the balloon when the temperature in the car reaches 90°C?

Plan We know the initial volume (V_1) and the initial (T_1) and final temperatures (T_2) of the gas; we must find the final volume (V_2). The pressure of the gas is fixed since the balloon is subjected to atmospheric pressure, and n is fixed since air cannot escape or enter the balloon. We convert both T values to kelvins, rearrange the ideal gas law, and solve for V_2 (see the road map).

Road Map



Solution Summarizing the gas variables:

$V_1 = 1.95$ L $\quad V_2$ = unknown

$T_1 = 25$°C (convert to K) $\quad T_2 = 90$°C (convert to K)

P and n remain constant

Converting T from °C to K:

T_1 (K) = 25°C + 273.15 = 298 K $\quad T_2$ (K) = 90°C + 273.15 = 363 K

Rearranging the ideal gas law and solving for V_2: At fixed n and P, we have

$$\frac{P_1V_1}{n_1T_1} = \frac{P_2V_2}{n_2T_2} \quad \text{or} \quad \frac{V_1}{T_1} = \frac{V_2}{T_2}$$

$$V_2 = V_1 \times \frac{T_2}{T_1} = 1.95\ \text{L} \times \frac{363\ \text{K}}{298\ \text{K}} = 2.38\ \text{L}$$

Check Let's predict the change to check the math: Because $T_2 > T_1$, we expect $V_2 > V_1$. Thus, the temperature ratio should be greater than 1 (T_2 in the numerator). The T ratio is about 1.2 (363/298), so the V ratio should also be about 1.2 ($2.4/2.0 \approx 1.2$).

FOLLOW-UP PROBLEMS

5.3A A steel tank used for fuel delivery is fitted with a safety valve that opens if the internal pressure exceeds 1.00×10^3 torr. It is filled with methane at 23°C and 0.991 atm and placed in boiling water at 100.°C. What is the pressure in the heated tank? Will the safety valve open?

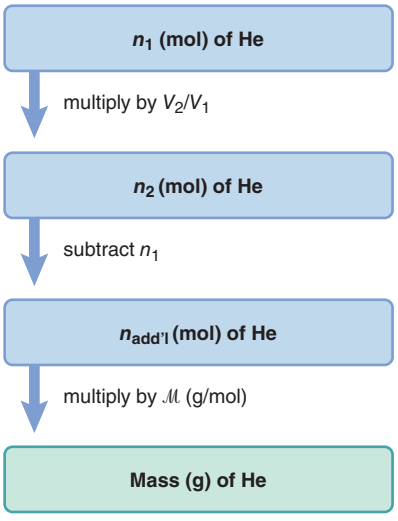
5.3B A sample of nitrogen occupies a volume of 32.5 L at 40°C. Assuming that the pressure remains constant, what temperature (in °C) will result in a decrease in the sample's volume to 28.6 L?

SOME SIMILAR PROBLEMS 5.26–5.29

SAMPLE PROBLEM 5.4 Applying the Volume-Amount and Pressure-Amount Relationships

Problem A scale model of a blimp rises when it is filled with helium to a volume of 55.0 dm^3. When 1.10 mol of He is added to the blimp, the volume is 26.2 dm^3. How many more grams of He must be added to make it rise? Assume constant T and P.

Road Map



Plan We are given the initial amount of helium (n_1), the initial volume of the blimp (V_1), and the volume needed for it to rise (V_2), and we need the additional mass of helium to make it rise. So we first need to find n_2. We rearrange the ideal gas law to the appropriate form, solve for n_2, subtract n_1 to find the additional amount ($n_{add'l}$), and then convert moles to grams (see the road map).

Solution Summarizing the gas variables:

$n_1 = 1.10$ mol — $n_2 =$ unknown (find, and then subtract n_1)
$V_1 = 26.2\ dm^3$ — $V_2 = 55.0\ dm^3$
P and T remain constant

Rearranging the ideal gas law and solving for n_2: At fixed P and T, we have

$$\frac{P_1V_1}{n_1T_1} = \frac{P_2V_2}{n_2T_2} \quad \text{or} \quad \frac{V_1}{n_1} = \frac{V_2}{n_2}$$

$$n_2 = n_1 \times \frac{V_2}{V_1} = 1.10\ \text{mol He} \times \frac{55.0\ dm^3}{26.2\ dm^3}$$
$$= 2.31\ \text{mol He}$$

Finding the additional amount of He:

$$n_{add'l} = n_2 - n_1 = 2.31\ \text{mol He} - 1.10\ \text{mol He}$$
$$= 1.21\ \text{mol He}$$

Converting amount (mol) of He to mass (g):

$$\text{Mass (g) of He} = 1.21\ \text{mol He} \times \frac{4.003\ \text{g He}}{1\ \text{mol He}}$$
$$= 4.84\ \text{g He}$$

Check We predict that $n_2 > n_1$ because $V_2 > V_1$: since V_2 is about twice V_1 ($55/26 \approx 2$), n_2 should be about twice n_1 ($2.3/1.1 \approx 2$). Since $n_2 > n_1$, we were right to multiply n_1 by a number >1 (that is, V_2/V_1). About 1.2 mol × 4 g/mol ≈ 4.8 g.

Comment 1. A different sequence of steps should give you the same answer: first find the additional volume ($V_{add'l} = V_2 - V_1$), and then solve directly for $n_{add'l}$. Try it for yourself.

2. You saw that Charles's law ($V \propto T$ at fixed P and n) becomes a similar relationship between P and T at fixed V and n. Follow-up Problem 5.4A demonstrates that Avogadro's law ($V \propto n$ at fixed P and T) becomes a similar relationship at fixed V and T.

FOLLOW-UP PROBLEMS

5.4A A rigid plastic container holds 35.0 g of ethylene gas (C_2H_4) at a pressure of 793 torr. What is the pressure if 5.0 g of ethylene is removed at constant temperature?

5.4B A balloon filled with 1.26 g of nitrogen gas has a volume of 1.12 L. Calculate the volume of the balloon after 1.26 g of helium gas is added while T and P remain constant.

SOME SIMILAR PROBLEMS 5.30 and 5.31

SAMPLE PROBLEM 5.5 Applying the Volume-Pressure-Temperature Relationship

Problem A helium-filled balloon has a volume of 15.8 L at a pressure of 0.980 atm and 22°C. What is its volume at the summit of Mt. Hood, Oregon's highest mountain, where the atmospheric pressure is 532 mmHg and the temperature is 0°C?

Plan We know the initial volume (V_1), pressure (P_1), and temperature (T_1) of the gas; we also know the final pressure (P_2) and temperature (T_2), and we must find the final volume (V_2). Since the amount of helium in the balloon does not change, n is fixed. We convert both T values to kelvins, the final pressure to atm, rearrange the ideal gas law, and solve for V_2.

Solution Summarizing the gas variables:

$V_1 = 15.8$ L
$T_1 = 22$°C (convert to K)
$P_1 = 0.980$ atm
n remains constant

V_2 = unknown
$T_2 = 0$°C (convert to K)
$P_2 = 532$ mmHg (convert to atm)

Converting T from °C to K:

$$T_1\,(\text{K}) = 22°\text{C} + 273.15 = 295\ \text{K} \qquad T_2\,(\text{K}) = 0°\text{C} + 273.15 = 273\ \text{K}$$

Converting P_2 to atm:

$$P_2\,(\text{atm}) = 532\ \text{mmHg} \times \frac{1\ \text{atm}}{760\ \text{mmHg}} = 0.700\ \text{atm}$$

Rearranging the ideal gas law and solving for V_2: At fixed n, we have

$$\frac{P_1V_1}{\cancel{n_1}T_1} = \frac{P_2V_2}{\cancel{n_2}T_2} \quad \text{or} \quad \frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$

$$V_2 = V_1 \times \frac{P_1T_2}{P_2T_1} = 15.8\ \text{L} \times \frac{(0.980\ \text{atm})(273\ \text{K})}{(0.700\ \text{atm})(295\ \text{K})} = 20.5\ \text{L}$$

Check Let's predict the change to check the math: Because $T_2 < T_1$, we expect $V_2 < V_1$; but because $P_2 < P_1$, we expect $V_2 > V_1$. The temperature ratio (T_2 in the numerator) is about 0.93 (273/295), and the pressure ratio (P_1 in the numerator) is about 1.4 (0.980/0.700), so the V ratio should be about 0.93 × 1.4, or 1.3 (20.5/15.8 ≈ 1.3). The pressure decreases by a larger factor than the temperature increases, so there is an overall increase in volume.

FOLLOW-UP PROBLEMS

5.5A A sample of nitrogen gas occupies a volume of 2.55 L at 755 mmHg and 23°C. Its volume increases to 4.10 L, and its temperature decreases to 18°C. What is the final pressure?

5.5B A diver has 2.2 L of air in his lungs at an air temperature of 28°C and a pressure of 0.980 atm. What is the volume of air in his lungs after he dives, while holding his breath, to a depth of 10 m, where the temperature is 21°C and the pressure is 1.40 atm?

SOME SIMILAR PROBLEMS 5.32 and 5.33

SAMPLE PROBLEM 5.6 Solving for an Unknown Gas Variable at Fixed Conditions

Problem A steel tank has a volume of 438 L and is filled with 0.885 kg of O_2. Calculate the pressure of O_2 at 21°C.

Plan We are given V, T, and the mass of O_2, and we must find P. Since conditions are not changing, we apply the ideal gas law without rearranging it. We use the given V in liters, convert T to kelvins and mass (kg) of O_2 to amount (mol), and solve for P.

Solution Summarizing the gas variables:

$V = 438$ L $\qquad T = 21$°C (convert to K)

$n = 0.885$ kg O_2 (convert to mol) $\qquad P =$ unknown

Converting T from °C to K:

$$T\,(\text{K}) = 21^\circ\text{C} + 273.15 = 294\ \text{K}$$

Converting from mass (g) of O_2 to amount (mol):

$$n = \text{mol of } O_2 = 0.885\ \text{kg } O_2 \times \frac{1000\ \text{g}}{1\ \text{kg}} \times \frac{1\ \text{mol } O_2}{32.00\ \text{g } O_2} = 27.7\ \text{mol } O_2$$

Solving for P (note the unit canceling here):

$$P = \frac{nRT}{V} = \frac{27.7\ \cancel{\text{mol}} \times 0.0821\ \frac{\text{atm}\cdot\cancel{\text{L}}}{\cancel{\text{mol}}\cdot\cancel{\text{K}}} \times 294\ \cancel{\text{K}}}{438\ \cancel{\text{L}}}$$

$$= 1.53\ \text{atm}$$

Check The amount of O_2 seems correct: ~900 g/(30 g/mol) = 30 mol. To check the approximate size of the final calculation, round off the values, including that for R:

$$P = \frac{30\ \text{mol } O_2 \times 0.1\ \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 300\ \text{K}}{450\ \text{L}} = 2\ \text{atm}$$

which is reasonably close to 1.53 atm.

FOLLOW-UP PROBLEMS

5.6A The tank in the sample problem develops a slow leak that is discovered and sealed. The new pressure is 1.37 atm. How many grams of O_2 remain?

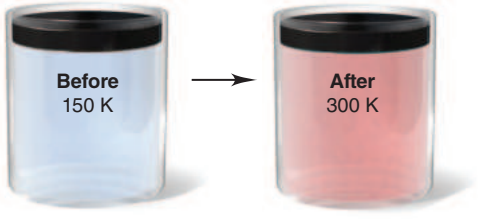
5.6B A blimp is filled with 3950 kg of helium at 731 mmHg and 20°C. What is the volume of the blimp under these conditions?

SOME SIMILAR PROBLEMS 5.34–5.37

Finally, in a picture problem, we apply the gas laws to determine the balanced equation for a gaseous reaction.

SAMPLE PROBLEM 5.7 Using Gas Laws to Determine a Balanced Equation

Problem The piston-cylinder below is depicted before and after a gaseous reaction that is carried out in it at constant pressure: the temperature is 150 K before and 300 K after the reaction. (Assume the cylinder is insulated.)



Which of the following balanced equations describes the reaction?

(1) $A_2(g) + B_2(g) \longrightarrow 2AB(g)$ $\qquad$ (2) $2AB(g) + B_2(g) \longrightarrow 2AB_2(g)$

(3) $A(g) + B_2(g) \longrightarrow AB_2(g)$ $\qquad$ (4) $2AB_2(g) \longrightarrow A_2(g) + 2B_2(g)$

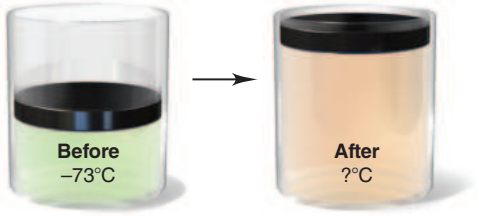
Plan We are shown a depiction of the volume and temperature of a gas mixture before and after a reaction and must deduce the balanced equation. The problem says that P is constant, and the picture shows that, when T doubles, V stays the same. If n were also constant, Charles's law tells us that V should double when T doubles. But, since V does not change, n cannot be constant. From Avogadro's law, the only way to maintain V constant, with P constant and T doubling, is for n to be halved. So we examine the four balanced equations and count the number of moles on each side to see in which equation n is halved.

Solution In equation (1), n does not change, so doubling T would double V.
In equation (2), n decreases from 3 mol to 2 mol, so doubling T would increase V by one-third.
In equation (3), n decreases from 2 mol to 1 mol. Doubling T would exactly balance the decrease from halving n, so V would stay the same.
In equation (4), n increases, so doubling T would more than double V.
Therefore, equation (3) is correct:

$$A(g) + B_2(g) \longrightarrow AB_2(g)$$

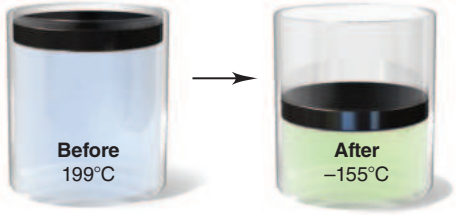
FOLLOW-UP PROBLEMS

5.7A The piston-cylinder below shows the volumes of a gaseous reaction mixture before and after a reaction that takes place at constant pressure and an initial temperature of −73°C.



If the *unbalanced* equation is $CD(g) \longrightarrow C_2(g) + D_2(g)$, what is the final temperature (in °C)?

5.7B The piston-cylinder below shows a gaseous reaction mixture before and after a reaction that takes place at constant pressure.



Which of the following balanced equations describes the reaction?
(1) $2X_2(g) + Y_2(g) \longrightarrow 2X_2Y(g)$ (2) $2XY_3(g) \longrightarrow X_2(g) + 3Y_2(g)$
(3) $X_2Y_2(g) \longrightarrow 2X(g) + Y_2(g)$ (4) $2XY(g) \longrightarrow X_2(g) + Y_2(g)$

SOME SIMILAR PROBLEMS 5.19 and 5.67

Summary of Section 5.3

- Four interdependent variables define the physical behavior of an ideal gas: volume (V), pressure (P), temperature (T), and amount (number of moles, n).
- Most simple gases display nearly ideal behavior at ordinary temperatures and pressures.
- Boyle's, Charles's, and Avogadro's laws refer to the linear relationships between the volume of a gas and the pressure, temperature, and amount of gas, respectively.
- At STP (0°C and 1 atm), 1 mol of an ideal gas occupies 22.4 L.
- The ideal gas law incorporates the individual gas laws into one equation: $PV = nRT$, where R is the universal gas constant.

5.4 REARRANGEMENTS OF THE IDEAL GAS LAW

The ideal gas law can be mathematically rearranged to find gas density, molar mass, the partial pressure of each gas in a mixture, and the amount of gaseous reactant or product in a reaction.

The Density of a Gas

One mole of any gas behaving ideally occupies the same volume at a given temperature and pressure, so differences in gas density ($d = m/V$) depend on differences in molar mass (see Figure 5.9, p. 209). For example, at STP, 1 mol of O_2 occupies the same volume as 1 mol of N_2; however, O_2 is denser because each O_2 molecule has a greater mass (32.00 amu) than each N_2 molecule (28.02 amu). Thus,

$$d \text{ of } O_2 = \frac{32.00}{28.02} \times d \text{ of } N_2$$

We can rearrange the ideal gas law to calculate the density of a gas from its molar mass. Recall that the number of moles (n) is the mass (m) divided by the molar mass ($\mathcal{M}$), $n = m/\mathcal{M}$. Substituting for n in the ideal gas law gives

$$PV = \frac{m}{\mathcal{M}}RT$$

Rearranging to isolate m/V gives

$$\frac{m}{V} = d = \frac{P \times \mathcal{M}}{RT} \qquad (5.9)$$

Two important ideas are expressed by Equation 5.9:

- *The density of a gas is directly proportional to its molar mass.* The volume of a given amount of a heavier gas equals the volume of the same amount of a lighter gas (Avogadro's law), so the density of the heavier gas is higher (as you just saw for O_2 and N_2).
- *The density of a gas is inversely proportional to the temperature.* As the volume of a gas increases with temperature (Charles's law), the same mass occupies more space, so the density of the gas is lower.

We use Equation 5.9 to find the density of a gas at any temperature and pressure near standard conditions.

SAMPLE PROBLEM 5.8 Calculating Gas Density

Problem To apply a green chemistry approach, a chemical engineer uses waste CO_2 from a manufacturing process, instead of chlorofluorocarbons, as a "blowing agent" in the production of polystyrene. Find the density (in g/L) of CO_2 and the number of molecules per liter **(a)** at STP (0°C and 1 atm) and **(b)** at room conditions (20.°C and 1.00 atm).

Plan We must find the density (d) and the number of molecules of CO_2, given two sets of P and T data. We find $\mathcal{M}$, convert T to kelvins, and calculate d with Equation 5.9. Then we convert the mass per liter to molecules per liter with Avogadro's number.

Solution **(a)** Density and molecules per liter of CO_2 at STP. Summary of gas properties:

$$T = 0°C + 273.15 = 273 \text{ K} \qquad P = 1 \text{ atm} \qquad \mathcal{M} \text{ of } CO_2 = 44.01 \text{ g/mol}$$

Calculating density (note the unit canceling here):

$$d = \frac{P \times \mathcal{M}}{RT} = \frac{1.00 \text{ atm} \times 44.01 \text{ g/mol}}{0.0821 \dfrac{\text{atm} \cdot \text{L}}{\text{mol} \cdot \text{K}} \times 273 \text{ K}} = 1.96 \text{ g/L}$$

Converting from mass/L to molecules/L:

$$\text{Molecules } CO_2/L = \frac{1.96 \text{ g } CO_2}{1 \text{ L}} \times \frac{1 \text{ mol } CO_2}{44.01 \text{ g } CO_2} \times \frac{6.022\times10^{23} \text{ molecules } CO_2}{1 \text{ mol } CO_2}$$
$$= 2.68\times10^{22} \text{ molecules } CO_2/L$$

(b) Density and molecules of CO_2 per liter at room conditions. Summary of gas properties:

$$T = 20.^\circ C + 273.15 = 293 \text{ K} \qquad P = 1.00 \text{ atm} \qquad \mathcal{M} \text{ of } CO_2 = 44.01 \text{ g/mol}$$

Calculating density:

$$d = \frac{P \times \mathcal{M}}{RT} = \frac{1.00 \text{ atm} \times 44.01 \text{ g/mol}}{0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 293 \text{ K}} = 1.83 \text{ g/L}$$

Converting from mass/L to molecules/L:

$$\text{Molecules } CO_2/L = \frac{1.83 \text{ g } CO_2}{1 \text{ L}} \times \frac{1 \text{ mol } CO_2}{44.01 \text{ g } CO_2} \times \frac{6.022\times10^{23} \text{ molecules } CO_2}{1 \text{ mol } CO_2}$$
$$= 2.50\times10^{22} \text{ molecules } CO_2/L$$

Check Round off to check the density values; for example, in (a), at STP:

$$\frac{50 \text{ g/mol} \times 1 \text{ atm}}{0.1 \dfrac{\text{atm·L}}{\text{mol·K}} \times 250 \text{ K}} = 2 \text{ g/L} \approx 1.96 \text{ g/L}$$

At the higher temperature in (b), the density should decrease, which can happen only if there are fewer molecules per liter, so the answer is reasonable.

Comment **1.** An *alternative approach* for finding the density of most simple gases, but *at STP only,* is to divide the molar mass by the standard molar volume, 22.4 L:

$$d = \frac{\mathcal{M}}{V} = \frac{44.01 \text{ g/mol}}{22.4 \text{ L/mol}} = 1.96 \text{ g/L}$$

Once you know the density at one temperature (0°C), you can find it at any other temperature with the following relationship: $d_1/d_2 = T_2/T_1$.

2. Note that we have different numbers of significant figures for the pressure values. In (a), "1 atm" is part of the definition of STP, so it is an exact number. In (b), we specified "1.00 atm" to allow three significant figures in the answer.

FOLLOW-UP PROBLEMS

5.8A Compare the density of CO_2 at 0°C and 380. torr with its density at STP.

5.8B Nitrogen oxide (NO_2) is a reddish-brown gas that is a component of smog. Calculate its density at 0.950 atm and 24°C. How does the density of NO_2 compare to that of dry air (d = 1.13 g/L at the same conditions)?

SOME SIMILAR PROBLEMS 5.45–5.48

Gas Density and the Human Condition A few applications demonstrate the wide-ranging relevance of gas density:

- *Engineering.* Architectural designers and heating engineers place heating ducts near the floor so that the warmer, and thus less dense, air coming from the ducts will rise and mix with the cooler room air.
- *Safety and air pollution.* In the absence of mixing, a less dense gas will lie above a more dense one. Fire extinguishers that release CO_2 are effective because this gas is heavier than air: it sinks onto the fire and keeps more O_2 from reaching the fuel. The dense gases in smog that blankets urban centers, such as Mexico City, Los Angeles, and Beijing, contribute to respiratory illnesses (see Follow-up Problem 5.8B).
- *Toxic releases.* During World War I, poisonous phosgene gas ($COCl_2$) was used against ground troops because it was dense enough to sink into their trenches. In

1984, the accidental release of poisonous methylisocyanate gas from a Union Carbide plant in India killed thousands of people as it blanketed nearby neighborhoods. In 1986, CO_2 released naturally from Lake Nyos in Cameroon suffocated thousands of people as it flowed down valleys into villages. Some paleontologists suggest that the release of CO_2 from volcanic lakes may have contributed to widespread dying off of dinosaurs.

- *Ballooning.* When the gas in a hot-air balloon is heated, its volume increases and the balloon inflates. Further heating causes some of the gas to escape. Thus, the gas density decreases and the balloon rises. In 1783, Jacques Charles (of Charles's law) made one of the first balloon flights, and 20 years later, Joseph Gay-Lussac (who studied the pressure-temperature relationship) set a solo altitude record that held for 50 years.

The Molar Mass of a Gas

Through another rearrangement of the ideal gas law, we can determine the molar mass of an unknown gas or a volatile liquid (one that is easily vaporized):

$$n = \frac{m}{\mathcal{M}} = \frac{PV}{RT} \qquad \text{so} \qquad \mathcal{M} = \frac{mRT}{PV} \tag{5.10}$$

Notice that this equation is just a rearrangement of Equation 5.9.

SAMPLE PROBLEM 5.9 Finding the Molar Mass of a Volatile Liquid

Problem An organic chemist isolates a colorless liquid from a petroleum sample. She places the liquid in a preweighed flask and puts the flask in boiling water, which vaporizes the liquid and fills the flask with gas. She closes the flask and reweighs it. She obtains the following data:

Volume (V) of flask = 213 mL T = 100.0°C P = 754 torr
Mass of flask + gas = 78.416 g Mass of flask = 77.834 g

Calculate the molar mass of the liquid.

Plan We are given V, T, P, and mass data and must find the molar mass ($\mathcal{M}$) of the liquid. We convert V to liters, T to kelvins, and P to atmospheres, find the mass of gas by subtracting the mass of the flask from the mass of the flask plus gas, and use Equation 5.10 to calculate $\mathcal{M}$.

Solution Summarizing and converting the gas variables:

$$V\,(\text{L}) = 213\ \text{mL} \times \frac{1\ \text{L}}{1000\ \text{mL}} = 0.213\ \text{L} \qquad T\,(\text{K}) = 100.0°\text{C} + 273.15 = 373.2\ \text{K}$$

$$P\,(\text{atm}) = 754\ \text{torr} \times \frac{1\ \text{atm}}{760\ \text{torr}} = 0.992\ \text{atm} \qquad m = 78.416\ \text{g} - 77.834\ \text{g} = 0.582\ \text{g}$$

Calculating $\mathcal{M}$:

$$\mathcal{M} = \frac{mRT}{PV} = \frac{0.582\ \text{g} \times 0.0821\ \frac{\text{atm·L}}{\text{mol·K}} \times 373.2\ \text{K}}{0.992\ \text{atm} \times 0.213\ \text{L}} = 84.4\ \text{g/mol}$$

Check Rounding to check the arithmetic, we have

$$\frac{0.6\ \text{g} \times 0.08\ \frac{\text{atm·L}}{\text{mol·K}} \times 375\ \text{K}}{1\ \text{atm} \times 0.2\ \text{L}} = 90\ \text{g/mol} \qquad \text{(which is close to 84.4 g/mol)}$$

FOLLOW-UP PROBLEMS

5.9A An empty 149-mL flask weighs 68.322 g before a sample of volatile liquid is added. The flask is then placed in a hot (95.0°C) water bath; the barometric pressure is 740. torr. The liquid vaporizes and the gas fills the flask. After cooling, flask and condensed liquid together weigh 68.697 g. What is the molar mass of the liquid?

5.9B An empty glass bulb has a volume of 350. mL and a mass of 82.561 g. When filled with an unknown gas at 733 mmHg and 22°C, the bulb has a mass of 82.786 g. Is the gas argon (Ar), methane (CH_4), or nitrogen monoxide (NO)?
SOME SIMILAR PROBLEMS 5.49 and 5.50

The Partial Pressure of Each Gas in a Mixture of Gases

The ideal gas law holds for virtually any gas at ordinary conditions, whether it is a pure gas or a mixture of gases such as air, because

- Gases mix homogeneously (form a solution) in any proportions.
- Each gas in a mixture behaves as if it were the only gas present (assuming no chemical interactions).

Dalton's Law of Partial Pressures The second point above was discovered by John Dalton during his lifelong study of humidity. He observed that when water vapor is added to dry air, the total air pressure increases by the pressure of the water vapor:

$$P_{\text{humid air}} = P_{\text{dry air}} + P_{\text{added water vapor}}$$

He concluded that each gas in the mixture exerts a **partial pressure** equal to the pressure it would exert *by itself.* Stated as **Dalton's law of partial pressures,** his discovery was that *in a mixture of unreacting gases, the total pressure is the sum of the partial pressures of the individual gases:*

$$P_{\text{total}} = P_1 + P_2 + P_3 + \cdots \qquad \textbf{(5.11)}$$

As an example, suppose we have a tank of fixed volume that contains nitrogen gas at a certain pressure, and we introduce a sample of hydrogen gas into the tank. Each gas behaves independently, so we can write an ideal gas law expression for each:

$$P_{N_2} = \frac{n_{N_2}RT}{V} \qquad \text{and} \qquad P_{H_2} = \frac{n_{H_2}RT}{V}$$

Because each gas occupies the same total volume and is at the same temperature, the pressure of each gas depends only on its amount, *n.* Thus, the total pressure is

$$P_{\text{total}} = P_{N_2} + P_{H_2} = \frac{n_{N_2}RT}{V} + \frac{n_{H_2}RT}{V} = \frac{(n_{N_2} + n_{H_2})RT}{V} = \frac{n_{\text{total}}RT}{V}$$

where $n_{\text{total}} = n_{N_2} + n_{H_2}$.

Each component in a mixture contributes a fraction of the total number of moles in the mixture; this portion is the **mole fraction (*X*)** of that component. Multiplying *X* by 100 gives the mole percent. The sum of the mole fractions of all components must be 1, and the sum of the mole percents must be 100%. For N_2 in our mixture, the mole fraction is

$$X_{N_2} = \frac{\text{mol of } N_2}{\text{total amount (mol)}} = \frac{n_{N_2}}{n_{N_2} + n_{H_2}}$$

If the total pressure is due to the total number of moles, the partial pressure of gas A is the total pressure multiplied by the mole fraction of A, X_A:

$$P_A = X_A \times P_{\text{total}} \qquad \textbf{(5.12)}$$

For example, if $\frac{1}{4}$ (0.25) of a gas mixture is gas A, then gas A contributes $\frac{1}{4}$ of the total pressure.

Equation 5.12 is a very useful result. To see that it is valid for the mixture of N_2 and H_2, we recall that $X_{N_2} + X_{H_2} = 1$; then we obtain

$$P_{\text{total}} = P_{N_2} + P_{H_2} = (X_{N_2} \times P_{\text{total}}) + (X_{H_2} \times P_{\text{total}}) = (X_{N_2} + X_{H_2})P_{\text{total}} = 1 \times P_{\text{total}}$$

SAMPLE PROBLEM 5.10 Applying Dalton's Law of Partial Pressures

Problem In a study of O_2 uptake by muscle at high altitude, a physiologist prepares an atmosphere consisting of 79 mole % N_2, 17 mole % $^{16}O_2$, and 4.0 mole % $^{18}O_2$. (The isotope ^{18}O will be measured to determine O_2 uptake.) The total pressure is 0.75 atm to simulate high altitude. Calculate the mole fraction and partial pressure of $^{18}O_2$ in the mixture.

Road Map

Mole % of $^{18}O_2$
↓ divide by 100
Mole fraction, $X_{^{18}O_2}$
↓ multiply by P_{total}
Partial pressure, $P_{^{18}O_2}$

Plan We must find $X_{^{18}O_2}$ and $P_{^{18}O_2}$ from P_{total} (0.75 atm) and the mole % of $^{18}O_2$ (4.0). Dividing the mole % by 100 gives the mole fraction, $X_{^{18}O_2}$. Then, using Equation 5.12, we multiply $X_{^{18}O_2}$ by P_{total} to find $P_{^{18}O_2}$ (see the road map).

Solution Calculating the mole fraction of $^{18}O_2$:

$$X_{^{18}O_2} = \frac{4.0 \text{ mol \% } ^{18}O_2}{100} = 0.040$$

Solving for the partial pressure of $^{18}O_2$:

$$P_{^{18}O_2} = X_{^{18}O_2} \times P_{total} = 0.040 \times 0.75 \text{ atm} = 0.030 \text{ atm}$$

Check $X_{^{18}O_2}$ is small because the mole % is small, so $P_{^{18}O_2}$ should be small also.

Comment At high altitudes, specialized brain cells that are sensitive to O_2 and CO_2 levels in the blood trigger an increase in rate and depth of breathing for several days, until a person becomes acclimated.

FOLLOW-UP PROBLEMS

5.10A To prevent the presence of air, noble gases are placed over highly reactive chemicals to act as inert "blanketing" gases. A chemical engineer places a mixture of noble gases consisting of 5.50 g of He, 15.0 g of Ne, and 35.0 g of Kr in a piston-cylinder assembly at STP. Calculate the partial pressure of each gas.

5.10B Trimix is a breathing mixture of He, O_2, and N_2 used by deep-sea scuba divers; He reduces the chances of N_2 narcosis and O_2 toxicity. A tank of Trimix has a total pressure of 204 atm and a partial pressure of He of 143 atm. What is the mole percent of He in the mixture?

SOME SIMILAR PROBLEMS 5.51 and 5.52

Collecting a Gas over Water Whenever a gas is in contact with water, some of the water vaporizes into the gas. The water vapor that mixes with the gas contributes the *vapor pressure,* a portion of the total pressure that depends only on the water temperature (Table 5.2). A common use of the law of partial pressures is to determine the yield of a water-insoluble gas formed in a reaction: the gaseous product bubbles through water, some water vaporizes into the bubbles, and the mixture of product gas and water vapor is collected into an inverted container (Figure 5.12).

To determine the yield, we look up the vapor pressure (P_{H_2O}) at the temperature of the experiment in Table 5.2 and subtract it from the total gas pressure (P_{total}, corrected for barometric pressure) to get the partial pressure of the gaseous product (P_{gas}). With V and T known, we can calculate the amount of product.

Table 5.2 Vapor Pressure of Water (P_{H_2O}) at Different T

T (°C)	P_{H_2O} (torr)	T (°C)	P_{H_2O} (torr)	T (°C)	P_{H_2O} (torr)	T (°C)	P_{H_2O} (torr)
0	4.6	20	17.5	40	55.3	75	289.1
5	6.5	22	19.8	45	71.9	80	355.1

12	10.5	26	25.2	55	118.0	90	525.8
14	12.0	28	28.3	60	149.4	95	633.9
16	13.6	30	31.8	65	187.5	100	760.0
18	15.5	35	42.2	70	233.7		

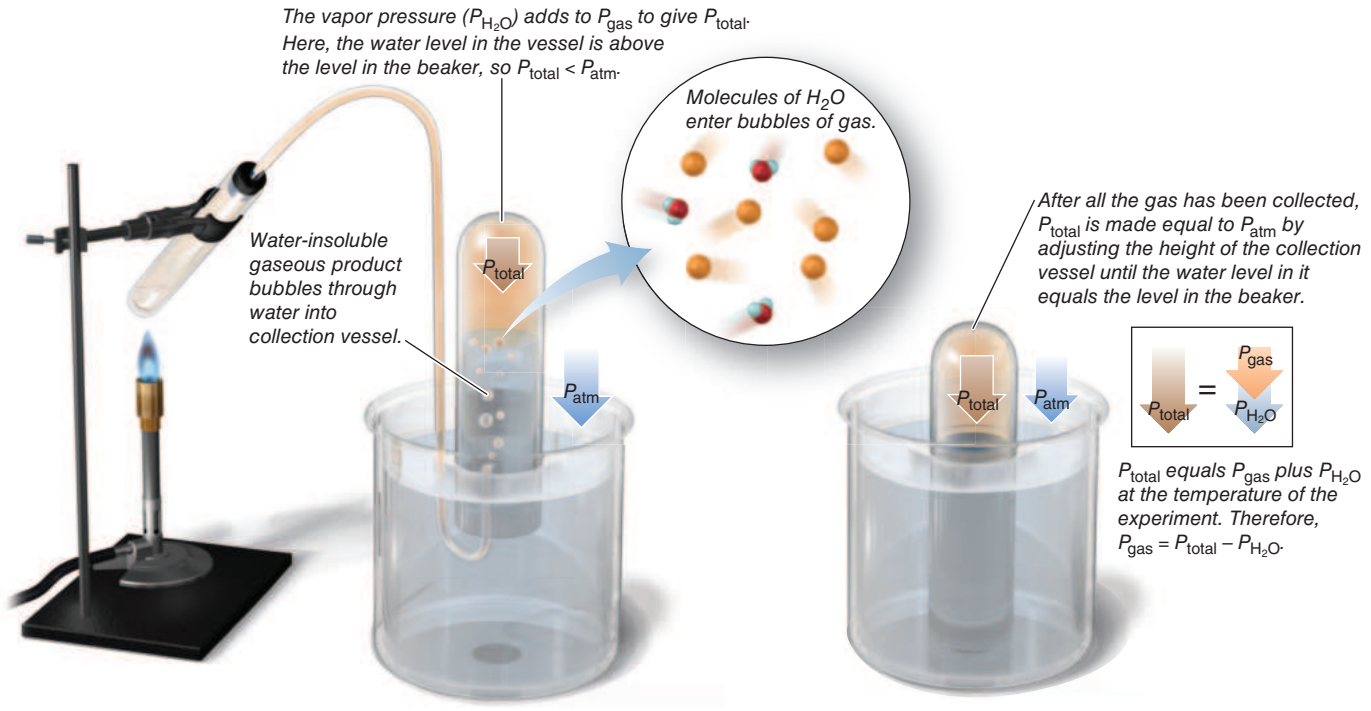

Figure 5.12 Collecting a water-insoluble gaseous product and determining its pressure.

SAMPLE PROBLEM 5.11 Calculating the Amount of Gas Collected over Water

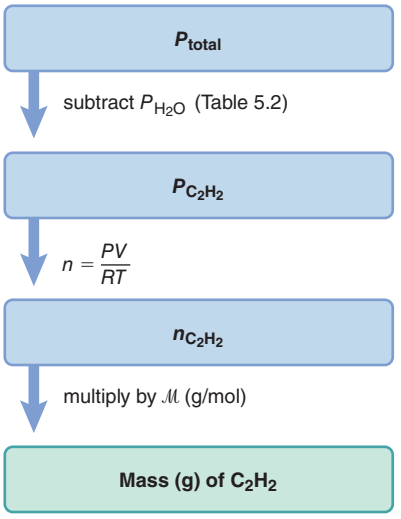
Problem Acetylene (C_2H_2), an important fuel in welding, is produced in the laboratory when calcium carbide (CaC_2) reacts with water:

$$CaC_2(s) + 2H_2O(l) \longrightarrow C_2H_2(g) + Ca(OH)_2(aq)$$

For a sample of acetylene collected over water, total gas pressure (adjusted to barometric pressure) is 738 torr and the volume is 523 mL. At the temperature of the gas (23°C), the vapor pressure of water is 21 torr. How many grams of acetylene are collected?

Plan In order to find the mass of C_2H_2, we first need to find the number of moles of C_2H_2, $n_{C_2H_2}$, which we can obtain from the ideal gas law by calculating $P_{C_2H_2}$. The barometer reading gives us P_{total}, which is the sum of $P_{C_2H_2}$ and P_{H_2O}, and we are given P_{H_2O}, so we subtract to find $P_{C_2H_2}$. We are also given V and T, so we convert to consistent units, and find $n_{C_2H_2}$ from the ideal gas law. Then we convert moles to grams using the molar mass from the formula, as shown in the road map.

Road Map



Solution Summarizing and converting the gas variables:

$$P_{C_2H_2}\,(\text{torr}) = P_{total} - P_{H_2O} = 738\text{ torr} - 21\text{ torr} = 717\text{ torr}$$

$$P_{C_2H_2}\,(\text{atm}) = 717\text{ torr} \times \frac{1\text{ atm}}{760\text{ torr}} = 0.943\text{ atm}$$

$$V\,(\text{L}) = 523\text{ mL} \times \frac{1\text{ L}}{1000\text{ mL}} = 0.523\text{ L}$$

$$T\,(\text{K}) = 23°\text{C} + 273.15 = 296\text{ K}$$

$$n_{C_2H_2} = \text{unknown}$$

Solving for $n_{C_2H_2}$:

$$n_{C_2H_2} = \frac{PV}{RT} = \frac{0.943\text{ atm} \times 0.523\text{ L}}{0.0821\ \frac{\text{atm·L}}{\text{mol·K}} \times 296\text{ K}} = 0.0203\text{ mol}$$

Converting $n_{C_2H_2}$ to mass (g):

$$\text{Mass (g) of } C_2H_2 = 0.0203\text{ mol } C_2H_2 \times \frac{26.04\text{ g } C_2H_2}{1\text{ mol } C_2H_2}$$

$$= 0.529\text{ g } C_2H_2$$

Check Rounding to one significant figure, a quick arithmetic check for n gives

$$n \approx \frac{1 \text{ atm} \times 0.5 \text{ L}}{0.08 \dfrac{\text{atm·L}}{\text{mol·K}} \times 300 \text{ K}} = 0.02 \text{ mol} \approx 0.0203 \text{ mol}$$

Comment The C_2^{2-} ion (called the *carbide,* or *acetylide, ion*) is an interesting anion. It is simply $^-C{\equiv}C^-$, which acts as a base in water, removing an H^+ ion from two H_2O molecules to form acetylene, $H{-}C{\equiv}C{-}H$.

FOLLOW-UP PROBLEMS

5.11A A small piece of zinc reacts with dilute HCl to form H_2, which is collected over water at 16°C into a large flask. The total pressure is adjusted to barometric pressure (752 torr), and the volume is 1495 mL. Use Table 5.2 (p. 220) to help calculate the partial pressure and mass of H_2.

5.11B Heating a sample of $KClO_3$ produces O_2, which is collected over water at 20.°C. The total pressure, after adjusting to barometric pressure, is 748 torr, and the gas volume is 307 mL. Use Table 5.2 to help calculate the partial pressure and mass of O_2.

SOME SIMILAR PROBLEMS 5.57 and 5.58

The Ideal Gas Law and Reaction Stoichiometry

As you saw in Chapters 3 and 4, and in the preceding discussion of collecting a gas over water, many reactions involve gases as reactants or products. From the balanced equation for such a reaction, you can calculate the amounts (mol) of reactants and products and convert these quantities into masses or numbers of molecules. Figure 5.13 shows how you use the ideal gas law to convert between gas variables (P, T, and V) and amounts (mol) of gaseous reactants and products. In effect, you combine a gas law problem with a stoichiometry problem, as you'll see in Sample Problems 5.12 and 5.13.

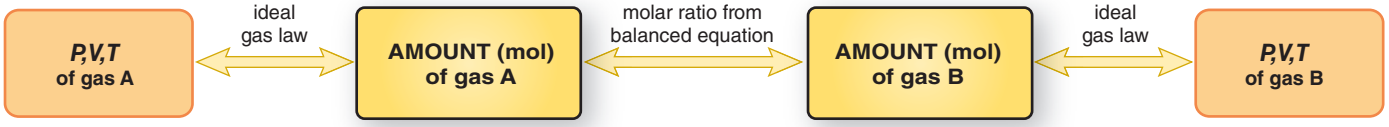


Figure 5.13 The relationships among the amount (mol, *n*) of gaseous reactant (or product) and the gas pressure (*P*), volume (*V*), and temperature (*T*).

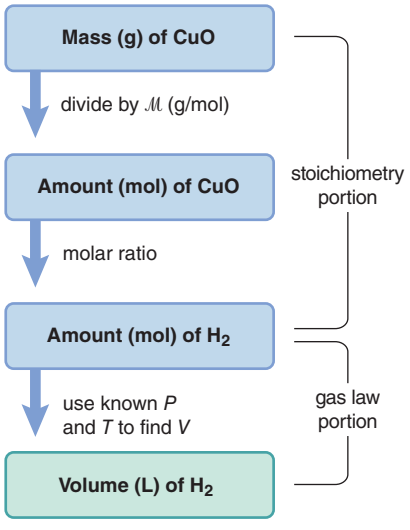
SAMPLE PROBLEM 5.12 Using Gas Variables to Find Amounts of Reactants or Products I

Problem Engineers use copper in absorbent beds to react with and remove oxygen impurities in ethylene used to make polyethylene. The beds are regenerated when hot H_2 reduces the copper(II) oxide, forming the pure metal and H_2O. On a laboratory scale, what volume of H_2 at 765 torr and 225°C is needed to reduce 35.5 g of copper(II) oxide?

Plan This is a stoichiometry *and* a gas law problem. To find V_{H_2}, we first need n_{H_2}. We write and balance the equation. Next, we convert the given mass (35.5 g) of copper(II) oxide, CuO, to amount (mol) and use the molar ratio to find amount (mol) of H_2 needed (stoichiometry portion). Then, we use the ideal gas law to convert moles of H_2 to liters (gas law portion). A road map is shown, but you are familiar with all the steps.

Road Map



Solution Writing the balanced equation:

$$CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(g)$$

Calculating n_{H_2}:

$$n_{H_2} = 35.5 \text{ g CuO} \times \frac{1 \text{ mol CuO}}{79.55 \text{ g CuO}} \times \frac{1 \text{ mol } H_2}{1 \text{ mol CuO}} = 0.446 \text{ mol } H_2$$

Summarizing and converting other gas variables:

$$V = \text{unknown} \qquad P \text{ (atm)} = 765 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}} = 1.01 \text{ atm}$$

$$T \text{ (K)} = 225°C + 273.15 = 498 \text{ K}$$

Solving for V_{H_2}:

$$V = \frac{nRT}{P} = \frac{0.446 \text{ mol} \times 0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 498 \text{ K}}{1.01 \text{ atm}} = \boxed{18.1 \text{ L}}$$

Check One way to check the answer is to compare it with the molar volume of an ideal gas at STP (22.4 L at 273.15 K and 1 atm). One mole of H_2 at STP occupies about 22 L, so less than 0.5 mol occupies less than 11 L. T is less than twice 273 K, so V should be less than twice 11 L.

Comment The main point here is that the stoichiometry provides one gas variable (n), two more are given, and the ideal gas law is used to find the fourth.

FOLLOW-UP PROBLEMS

5.12A Sulfuric acid reacts with sodium chloride to form aqueous sodium sulfate and hydrogen chloride gas. How many milliliters of gas form at STP when 0.117 kg of sodium chloride reacts with excess sulfuric acid?

5.12B Solid lithium hydroxide is used to "scrub" CO_2 from the air in spacecraft and submarines; it reacts with the CO_2 to produce lithium carbonate and water. What mass of lithium hydroxide is required to remove 215 L of CO_2 at 23°C and 0.942 atm?

SOME SIMILAR PROBLEMS 5.53 and 5.54

SAMPLE PROBLEM 5.13 Using Gas Variables to Find Amounts of Reactants or Products II

Problem The alkali metals [Group 1A(1)] react with the halogens [Group 7A(17)] to form ionic metal halides. What mass of potassium chloride forms when 5.25 L of chlorine gas at 0.950 atm and 293 K reacts with 17.0 g of potassium *(see photo)*?

Chlorine gas reacting with potassium.

Plan The amounts of two reactants are given, so this is a limiting-reactant problem. The only difference between this and previous limiting-reactant problems (see Sample Problem 3.20, pp. 121–122) is that here we use the ideal gas law to find the amount (n) of gaseous reactant from the known V, P, and T. We first write the balanced equation and then use it to find the limiting reactant and the amount and mass of product.

Solution Writing the balanced equation:

$$2K(s) + Cl_2(g) \longrightarrow 2KCl(s)$$

Summarizing the gas variables:

$$P = 0.950 \text{ atm} \qquad V = 5.25 \text{ L}$$
$$T = 293 \text{ K} \qquad n = \text{unknown}$$

Solving for n_{Cl_2}:

$$n_{Cl_2} = \frac{PV}{RT} = \frac{0.950 \text{ atm} \times 5.25 \text{ L}}{0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 293 \text{ K}} = 0.207 \text{ mol}$$

Converting from mass (g) of potassium (K) to amount (mol):

$$\text{Amount (mol) of K} = 17.0 \text{ g K} \times \frac{1 \text{ mol K}}{39.10 \text{ g K}} = 0.435 \text{ mol K}$$

Determining the limiting reactant: If Cl_2 is limiting,

$$\text{Amount (mol) of KCl} = 0.207 \text{ mol } Cl_2 \times \frac{2 \text{ mol KCl}}{1 \text{ mol } Cl_2} = 0.414 \text{ mol KCl}$$

If K is limiting,

$$\text{Amount (mol) of KCl} = 0.435 \text{ mol K} \times \frac{2 \text{ mol KCl}}{2 \text{ mol K}} = 0.435 \text{ mol KCl}$$

Cl_2 is the limiting reactant because it forms less KCl.
Converting from amount (mol) of KCl to mass (g):

$$\text{Mass (g) of KCl} = 0.414 \text{ mol KCl} \times \frac{74.55 \text{ g KCl}}{1 \text{ mol KCl}} = \boxed{30.9 \text{ g KCl}}$$

Check The gas law calculation seems correct. At STP, 22 L of Cl_2 gas contains about 1 mol, so a 5-L volume will contain a bit less than 0.25 mol of Cl_2. Moreover, since P (in numerator) is slightly lower than STP, and T (in denominator) is slightly higher than STP, these should lower the calculated n further below the ideal value. The mass of KCl seems correct: less than 0.5 mol of KCl gives $< 0.5 \text{ mol} \times \mathcal{M}$ (~75 g/mol), and 30.9 g $<$ 0.5 mol $\times$ 75 g/mol.

FOLLOW-UP PROBLEMS

5.13A Ammonia and hydrogen chloride gases react to form solid ammonium chloride. A 10.0-L reaction flask contains ammonia at 0.452 atm and 22°C, and 155 mL of hydrogen chloride gas at 7.50 atm and 271 K is introduced. After the reaction occurs and the temperature returns to 22°C, what is the pressure inside the flask? (Neglect the volume of the solid product.)

5.13B What volume of gaseous iodine pentafluoride, measured at 105°C and 0.935 atm, can be prepared by the reaction of 4.16 g of solid iodine with 2.48 L of gaseous fluorine at 18°C and 0.974 atm?

SOME SIMILAR PROBLEMS 5.55 and 5.56

Summary of Section 5.4

- Gas density is inversely related to temperature: higher T causes lower d, and vice versa. At the same P and T, gases with larger $\mathcal{M}$ have higher d.
- In a mixture of gases, each component contributes its partial pressure to the total pressure (Dalton's law of partial pressures). The mole fraction of each component is the ratio of its partial pressure to the total pressure.
- When a gaseous reaction product is collected by bubbling it through water, the total pressure is the sum of the gas pressure and the vapor pressure of water at the given temperature.
- By converting the variables P, V, and T for a gaseous reactant (or product) to amount (n, mol), we can solve stoichiometry problems for gaseous reactions.

5.5 THE KINETIC-MOLECULAR THEORY: A MODEL FOR GAS BEHAVIOR

The **kinetic-molecular theory** is the model that accounts for macroscopic gas behavior at the level of individual particles (atoms or molecules). Developed by some of the great scientists of the 19th century, most notably James Clerk Maxwell and Ludwig Boltzmann, the theory was able to explain the gas laws that some of the great scientists of the 18th century had arrived at empirically. The theory draws quantitative conclusions based on a few postulates (assumptions), but our discussion will be largely qualitative.

How the Kinetic-Molecular Theory Explains the Gas Laws

Let's address some questions the theory must answer, then state the postulates, and draw conclusions that explain the gas laws and related phenomena.

Questions Concerning Gas Behavior Observing gas behavior at the macroscopic level, we must derive a molecular model that explains it:

1. *Origin of pressure.* Pressure is a measure of the force a gas exerts on a surface. How do individual gas particles create this force?
2. *Boyle's law ($V \propto 1/P$).* A change in gas pressure in one direction causes a change in gas volume in the other. What happens to the particles when external pressure compresses the gas volume? And why aren't liquids and solids compressible?
3. *Dalton's law ($P_{total} = P_1 + P_2 + P_3 + \cdots$).* The pressure of a gas mixture is the sum of the pressures of the individual gases. Why does each gas contribute to the total pressure in proportion to its number of particles?

4. *Charles's law ($V \propto T$).* A change in temperature causes a corresponding change in volume. What effect does higher temperature have on gas particles that increases gas volume? This question raises a more fundamental one: what does temperature measure on the molecular scale?
5. *Avogadro's law ($V \propto n$).* Gas volume depends on the number of moles present, not on the chemical nature of the gas. But shouldn't 1 mol of heavier particles exert more pressure, and thus take up more space, than 1 mol of lighter ones?

Postulates of the Kinetic-Molecular Theory The theory is based on three postulates:

Postulate 1. *Particle volume.* A gas consists of a large collection of individual particles with empty space between them. The volume of each particle is so small compared with the volume of the whole sample that it is assumed to be zero; each particle is essentially a point of mass.

Postulate 2. *Particle motion.* The particles are in constant, random, straight-line motion, except when they collide with the container walls or with each other.

Postulate 3. *Particle collisions.* The collisions are *elastic,* which means that, like minute billiard balls on a frictionless billiards table, the colliding molecules exchange energy but do not lose any energy through friction. Thus, *their total kinetic energy (E_k) is constant.* Between collisions, the molecules do not influence each other by attractive or repulsive forces.

Imagine what a sample of gas in a container looks like. Countless minute particles move in every direction, smashing into the container walls and each other. Any given particle changes its speed often—at one moment standing still from a head-on collision and the next moment zooming away from a smash on the side.

In the sample as a whole, *each particle has a molecular speed (u); most are moving near the most probable speed, but some are much faster and others much slower.* Figure 5.14 depicts this distribution of molecular speeds for N_2 gas at three temperatures.

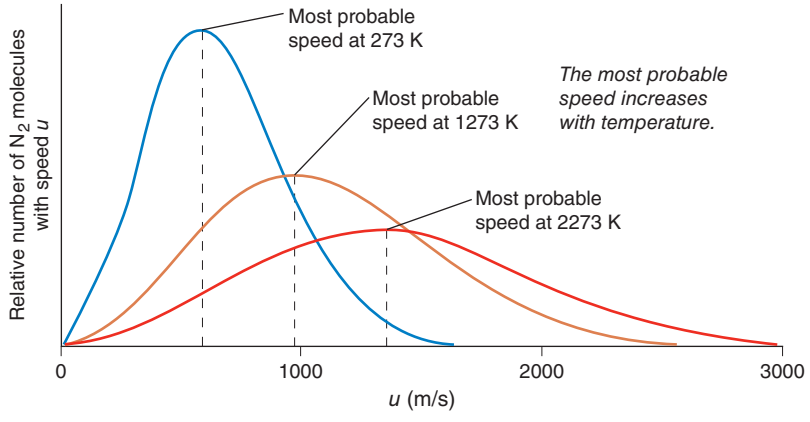


Figure 5.14 Distribution of molecular speeds for N_2 at three temperatures.

Note that the curves flatten and spread at higher temperatures and that the *most probable speed (the peak of each curve) increases as the temperature increases.* This increase occurs because the average kinetic energy of the molecules, which is related to the most probable speed, is proportional to the absolute temperature: $\overline{E_k} \propto T$, or $\overline{E_k} = c \times T$, where $\overline{E_k}$ is the average kinetic energy of the molecules (an overbar indicates the average value of a quantity) and c is a constant that is the same for any gas. (We'll return to this equation shortly.) Thus, a major conclusion based on the distribution of speeds, which arises directly from postulate 3, is that *at a given temperature, all gases have the same average kinetic energy.*

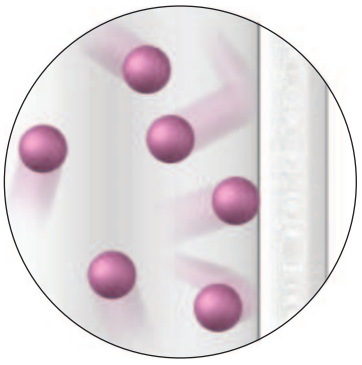

Figure 5.15 Pressure arises from countless collisions between gas particles and walls.

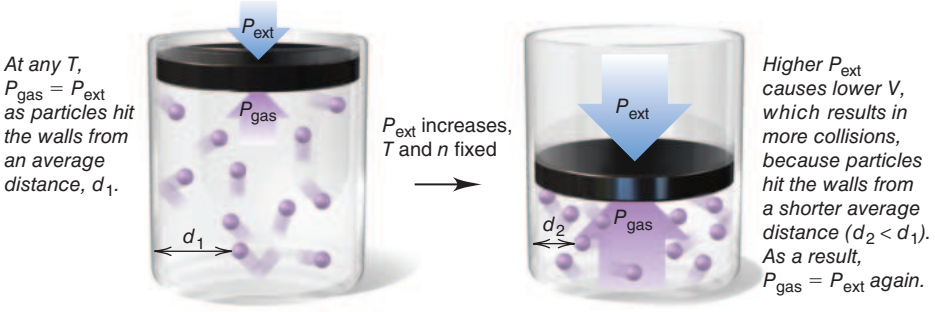
A Molecular View of the Gas Laws Let's keep visualizing gas particles in a container to see how the theory explains the macroscopic behavior of gases and answers the questions we just posed:

1. *Origin of pressure* (Figure 5.15). From postulates 1 and 2, each gas particle (point of mass) colliding with the container walls (and bottom of piston) exerts a force. Countless collisions over the inner surface of the container result in a pressure. The greater the number of particles, the more frequently they collide with the container, and so the greater the pressure.

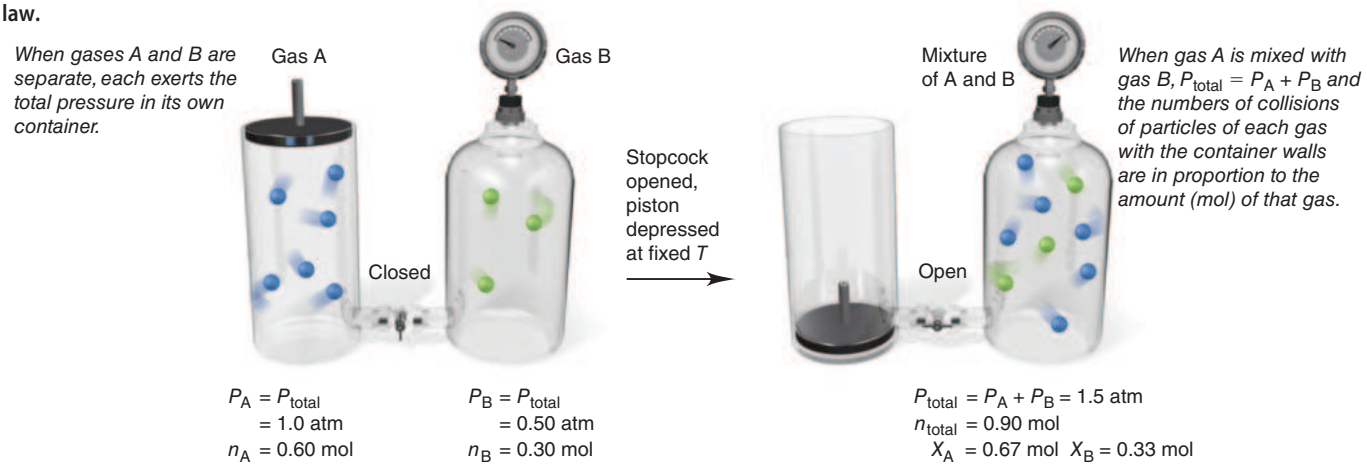
2. *Boyle's law ($V \propto 1/P$)* (Figure 5.16). The particles in a gas are points of mass with empty space between them (postulate 1). Before any change in pressure, the pressure exerted *by* the gas (P_{gas}) equals the pressure exerted *on* the gas (P_{ext}), and there is some average distance (d_1) between the particles and the container walls. As P_{ext} increases at constant temperature, the average distance (d_2) between the particles and the walls decreases (that is, $d_2 < d_1$), and so the sample volume decreases. Collisions of the particles with the walls become more frequent over the shorter average distance, which causes P_{gas} to increase until it again equals P_{ext}. The fact that liquids and solids cannot be compressed implies there is little, if any, free space between their particles.

Figure 5.16 A molecular view of Boyle's law.



3. *Dalton's law of partial pressures ($P_{total} = P_A + P_B$)* (Figure 5.17). Adding a given amount (mol) of gas A to a given amount of gas B causes an increase in the total number of particles, in proportion to the particles of A added. This increase causes a corresponding increase in the total number of collisions with the walls per second (postulate 2), which causes a corresponding increase in the total pressure of the gas mixture (P_{total}). Each gas exerts a fraction of P_{total} in proportion to its fraction of the total number of particles (or equivalently, its fraction of the total number of moles, that is, the mole fraction).

Figure 5.17 A molecular view of Dalton's law.



4. *Charles's law ($V \propto T$)* (Figure 5.18). At some starting temperature, T_1, the external (atmospheric) pressure (P_{atm}) equals the pressure of the gas (P_{gas}). When the gas is heated and the temperature increases to T_2, the most probable molecular speed and the average kinetic energy increase (postulate 3). Thus, the particles hit the walls more frequently *and* more energetically. This change temporarily increases P_{gas}. As a result, the piston moves up, which increases the volume and lowers the number of collisions with the walls until P_{atm} and P_{gas} are again equal.

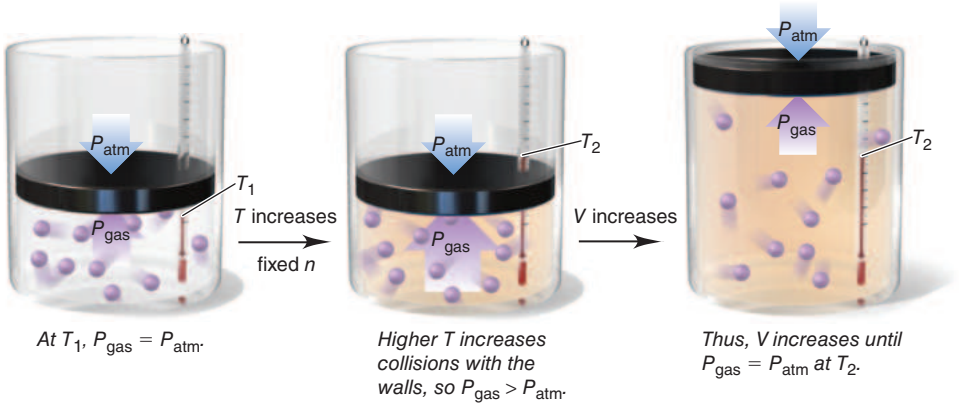


Figure 5.18 A molecular view of Charles's law.

5. *Avogadro's law ($V \propto n$)* (Figure 5.19). At some starting amount, n_1, of gas, P_{atm} equals P_{gas}. When more gas is added from the attached tank, the amount increases to n_2. Thus, more particles hit the walls more frequently, which temporarily increases P_{gas}. As a result, the piston moves up, which increases the volume and lowers the number of collisions with the walls until P_{atm} and P_{gas} are again equal.

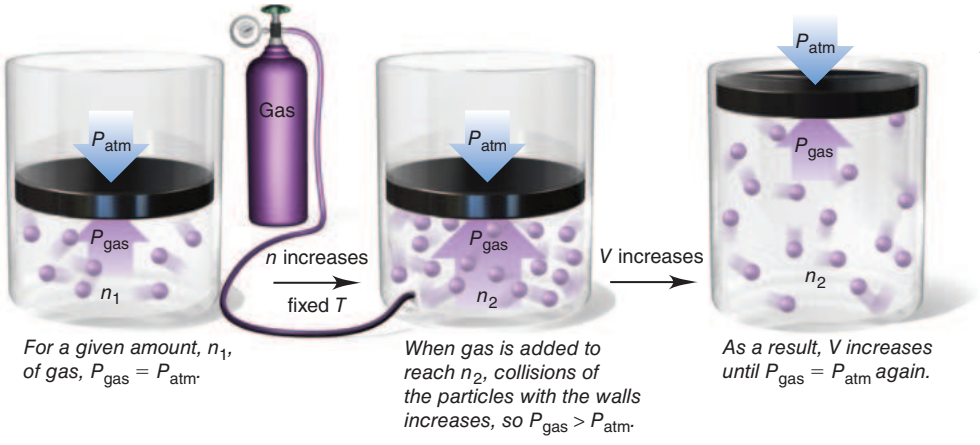

Figure 5.19 A molecular view of Avogadro's law.

The Central Importance of Kinetic Energy Recall from Chapter 1 that the kinetic energy of an object is the energy associated with its motion. It is key to explaining some implications of Avogadro's law and, most importantly, the meaning of temperature.

1. *Key implication of Avogadro's law*. As we just saw, Avogadro's law says that, at any given T and P, the volume of a gas depends only on the number of moles—that is, number of particles—in the sample. Notice that the law doesn't mention the chemical nature of the gas, so equal numbers of particles of any two gases, say O_2 and H_2, should occupy the same volume. But why don't the heavier O_2 molecules, which strike the container walls with more force than the lighter H_2 molecules, exert more

pressure and thus take up more volume? To answer this, we'll use three important relationships, the third of which you've already seen:

- *Kinetic energy*. One way to express kinetic energy mathematically is

$$E_k = \tfrac{1}{2}\,\text{mass} \times \text{speed}^2$$

  This equation means that, for a given E_k, an object's mass and speed are inversely related: *a heavy object moving slower can have the same kinetic energy as a light object moving faster*.
- *Molecular speed*. Figure 5.20 shows that, for several gases, the most probable molecular speed (top of the curve) increases as the molar mass (number in parentheses) decreases: *lighter molecules move faster, on average, than heavier molecules*.
- *Postulate 3 of the kinetic-molecular theory*. Recall that this postulate implies that, *at a given T, all gases have the same average kinetic energy*.

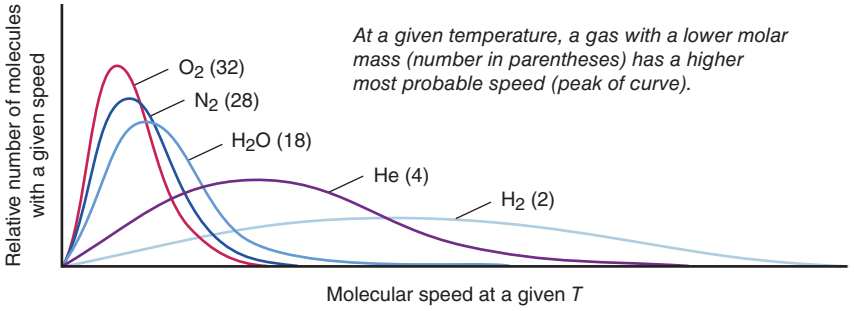

Figure 5.20 The relationship between molar mass and molecular speed.

Their higher most probable speed means that H_2 molecules collide with the walls of a container more often than O_2 molecules do, but their lower mass means that each collision has less force. Therefore, because the molecules of any gas hit the walls with the same kinetic energy, *at a given T, equimolar samples of any gases exert the same pressure (force per unit area) and, thus, occupy the same volume*.

2. *The meaning of temperature.* Closely related to these ideas is the central relation between kinetic energy and temperature. Earlier we saw that the average kinetic energy of the particles ($\overline{E_k}$) equals the absolute temperature times a constant; that is, $\overline{E_k} = c \times T$. The definitions of velocity, momentum, force, and pressure let us express this relationship by the following equation (although we won't derive it):

$$\overline{E_k} = \tfrac{3}{2}\left(\frac{R}{N_A}\right)T$$

where R is the gas constant and N_A is the symbol for Avogadro's number. This equation makes the essential point that *temperature is a* ***measure*** *of the average kinetic energy of the particles:* as T goes up, $\overline{E_k}$ increases, and as T goes down, $\overline{E_k}$ decreases. Temperature is an intensive property (Section 1.4), so it is not related to the *total* energy of motion of the particles, which depends on the size of the sample, but to the *average* energy.

Thus, for example, in the macroscopic world, we heat a beaker of water over a flame and see the mercury rise inside a thermometer in the beaker. We see this because, in the molecular world, kinetic energy transfers, in turn, from higher energy gas particles in the flame to lower energy particles in the beaker glass, the water molecules, the particles in the thermometer glass, and the atoms of mercury.

Root-Mean-Square Speed Finally, let's derive an expression for the speed of a gas particle that has the average kinetic energy of the particles in a sample. From the general expression for kinetic energy of an object,

$$E_k = \tfrac{1}{2}\text{mass} \times \text{speed}^2$$

the average kinetic energy of each particle in a large population is

$$\overline{E_k} = \tfrac{1}{2}m\overline{u^2}$$

where m is the particle's mass (atomic or molecular) and $\overline{u^2}$ is the average of the squares of the molecular speeds. Setting this expression for average kinetic energy equal to the earlier one gives

$$\tfrac{1}{2}m\overline{u^2} = \tfrac{3}{2}\left(\frac{R}{N_A}\right)T$$

Multiplying through by Avogadro's number, N_A, gives the average kinetic energy for a mole of gas particles:

$$\tfrac{1}{2}N_A\, m\overline{u^2} = \tfrac{3}{2}RT$$

Avogadro's number times the molecular mass, $N_A \times m$, is the molar mass, $\mathcal{M}$, and solving for $\overline{u^2}$, we have

$$\overline{u^2} = \frac{3RT}{\mathcal{M}}$$

The square root of $\overline{u^2}$ is the root-mean-square speed, or **rms speed (u_{rms}):** *a particle moving at this speed has the average kinetic energy.** That is, taking the square root of both sides of the previous equation gives

$$u_{rms} = \sqrt{\frac{3RT}{\mathcal{M}}} \qquad \textbf{(5.13)}$$

where R is the gas constant, T is the absolute temperature, and $\mathcal{M}$ is the molar mass. (Because we want u in m/s and R includes the joule, which has units of kg·m^2/s^2, we use the value 8.314 J/mol·K for R and express $\mathcal{M}$ in kg/mol.)

Thus, as an example, the root-mean-square speed of an O_2 molecule ($\mathcal{M} = 3.200\times10^{-2}$ kg/mol) at room temperature (20°C, or 293 K) in the air you're breathing right now is

$$u_{rms} = \sqrt{\frac{3RT}{\mathcal{M}}} = \sqrt{\frac{3(8.314\ \text{J/mol·K})(293\ \text{K})}{3.200\times10^{-2}\ \text{kg/mol}}}$$

$$= \sqrt{\frac{3(8.314\ \cancel{\text{kg}}\cdot\text{m}^2/\text{s}^2/\cancel{\text{mol}}\cdot\cancel{\text{K}})(293\ \cancel{\text{K}})}{3.200\times10^{-2}\ \cancel{\text{kg}}/\cancel{\text{mol}}}}$$

$$= 478\ \text{m/s (about 1070 mi/hr)}$$

Effusion and Diffusion

The movement of a gas into a vacuum and the movement of gases through one another are phenomena with some vital applications.

The Process of Effusion One of the early triumphs of the kinetic-molecular theory was an explanation of **effusion,** the process by which a gas escapes through a tiny hole in its container into an evacuated space. In 1846, Thomas Graham studied the effusion rate of a gas, the number of molecules escaping per unit time, and found that it was inversely proportional to the square root of the gas density. But, density is directly related to molar mass, so **Graham's law of effusion** is stated as follows: *the rate of effusion of a gas is inversely proportional to the square root of its molar mass,* or

$$\text{Rate of effusion} \propto \frac{1}{\sqrt{\mathcal{M}}}$$

* The rms speed, u_{rms}, is proportional to, but slightly higher than, the most probable speed; for an ideal gas, $u_{rms} = 1.09 \times$ average speed.

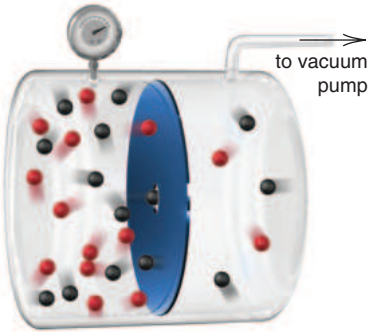

Figure 5.21 Effusion. Lighter *(black)* particles effuse faster than heavier *(red)* particles.

From Equation 5.13, we see that, at a given temperature and pressure, a gas with a lower molar mass has a greater rms speed than a gas with a higher molar mass; *since the rms speed of its atoms is higher, more atoms of the lighter gas reach the hole and escape per unit time* (Figure 5.21). At constant T, the ratio of the effusion rates of two gases, A and B, is

$$\frac{\text{Rate}_A}{\text{Rate}_B} = \frac{u_{\text{rms of A}}}{u_{\text{rms of B}}} = \frac{\sqrt{3RT/\mathcal{M}_A}}{\sqrt{3RT/\mathcal{M}_B}} = \frac{\sqrt{\mathcal{M}_B}}{\sqrt{\mathcal{M}_A}} = \sqrt{\frac{\mathcal{M}_B}{\mathcal{M}_A}} \qquad (5.14)$$

Graham's law can be used to determine the molar mass of an unknown gas. By comparing the effusion rate of gas X with that of a known gas, such as He, we can solve for the molar mass of X:

$$\frac{\text{Rate}_X}{\text{Rate}_{He}} = \sqrt{\frac{\mathcal{M}_{He}}{\mathcal{M}_X}}$$

Squaring both sides and solving for the molar mass of X gives

$$\mathcal{M}_X = \mathcal{M}_{He} \times \left(\frac{\text{rate}_{He}}{\text{rate}_X}\right)^2$$

SAMPLE PROBLEM 5.14 Applying Graham's Law of Effusion

Problem A mixture of helium (He) and methane (CH_4) is placed in an effusion apparatus. Calculate the ratio of their effusion rates.

Plan The effusion rate is inversely proportional to $\sqrt{\mathcal{M}}$, so we find the molar mass of each substance from the formula and take its square root. The inverse of the ratio of the square roots is the ratio of the effusion rates.

Solution

$$\mathcal{M} \text{ of } CH_4 = 16.04 \text{ g/mol} \qquad \mathcal{M} \text{ of He} = 4.003 \text{ g/mol}$$

Calculating the ratio of the effusion rates:

$$\frac{\text{Rate}_{He}}{\text{Rate}_{CH_4}} = \sqrt{\frac{\mathcal{M}_{CH_4}}{\mathcal{M}_{He}}} = \sqrt{\frac{16.04 \text{ g/mol}}{4.003 \text{ g/mol}}} = \sqrt{4.007} = 2.002$$

Check A ratio >1 makes sense because the lighter He should effuse faster than the heavier CH_4. Because the molar mass of CH_4 is about four times the molar mass of He, He should effuse about twice as fast as CH_4 ($\sqrt{4}$).

FOLLOW-UP PROBLEMS

5.14A If it takes 1.25 min for 0.010 mol of He to effuse, how long will it take for the same amount of ethane (C_2H_6) to effuse?

5.14B If 7.23 mL of an unknown gas effuses in the same amount of time as 13.8 mL of argon under the same conditions, what is the molar mass of the unknown gas?

SOME SIMILAR PROBLEMS 5.75, 5.76, 5.79, and 5.80

A Key Application of Effusion: Preparation of Nuclear Fuel By far the most important application of Graham's law is in the preparation of fuel for nuclear energy reactors. The process of *isotope enrichment* increases the proportion of fissionable, but rarer, ^{235}U (only 0.7% by mass of naturally occurring uranium) to the nonfissionable, more abundant ^{238}U (99.3% by mass). Because the two isotopes have identical chemical properties, they are extremely difficult to separate chemically. But, one way to separate them takes advantage of a difference in a physical property—the effusion rate of gaseous compounds. Uranium ore is treated with fluorine to yield

a gaseous mixture of $^{238}UF_6$ and $^{235}UF_6$ that is pumped through a series of chambers separated by porous barriers. Molecules of $^{235}UF_6$ are slightly lighter ($\mathcal{M}$ = 349.03) than molecules of $^{238}UF_6$ ($\mathcal{M}$ = 352.04), so they move slightly faster and effuse through each barrier 1.0043 times faster. Many passes must be made, each one increasing the fraction of $^{235}UF_6$, until the mixture obtained is 3–5% by mass $^{235}UF_6$. This process was developed during the latter years of World War II and produced enough ^{235}U for two of the world's first atomic bombs. Today, a less expensive centrifuge process is used more often. The ability to enrich uranium has become a key international concern, as more countries aspire to develop nuclear energy and nuclear arms.

The Process of Diffusion Closely related to effusion is the process of gaseous **diffusion,** the movement of one gas through another. Diffusion rates are also described generally by Graham's law:

$$\text{Rate of diffusion} \propto \frac{1}{\sqrt{\mathcal{M}}}$$

For two gases at equal pressures, such as NH_3 and HCl, moving through another gas or a mixture of gases, such as air, we find

$$\frac{\text{Rate}_{NH_3}}{\text{Rate}_{HCl}} = \sqrt{\frac{\mathcal{M}_{HCl}}{\mathcal{M}_{NH_3}}}$$

The reason for this dependence on molar mass is the same as for effusion rates: *lighter molecules have higher average speeds than heavier molecules, so they move farther in a given time.*

If gas molecules move at hundreds of meters per second (see Figure 5.14), why does it take a second or two after you open a bottle of perfume to smell it? Although convection plays an important role in this process, another reason for the time lag is that a gas particle does not travel very far before it collides with another particle (Figure 5.22). Thus, a perfume molecule travels slowly because it collides with countless molecules in the air. The presence of so many other particles means that *diffusion rates are much lower than effusion rates.* Imagine how much quicker you can walk through an empty room than through a room crowded with other moving people.

Diffusion also occurs when a gas enters a liquid (and even to a small extent a solid). However, the average distances between molecules are so much shorter in a liquid that collisions are much more frequent; thus, diffusion of a gas through

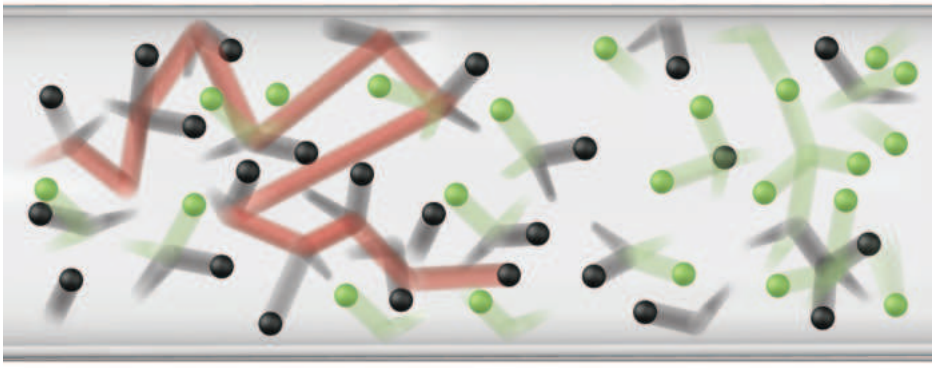

Figure 5.22 Diffusion of gases. Different gases (*black*, from the left, and *green*, from the right) move through each other in a tube and mix. For simplicity, the complex path of only one black particle is shown (in *red*). In reality, all the particles have similar paths.

a liquid is *much* slower than through a gas. Nevertheless, this type of diffusion is a vital process in biological systems, for example, in the movement of O_2 from lungs to blood.

The Chaotic World of Gases: Mean Free Path and Collision Frequency

Refinements of the basic kinetic-molecular theory provide a view into the chaotic molecular world of gases. Try to visualize an "average" N_2 molecule in the room you are in now. It is continually changing speed as it collides with other molecules—at one instant, going 2500 mi/h, and at another, standing still. But these extreme speeds are *much* less likely than the most probable one and those near it (see Figure 5.14). At 20°C and 1 atm pressure, the N_2 molecule is hurtling at an average speed of 470 m/s (rms speed= 510 m/s), or nearly 1100 mi/h!

Mean Free Path From a particle's diameter, we can obtain the **mean free path,** the average distance it travels between collisions at a given temperature and pressure. The N_2 molecule (3.7×10^{-10} m in diameter) has a mean free path of 6.6×10^{-8} m, which means it travels an average of 180 molecular diameters before smashing into a fellow traveler. (An N_2 molecule the size of a billiard ball would travel an average of about 30 ft before hitting another molecule.) Therefore, even though gas molecules are *not* points of mass, it is still valid to assume that a gas sample *is* nearly all empty space. Mean free path is a key factor in the rate of diffusion and the rate of heat flow through a gas.

Danger in a Molecular Amusement Park

To really appreciate the astounding events in the molecular world, let's use a two-dimensional analogy to compare the N_2 molecule moving in air at 1 atm with a bumper car you are driving in an enormous amusement park ride. To match the collision frequency of the N_2 molecule, you would need to be traveling 2.8 billion mi/s (4.5 billion km/s, much faster than the speed of light!) and would smash into another bumper car every 700 yd (640 m).

Collision Frequency Divide the most probable speed (meters per second) by the mean free path (meters per collision) and you obtain the **collision frequency,** the average number of collisions per second that each particle undergoes, whether with another particle or with the container. As you can see, the N_2 molecule experiences, on average, an enormous number of collisions every second:

$$\text{Collision frequency} = \frac{4.7\times10^{2}\ \text{m/s}}{6.6\times10^{-8}\ \text{m/collision}} = 7.0\times10^{9}\ \text{collision/s}$$

Distribution of speed (and kinetic energy) and collision frequency are essential ideas for understanding the speed of a reaction, as you'll see in Chapter 16. As the Chemical Connections essay shows, many of the concepts we've discussed so far apply directly to our planet's atmosphere.

Summary of Section 5.5

- The kinetic-molecular theory postulates that gas particles have no volume, move in straight-line paths between elastic (energy-conserving) collisions, and have average kinetic energies proportional to the absolute temperature of the gas.
- This theory explains the gas laws in terms of changes in distances between particles and the container walls, changes in molecular speed, and the energy of collisions.
- Temperature is a measure of the average kinetic energy of the particles.
- Effusion and diffusion rates are *inversely* proportional to the square root of the molar mass (Graham's law) because they are *directly* proportional to molecular speed.
- Molecular motion is characterized by a temperature-dependent, most probable speed (within a range of speeds), which affects mean free path and collision frequency.
- The atmosphere is a complex mixture of gases that exhibits variations in pressure and temperature with altitude. High temperatures in the upper atmosphere result from absorption of high-energy solar radiation. The lower atmosphere has a uniform composition as a result of convective mixing.

How the Gas Laws Apply to Earth's Atmosphere

An **atmosphere** is the envelope of gases that extends continuously from a planet's surface outward, thinning gradually until it is identical with outer space. A sample of clean, dry air at sea level on Earth contains 18 gases (Table B5.1). Under standard conditions, they behave nearly ideally, so volume percent equals mole percent (Avogadro's law), and the mole fraction of a component relates directly to its partial pressure (Dalton's law). Let's see how the gas laws and kinetic-molecular theory apply to our atmosphere, first with regard to variations in pressure and temperature, and then as explanations of some very familiar phenomena.

The Smooth Variation in Pressure with Altitude

Because gases are compressible (Boyle's law), the pressure of the atmosphere *increases* smoothly as we approach Earth's surface, with a more rapid increase at lower altitudes (Figure B5.1, *left*). No boundary delineates the beginning of the atmosphere from the end of outer space, but the densities and compositions are identical at an altitude of about 10,000 km (6000 mi). Yet, about 99% of the atmosphere's mass lies within 30 km (almost 19 mi) of the surface, and 75% lies within the lowest 11 km (almost 7 mi).

Table B5.1 Composition of Clean, Dry Air at Sea Level

Component	Mole Fraction
Nitrogen (N_2)	0.78084
Oxygen (O_2)	0.20946
Argon (Ar)	0.00934
Carbon dioxide (CO_2)	0.00040
Neon (Ne)	1.818×10^{-5}
Helium (He)	5.24×10^{-6}
Methane (CH_4)	2×10^{-6}
Krypton (Kr)	1.14×10^{-6}
Hydrogen (H_2)	5×10^{-7}
Dinitrogen monoxide (N_2O)	5×10^{-7}
Carbon monoxide (CO)	1×10^{-7}
Xenon (Xe)	8×10^{-8}
Ozone (O_3)	2×10^{-8}
Ammonia (NH_3)	6×10^{-9}
Nitrogen dioxide (NO_2)	6×10^{-9}
Nitrogen monoxide (NO)	6×10^{-10}
Sulfur dioxide (SO_2)	2×10^{-10}
Hydrogen sulfide (H_2S)	2×10^{-10}

The Zig-Zag Variation in Temperature with Altitude

Unlike pressure, temperature does *not* change smoothly with altitude above Earth's surface. The atmosphere is classified into regions based on the direction of temperature change, and we'll start at the surface (Figure B5.1, *right*).

1. *The troposphere.* In the troposphere, which extends from the surface to between 7 km (23,000 ft) at the poles and 17 km (60,000 ft) at the equator, the temperature *drops* 7°C per kilometer to −55°C (218 K). This region contains about 80% of the total mass of the atmosphere, with 50% of the mass in the lower 5.6 km (18,500 ft). All weather occurs in this region, and nearly all, except supersonic, aircraft fly here.

(continued)

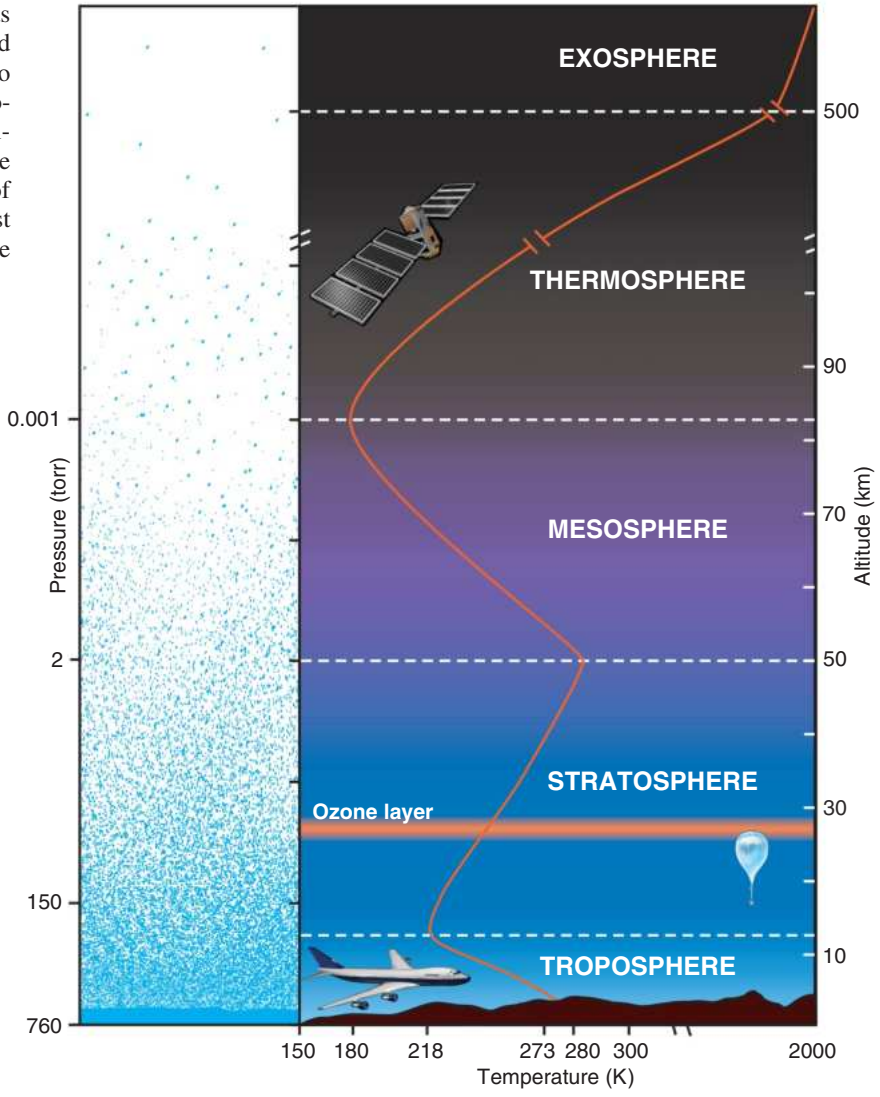

Figure B5.1 Variations in pressure and temperature with altitude in Earth's atmosphere.

2. *The stratosphere and the ozone layer.* In the stratosphere, the temperature *rises* from −55°C to about 7°C (280 K) at 50 km. This rise is due to a variety of complex reactions, mostly involving ozone, and is caused by the absorption of solar radiation. Most high-energy radiation is absorbed by upper levels of the atmosphere, but some that reaches the stratosphere breaks O_2 into O atoms. The energetic O atoms collide with more O_2 to form ozone (O_3), another molecular form of oxygen:

$$O_2(g) \xrightarrow{\text{high-energy radiation}} 2O(g)$$

$$M + O(g) + O_2(g) \longrightarrow O_3(g) + M + \textit{heat}$$

where M is any particle that can carry away excess energy. This reaction releases heat, which is why stratospheric temperatures increase with altitude. Over 90% of atmospheric ozone remains in a thin layer within the stratosphere, its thickness varying both geographically (greatest at the poles) and seasonally (greatest in spring in the northern hemisphere and in fall in the southern). Stratospheric ozone is vital to life because it absorbs over 95% of the harmful ultraviolet (UV) solar radiation that would otherwise reach the surface. In Chapter 16, we'll discuss the destructive effect of certain industrial chemicals on the ozone layer.

3. *The mesosphere.* In the mesosphere, the temperature *drops* again to −93°C (180 K) at around 80 km.

4. *The outer atmosphere.* Within the *thermosphere,* which extends to around 500 km, the temperature *rises* again, but varies between 700 and 2000 K, depending on the intensity of solar radiation and sunspot activity. The *exosphere,* the outermost region, maintains these temperatures and merges with outer space.

What does it actually mean to have a temperature of 2000 K at 500 km (300 mi) above Earth's surface? Would a piece of iron (melting point = 1808 K) glow red-hot within a minute or so and melt in the thermosphere, as it does if heated to 2000 K in the troposphere? The answer involves the relation between temperature and the time it takes to transfer kinetic energy. Our use of the words "hot" and "cold" refers to measurements near the surface. There, the collision frequency of gas particles with a thermometer is enormous, and so the transfer of their kinetic energy is very fast. But, at an altitude of 500 km, where the density of gas particles is a million times *less,* collision frequency is extremely low, and a thermometer, or any object, experiences *very slow transfer of kinetic energy.* Thus, the object would not become "hot" in the usual sense in any reasonable time. But the high-energy solar radiation that *is* transferred to the few particles present in these regions makes their average kinetic energy extremely high, as indicated by the high absolute temperature.

Convection in the Lower Atmosphere

Why must you take more breaths per minute on a high mountaintop than at sea level? Because at the higher elevation, there is a smaller *amount* of O_2 in each breath. However, the *proportion* (mole percent) of O_2 throughout the lower atmosphere remains about 21%. This uniform composition arises from *vertical (convective) mixing,* and the gas laws explain how it occurs.

Let's follow an air mass from ground level, as solar heating of Earth's surface warms it. The warmer air mass expands (Charles's law), which makes it less dense, so it rises. As it does so, the pressure on it decreases, making it expand further (Boyle's law). Pushing against the surrounding air requires energy, so the temperature of the air mass decreases and thus the air mass shrinks slightly (Charles's law). But, as its temperature drops, its water vapor condenses (or solidifies), and these changes of state release heat; therefore, the air mass becomes warmer and rises further. Meanwhile, the cooler, and thus denser, air that was above it sinks, becomes warmer through contact with the surface, and goes through the same process as the first air mass. As a result of this vertical mixing, the composition of the lower atmosphere remains uniform.

Warm air rising from the ground, called a *thermal,* is used by soaring birds and glider pilots to stay aloft. Convection helps clean the air in urban areas, because the rising air carries up pollutants, which are dispersed by winds. Under certain conditions, however, a warm air mass remains stationary over a cool one. The resulting *temperature inversion* blocks normal convection, and harmful pollutants build up, causing severe health problems.

Problems

B5.1 Suggest a reason why supersonic aircraft are kept well below their maximum speeds until they reach their highest altitudes.

B5.2 Gases behave nearly ideally under Earth's conditions. Elsewhere in the Solar System, however, conditions are very different. On which would you expect atmospheric gases to deviate most from ideal behavior, Saturn (4×10^6 atm and 130 K) or Venus (90 atm and 730 K)? Explain.

B5.3 What is the volume percent and partial pressure (in torr) of argon in a sample of dry air at sea level?

B5.4 Earth's atmosphere is estimated to have a mass of 5.14×10^{15} t (1 t = 1000 kg).
(a) If the average molar mass of air is 28.8 g/mol, how many moles of gas are in the atmosphere?
(b) How many liters would the atmosphere occupy at 25°C and 1 atm?

5.6 REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR

A fundamental principle of science is that simpler models are more useful than complex ones, as long as they explain the data. With only a few postulates, the kinetic-molecular theory explains the behavior of most gases under ordinary conditions of temperature and pressure. But, two of the postulates are useful approximations that do not reflect reality:

1. *Gas particles are **not** points of mass with zero volume* but have volumes determined by the sizes of their atoms and the lengths and directions of their bonds.
2. *Attractive and repulsive forces **do** exist among gas particles* because atoms contain charged subatomic particles and many substances are polar. (As you'll see in Chapter 12, such forces lead to changes of physical state.)

These two features cause deviations from ideal behavior under *extreme conditions of low temperature and high pressure.* These deviations mean that we must alter the simple model and the ideal gas law to predict the behavior of real gases.

Effects of Extreme Conditions on Gas Behavior

At ordinary conditions—relatively high temperatures and low pressures—most real gases exhibit nearly ideal behavior. Yet, even at STP (0°C and 1 atm), gases deviate *slightly* from ideal behavior. Table 5.3 shows that the standard molar volumes of several gases, when measured to five significant figures, do not equal the ideal value. Note that the deviations increase as the boiling point rises.

The phenomena that cause slight deviations under standard conditions exert more influence as temperature decreases and pressure increases. Figure 5.23 shows a plot of *PV/RT* versus external pressure (P_{ext}) for 1 mol of several real gases and an ideal gas. The *PV/RT* values range from normal (at $P_{ext} = 1$ atm, $PV/RT = 1$) to very high (at $P_{ext} \approx 1000$ atm, $PV/RT \approx 1.6$ to 2.3). For the *ideal* gas, *PV/RT* is 1 at any P_{ext}.

Table 5.3 Molar Volume of Some Common Gases at STP (0°C and 1 atm)

Gas	Molar Volume (L/mol)	Boiling Point (°C)
He	22.435	−268.9
H_2	22.432	−252.8
Ne	22.422	−246.1
Ideal gas	**22.414**	—
Ar	22.397	−185.9
N_2	22.396	−195.8
O_2	22.390	−183.0
CO	22.388	−191.5
Cl_2	22.184	−34.0
NH_3	22.079	−33.4

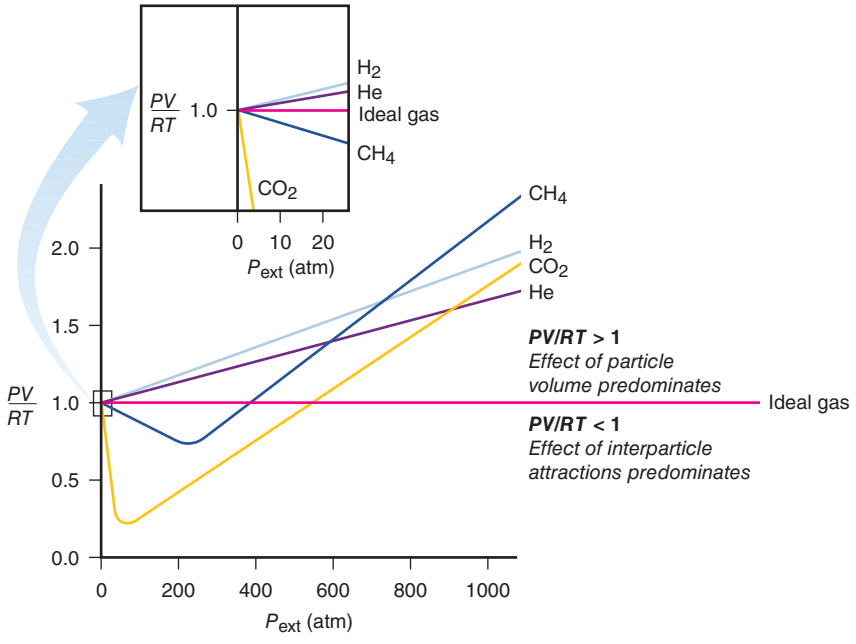

Figure 5.23 Deviations from ideal behavior with increasing external pressure. The horizontal line shows that, for 1 mol of ideal gas, $PV/RT = 1$ at all P_{ext}. At very high P_{ext}, real gases deviate significantly from ideal behavior, but small deviations appear even at ordinary pressures (expanded portion).

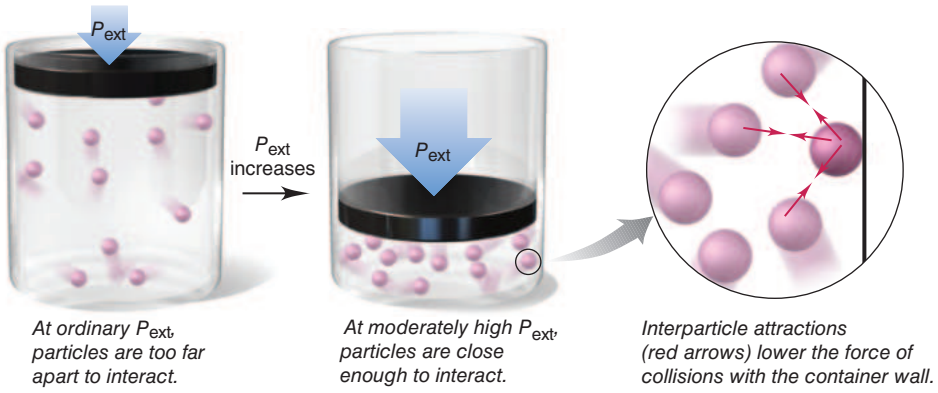
Figure 5.24 The effect of interparticle attractions on measured gas pressure.



The *PV/RT* curve for methane (CH_4) is typical of most gases: it decreases *below* the ideal value at moderately high P_{ext} and then rises *above* the ideal value as P_{ext} increases to very high values. This shape arises from two overlapping effects:

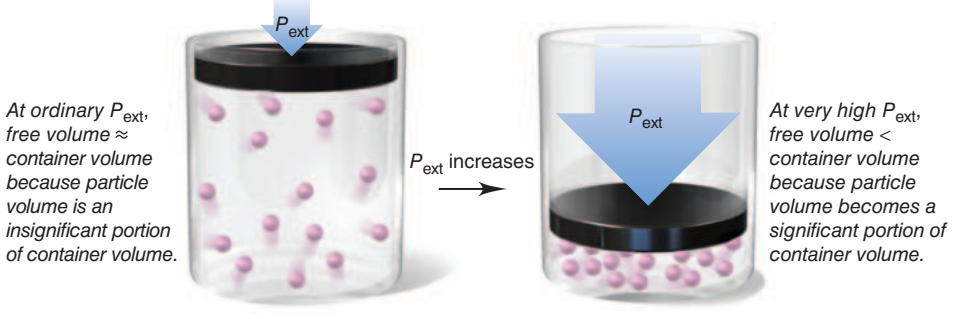
- At moderately high P_{ext}, *PV/RT* values are lower than ideal values (less than 1) because of *interparticle attractions.*
- At very high P_{ext}, *PV/RT* values are greater than ideal values (more than 1) because of *particle volume.*

Let's examine these effects on the molecular level:

1. *Effect of interparticle attractions.* Interparticle attractions occur between separate atoms or molecules and are caused by imbalances in electron distributions. They are important only over *very* short distances and are *much* weaker than the covalent bonding forces that hold a molecule together. At normal P_{ext}, the spaces between the particles are so large that attractions are negligible and the gas behaves nearly ideally. As P_{ext} rises, the volume of the sample decreases and the particles get closer together, so interparticle attractions have a greater effect. As a particle approaches the container wall under these higher pressures, nearby particles attract it, which lessens the force of its impact (Figure 5.24). *Repeated throughout the sample, this effect results in decreased gas pressure and, thus, a smaller numerator in PV/RT.* Similarly, lowering the temperature slows the particles, so they attract each other for a longer time. (As you'll see in Chapter 12, given a low enough temperature, the interparticle attractions cause the gas particles to lose enough kinetic energy that they condense to a liquid.)

2. *Effect of particle volume.* At normal P_{ext}, the space between particles (free volume) is enormous compared with the volume of the particles *themselves* (particle volume); thus, the free volume is essentially equal to *V*, the container volume in *PV/RT*. At *moderately* high P_{ext} and as free volume decreases, the particle volume makes up an increasing proportion of the container volume (Figure 5.25). At *extremely* high pressures, the space taken up by the particles themselves makes the free volume significantly *less* than the container volume. Nevertheless, we continue to use the container volume for *V* in *PV/RT,* which causes the numerator, and thus the ratio, to become artificially high. This particle volume effect increases as P_{ext} increases, eventually outweighing the effect of interparticle attractions and causing *PV/RT* to rise above the ideal value.

Figure 5.25 The effect of particle volume on measured gas volume.



In Figure 5.23, note that the H_2 and He curves do not show the typical dip at moderate pressures. These gases consist of particles with such weak interparticle attractions that the particle volume effect predominates at all pressures.

The van der Waals Equation: Adjusting the Ideal Gas Law

To describe real gas behavior more accurately, we need to adjust the ideal gas equation in two ways:

1. Adjust *P up* by adding a factor that accounts for interparticle attractions.
2. Adjust *V down* by subtracting a factor that accounts for particle volume.

In 1873, Johannes van der Waals revised the ideal gas equation to account for the behavior of real gases. The **van der Waals equation** for n moles of a real gas is

$$\left(P + \frac{n^2a}{V^2}\right)(V - nb) = nRT \qquad \textbf{(5.15)}$$

adjusts P up; adjusts V down

where P is the measured pressure, V is the known container volume, n and T have their usual meanings, and a and b are **van der Waals constants,** experimentally determined and specific for a given gas (Table 5.4). The constant a depends on the number and distribution of electrons, which relates to the complexity of a particle and the strength of its interparticle attractions. The constant b relates to particle volume. For instance, CO_2 is both more complex and larger than H_2, and the values of their constants reflect this.

Here is a typical application of the van der Waals equation. A 1.98-L vessel contains 215 g (4.89 mol) of dry ice. After standing at 26°C (299 K), the $CO_2(s)$ changes to $CO_2(g)$. The pressure is measured (P_{real}) and then calculated by the ideal gas law (P_{IGL}) and, using the appropriate values of a and b, by the van der Waals equation (P_{VDW}). The results are revealing:

$$P_{real} = 44.8 \text{ atm} \qquad P_{IGL} = 60.6 \text{ atm} \qquad P_{VDW} = 45.9 \text{ atm}$$

Comparing the real value with each calculated value shows that P_{IGL} is 35.3% greater than P_{real}, but P_{VDW} is only 2.5% greater than P_{real}. At these conditions, CO_2 deviates so much from ideal behavior that the ideal gas law is not very useful.

A key point to realize: According to kinetic-molecular theory, the constants a and b are zero for an ideal gas because the gas particles do not attract each other and have no volume. Yet, even in a real gas at ordinary pressures, the particles are very far apart. This large average interparticle distance has two consequences:

- Attractive forces are miniscule, so $P + \frac{n^2a}{V^2} \approx P$.
- The particle volume is a minute fraction of the container volume, so $V - nb \approx V$.

Therefore, *at ordinary conditions, the van der Waals equation* ***becomes*** *the ideal gas equation.*

Table 5.4 Van der Waals Constants for Some Common Gases

Gas	$a\left(\frac{\text{atm·L}^2}{\text{mol}^2}\right)$	$b\left(\frac{\text{L}}{\text{mol}}\right)$
He	0.034	0.0237
Ne	0.211	0.0171
Ar	1.35	0.0322
Kr	2.32	0.0398
Xe	4.19	0.0511
H_2	0.244	0.0266
N_2	1.39	0.0391
O_2	1.36	0.0318
Cl_2	6.49	0.0562
CH_4	2.25	0.0428
CO	1.45	0.0395
CO_2	3.59	0.0427
NH_3	4.17	0.0371
H_2O	5.46	0.0305

Summary of Section 5.6

- At very high P or low T, all gases deviate significantly from ideal behavior.
- As external pressure increases, most real gases exhibit first a lower and then a higher PV/RT; for 1 mol of an ideal gas, this ratio remains constant at 1.
- The deviations from ideal behavior are due to (1) attractions between particles, which lower the pressure (and decrease PV/RT), and (2) the volume of the particles themselves, which takes up an increasingly larger fraction of the container volume (and increases PV/RT).
- The van der Waals equation includes constants specific for a given gas to correct for deviations from ideal behavior. At ordinary P and T, the van der Waals equation reduces to the ideal gas equation.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How gases differ in their macroscopic properties from liquids and solids (§5.1)
2. The meaning of pressure and the operation of a barometer and a manometer (§5.2)
3. The relations among gas variables expressed by Boyle's, Charles's, and Avogadro's laws (§5.3)
4. How the individual gas laws are incorporated into the ideal gas law (§5.3)
5. How the ideal gas law can be used to study gas density, molar mass, and amounts of gases in reactions (§5.4)
6. The relation between the density and the temperature of a gas (§5.4)
7. The meaning of Dalton's law and the relation between partial pressure and mole fraction of a gas; how Dalton's law applies to collecting a gas over water (§5.4)
8. How the postulates of the kinetic-molecular theory are applied to explain the origin of pressure and the gas laws (§5.5)
9. The relations among molecular speed, average kinetic energy, and temperature (§5.5)
10. The meanings of *effusion* and *diffusion* and how their rates are related to molar mass (§5.5)
11. The relations among mean free path, molecular speed, and collision frequency (§5.5)
12. Why intermolecular attractions and molecular volume cause gases to deviate from ideal behavior at low temperatures and high pressures (§5.6)
13. How the van der Waals equation corrects the ideal gas law for extreme conditions (§5.6)

Master These Skills

1. Interconverting among the units of pressure (atm, mmHg, torr, pascal, lb/in^2) (SP 5.1)
2. Reducing the ideal gas law to the individual gas laws (SPs 5.2–5.6)
3. Applying gas laws to choose the correct chemical equation (SP 5.7)
4. Rearranging the ideal gas law to calculate gas density (SP 5.8) and molar mass of a volatile liquid (SP 5.9)
5. Calculating the mole fraction and the partial pressure of a gas (SP 5.10)
6. Using the vapor pressure of water to correct for the amount of a gas collected over water (SP 5.11)
7. Applying stoichiometry and gas laws to calculate amounts of reactants and products (SPs 5.12, 5.13)
8. Using Graham's law to solve problems of gaseous effusion (SP 5.14)

Key Equations and Relationships

Page numbers appear in parentheses.

5.1 Expressing the volume-pressure relationship (Boyle's law) (205):

$$V \propto \frac{1}{P} \quad \text{or} \quad PV = \text{constant} \quad [T \text{ and } n \text{ fixed}]$$

5.2 Expressing the volume-temperature relationship (Charles's law) (207):

$$V \propto T \quad \text{or} \quad \frac{V}{T} = \text{constant} \quad [P \text{ and } n \text{ fixed}]$$

5.3 Expressing the pressure-temperature relationship (Amontons's law) (207):

$$P \propto T \quad \text{or} \quad \frac{P}{T} = \text{constant} \quad [V \text{ and } n \text{ fixed}]$$

5.4 Expressing the volume-amount relationship (Avogadro's law) (208):

$$V \propto n \quad \text{or} \quad \frac{V}{n} = \text{constant} \quad [P \text{ and } T \text{ fixed}]$$

5.5 Defining standard temperature and pressure (209):

STP: 0°C (273.15 K) and 1 atm (760 torr)

5.6 Defining the volume of 1 mol of an ideal gas at STP (209):

Standard molar volume = 22.4141 L = 22.4 L [3 sf]

5.7 Relating volume to pressure, temperature, and amount (ideal gas law) (209):

$$PV = nRT \qquad \text{and} \qquad \frac{P_1V_1}{n_1T_1} = \frac{P_2V_2}{n_2T_2}$$

5.8 Calculating the value of R (210):

$$R = \frac{PV}{nT} = \frac{1\text{ atm} \times 22.4141\text{ L}}{1\text{ mol} \times 273.15\text{ K}}$$

$$= 0.082058\ \frac{\text{atm·L}}{\text{mol·K}} = 0.0821\ \frac{\text{atm·L}}{\text{mol·K}} \qquad [3\text{ sf}]$$

5.9 Rearranging the ideal gas law to find gas density (216):

$$PV = \frac{m}{\mathcal{M}}RT \qquad \text{so} \qquad \frac{m}{V} = d = \frac{P \times \mathcal{M}}{RT}$$

5.10 Rearranging the ideal gas law to find molar mass (218):

$$n = \frac{m}{\mathcal{M}} = \frac{PV}{RT} \qquad \text{so} \qquad \mathcal{M} = \frac{mRT}{PV}$$

5.11 Relating the total pressure of a gas mixture to the partial pressures of the components (Dalton's law of partial pressures) (219):

$$P_{\text{total}} = P_1 + P_2 + P_3 + \cdots$$

5.12 Relating partial pressure to mole fraction (219):

$$P_A = X_A \times P_{\text{total}}$$

5.13 Defining rms speed as a function of molar mass and temperature (229):

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}}$$

5.14 Applying Graham's law of effusion (230):

$$\frac{\text{Rate}_A}{\text{Rate}_B} = \frac{\sqrt{\mathcal{M}_B}}{\sqrt{\mathcal{M}_A}} = \sqrt{\frac{\mathcal{M}_B}{\mathcal{M}_A}}$$

5.15 Applying the van der Waals equation to find the pressure or volume of a gas under extreme conditions (237):

$$\left(P + \frac{n^2a}{V^2}\right)(V - nb) = nRT$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

5.1A $P_{CO_2}\text{ (torr)} = (753.6\text{ mmHg} - 174.0\text{ mmHg}) \times \dfrac{1\text{ torr}}{1\text{ mmHg}}$

$$= 579.6\text{ torr}$$

$$P_{CO_2}\text{(Pa)} = 579.6\text{ torr} \times \frac{1\text{ atm}}{760\text{ torr}} \times \frac{1.01325\times10^5\text{ Pa}}{1\text{ atm}}$$

$$= 7.727\times10^4\text{ Pa}$$

$$P_{CO_2}\text{ (lb/in}^2\text{)} = 579.6\text{ torr} \times \frac{1\text{ atm}}{760\text{ torr}} \times \frac{14.7\text{ lb/in}^2}{1\text{ atm}}$$

$$= 11.2\text{ lb/in}^2$$

5.1B $P_{\text{atm}}\text{ (torr)} = 0.9475\text{ atm} \times \dfrac{760\text{ torr}}{1\text{ atm}} = 720.1\text{ torr}$

$$P_{CO_2}\text{(mmHg)} = (720.1\text{ torr} + 25.8\text{ torr}) \times \frac{1\text{ mmHg}}{1\text{ torr}}$$

$$= 745.9\text{ mmHg}$$

$$P_{CO_2}\text{(Pa)} = 745.9\text{ mmHg} \times \frac{1\text{ atm}}{760\text{ mmHg}} \times \frac{1.01325\times10^5\text{ Pa}}{1\text{ atm}}$$

$$= 9.945\times10^4\text{ Pa}$$

$$P_{CO_2}\text{ (lb/in}^2\text{)} = 745.9\text{ mmHg} \times \frac{1\text{ atm}}{760\text{ mmHg}} \times \frac{14.7\text{ lb/in}^2}{1\text{ atm}}$$

$$= 14.4\text{ lb/in}^2$$

5.2A $P_2 = P_1 \times \dfrac{V_1}{V_2}$

$$P_2\text{ (atm)} = 0.871\text{ atm} \times \frac{105\text{ mL}}{352\text{ mL}} = 0.260\text{ atm}$$

$$P_2\text{ (kPa)} = 0.260\text{ atm} \times \frac{101.325\text{ kPa}}{1\text{ atm}} = 26.3\text{ kPa}$$

5.2B $P_2\text{ (atm)} = 745\text{ mmHg} \times \dfrac{1\text{ atm}}{760\text{ mmHg}} = 0.980\text{ atm}$

$$V_2 = V_1 \times \frac{P_1}{P_2}$$

$$V_2\text{ (L)} = 651\text{ L} \times \frac{122\text{ atm}}{0.980\text{ atm}} = 8.10\times10^4\text{ L}$$

5.3A $P_1\text{ (torr)} = 0.991\text{ atm} \times \dfrac{760\text{ torr}}{1\text{ atm}} = 753\text{ torr}$

$$P_2 = P_1 \times \frac{T_2}{T_1} = 753\text{ torr} \times \frac{373\text{ K}}{296\text{ K}} = 949\text{ torr}$$

$P_2 < 1.00\times10^3$ torr, so the safety valve will not open.

5.3B $T_2\text{ (K)} = T_1 \times \dfrac{V_2}{V_1} = 313\text{ K} \times \dfrac{28.6\text{ L}}{32.5\text{ L}} = 275\text{ K}$

$T_2\text{ (°C)} = 275\text{ K} - 273.15 = 2\text{°C}$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

5.4A $P_2\ (\text{torr}) = 793\ \text{torr} \times \dfrac{35.0\ \text{g} - 5.0\ \text{g}}{35.0\ \text{g}} = 680.\ \text{torr}$

(There is no need to convert mass to moles because the ratio of masses equals the ratio of moles.)

5.4B $\text{Amount (mol) of } N_2 = 1.26\ \text{g } N_2 \times \dfrac{1\ \text{mol } N_2}{28.02\ \text{g } N_2}$

$= 0.0450\ \text{mol } N_2$

$\text{Amount (mol) of He} = 1.26\ \text{g He} \times \dfrac{1\ \text{mol He}}{4.003\ \text{g He}} = 0.315\ \text{mol He}$

$V_2 = V_1 \times \dfrac{n_2}{n_1} = 1.12\ \text{L} \times \dfrac{0.0450\ \text{mol} + 0.315\ \text{mol}}{0.0450\ \text{mol}}$

$= 8.96\ \text{L}$

5.5A

$P_2\ (\text{mmHg}) = P_1 \times \dfrac{V_1 T_2}{V_2 T_1} = 755\ \text{mmHg} \times \dfrac{(2.55\ \text{L})(291\ \text{K})}{(4.10\ \text{L})(296\ \text{K})}$

$= 462\ \text{mmHg}$

5.5B $V_2\ (\text{L}) = V_1 \times \dfrac{P_1 T_2}{P_2 T_1} = 2.2\ \text{L} \times \dfrac{(0.980\ \text{atm})(294\ \text{K})}{(1.40\ \text{atm})(301\ \text{K})}$

$= 1.5\ \text{L}$

5.6A $n = \dfrac{PV}{RT} = \dfrac{1.37\ \text{atm} \times 438\ \text{L}}{0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 294\ \text{K}} = 24.9\ \text{mol } O_2$

$\text{Mass (g) of } O_2 = 24.9\ \text{mol } O_2 \times \dfrac{32.00\ \text{g } O_2}{1\ \text{mol } O_2} = 7.97{\times}10^2\ \text{g } O_2$

5.6B

$\text{Amount (mol) of He} = 3950\ \text{kg He} \times \dfrac{1000\ \text{g}}{1\ \text{kg}} \times \dfrac{1\ \text{mol He}}{4.003\ \text{g He}}$

$= 9.87{\times}10^5\ \text{mol He}$

$V = \dfrac{nRT}{P} = \dfrac{9.87{\times}10^5\ \text{mol} \times 0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 293\ \text{K}}{731\ \text{mmHg} \times \dfrac{1\ \text{atm}}{760\ \text{mmHg}}}$

$= 2.47{\times}10^7\ \text{L}$

5.7A The balanced equation is $2\text{CD}(g) \longrightarrow \text{C}_2(g) + \text{D}_2(g)$, so n does not change. Therefore, given constant P, the temperature, T, must double: $T_1 = -73°\text{C} + 273.15 = 200\ \text{K}$; so $T_2 = 400\ \text{K}$, or $400\ \text{K} - 273.15 = 127°\text{C}$.

5.7B $T_1 = 199°\text{C} + 273.15 = 472\ \text{K}$

$T_2 = -155°\text{C} + 273.15 = 118\ \text{K}$

The temperature has been reduced by $\frac{1}{4}$; if n were constant, V would also be reduced by $\frac{1}{4}$. But, since V has been halved, n must be doubled. The number of moles of gas doubles (from 2 mol to 4 mol) in equation (2).

5.8A $d\ (\text{at } 0°\text{C and } 380\ \text{torr}) = \dfrac{\dfrac{380\ \text{torr}}{760\ \text{torr/atm}} \times 44.01\ \text{g/mol}}{0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 273\ \text{K}}$

$= 0.982\ \text{g/L}$

The density is lower at the smaller P because V is larger. In this case, d is lowered by one-half because P is one-half as much.

5.8B $d\ (\text{at } 24°\text{C and } 0.950\ \text{atm}) = \dfrac{0.950\ \text{atm} \times 46.01\ \text{g/mol}}{0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 297\ \text{K}}$

$= 1.79\ \text{g/L}$

NO_2 is more dense than dry air.

5.9A

$$\mathcal{M} = \frac{(68.697\ \text{g} - 68.322\ \text{g}) \times 0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times (273.15 + 95.0)\ \text{K}}{\dfrac{740.\ \text{torr}}{760\ \text{torr/atm}} \times \dfrac{149\ \text{mL}}{1000\ \text{mL/L}}}$$

$= 78.1\ \text{g/mol}$

5.9B

$$\mathcal{M} = \frac{(82.786\ \text{g} - 82.561\ \text{g}) \times 0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times (273.15 + 22)\ \text{K}}{\dfrac{733\ \text{mmHg}}{760\ \text{mmHg/atm}} \times \dfrac{350.\ \text{mL}}{1000\ \text{mL/L}}}$$

$= 16.1\ \text{g/mol}$

This is the molar mass of CH_4.

5.10A

$$n_{\text{total}} = \left(5.50\ \text{g He} \times \frac{1\ \text{mol He}}{4.003\ \text{g He}}\right) + \left(15.0\ \text{g Ne} \times \frac{1\ \text{mol Ne}}{20.18\ \text{g Ne}}\right) + \left(35.0\ \text{g Kr} \times \frac{1\ \text{mol Kr}}{83.80\ \text{g Kr}}\right)$$

$= 2.53\ \text{mol}$

$$P_{\text{He}} = \left(\frac{5.50\ \text{g He} \times \dfrac{1\ \text{mol He}}{4.003\ \text{g He}}}{2.53\ \text{mol}}\right) \times 1\ \text{atm} = 0.543\ \text{atm}$$

$P_{\text{Ne}} = 0.294\ \text{atm} \qquad P_{\text{Kr}} = 0.165\ \text{atm}$

5.10B $X_{\text{He}} = \dfrac{P_{\text{He}}}{P_{\text{total}}} = \dfrac{143\ \text{atm}}{204\ \text{atm}} = 0.701$

$\text{Mole \% He} = 0.701 \times 100 = 70.1\%$

5.11A $P_{H_2} = 752\ \text{torr} - 13.6\ \text{torr} = 738\ \text{torr}$

$$\text{Mass (g) of } H_2 = \left(\frac{\dfrac{738\ \text{torr}}{760\ \text{torr/atm}} \times 1.495\ \text{L}}{0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 289\ \text{K}}\right) \times \frac{2.016\ \text{g } H_2}{1\ \text{mol } H_2}$$

$= 0.123\ \text{g } H_2$

5.11B $P_{H_2} = 748\ \text{torr} - 17.5\ \text{torr} = 730.\ \text{torr}$

$$\text{Mass (g) of } H_2 = \left(\frac{\dfrac{730.\ \text{torr}}{760\ \text{torr/atm}} \times 0.307\ \text{L}}{0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 293\ \text{K}}\right) \times \frac{32.00\ \text{g } O_2}{1\ \text{mol } O_2}$$

$= 0.392\ \text{g } O_2$

5.12A $H_2SO_4(aq) + 2NaCl(s) \longrightarrow Na_2SO_4(aq) + 2HCl(g)$

$$n_{HCl} = 0.117 \text{ kg NaCl} \times \frac{10^3 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol NaCl}}{58.44 \text{ g NaCl}} \times \frac{2 \text{ mol HCl}}{2 \text{ mol NaCl}}$$
$$= 2.00 \text{ mol HCl}$$

$$\text{At STP, } V \text{ (mL)} = 2.00 \text{ mol} \times \frac{22.4 \text{ L}}{1 \text{ mol}} \times \frac{10^3 \text{ mL}}{1 \text{ L}}$$
$$= 4.48 \times 10^4 \text{ mL}$$

5.12B $2LiOH(s) + CO_2(g) \longrightarrow Li_2CO_3(s) + H_2O(l)$

$$n_{CO_2} = \frac{0.942 \text{ atm} \times 215 \text{ L}}{0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 296 \text{ K}}$$
$$= 8.33 \text{ mol } CO_2$$

$$\text{Mass (g) of LiOH} = 8.33 \text{ mol } CO_2 \times \frac{2 \text{ mol LiOH}}{1 \text{ mol } CO_2} \times \frac{23.95 \text{ g LiOH}}{1 \text{ mol LiOH}}$$
$$= 399 \text{ g LiOH}$$

5.13A $NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$

$n_{NH_3} = 0.187$ mol and $n_{HCl} = 0.0522$ mol; thus, HCl is the limiting reactant.

n_{NH_3} after reaction

$$= 0.187 \text{ mol } NH_3 - \left(0.0522 \text{ mol HCl} \times \frac{1 \text{ mol } NH_3}{1 \text{ mol HCl}}\right)$$
$$= 0.135 \text{ mol } NH_3$$

$$P = \frac{0.135 \text{ mol} \times 0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 295 \text{ K}}{10.0 \text{ L}} = 0.327 \text{ atm}$$

5.13B $I_2(s) + 5F_2(g) \longrightarrow 2IF_5(g)$

For I_2:

$$\text{Amount (mol) of } IF_5 = 4.16 \text{ g } I_2 \times \frac{1 \text{ mol } I_2}{253.8 \text{ g } I_2} \times \frac{2 \text{ mol } IF_5}{1 \text{ mol } I_2}$$
$$= 0.0328 \text{ mol } IF_5$$

For F_2:

$$n_{F_2} = \frac{0.974 \text{ atm} \times 2.48 \text{ L}}{0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 291 \text{ K}} = 0.101 \text{ mol } F_2$$

$$\text{Amount (mol) of } IF_5 = 0.101 \text{ mol } F_2 \times \frac{2 \text{ mol } IF_5}{5 \text{ mol } F_2}$$
$$= 0.0404 \text{ mol } IF_5$$

Thus, I_2 is the limiting reactant.

$$\text{Volume (L) of } IF_5 = \frac{0.0328 \text{ mol} \times 0.0821 \dfrac{\text{atm·L}}{\text{mol·K}} \times 378 \text{ K}}{0.935 \text{ atm}}$$
$$= 1.09 \text{ L}$$

5.14A $$\frac{\text{Rate of He}}{\text{Rate of } C_2H_6} = \sqrt{\frac{30.07 \text{ g/mol}}{4.003 \text{ g/mol}}} = 2.741$$

Time for C_2H_6 to effuse $= 1.25 \text{ min} \times 2.741 = 3.43 \text{ min}$

5.14B $$\mathcal{M} \text{ of unknown gas} = \mathcal{M}_{Ar} \times \left(\frac{\text{rate of Ar}}{\text{rate of unknown gas}}\right)^2$$
$$= \left(\frac{13.8 \text{ mL/time}}{7.23 \text{ mL/time}}\right)^2 \times 39.95 \text{ g/mol}$$
$$= 146 \text{ g/mol}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

An Overview of the Physical States of Matter

Concept Review Questions

5.1 How does a sample of gas differ in its behavior from a sample of liquid in each of the following situations?
(a) The sample is transferred from one container to a larger one.
(b) The sample is heated in an expandable container, but no change of state occurs.
(c) The sample is placed in a cylinder with a piston, and an external force is applied.

5.2 Are the particles in a gas farther apart or closer together than the particles in a liquid? Use your answer to explain each of the following general observations:
(a) Gases are more compressible than liquids.
(b) Gases have lower viscosities than liquids.
(c) After thorough stirring, all gas mixtures are solutions.
(d) The density of a substance in the gas state is lower than in the liquid state.

Gas Pressure and Its Measurement

(Sample Problem 5.1)

Concept Review Questions

5.3 How does a barometer work? Is the column of mercury in a barometer shorter when it is on a mountaintop or at sea level? Explain.

5.4 How can a unit of length such as millimeter of mercury (mmHg) be used as a unit of pressure, which has the dimensions of force per unit area?

5.5 In a closed-end manometer, the mercury level in the arm attached to the flask can never be higher than the mercury level in the other arm, whereas in an open-end manometer, it *can* be higher. Explain.

Skill-Building Exercises (grouped in similar pairs)

5.6 On a cool, rainy day, the barometric pressure is 730 mmHg. Calculate the barometric pressure in centimeters of water (cmH_2O) (d of Hg = 13.5 g/mL; d of H_2O = 1.00 g/mL).

5.7 A long glass tube, sealed at one end, has an inner diameter of 10.0 mm. The tube is filled with water and inverted into a pail of water. If the atmospheric pressure is 755 mmHg, how high (in mmH_2O) is the column of water in the tube (d of Hg = 13.5 g/mL; d of H_2O = 1.00 g/mL)?

5.8 Convert the following:
(a) 0.745 atm to mmHg
(b) 992 torr to bar
(c) 365 kPa to atm
(d) 804 mmHg to kPa

5.9 Convert the following:
(a) 76.8 cmHg to atm
(b) 27.5 atm to kPa
(c) 6.50 atm to bar
(d) 0.937 kPa to torr

5.10 In Figure P5.10, what is the pressure of the gas in the flask (in atm) if the barometer reads 738.5 torr?

5.11 In Figure P5.11, what is the pressure of the gas in the flask (in kPa) if the barometer reads 765.2 mmHg?

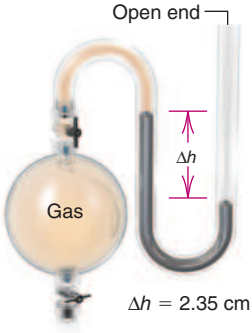

Figure P5.10

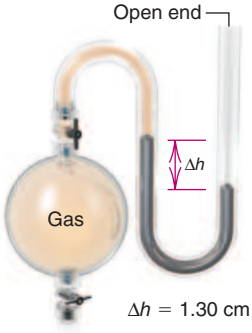

Figure P5.11

5.12 If the sample flask in Figure P5.12 is open to the air, what is the atmospheric pressure (in atm)?

5.13 In Figure P5.13, what is the pressure (in Pa) of the gas in the flask?

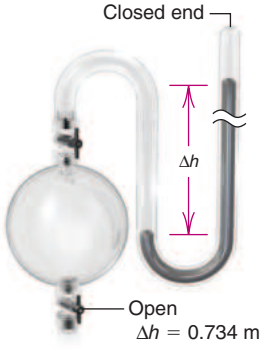

Figure P5.12

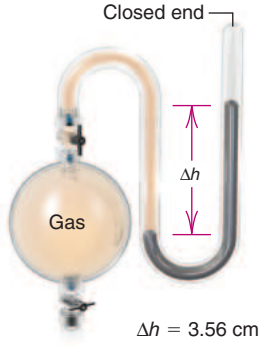

Figure P5.13

Problems in Context

5.14 Convert each of the pressures described below to atm:
(a) At the peak of Mt. Everest, atmospheric pressure is only 2.75×10^2 mmHg.
(b) A cyclist fills her bike tires to 86 psi.
(c) The surface of Venus has an atmospheric pressure of 9.15×10^6 Pa.
(d) At 100 ft below sea level, a scuba diver experiences a pressure of 2.54×10^4 torr.

5.15 The gravitational force exerted by an object is given by $F = mg$, where F is the force in newtons, m is the mass in kilograms, and g is the acceleration due to gravity (9.81 m/s^2).
(a) Use the definition of the pascal to calculate the mass (in kg) of the atmosphere above 1 m^2 of ocean.
(b) Osmium (Z = 76) is a transition metal in Group 8B(8) and has the highest density of any element (22.6 g/mL). If an osmium column is 1 m^2 in area, how high must it be for its pressure to equal atmospheric pressure? [Use the answer from part (a) in your calculation.]

The Gas Laws and Their Experimental Foundations

(Sample Problems 5.2 to 5.7)

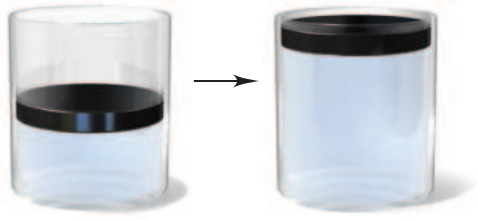
Concept Review Questions

5.16 A student states Boyle's law as follows: "The volume of a gas is inversely proportional to its pressure." How is this statement incomplete? Give a correct statement of Boyle's law.

5.17 In the following relationships, which quantities are variables and which are fixed: (a) Charles's law; (b) Avogadro's law; (c) Amontons's law?

5.18 Boyle's law relates gas volume to pressure, and Avogadro's law relates gas volume to amount (mol). State a relationship between gas pressure and amount (mol).

5.19 Each of the following processes caused the gas volume to double, as shown. For each process, tell how the remaining gas variable changed or state that it remained fixed:
(a) T doubles at fixed P.
(b) T and n are fixed.
(c) At fixed T, the reaction is $CD_2(g) \longrightarrow C(g) + D_2(g)$.
(d) At fixed P, the reaction is $A_2(g) + B_2(g) \longrightarrow 2AB(g)$.



Skill-Building Exercises (grouped in similar pairs)

5.20 What is the effect of the following on the volume of 1 mol of an ideal gas?
(a) The pressure is tripled (at constant T).
(b) The absolute temperature is increased by a factor of 3.0 (at constant P).
(c) Three more moles of the gas are added (at constant P and T).

5.21 What is the effect of the following on the volume of 1 mol of an ideal gas?
(a) The pressure changes from 760 torr to 202 kPa, and the temperature changes from 37°C to 155 K.
(b) The temperature changes from 305 K to 32°C, and the pressure changes from 2 atm to 101 kPa.
(c) The pressure is reduced by a factor of 4 (at constant T).

5.22 What is the effect of the following on the volume of 1 mol of an ideal gas?
(a) Temperature decreases from 800 K to 400 K (at constant P).
(b) Temperature increases from 250°C to 500°C (at constant P).
(c) Pressure increases from 2 atm to 6 atm (at constant T).

5.23 What is the effect of the following on the volume of 1 mol of an ideal gas?
(a) The initial pressure is 722 torr, and the final pressure is 0.950 atm; the initial temperature is 32°F, and the final temperature is 273 K.
(b) Half the gas escapes (at constant P and T).
(c) Both the pressure and temperature decrease to one-fourth of their initial values.

5.24 A weather balloon is filled with helium to a volume of 1.61 L at 734 torr. What is the volume of the balloon after it has been released and its pressure has dropped to 0.844 atm? Assume that the temperature remains constant.

5.25 A sample of methane is placed in a 10.0-L container at 25°C and 725 mmHg. The gas sample is then moved to a 7.50-L container at 25°C. What is the gas pressure in the second container?

5.26 A sample of sulfur hexafluoride gas occupies 9.10 L at 198°C. Assuming that the pressure remains constant, what temperature (in °C) is needed to reduce the volume to 2.50 L?

5.27 A 93-L sample of dry air cools from 145°C to −22°C while the pressure is maintained at 2.85 atm. What is the final volume?

5.28 A gas cylinder is filled with argon at a pressure of 177 atm and 25°C. What is the gas pressure when the temperature of the cylinder and its contents are heated to 195°C by exposure to fire?

5.29 A bicycle tire is filled to a pressure of 110. psi at a temperature of 30.0°C. At what temperature will the air pressure in the tire decrease to 105 psi? Assume that the volume of the tire remains constant.

5.30 A balloon filled with 1.92 g of helium has a volume of 12.5 L. What is the balloon's volume after 0.850 g of helium has leaked out through a small hole (assume constant pressure and temperature)?

5.31 The average person takes 500 mL of air into the lungs with each normal inhalation, which corresponds to approximately 1×10^{22} molecules of air. Calculate the number of molecules of air inhaled by a person with a respiratory problem who takes in only 350 mL of air with each breath. Assume constant pressure and temperature.

5.32 A sample of Freon-12 (CF_2Cl_2) occupies 25.5 L at 298 K and 153.3 kPa. Find its volume at STP.

5.33 A sample of carbon monoxide occupies 3.65 L at 298 K and 745 torr. Find its volume at −14°C and 367 torr.

5.34 A sample of chlorine gas is confined in a 5.0-L container at 328 torr and 37°C. How many moles of gas are in the sample?

5.35 If 1.47×10^{-3} mol of argon occupies a 75.0-mL container at 26°C, what is the pressure (in torr)?

5.36 You have 357 mL of chlorine trifluoride gas at 699 mmHg and 45°C. What is the mass (in g) of the sample?

5.37 A 75.0-g sample of dinitrogen monoxide is confined in a 3.1-L vessel. What is the pressure (in atm) at 115°C?

Problems in Context

5.38 In preparation for a demonstration, your professor brings a 1.5-L bottle of sulfur dioxide into the lecture hall before class to allow the gas to reach room temperature. If the pressure gauge reads 85 psi and the temperature in the classroom is 23°C, how many moles of sulfur dioxide are in the bottle? (*Hint:* The gauge reads zero when the gas pressure in the bottle is 14.7 psi.)

5.39 A gas-filled weather balloon with a volume of 65.0 L is released at sea-level conditions of 745 torr and 25°C. The balloon can expand to a maximum volume of 835 L. When the balloon rises to an altitude at which the temperature is −5°C and the pressure is 0.066 atm, will it reach its maximum volume?

Rearrangements of the Ideal Gas Law

(Sample Problems 5.8 to 5.13)

Concept Review Questions

5.40 Why is moist air less dense than dry air?

5.41 To collect a beaker of H_2 gas by displacing the air already in the beaker, would you hold the beaker upright or inverted? Why? How would you hold the beaker to collect CO_2?

5.42 Why can we use a gas mixture, such as air, to study the general behavior of an ideal gas under ordinary conditions?

5.43 How does the partial pressure of gas A in a mixture compare to its mole fraction in the mixture? Explain.

5.44 The scene at right represents a portion of a mixture of four gases A *(purple)*, B *(black)*, C *(green)*, and D_2 *(orange)*.
(a) Which has the highest partial pressure?
(b) Which has the lowest partial pressure?
(c) If the total pressure is 0.75 atm, what is the partial pressure of D_2?

Skill-Building Exercises (grouped in similar pairs)

5.45 What is the density of Xe gas at STP?

5.46 Find the density of Freon-11 ($CFCl_3$) at 120°C and 1.5 atm.

5.47 How many moles of gaseous arsine (AsH_3) occupy 0.0400 L at STP? What is the density of gaseous arsine?

5.48 The density of a noble gas is 2.71 g/L at 3.00 atm and 0°C. Identify the gas.

5.49 Calculate the molar mass of a gas at 388 torr and 45°C if 206 ng occupies 0.206 μL.

5.50 When an evacuated 63.8-mL glass bulb is filled with a gas at 22°C and 747 mmHg, the bulb gains 0.103 g in mass. Is the gas N_2, Ne, or Ar?

5.51 After 0.600 L of Ar at 1.20 atm and 227°C is mixed with 0.200 L of O_2 at 501 torr and 127°C in a 400-mL flask at 27°C, what is the pressure in the flask?

5.52 A 355-mL container holds 0.146 g of Ne and an unknown amount of Ar at 35°C and a total pressure of 626 mmHg. Calculate the number of moles of Ar present.

5.53 How many grams of phosphorus react with 35.5 L of O_2 at STP to form tetraphosphorus decoxide?

$$P_4(s) + 5O_2(g) \longrightarrow P_4O_{10}(s)$$

5.54 How many grams of potassium chlorate decompose to potassium chloride and 638 mL of O_2 at 128°C and 752 torr?

$$2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$$

5.55 How many grams of phosphine (PH_3) can form when 37.5 g of phosphorus and 83.0 L of hydrogen gas react at STP?

$$P_4(s) + H_2(g) \longrightarrow PH_3(g) \quad \text{[unbalanced]}$$

5.56 When 35.6 L of ammonia and 40.5 L of oxygen gas at STP burn, nitrogen monoxide and water form. After the products return to STP, how many grams of nitrogen monoxide are present?

$$NH_3(g) + O_2(g) \longrightarrow NO(g) + H_2O(l) \quad \text{[unbalanced]}$$

5.57 Aluminum reacts with excess hydrochloric acid to form aqueous aluminum chloride and 35.8 mL of hydrogen gas over water at 27°C and 751 mmHg. How many grams of aluminum reacted?

5.58 How many liters of hydrogen gas are collected over water at 18°C and 725 mmHg when 0.84 g of lithium reacts with water? Aqueous lithium hydroxide also forms.

Problems in Context

5.59 The air in a hot-air balloon at 744 torr is heated from 17°C to 60.0°C. Assuming that the amount (mol) of air and the pressure remain constant, what is the density of the air at each temperature? (The average molar mass of air is 28.8 g/mol.)

5.60 On a certain winter day in Utah, the average atmospheric pressure is 650. torr. What is the molar density (in mol/L) of the air if the temperature is −25°C?

5.61 A sample of a liquid hydrocarbon known to consist of molecules with five carbon atoms is vaporized in a 0.204-L flask by immersion in a water bath at 101°C. The barometric pressure is 767 torr, and the remaining gas weighs 0.482 g. What is the molecular formula of the hydrocarbon?

5.62 A sample of air contains 78.08% nitrogen, 20.94% oxygen, 0.05% carbon dioxide, and 0.93% argon, by volume. How many molecules of each gas are present in 1.00 L of the sample at 25°C and 1.00 atm?

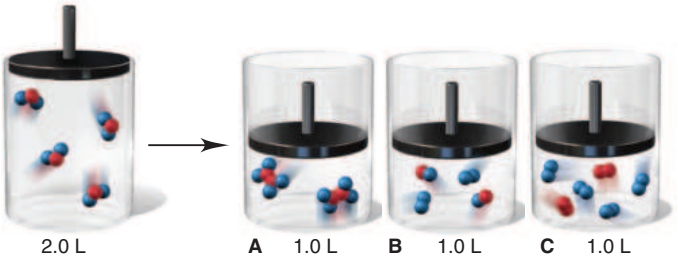
5.63 An environmental chemist sampling industrial exhaust gases from a coal-burning plant collects a CO_2-SO_2-H_2O mixture in a 21-L steel tank until the pressure reaches 850. torr at 45°C.
(a) How many moles of gas are collected?
(b) If the SO_2 concentration in the mixture is 7.95×10^3 parts per million by volume (ppmv), what is its partial pressure? [*Hint:* ppmv = (volume of component/volume of mixture) × 10^6.]

5.64 "Strike anywhere" matches contain the compound tetraphosphorus trisulfide, which burns to form tetraphosphorus decoxide and sulfur dioxide gas. How many milliliters of sulfur dioxide, measured at 725 torr and 32°C, can be produced from burning 0.800 g of tetraphosphorus trisulfide?

5.65 Freon-12 (CF_2Cl_2), widely used as a refrigerant and aerosol propellant, is a dangerous air pollutant. In the troposphere, it traps heat 25 times as effectively as CO_2, and in the stratosphere, it participates in the breakdown of ozone. Freon-12 is prepared industrially by reaction of gaseous carbon tetrachloride with hydrogen fluoride. Hydrogen chloride gas also forms. How many grams of carbon tetrachloride are required for the production of 16.0 dm^3 of Freon-12 at 27°C and 1.20 atm?

5.66 Xenon hexafluoride was one of the first noble gas compounds synthesized. The solid reacts rapidly with the silicon dioxide in glass or quartz containers to form liquid $XeOF_4$ and gaseous silicon tetrafluoride. What is the pressure in a 1.00-L container at 25°C after 2.00 g of xenon hexafluoride reacts? (Assume that silicon tetrafluoride is the only gas present and that it occupies the entire volume.)

5.67 In the four piston-cylinder assemblies below, the reactant in the left cylinder is about to undergo a reaction at constant T and P:



Which of the other three depictions best represents the products of the reaction?

5.68 Roasting galena [lead(II) sulfide] is a step in the industrial isolation of lead. How many liters of sulfur dioxide, measured at STP, are produced by the reaction of 3.75 kg of galena with 228 L of oxygen gas at 220°C and 2.0 atm? Lead(II) oxide also forms.

5.69 In one of his most critical studies into the nature of combustion, Lavoisier heated mercury(II) oxide and isolated elemental mercury and oxygen gas. If 40.0 g of mercury(II) oxide is heated in a 502-mL vessel and 20.0% (by mass) decomposes, what is the pressure (in atm) of the oxygen that forms at 25.0°C? (Assume that the gas occupies the entire volume.)

The Kinetic-Molecular Theory: A Model for Gas Behavior

(Sample Problem 5.14)

Concept Review Questions

5.70 Use the kinetic-molecular theory to explain the change in gas pressure that results from warming a sample of gas.

5.71 How does the kinetic-molecular theory explain why 1 mol of krypton and 1 mol of helium have the same volume at STP?

5.72 Is the rate of effusion of a gas higher than, lower than, or equal to its rate of diffusion? Explain. For two gases with molecules of approximately the same size, is the ratio of their effusion rates higher than, lower than, or equal to the ratio of their diffusion rates? Explain.

5.73 Consider two 1-L samples of gas: one is H_2 and the other is O_2. Both are at 1 atm and 25°C. How do the samples compare in terms of (a) mass, (b) density, (c) mean free path, (d) average molecular kinetic energy, (e) average molecular speed, and (f) time for a given fraction of molecules to effuse?

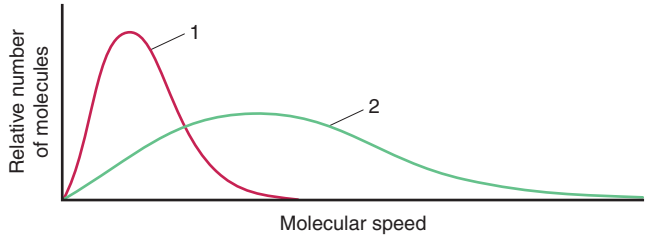
5.74 Three 5-L flasks, fixed with pressure gauges and small valves, each contain 4 g of gas at 273 K. Flask A contains H_2, flask B contains He, and flask C contains CH_4. Rank the flask contents in terms of (a) pressure, (b) average molecular kinetic energy, (c) diffusion rate after the valve is opened, (d) total kinetic energy of the molecules, (e) density, and (f) collision frequency.

Skill-Building Exercises (grouped in similar pairs)

5.75 What is the ratio of effusion rates for the lightest gas, H_2, and the heaviest known gas, UF_6?

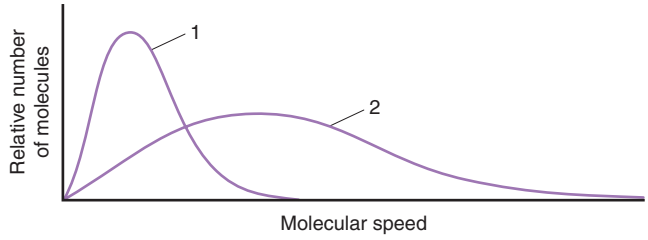
5.76 What is the ratio of effusion rates for O_2 and Kr?

5.77 The graph below shows the distribution of molecular speeds for argon and helium at the same temperature.



(a) Does curve 1 or 2 better represent the behavior of argon?
(b) Which curve represents the gas that effuses more slowly?
(c) Which curve more closely represents the behavior of fluorine gas? Explain.

5.78 The graph below shows the distribution of molecular speeds for a gas at two different temperatures.



(a) Does curve 1 or 2 better represent the behavior of the gas at the lower temperature?
(b) Which curve represents the gas when it has a higher $\overline{E_k}$?
(c) Which curve is consistent with a higher diffusion rate?

5.79 At a given pressure and temperature, it takes 4.85 min for a 1.5-L sample of He to effuse through a membrane. How long does it take for 1.5 L of F_2 to effuse under the same conditions?

5.80 A sample of an unknown gas effuses in 11.1 min. An equal volume of H_2 in the same apparatus under the same conditions effuses in 2.42 min. What is the molar mass of the unknown gas?

Problems in Context

5.81 White phosphorus melts and then vaporizes at high temperature. The gas effuses at a rate that is 0.404 times that of neon in the same apparatus under the same conditions. How many atoms are in a molecule of gaseous white phosphorus?

5.82 Helium (He) is the lightest noble gas component of air, and xenon (Xe) is the heaviest. [For this problem, use $R = 8.314$ J/(mol·K) and $\mathcal{M}$ in kg/mol.]
(a) Find the rms speed of He in winter (0.°C) and in summer (30.°C).
(b) Compare the rms speed of He with that of Xe at 30.°C.
(c) Find the average kinetic energy per mole of He and of Xe at 30.°C.
(d) Find the average kinetic energy per molecule of He at 30.°C.

5.83 A mixture of gaseous disulfur difluoride, dinitrogen tetrafluoride, and sulfur tetrafluoride is placed in an effusion apparatus.
(a) Rank the gases in order of increasing effusion rate.
(b) Find the ratio of effusion rates of disulfur difluoride and dinitrogen tetrafluoride.
(c) If gas X is added, and it effuses at 0.935 times the rate of sulfur tetrafluoride, find the molar mass of X.

Real Gases: Deviations from Ideal Behavior

Skill-Building Exercises (grouped in similar pairs)

5.84 Do interparticle attractions cause negative or positive deviations from the *PV/RT* ratio of an ideal gas? Use Table 5.3 to rank Kr, CO_2, and N_2 in order of increasing magnitude of these deviations.

5.85 Does particle volume cause negative or positive deviations from the *PV/RT* ratio of an ideal gas? Use Table 5.3 to rank Cl_2, H_2, and O_2 in order of increasing magnitude of these deviations.

5.86 Does N_2 behave more ideally at 1 atm or at 500 atm? Explain.

5.87 Does SF_6 (boiling point = 16°C at 1 atm) behave more ideally at 150°C or at 20°C? Explain.

Comprehensive Problems

5.88 An "empty" gasoline can with dimensions 15.0 cm by 40.0 cm by 12.5 cm is attached to a vacuum pump and evacuated. If the atmospheric pressure is 14.7 lb/in^2, what is the total force (in pounds) on the outside of the can?

5.89 Hemoglobin is the protein that transports O_2 through the blood from the lungs to the rest of the body. To do so, each molecule of hemoglobin combines with four molecules of O_2. If 1.00 g of hemoglobin combines with 1.53 mL of O_2 at 37°C and 743 torr, what is the molar mass of hemoglobin?

5.90 A baker uses sodium hydrogen carbonate (baking soda) as the leavening agent in a banana-nut quickbread. The baking soda decomposes in either of two possible reactions:
(1) $2NaHCO_3(s) \longrightarrow Na_2CO_3(s) + H_2O(l) + CO_2(g)$
(2) $NaHCO_3(s) + H^+(aq) \longrightarrow H_2O(l) + CO_2(g) + Na^+(aq)$
Calculate the volume (in mL) of CO_2 that forms at 200.°C and 0.975 atm per gram of $NaHCO_3$ by each of the reaction processes.

5.91 A weather balloon containing 600. L of He is released near the equator at 1.01 atm and 305 K. It rises to a point where conditions are 0.489 atm and 218 K and eventually lands in the northern hemisphere under conditions of 1.01 atm and 250 K. If one-fourth of the helium leaked out during this journey, what is the volume (in L) of the balloon at landing?

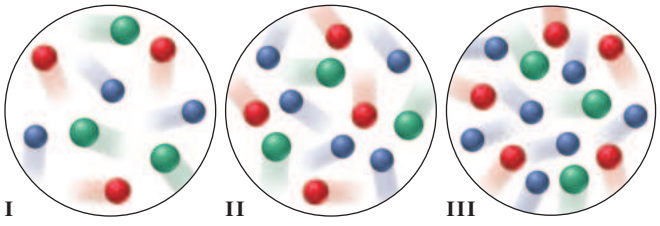
5.92 Chlorine is produced from sodium chloride by the electrochemical chlor-alkali process. During the process, the chlorine is collected in a container that is isolated from the other products to prevent unwanted (and explosive) reactions. If a 15.50-L container holds 0.5950 kg of Cl_2 gas at 225°C, calculate:

(a) P_{IGL} (b) P_{VDW} $\left(\text{use } R = 0.08206 \dfrac{\text{atm·L}}{\text{mol·K}}\right)$

5.93 In a certain experiment, magnesium boride (Mg_3B_2) reacted with acid to form a mixture of four boron hydrides (B_xH_y), three as liquids (labeled I, II, and III) and one as a gas (IV).
(a) When a 0.1000-g sample of each liquid was transferred to an evacuated 750.0-mL container and volatilized at 70.00°C, sample I had a pressure of 0.05951 atm; sample II, 0.07045 atm; and sample III, 0.05767 atm. What is the molar mass of each liquid?
(b) Boron is 85.63% by mass in sample I, 81.10% in II, and 82.98% in III. What is the molecular formula of each sample?
(c) Sample IV was found to be 78.14% boron. Its rate of effusion was compared to that of sulfur dioxide; under identical conditions, 350.0 mL of sample IV effused in 12.00 min and 250.0 mL of

sulfur dioxide effused in 13.04 min. What is the molecular formula of sample IV?

5.94 Three equal volumes of gas mixtures, all at the same *T*, are depicted below (with gas A *red,* gas B *green,* and gas C *blue*):



(a) Which sample, if any, has the highest partial pressure of A?
(b) Which sample, if any, has the lowest partial pressure of B?
(c) In which sample, if any, do the gas particles have the highest average kinetic energy?

5.95 Will the volume of a gas increase, decrease, or remain unchanged for each of the following sets of changes?
(a) The pressure is decreased from 2 atm to 1 atm, while the temperature is decreased from 200°C to 100°C.
(b) The pressure is increased from 1 atm to 3 atm, while the temperature is increased from 100°C to 300°C.
(c) The pressure is increased from 3 atm to 6 atm, while the temperature is increased from −73°C to 127°C.
(d) The pressure is increased from 0.2 atm to 0.4 atm, while the temperature is decreased from 300°C to 150°C.

5.96 When air is inhaled, it enters the alveoli of the lungs, and varying amounts of the component gases exchange with dissolved gases in the blood. The resulting alveolar gas mixture is quite different from the atmospheric mixture. The following table presents selected data on the composition and partial pressure of four gases in the atmosphere and in the alveoli:

	Atmosphere (sea level)		Alveoli	
Gas	Mole %	Partial Pressure (torr)	Mole %	Partial Pressure (torr)
N_2	78.6	—	—	569
O_2	20.9	—	—	104
CO_2	00.04	—	—	40
H_2O	00.46	—	—	47

If the total pressure of each gas mixture is 1.00 atm, calculate:
(a) The partial pressure (in torr) of each gas in the atmosphere
(b) The mole % of each gas in the alveoli
(c) The number of O_2 molecules in 0.50 L of alveolar air (volume of an average breath of a person at rest) at 37°C

5.97 Radon (Rn) is the heaviest, and only radioactive, member of Group 8A(18) (noble gases). It is a product of the disintegration of heavier radioactive nuclei found in minute concentrations in many common rocks used for building and construction. In recent years, there has been growing concern about the cancers caused from inhaled residential radon. If 1.0×10^{15} atoms of radium (Ra) produce an average of 1.373×10^{4} atoms of Rn per second, how many liters of Rn, measured at STP, are produced per day by 1.0 g of Ra?

5.98 At 1450. mmHg and 286 K, a skin diver exhales a 208-mL bubble of air that is 77% N_2, 17% O_2, and 6.0% CO_2 by volume.
(a) How many milliliters would the volume of the bubble be if it were exhaled at the surface at 1 atm and 298 K?
(b) How many moles of N_2 are in the bubble?

5.99 Nitrogen dioxide is used industrially to produce nitric acid, but it contributes to acid rain and photochemical smog. What volume (in L) of nitrogen dioxide is formed at 735 torr and 28.2°C by reacting 4.95 cm^3 of copper (d = 8.95 g/cm^3) with 230.0 mL of nitric acid (d = 1.42 g/cm^3, 68.0% HNO_3 by mass)?

$$Cu(s) + 4HNO_3(aq) \longrightarrow Cu(NO_3)_2(aq) + 2NO_2(g) + 2H_2O(l)$$

5.100 In the average adult male, the *residual volume* (RV) of the lungs, the volume of air remaining after a forced exhalation, is 1200 mL. (a) How many moles of air are present in the RV at 1.0 atm and 37°C? (b) How many molecules of gas are present under these conditions?

5.101 In a bromine-producing plant, how many liters of gaseous elemental bromine at 300°C and 0.855 atm are formed by the reaction of 275 g of sodium bromide and 175.6 g of sodium bromate in aqueous acid solution? (Assume that no Br_2 dissolves.)

$$5NaBr(aq) + NaBrO_3(aq) + 3H_2SO_4(aq) \longrightarrow 3Br_2(g) + 3Na_2SO_4(aq) + 3H_2O(g)$$

5.102 In a collision of sufficient force, automobile air bags respond by electrically triggering the explosive decomposition of sodium azide (NaN_3) to its elements. A 50.0-g sample of sodium azide was decomposed, and the nitrogen gas generated was collected over water at 26°C. The total pressure was 745.5 mmHg. How many liters of dry N_2 were generated?

5.103 An anesthetic gas contains 64.81% carbon, 13.60% hydrogen, and 21.59% oxygen, by mass. If 2.00 L of the gas at 25°C and 0.420 atm weighs 2.57 g, what is the molecular formula of the anesthetic?

5.104 Aluminum chloride is easily vaporized above 180°C. The gas escapes through a pinhole 0.122 times as fast as helium at the same conditions of temperature and pressure in the same apparatus. What is the molecular formula of aluminum chloride gas?

5.105 (a) What is the total volume (in L) of gaseous *products,* measured at 350°C and 735 torr, when an automobile engine burns 100. g of C_8H_{18} (a typical component of gasoline)?
(b) For part (a), the source of O_2 is air, which is 78% N_2, 21% O_2, and 1.0% Ar by volume. Assuming all the O_2 reacts, but no N_2 or Ar does, what is the total volume (in L) of gaseous *exhaust?*

5.106 An atmospheric chemist studying the pollutant SO_2 places a mixture of SO_2 and O_2 in a 2.00-L container at 800. K and 1.90 atm. When the reaction occurs, gaseous SO_3 forms, and the pressure falls to 1.65 atm. How many moles of SO_3 form?

5.107 The thermal decomposition of ethylene occurs during the compound's transit in pipelines and during the formation of polyethylene. The decomposition reaction is

$$CH_2{=}CH_2(g) \longrightarrow CH_4(g) + C(\text{graphite})$$

If the decomposition begins at 10°C and 50.0 atm with a gas density of 0.215 g/mL and the temperature increases by 950 K,
(a) What is the final pressure of the confined gas (ignore the volume of graphite and use the van der Waals equation)?
(b) How does the *PV/RT* value of CH_4 compare to that in Figure 5.23? Explain.

5.108 Ammonium nitrate, a common fertilizer, was used by terrorists in the tragic explosion in Oklahoma City in 1995. How many liters of gas at 307°C and 1.00 atm are formed by the explosive decomposition of 15.0 kg of ammonium nitrate to nitrogen, oxygen, and water vapor?

5.109 An environmental engineer analyzes a sample of air contaminated with sulfur dioxide. To a 500.-mL sample at 700. torr and 38°C, she adds 20.00 mL of 0.01017 *M* aqueous iodine, which reacts as follows:

$$SO_2(g) + I_2(aq) + H_2O(l) \longrightarrow HSO_4^-(aq) + I^-(aq) + H^+(aq) \quad [\text{unbalanced}]$$

Excess I_2 reacts with 11.37 mL of 0.0105 *M* sodium thiosulfate:

$$I_2(aq) + S_2O_3^{2-}(aq) \longrightarrow I^-(aq) + S_4O_6^{2-}(aq) \quad [\text{unbalanced}]$$

What is the volume % of SO_2 in the air sample?

5.110 Canadian chemists have developed a modern variation of the 1899 Mond process for preparing extremely pure metallic nickel. A sample of impure nickel reacts with carbon monoxide at 50°C to form gaseous nickel carbonyl, $Ni(CO)_4$.
(a) How many grams of nickel can be converted to the carbonyl with 3.55 m^3 of CO at 100.7 kPa?
(b) The carbonyl is then decomposed at 21 atm and 155°C to pure (>99.95%) nickel. How many grams of nickel are obtained per cubic meter of the carbonyl?
(c) The released carbon monoxide is cooled and collected for reuse by passing it through water at 35°C. If the barometric pressure is 769 torr, what volume (in m^3) of CO is formed per cubic meter of carbonyl?

5.111 Analysis of a newly discovered gaseous silicon-fluorine compound shows that it contains 33.01 mass % silicon. At 27°C, 2.60 g of the compound exerts a pressure of 1.50 atm in a 0.250-L vessel. What is the molecular formula of the compound?

5.112 A gaseous organic compound containing only carbon, hydrogen, and nitrogen is burned in oxygen gas, and the volume of each reactant and product is measured under the same conditions of temperature and pressure. Reaction of four volumes of the compound produces four volumes of CO_2, two volumes of N_2, and ten volumes of water vapor. (a) How many volumes of O_2 were required? (b) What is the empirical formula of the compound?

5.113 Containers A, B, and C are attached by closed stopcocks of negligible volume.

If each particle shown in the picture represents 10^6 particles,
(a) How many blue particles and black particles are in B after the stopcocks are opened and the system reaches equilibrium?
(b) How many blue particles and black particles are in A after the stopcocks are opened and the system reaches equilibrium?
(c) If the pressure in C, P_C, is 750 torr before the stopcocks are opened, what is P_C afterward?
(d) What is P_B afterward?

5.114 Combustible vapor-air mixtures are flammable over a limited range of concentrations. The minimum volume % of vapor that gives a combustible mixture is called the *lower flammable limit* (LFL). Generally, the LFL is about half the stoichiometric mixture, the concentration required for complete combustion of the vapor in air. (a) If oxygen is 20.9 vol % of air, estimate the LFL for *n*-hexane, C_6H_{14}. (b) What volume (in mL) of *n*-hexane (d = 0.660 g/cm^3) is required to produce a flammable mixture of hexane in 1.000 m^3 of air at STP?

5.115 By what factor would a scuba diver's lungs expand if she ascended rapidly to the surface from a depth of 125 ft without inhaling or exhaling? If an expansion factor greater than 1.5 causes lung rupture, how far could she safely ascend from 125 ft without breathing? Assume constant temperature (d of seawater = 1.04 g/mL; d of Hg = 13.5 g/mL).

5.116 When 15.0 g of fluorite (CaF_2) reacts with excess sulfuric acid, hydrogen fluoride gas is collected at 744 torr and 25.5°C. Solid calcium sulfate is the other product. What gas temperature is required to store the gas in an 8.63-L container at 875 torr?

5.117 Dilute aqueous hydrogen peroxide is used as a bleaching agent and for disinfecting surfaces and small cuts. Its concentration is sometimes given as a certain number of "volumes hydrogen peroxide," which refers to the number of volumes of O_2 gas, measured at STP, that a given volume of hydrogen peroxide solution will release when it decomposes to O_2 and liquid H_2O. How many grams of hydrogen peroxide are in 0.100 L of "20 volumes hydrogen peroxide" solution?

5.118 At a height of 300 km above Earth's surface, an astronaut finds that the atmospheric pressure is about 10^{-8} mmHg and the temperature is 500 K. How many molecules of gas are there per milliliter at this altitude?

5.119 (a) What is the rms speed of O_2 at STP? (b) If the mean free path of O_2 molecules at STP is 6.33×10^{-8} m, what is their collision frequency? [Use R = 8.314 J/(mol·K) and $\mathcal{M}$ in kg/mol.]

5.120 Acrylic acid (CH_2=CHCOOH) is used to prepare polymers, adhesives, and paints. The first step in making acrylic acid involves the vapor-phase oxidation of propylene (CH_2=$CHCH_3$) to acrolein (CH_2=CHCHO). This step is carried out at 330°C and 2.5 atm in a large bundle of tubes around which a heat-transfer agent circulates. The reactants spend an average of 1.8 s in the tubes, which have a void space of 100 ft^3. How many pounds of propylene must be added per hour in a mixture whose mole fractions are 0.07 propylene, 0.35 steam, and 0.58 air?

5.121 Standard conditions are based on relevant environmental conditions. If normal average surface temperature and pressure on Venus are 730. K and 90 atm, respectively, what is the standard molar volume of an ideal gas on Venus?

5.122 A barometer tube is 1.00×10^2 cm long and has a cross-sectional area of 1.20 cm^2. The height of the mercury column is 74.0 cm, and the temperature is 24°C. A small amount of N_2 is introduced into the evacuated space above the mercury, which causes the mercury level to drop to a height of 64.0 cm. How many grams of N_2 were introduced?

5.123 What is the molarity of the cleaning solution formed when 10.0 L of ammonia gas at 33°C and 735 torr dissolves in enough water to give a final volume of 0.750 L?

5.124 The Hawaiian volcano Kilauea emits an average of 1.5×10^3 m^3 of gas each day, when corrected to 298 K and 1.00 atm. The mixture contains gases that contribute to global warming and acid rain, and some are toxic. An atmospheric chemist analyzes a sample and finds the following mole fractions: 0.4896 CO_2, 0.0146 CO, 0.3710 H_2O, 0.1185 SO_2, 0.0003 S_2, 0.0047 H_2, 0.0008 HCl, and 0.0003 H_2S. How many metric tons (t) of each gas are emitted per year (1 t = 1000 kg)?

5.125 To study a key fuel-cell reaction, a chemical engineer has 20.0-L tanks of H_2 and of O_2 and wants to use up both tanks to form 28.0 mol of water at 23.8°C. (a) Use the ideal gas law to find the pressure needed in each tank. (b) Use the van der Waals equation to find the pressure needed in each tank. (c) Compare the results from the two equations.

5.126 For each of the following, which shows the greater deviation from ideal behavior at the same set of conditions? Explain.
(a) Argon or xenon (b) Water vapor or neon
(c) Mercury vapor or radon (d) Water vapor or methane

5.127 How many liters of gaseous hydrogen bromide at 29°C and 0.965 atm will a chemist need if she wishes to prepare 3.50 L of 1.20 *M* hydrobromic acid?

5.128 A mixture consisting of 7.0 g of CO and 10.0 g of SO_2, two atmospheric pollutants, has a pressure of 0.33 atm when placed in a sealed container. What is the partial pressure of CO?

5.129 Sulfur dioxide is used to make sulfuric acid. One method of producing it is by roasting mineral sulfides, for example,

$$FeS_2(s) + O_2(g) \xrightarrow{\Delta} SO_2(g) + Fe_2O_3(s) \quad [\text{unbalanced}]$$

A production error leads to the sulfide being placed in a 950-L vessel with insufficient oxygen. Initially, the partial pressure of O_2 is 0.64 atm, and the total pressure is 1.05 atm, with the balance due to N_2. The reaction is run until 85% of the O_2 is consumed, and the vessel is then cooled to its initial temperature. What is the total pressure in the vessel and the partial pressure of each gas in it?

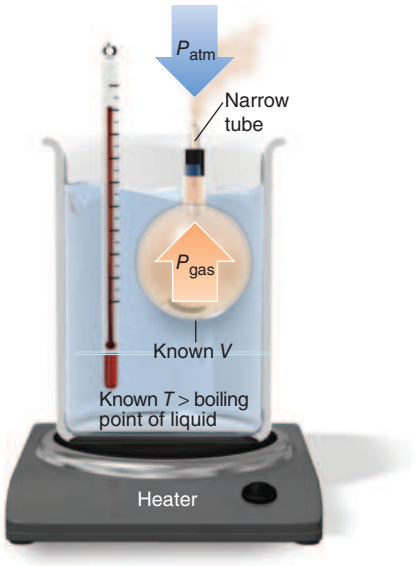
5.130 A mixture of CO_2 and Kr weighs 35.0 g and exerts a pressure of 0.708 atm in its container. Since Kr is expensive, you wish to recover it from the mixture. After the CO_2 is completely removed by absorption with NaOH(*s*), the pressure in the container is 0.250 atm. How many grams of CO_2 were originally present? How many grams of Kr can you recover?

5.131 When a car accelerates quickly, the passengers feel a force that presses them back into their seats, but a balloon filled with helium floats forward. Why?

5.132 Gases such as CO are gradually oxidized in the atmosphere, not by O_2 but by the hydroxyl radical, ·OH, a species with one fewer electron than a hydroxide ion. At night, the ·OH concentration is nearly zero, but it increases to 2.5×10^{12} molecules/m^3 in polluted air during the day. At daytime conditions of 1.00 atm and 22°C, what is the partial pressure and mole percent of ·OH in air?

5.133 Aqueous sulfurous acid (H_2SO_3) was made by dissolving 0.200 L of sulfur dioxide gas at 19°C and 745 mmHg in water to yield 500.0 mL of solution. The acid solution required 10.0 mL of sodium hydroxide solution to reach the titration end point. What was the molarity of the sodium hydroxide solution?

5.134 In the 19th century, J. B. A. Dumas devised a method for finding the molar mass of a volatile liquid from the volume, temperature, pressure, and mass of its vapor *(next column)*. He placed a sample of such a liquid in a flask that was closed with a stopper fitted with a narrow tube, immersed the flask in a hot water bath to vaporize the liquid, and then cooled the flask. Find the molar mass of a volatile liquid from the following:
Mass of empty flask = 65.347 g
Mass of flask filled with water at 25°C = 327.4 g
Density of water at 25°C = 0.997 g/mL
Mass of flask plus condensed unknown liquid = 65.739 g
Barometric pressure = 101.2 kPa
Temperature of water bath = 99.8°C



5.135 During World War II, a portable source of hydrogen gas was needed for weather balloons, and solid metal hydrides were the most convenient form. Many metal hydrides react with water to generate the metal hydroxide and hydrogen. Two candidates were lithium hydride and magnesium hydride. What volume (in L) of gas is formed from 1.00 lb of each hydride reacting with excess water at 750. torr and 27°C?

5.136 The lunar surface reaches 370 K at midday. The atmosphere consists of neon, argon, and helium at a total pressure of only 2×10^{-14} atm. Calculate the rms speed of each component in the lunar atmosphere. [Use R = 8.314 J/(mol·K) and $\mathcal{M}$ in kg/mol.]

5.137 A person inhales air richer in O_2 and exhales air richer in CO_2 and water vapor. During each hour of sleep, a person exhales a total of about 300 L of this CO_2-enriched and H_2O-enriched air. (a) If the partial pressures of CO_2 and H_2O in exhaled air are each 30.0 torr at 37.0°C, calculate the mass (g) of CO_2 and of H_2O exhaled in 1 h of sleep. (b) How many grams of body mass does the person lose in 8 h of sleep if all the CO_2 and H_2O exhaled come from the metabolism of glucose?

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g)$$

5.138 Popcorn pops because the horny endosperm, a tough, elastic material, resists gas pressure within the heated kernel until it reaches explosive force. A 0.25-mL kernel has a water content of 1.6% by mass, and the water vapor reaches 170°C and 9.0 atm before the kernel ruptures. Assume that water vapor can occupy 75% of the kernel's volume. (a) What is the mass (in g) of the kernel? (b) How many milliliters would this amount of water vapor occupy at 25°C and 1.00 atm?

5.139 Sulfur dioxide emissions from coal-burning power plants are removed by *flue-gas desulfurization.* The flue gas passes through a scrubber, and a slurry of wet calcium carbonate reacts with it to form carbon dioxide and calcium sulfite. The calcium sulfite then reacts with oxygen to form calcium sulfate, which is sold as gypsum. (a) If the sulfur dioxide concentration is 1000 times higher than its mole fraction in clean dry air (2×10^{-10}), how much calcium sulfate (kg) can be made from scrubbing 4 GL of flue gas (1 GL = 1×10^9 L)? A state-of-the-art scrubber removes at least 95% of the sulfur dioxide. (b) If the mole fraction of oxygen in air is 0.209, what volume (L) of air at 1.00 atm and 25°C is needed to react with all the calcium sulfite?

5.140 Many water treatment plants use chlorine gas to kill microorganisms before the water is released for residential use. A plant engineer has to maintain the chlorine pressure in a tank below the 85.0-atm rating and, to be safe, decides to fill the tank to 80.0% of this maximum pressure. (a) How many moles of Cl_2 gas can be kept in an 850.-L tank at 298 K if she uses the ideal gas law in the calculation? (b) What is the tank pressure if she uses the van der Waals equation for this amount of gas? (c) Did the engineer fill the tank to the desired pressure?

5.141 At 10.0°C and 102.5 kPa, the density of dry air is 1.26 g/L. What is the average "molar mass" of dry air at these conditions?

5.142 In A, the picture shows a cylinder with 0.1 mol of a gas that behaves ideally. Choose the cylinder (B, C, or D) that correctly represents the volume of the gas after each of the following changes. If none of the cylinders is correct, specify "none."
(a) *P* is doubled at fixed *n* and *T*.
(b) *T* is reduced from 400 K to 200 K at fixed *n* and *P*.
(c) *T* is increased from 100°C to 200°C at fixed *n* and *P*.
(d) 0.1 mol of gas is added at fixed *P* and *T*.
(e) 0.1 mol of gas is added and *P* is doubled at fixed *T*.

5.143 Ammonia is essential to so many industries that, on a molar basis, it is the most heavily produced substance in the world. Calculate P_{IGL} and P_{VDW} (in atm) of 51.1 g of ammonia in a 3.000-L container at 0°C and 400.°C, the industrial temperature. (See Table 5.4 for the values of the van der Waals constants.)

5.144 A 6.0-L flask contains a mixture of methane (CH_4), argon, and helium at 45°C and 1.75 atm. If the mole fractions of helium and argon are 0.25 and 0.35, respectively, how many molecules of methane are present?

5.145 A large portion of metabolic energy arises from the biological combustion of glucose:

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g)$$

(a) If this reaction is carried out in an expandable container at 37°C and 780. torr, what volume of CO_2 is produced from 20.0 g of glucose and excess O_2?
(b) If the reaction is carried out at the same conditions with the stoichiometric amount of O_2, what is the partial pressure of each gas when the reaction is 50% complete (10.0 g of glucose remains)?

5.146 What is the average kinetic energy and rms speed of N_2 molecules at STP? Compare these values with those of H_2 molecules at STP. [Use $R = 8.314$ J/(mol·K) and $\mathcal{M}$ in kg/mol.]

5.147 According to government standards, the *8-h threshold limit value* is 5000 ppmv for CO_2 and 0.1 ppmv for Br_2 (1 ppmv is 1 part by volume in 10^6 parts by volume). Exposure to either gas for 8 h above these limits is unsafe. At STP, which of the following would be unsafe for 8 h of exposure?
(a) Air with a partial pressure of 0.2 torr of Br_2
(b) Air with a partial pressure of 0.2 torr of CO_2
(c) 1000 L of air containing 0.0004 g of Br_2 gas
(d) 1000 L of air containing 2.8×10^{22} molecules of CO_2

5.148 One way to prevent emission of the pollutant NO from industrial plants is by a catalyzed reaction with NH_3:

$$4NH_3(g) + 4NO(g) + O_2(g) \xrightarrow{\text{catalyst}} 4N_2(g) + 6H_2O(g)$$

(a) If the NO has a partial pressure of 4.5×10^{-5} atm in the flue gas, how many liters of NH_3 are needed per liter of flue gas at 1.00 atm? (b) If the reaction takes place at 1.00 atm and 365°C, how many grams of NH_3 are needed per kL of flue gas?

5.149 An equimolar mixture of Ne and Xe is accidentally placed in a container that has a tiny leak. After a short while, a very small proportion of the mixture has escaped. What is the mole fraction of Ne in the effusing gas?

5.150 From the relative rates of effusion of $^{235}UF_6$ and $^{238}UF_6$, find the number of steps needed to produce a sample of the enriched fuel used in many nuclear reactors, which is 3.0 mole % ^{235}U. The natural abundance of ^{235}U is 0.72%.

5.151 A slight deviation from ideal behavior exists even at normal conditions. If it behaved ideally, 1 mol of CO would occupy 22.414 L and exert 1 atm pressure at 273.15 K. Calculate P_{VDW} for 1.000 mol of CO at 273.15 K. $\left(\text{Use } R = 0.08206 \dfrac{\text{atm·L}}{\text{mol·K}}.\right)$

5.152 In preparation for a combustion demonstration, a professor fills a balloon with equal molar amounts of H_2 and O_2, but the demonstration has to be postponed until the next day. During the night, both gases leak through pores in the balloon. If 35% of the H_2 leaks, what is the O_2/H_2 ratio in the balloon the next day?

5.153 Phosphorus trichloride is important in the manufacture of insecticides, fuel additives, and flame retardants. Phosphorus has only one naturally occurring isotope, ^{31}P, whereas chlorine has two, ^{35}Cl (75%) and ^{37}Cl (25%). (a) What different molecular masses (in amu) can be found for PCl_3? (b) Which is the most abundant? (c) What is the ratio of the effusion rates of the heaviest and the lightest PCl_3 molecules?

5.154 A truck tire has a volume of 218 L and is filled with air to 35.0 psi at 295 K. After a drive, the air heats up to 318 K. (a) If the tire volume is constant, what is the pressure (in psi)? (b) If the tire volume increases 2.0%, what is the pressure (in psi)? (c) If the tire leaks 1.5 g of air per minute and the temperature is constant, how many minutes will it take for the tire to reach the original pressure of 35.0 psi ($\mathcal{M}$ of air = 28.8 g/mol)?

5.155 *Allotropes* are different molecular forms of an element, such as dioxygen (O_2) and ozone (O_3). (a) What is the density of each oxygen allotrope at 0°C and 760 torr? (b) Calculate the ratio of densities, d_{O_3}/d_{O_2}, and explain the significance of this number.

5.156 When gaseous F_2 and solid I_2 are heated to high temperatures, the I_2 sublimes and gaseous iodine heptafluoride forms. If 350. torr of F_2 and 2.50 g of solid I_2 are put into a 2.50-L container at 250. K and the container is heated to 550. K, what is the final pressure (in torr)? What is the partial pressure of I_2 gas?

Concepts and Skills to Review Before You Study This Chapter

- interconverting potential and kinetic energy (Section 1.1)
- distinction between heat and temperature (Section 1.4)
- nature of chemical bonding (Section 2.7)
- calculations of reaction stoichiometry (Section 3.4)
- properties of the gaseous state (Section 5.1)
- relation between kinetic energy and temperature (Section 5.5)

All matter contains energy, so *whenever matter undergoes a change, the quantity of energy that the matter contains also changes.* In a thunderstorm, both chemical and physical changes occur: In one chemical change, lower energy N_2 and O_2 *absorb* energy from lightning to form higher energy NO. In a physical change, higher energy water vapor *releases* energy as it condenses to lower energy liquid water that falls as rain. Or, when a burning candle melts a piece of ice, those changes in energy are reversed: In the chemical change, the reactants (wax and O_2) contain more energy than the products (CO_2 and H_2O), and the difference in energy is *released* as heat and light. Then, during the physical change, some of that heat is *absorbed* when lower energy ice melts and forms higher energy water.

This interplay of matter and energy is profoundly important and has an enormous impact on society. On an everyday level, many familiar materials release, absorb, or alter the flow of energy. Fuels such as natural gas and oil release energy to warm our homes or power our vehicles. Fertilizers help crops convert solar energy into food. Metal wires increase the flow of electrical energy, and polymer fibers in winter clothing slow the flow of thermal energy away from our bodies.

Thermodynamics is the study of energy and its transformations, and three chapters in this text address this central topic. Our focus here is on **thermochemistry,** the branch of thermodynamics that deals with heat in chemical and physical change. In Chapter 20, we consider *why* reactions occur, and in Chapter 21, we apply those insights to electrical energy.

IN THIS CHAPTER . . . *We see how heat, or thermal energy, flows when matter changes, how to measure the quantity of heat for a given change, and how to determine the direction and magnitude of heat flow for any reaction.*

- We see that energy always flows between a system and its surroundings in the form of heat or work, so the total energy is conserved.
- We discuss the units of energy and show that the total size of an energy change does not depend on how the change occurs.
- We identify the heat of a reaction in an open container as a change in enthalpy, which can be negative (exothermic reaction) or positive (endothermic reaction).
- We describe how a calorimeter measures heat and how the quantity of heat in a reaction is proportional to the amounts of substances.
- We define standard conditions in order to compare enthalpies of reactions and see how to obtain the change in enthalpy for any reaction.
- We discuss some current and future energy sources and describe the critical relation between energy demand and climate change.

6.1 FORMS OF ENERGY AND THEIR INTERCONVERSION

In Chapter 1, we saw that all energy is either potential or kinetic, and that these forms are interconvertible. An object has potential energy by virtue of its position and kinetic energy by virtue of its motion. Let's re-examine these ideas by considering a weight raised above the ground. As your muscles or a motor raise the weight, its potential energy increases; this energy is converted to kinetic energy as the weight falls

(see Figure 1.3, p. 9). When it hits the ground, some of that kinetic energy appears as *work* done to move the soil and pebbles slightly, and some appears as *heat* when it warms them slightly. Thus, in this situation, *potential energy is converted to kinetic energy, which appears as work and heat.*

Several other forms of energy—solar, electrical, nuclear, and chemical—are examples of potential and kinetic energy on the atomic scale. No matter what the form of energy or the situation, *when energy is transferred from one object to another, it appears as work and/or heat.* In this section, we examine this idea in terms of the release or absorption of energy during a chemical or physical change.

Figure 6.1 A chemical system and its surroundings.

Defining the System and Its Surroundings

In any thermodynamic study, including measuring a change in energy, the first step is to define the **system**—the part of the universe we are focusing on. And the moment we define the system, everything else is defined as the **surroundings.**

Figure 6.1 shows a typical chemical system—the contents of a flask. In this case, the flask itself, other equipment, and perhaps the rest of the laboratory are the surroundings. In principle, the rest of the universe is the surroundings, but in practice, we consider only the parts that are relevant to the system: it's not likely that a thunderstorm in central Asia or a methane blizzard on Neptune will affect the contents of the flask, but the temperature and pressure of the lab might. Thus, the experimenter defines the system and the relevant surroundings. An astronomer defines a galaxy as the system and nearby galaxies as the surroundings; a microbiologist defines a given cell as the system and neighboring cells and the extracellular fluid as the surroundings; and so forth.

Energy Change (ΔE): Energy Transfer to or from a System

Each particle in a system has potential energy and kinetic energy, and the sum of all these energies is the **internal energy, *E,*** of the system (some texts use the symbol U). When the reactants in a chemical system change to products, the system's internal energy has changed. This change, ΔE, is the difference between the internal energy *after* the change (E_{final}) and *before* the change ($E_{initial}$), where Δ (Greek *delta*) means "change (or difference) in" and refers to the *final state* ***minus*** *the initial state.* Thus, ΔE is the final quantity of energy of the system **minus** the initial quantity:

$$\Delta E = E_{final} - E_{initial} = E_{products} - E_{reactants} \qquad (6.1)$$

Because the universe consists of only system and surroundings, *a change in the energy of the system must be accompanied by an* ***equal*** *and* ***opposite*** *change in the energy of the surroundings.* In an *energy diagram,* the final and initial states are horizontal lines along a vertical energy axis, with ΔE the difference in the heights of the lines. A system can change its internal energy in one of two ways:

- By releasing some energy in a transfer *to* the surroundings (Figure 6.2A):

$$E_{final} < E_{initial} \quad \text{so} \quad \Delta E < 0$$

- By absorbing some energy in a transfer *from* the surroundings (Figure 6.2B):

$$E_{final} > E_{initial} \quad \text{so} \quad \Delta E > 0$$

Thus, ΔE is a *transfer* of energy from system to surroundings, or vice versa.

Heat and Work: Two Forms of Energy Transfer

Energy transferred from system to surroundings or vice versa appears in two forms:

1. *Heat.* **Heat** or *thermal energy* (symbolized by ***q***) is the energy transferred as a result of a difference in temperature between the system and the surroundings. For example, energy in the form of heat is transferred from hot soup (system) to the bowl, air, and table (surroundings) because they are at a lower temperature.

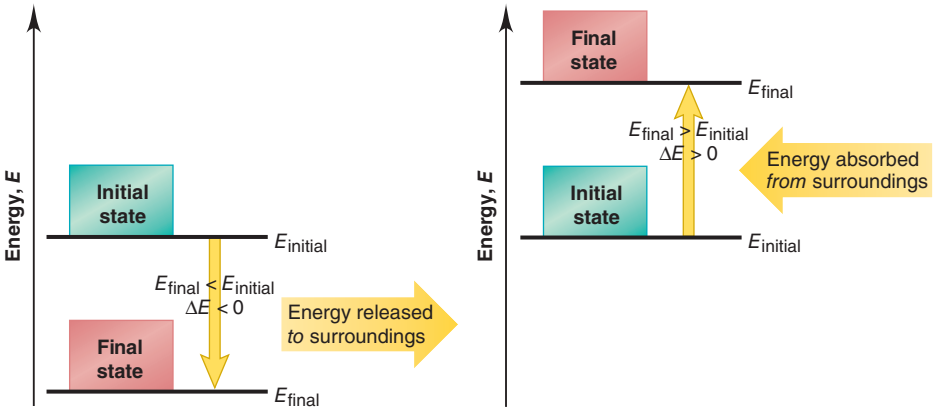

Figure 6.2 Energy diagrams for the transfer of internal energy (E) between two systems and their surroundings. **A,** When the system releases energy, ΔE ($E_{final} - E_{initial}$) is negative. **B,** When the system absorbs energy, ΔE ($E_{final} - E_{initial}$) is positive. (The vertical yellow arrow always has its tail at the initial state.)

2. *Work*. All other forms of energy transfer involve some type of **work (*w*),** the energy transferred when an object is moved by a force. When you (system) kick a football, energy is transferred as work because the force of the kick moves the ball and air (surroundings). When you pump up a ball, energy is transferred as work because the added air (system) exerts a force on the inner wall of the ball (surroundings) and moves it outward.

The total change in a system's internal energy is the sum of the energy transferred as heat and/or as work:

$$\Delta E = q + w \qquad (6.2)$$

The values of q and w (and, therefore, of ΔE) can have either a positive or negative sign. *We define the sign of the energy change from the* ***system's*** *perspective:*

- Energy transferred *into* the system is *positive* because the *system ends up with more* energy.
- Energy transferred *out from* the system is *negative,* because the *system ends up with less* energy.

Innumerable combinations of heat and/or work can change a system's internal energy. In the rest of this subsection, we'll examine the four simplest cases—two that involve only heat and two that involve only work.

Energy Transferred as Heat Only For a system that transfers energy only as heat (q) and does no work ($w = 0$), we have, from Equation 6.2, $\Delta E = q + 0 = q$. There are two ways this transfer can happen:

1. *Heat flowing* ***out*** *from a system* (Figure 6.3A, *next page*). Suppose hot water is the system, and the beaker holding it and the rest of the lab are the surroundings. The water transfers energy as heat outward until the temperature of the water and the surroundings are equal. Since heat flows *out* from the system, the final energy of the system is less than the initial energy. Heat is released, so *q is negative,* and therefore *ΔE is negative*.

2. *Heat flowing* ***into*** *a system* (Figure 6.3B, *next page*). If the system consists of ice water, the surroundings transfer energy as heat *into* the system, once again until the ice melts and the temperature of the water and the surroundings become equal. In this case, heat flows *in,* so the final energy of the system is higher than its initial energy. Heat is absorbed, so *q is positive,* and therefore *ΔE is positive*.

Energy Transferred as Work Only For a system that transfers energy only as work, $q = 0$; therefore, $\Delta E = 0 + w = w$. There are two ways this transfer can happen:

1. *Work done* ***by*** *a system* (Figure 6.4A, *next page*). Consider the aqueous reaction between zinc and hydrochloric acid taking place in a nearly evacuated (narrow P_{sys} arrow), insulated container attached to a piston-cylinder assembly; H_2 gas is one of

Thermodynamics in the Kitchen

A new view of two familiar kitchen appliances can clarify the sign of q. The air in a refrigerator (surroundings) has a lower temperature than a newly added piece of food (system), so the food releases energy as heat to the refrigerator air, $q < 0$. The air in a hot oven (surroundings) has a higher temperature than a newly added piece of food (system), so the food absorbs energy as heat from the oven air, $q > 0$.

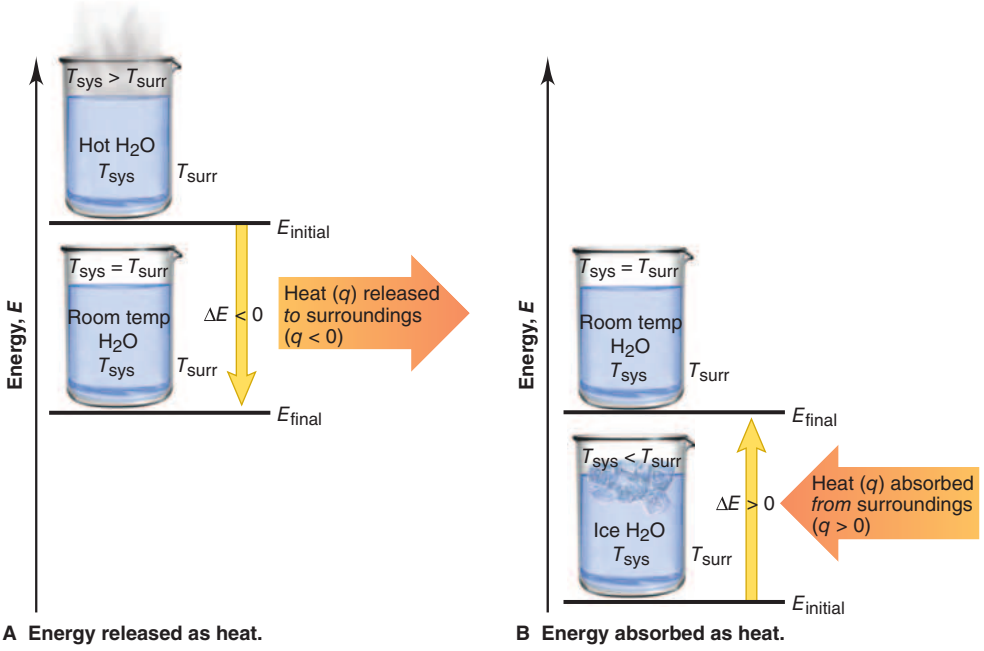

Figure 6.3 **The two cases where energy is transferred as heat only. A,** The system releases heat. **B,** The system absorbs heat.

the products. (The container is insulated so that heat does not flow.) We define the system as the reaction mixture, and the container, piston-cylinder, outside air, and so forth as the surroundings. In the initial state, the internal energy is the energy of the reactants, and in the final state, it is the energy of the products. As the gas forms, it pushes back the piston. Thus, energy is transferred as work done *by* the system *on* the surroundings. Since the system releases energy as work, *w is negative;* the final energy of the system is less than the initial energy, so ΔE *is negative*. (The work done here is not very useful because it just pushes back the piston and outside air. But, if the reaction mixture is gasoline and oxygen and the surroundings are an automobile engine, much of the internal energy is transferred as the work done to move the car.)

2. *Work done* ***on*** *a system* (Figure 6.4B). Suppose that, after the reaction is over, we increase the pressure of the surroundings (wider P_{surr} arrow) so that the piston moves in. Energy is transferred as work done *by* the surroundings *on* the system, so *w is positive.* The final energy of the system is greater than the initial energy, so ΔE *is positive.*

Table 6.1 summarizes the sign conventions for q and w and their effect on the sign of ΔE.

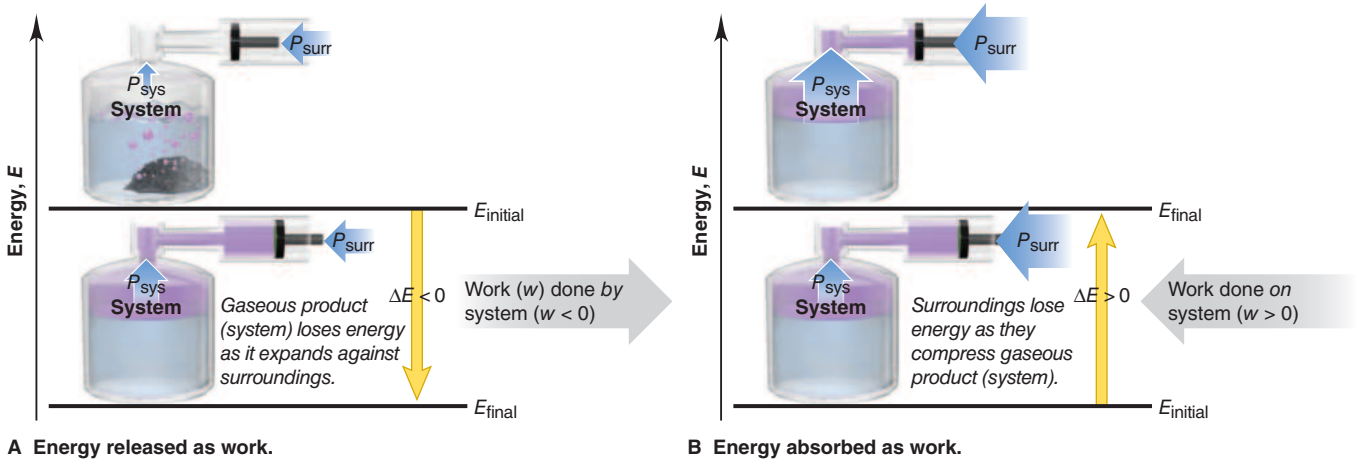

Figure 6.4 **The two cases where energy is transferred as work only. A,** The system does work *on* the surroundings. **B,** The system has work done on it *by* the surroundings.

Table 6.1 The Sign Conventions* for *q*, *w*, and ΔE

q	+	*w*	=	ΔE
+ (heat *absorbed*)		+ (work done *on*)		+ (energy *absorbed*)
+ (heat *absorbed*)		− (work done *by*)		Depends on the ***sizes*** of *q* and *w*
− (heat *released*)		+ (work done *on*)		Depends on the ***sizes*** of *q* and *w*
− (heat *released*)		− (work done *by*)		− (energy *released*)

*From the perspective of the system.

The Law of Energy Conservation

As you've seen, when a system absorbs energy, the surroundings release it, and when a system releases energy, the surroundings absorb it. Energy transferred between system and surroundings can be in the form of heat and/or various types of work—mechanical, electrical, radiant, chemical, and so forth.

Indeed, energy is often converted from one form to another during transfers. For example, when gasoline burns in a car engine, the reaction releases energy that is transferred as heat and work. The heat warms the car parts, passenger compartment, and surrounding air. The work is done when mechanical energy turns the car's wheels and belts. That energy is converted into the electrical energy of the sound system, the radiant energy of the headlights, the chemical energy of the battery, and so forth. The sum of all these forms equals the change in energy between reactants and products as the gasoline burns and the exhaust forms.

Complex biological processes follow the same general pattern. During photosynthesis, green plants use solar energy to convert the chemical energy of the bonds in CO_2 and H_2O into the energy of the bonds in starch and O_2; when you digest starch, the energy in its bonds is converted into the muscular (mechanical) energy needed to run a marathon.

The most important point to realize in these, and all other situations, is that the form of energy may change, but energy does not appear or disappear—energy cannot be created or destroyed. Put another way, *energy is conserved: the total energy of the system plus the surroundings remains constant*. The **law of conservation of energy,** also known as the **first law of thermodynamics,** restates this basic observation: *the total energy of the universe is constant.* It is expressed mathematically as

$$\Delta E_{\text{universe}} = \Delta E_{\text{system}} + \Delta E_{\text{surroundings}} = 0 \qquad \textbf{(6.3)}$$

This law applies, as far as we know, to all systems, from a burning match to continental drift, from the pumping of your heart to the formation of the Solar System.

Units of Energy

The SI unit of energy is the **joule (J),** a derived unit composed of three base units:

$$1\ \text{J} = 1\ \text{kg}\cdot\text{m}^2/\text{s}^2$$

Both heat and work are expressed in joules. Let's see why the joule is the unit for work. The work (*w*) done on a mass is the force (*F*) times the distance (*d*) that the mass moves: $w = F \times d$. A *force* changes the velocity of a mass over time; that is, a force *accelerates* a mass. Velocity has units of meters per second (m/s), so acceleration (*a*) has units of meters per second per second (m/s^2). Force, therefore, has units of mass (*m,* in kilograms) times acceleration:

$F = m \times a$ has units of $\text{kg}\cdot\text{m/s}^2$

Therefore, $w = F \times d$ has units of $(\text{kg}\cdot\text{m/s}^2) \times \text{m} = \text{kg}\cdot\text{m}^2/\text{s}^2 = \text{J}$

The **calorie (cal)** is an older unit defined originally as the quantity of energy needed to raise the temperature of 1 g of water by 1°C (specifically, from 14.5°C to 15.5°C). The calorie is now defined in terms of the joule:

$$1\ \text{cal} \equiv 4.184\ \text{J} \qquad \text{or} \qquad 1\ \text{J} = \frac{1}{4.184}\ \text{cal} = 0.2390\ \text{cal}$$

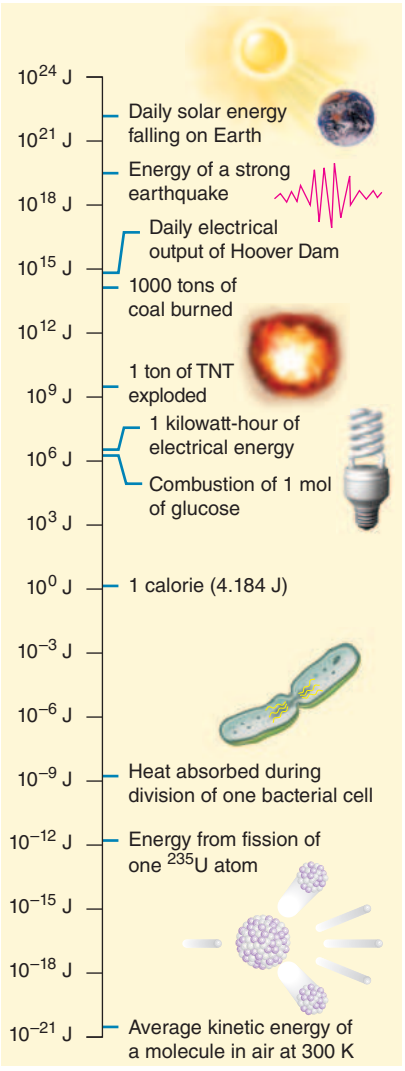

Figure 6.5 **Some quantities of energy.** The vertical scale is exponential.

Since the quantities of energy involved in chemical reactions are usually quite large, chemists use the kilojoule (kJ), or, in earlier sources, the kilocalorie (kcal):

$$1\ \text{kJ} = 1000\ \text{J} = 0.2390\ \text{kcal} = 239.0\ \text{cal}$$

The nutritional Calorie (note the capital C), the unit that shows the energy available from food, is actually a kilocalorie: 1 Cal = 1000 cal = 1 kcal = 4184 J.

The *British thermal unit (Btu),* a unit that you may have seen used for the energy output of appliances, is the quantity of energy required to raise the temperature of 1 lb of water by 1°F; *1 Btu is equivalent to 1055 J*. In general, the SI unit (J or kJ) is used in this text. Some interesting quantities of energy appear in Figure 6.5.

SAMPLE PROBLEM 6.1 **Determining the Change in Internal Energy of a System**

Problem When gasoline burns in a car engine, the heat released causes the gaseous products CO_2 and H_2O to expand, which pushes the pistons outward. Excess heat is removed by the radiator. If the expanding gases do 451 J of work on the pistons and the system releases 325 J to the surroundings as heat, calculate the change in energy (ΔE) in J, kJ, and kcal.

Plan We define system and surroundings to choose signs for q and w, and then we calculate ΔE with Equation 6.2. The system is the reactants and products, and the surroundings are the pistons, the radiator, and the rest of the car. Heat is released by the system, so q is negative. Work is done by the system to push the pistons outward, so w is also negative. We obtain the answer in J and then convert it to kJ and kcal.

Solution Calculating ΔE (from Equation 6.2) in J:

$$q = -325\ \text{J}$$
$$w = -451\ \text{J}$$
$$\Delta E = q + w = -325\ \text{J} + (-451\ \text{J}) = \boxed{-776\ \text{J}}$$

Converting from J to kJ:

$$\Delta E = -776\ \text{J} \times \frac{1\ \text{kJ}}{1000\ \text{J}} = \boxed{-0.776\ \text{kJ}}$$

Converting from kJ to kcal:

$$\Delta E = -0.776\ \text{kJ} \times \frac{1\ \text{kcal}}{4.184\ \text{kJ}} = \boxed{-0.185\ \text{kcal}}$$

Check The answer is reasonable: combustion of gasoline releases energy from the system, so $E_{\text{final}} < E_{\text{initial}}$ and ΔE should be negative. Rounding shows that, since 4 kJ ≈ 1 kcal, nearly 0.8 kJ should be nearly 0.2 kcal.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

6.1A A sample of liquid absorbs 13.5 kJ of heat and does 1.8 kJ of work when it vaporizes. Calculate ΔE (in J).

6.1B In a reaction, gaseous reactants form a liquid product. The heat absorbed by the surroundings is 26.0 kcal, and the work done on the system is 15.0 Btu. Calculate ΔE (in kJ).

SOME SIMILAR PROBLEMS 6.8–6.11

State Functions and the Path Independence of the Energy Change

The internal energy (E) of a system is called a **state function,** a property dependent only on the *current* state of the system (its composition, volume, pressure, and temperature), *not* on the path the system takes to reach that state. The energy change of a system can occur by countless combinations of heat (q) and/or work (w). However,

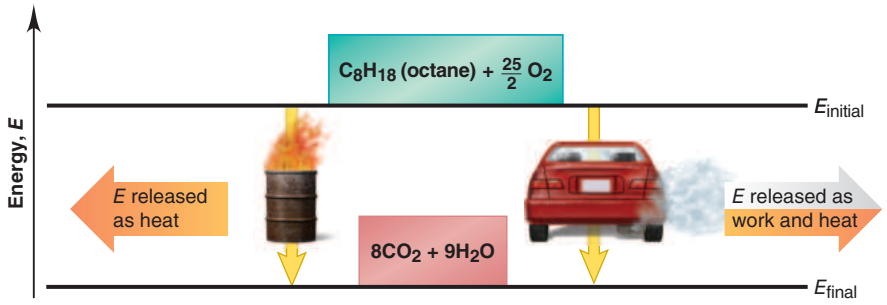

Figure 6.6 Two different paths for the energy change of a system. Even though q and w for the two paths are different, ΔE is the same.

because E is a state function, the overall ΔE is the same no matter what the specific combination may be. That is, ΔE *does* ***not*** *depend on how the change takes place, but only on the* ***difference*** *between the final and initial states.*

As an example, let's define a system in its initial state as 1 mol of octane (a component of gasoline) together with enough O_2 to burn it completely. In its final state, the system is the CO_2 and H_2O that form:

$$C_8H_{18}(l) + \tfrac{25}{2}O_2(g) \longrightarrow 8CO_2(g) + 9H_2O(g)$$

initial state ($E_{initial}$) final state (E_{final})

Energy is transferred *out* from the system as heat and/or work, so ΔE is negative. Figure 6.6 shows just two of the many ways the change can occur. If we burn the octane in an open container *(left),* ΔE is transferred almost completely as heat (with a small quantity of work done to push back the atmosphere). If we burn it in a car engine *(right),* a much larger portion (~30%) of ΔE is transferred as work that moves the car, with the rest transferred as heat that warms the car, exhaust gases, and surrounding air. If we burn the octane in a lawn mower or a motorcycle, ΔE appears as other combinations of work and heat. Thus, q and w are *not* state functions because their values *do* depend on the path the system takes, but ΔE (the *sum* of q and w) *does not.*

Pressure (P), volume (V), and temperature (T) are some other state functions. Path independence means that *changes in state functions—*ΔE, ΔP, ΔV, *and* ΔT*—depend only on the initial and final states.*

Your Personal Financial State Function

The *balance* in your checkbook is a state function of your personal financial system. You can open a new checking account with a birthday gift of $50, or you can open one with a deposit of a $100 paycheck and then write two $25 checks. The two paths to the balance are different, but the balance (current state) is the same.

Summary of Section 6.1

- Internal energy (E) is transferred as heat (q) when system and surroundings are at different temperatures or as work (w) when an object is moved by a force.
- Heat absorbed by a system ($q > 0$) or work done on a system ($w > 0$) increases the system's E; heat released by a system ($q < 0$) or work done by a system ($w < 0$) decreases its E. The change in the internal energy is the sum of the heat and work: $\Delta E = q + w$. Heat and work are measured in joules (J).
- Energy is always conserved: it can change from one form to another and be transferred into or out of a system, but the total quantity of energy in the universe (system *plus* surroundings) is constant.
- The internal energy of a system is a state function and, thus, is independent of how the system attained that energy; therefore, the same overall ΔE can occur through any combination of q and w.

6.2 ENTHALPY: CHANGES AT CONSTANT PRESSURE

Most physical and chemical changes occur at nearly constant atmospheric pressure—a reaction in an open flask, the freezing of a lake, a biochemical process in an organism. In this section, we discuss *enthalpy,* a thermodynamic variable that relates directly to energy changes at constant pressure.

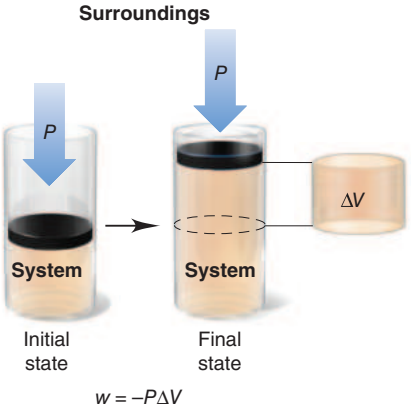

Figure 6.7 **Pressure-volume work.** An expanding gas pushing back the atmosphere does *PV* work ($w = -P\Delta V$).

PV Work and the Meaning of Enthalpy

To determine ΔE, we must measure both heat and work. The two most important types of chemical work are electrical work, done by moving charged particles (Chapter 21), and **pressure-volume work (*PV* work),** the mechanical work done when the volume of the system changes in the presence of an external pressure (P). The quantity of PV work equals P times the change in volume (ΔV, or $V_{final} - V_{initial}$). In an open flask (or in a cylinder with a weightless, frictionless piston) (Figure 6.7), a system of an expanding gas does PV work *on* the surroundings, so it has a negative sign:

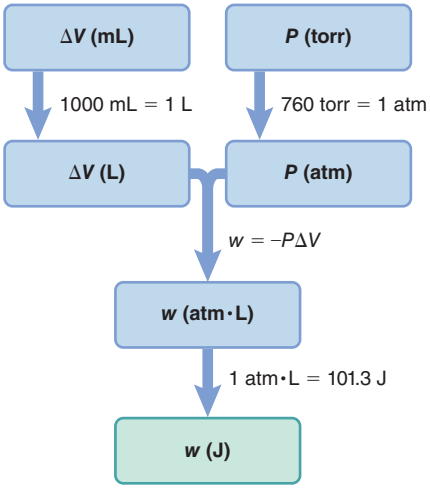
$$w = -P\Delta V \qquad (6.4)$$

SAMPLE PROBLEM 6.2 Calculating Pressure-Volume Work Done by or on a System

Problem A reaction taking place in a container with a piston-cylinder assembly at constant temperature produces a gas, and the volume increases from 125 mL to 652 mL against an external pressure of 988 torr. Calculate the work done (in J; 1 atm·L = 101.3 J).

Plan We are given the external pressure (988 torr) and initial (125 mL) and final volumes (652 mL) and have to find the work done by the gas. We subtract the initial V from the final V to find ΔV and convert it from mL to L. We convert the given P from torr to atm and use Equation 6.4 to calculate w. Then we convert the answer from atm·L to J (see the road map).

Road Map



Solution Calculating ΔV:

$$\Delta V\,(\text{L}) = V_{final} - V_{initial} = 652\ \text{mL} - 125\ \text{mL} = 527\ \text{mL}$$

Converting ΔV from mL to L:

$$\Delta V\,(\text{L}) = 527\ \text{mL} \times \frac{1\ \text{L}}{1000\ \text{mL}} = 0.527\ \text{L}$$

Converting P from torr to atm:

$$P\,(\text{atm}) = 988\ \text{torr} \times \frac{1\ \text{atm}}{760\ \text{torr}} = 1.30\ \text{atm}$$

Calculating w (using Equation 6.4):

$$w\ (\text{atm·L}) = -P\Delta V = -(1.30\ \text{atm} \times 0.527\ \text{L}) = -0.685\ \text{atm·L}$$

Converting from atm·L to J:

$$w\,(\text{J}) = -0.685\ \text{atm·L} \times \frac{101.3\ \text{J}}{1\ \text{atm·L}} = -69.4\ \text{J}$$

Check Since gas is produced, the system expands and does work on the surroundings (energy is released as work), so the negative sign is correct. Rounding shows that the size of the answer is reasonable: $w \approx -1\ \text{atm·L} \times 0.5\ \text{L} = -0.5\ \text{atm·L}$.

FOLLOW-UP PROBLEMS

6.2A A gas is compressed at constant temperature from a volume of 5.68 L to a volume of 2.35 L by an external pressure of 732 torr. Calculate the work done (in J).

6.2B A gas-producing reaction occurs in a container with a piston-cylinder assembly under an external pressure of 5.5 atm. At constant temperature, the volume increases from 10.5 L to 16.3 L. Calculate the work done (in J).

SOME SIMILAR PROBLEMS 6.22 and 6.23

For reactions *at constant pressure,* a thermodynamic variable called **enthalpy (*H*)** eliminates the need to measure PV work. The enthalpy of a system is defined as the internal energy *plus* the product of the pressure and volume:

$$H = E + PV$$

The **change in enthalpy (ΔH)** is the change in internal energy *plus* the product of the pressure, which is constant, and the change in volume (ΔV):

$$\Delta H = \Delta E + P\Delta V \qquad (6.5)$$

Combining equations 6.2 ($\Delta E = q + w$) and 6.4 ($w = -P\Delta V$) gives

$$\Delta E = q + w = q + (-P\Delta V) = q - P\Delta V$$

At constant pressure, we denote q as q_P, giving $\Delta E = q_P - P\Delta V$, which we can use to solve for q_P:

$$q_P = \Delta E + P\Delta V$$

Notice that the right side of this equation equals the right side of Equation 6.5:

$$q_P = \Delta E + P\Delta V = \Delta H \qquad \textbf{(6.6)}$$

Thus, *the change in enthalpy equals the heat absorbed or released at* ***constant*** *pressure*. For most changes occurring at constant pressure, ΔH is more relevant than ΔE *and* easier to obtain: *to find* ΔH, *measure* q_P. We discuss the laboratory method for doing this in Section 6.3.

Comparing ΔE and ΔH

Knowing the *enthalpy* change of a system tells us a lot about its *energy* change as well. In fact, because many reactions involve little (if any) PV work, most (or all) of the energy change occurs as a transfer of heat. Here are three cases:

1. *Reactions that do not involve gases.* Gases do not appear in precipitation, many acid-base, many redox reactions, and so forth. For example,

   $$2KOH(aq) + H_2SO_4(aq) \longrightarrow K_2SO_4(aq) + 2H_2O(l)$$

   Because liquids and solids undergo *very* small volume changes, $\Delta V \approx 0$; thus $P\Delta V \approx 0$ and $\Delta H \approx \Delta E$.
2. *Reactions in which the amount (mol) of gas does* ***not*** *change.* When the total amount of gaseous reactants equals the total amount of gaseous products, the volume is constant, $\Delta V = 0$, so $P\Delta V = 0$ and $\Delta H = \Delta E$. For example,

   $$N_2(g) + O_2(g) \longrightarrow 2NO(g)$$
3. *Reactions in which the amount (mol) of gas* ***does*** *change*. In these cases, $P\Delta V \neq 0$. However, q_P is usually *much* larger than $P\Delta V$, so ΔH is still very close to ΔE. For instance, in the combustion of H_2, 3 mol of gas yields 2 mol of gas:

   $$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

   In this reaction, $\Delta H = -483.6$ kJ and $P\Delta V = -2.5$ kJ, so (using Equation 6.5),

   $\Delta H = \Delta E + P\Delta V$ and $\Delta E = \Delta H - P\Delta V = -483.6 \text{ kJ} - (-2.5 \text{ kJ}) = -481.1 \text{ kJ}$

   Since most of ΔE occurs as energy transferred as heat, $\Delta H \approx \Delta E$.

Thus, *for most reactions,* ΔH *equals, or is very close to,* ΔE.

Exothermic and Endothermic Processes

Because H is a combination of the three state functions E, P, and V, it is also a state function. Therefore, ΔH equals H_{final} ***minus*** H_{initial}. For a reaction, H_{final} is H_{products} and H_{initial} is $H_{\text{reactants}}$, so the enthalpy change of a reaction is

$$\Delta H = H_{\text{final}} - H_{\text{initial}} = H_{\text{products}} - H_{\text{reactants}}$$

Since H_{products} can be either more or less than $H_{\text{reactants}}$, the *sign* of ΔH indicates whether heat is absorbed or released during the reaction. We determine the sign of ΔH *by imagining the heat as "reactant" or "product."* The two possible types of processes are

1. *Exothermic process: heat as a "product."* An **exothermic** ("heat out") **process** *releases* heat and results in a *decrease* in the enthalpy of the system:

   Exothermic: $H_{\text{products}} < H_{\text{reactants}}$ so $\Delta H < 0$

For example, when methane burns in air, heat flows *out of* the system into the surroundings, so we show it as a "product":

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g) + \textit{heat}$$

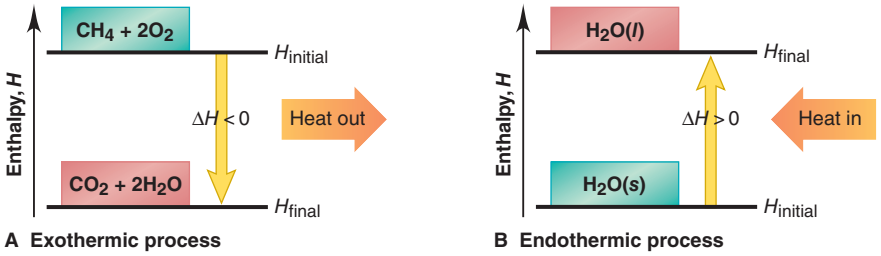


Figure 6.8 **Enthalpy diagrams for exothermic and endothermic processes.** **A,** The combustion of methane is exothermic: $\Delta H < 0$. **B,** The melting of ice is endothermic: $\Delta H > 0$.

The reactants (1 mol of CH_4 and 2 mol of O_2) release heat during the reaction, so they originally had more enthalpy than the products (1 mol of CO_2 and 2 mol of H_2O):

$$H_{reactants} > H_{products} \quad \text{so} \quad \Delta H\ (H_{products} - H_{reactants}) < 0$$

This exothermic change is shown in the **enthalpy diagram** in Figure 6.8A.

2. *Endothermic process: heat as a "reactant."* An **endothermic** ("heat in") **process** *absorbs* heat and results in an *increase* in the enthalpy of the system:

$$\text{Endothermic:} \qquad H_{products} > H_{reactants} \quad \text{so} \quad \Delta H > 0$$

When ice melts, for instance, heat flows *into* the ice from the surroundings, so we show the heat as a "reactant":

$$heat + H_2O(s) \longrightarrow H_2O(l)$$

Because heat is absorbed, the enthalpy of the product (water) must be higher than that of the reactant (ice):

$$H_{water} > H_{ice} \quad \text{so} \quad \Delta H\ (H_{water} - H_{ice}) > 0$$

This endothermic change is shown in Figure 6.8B. (In general, the value of an enthalpy change is determined with reactants and products at the same temperature.)

SAMPLE PROBLEM 6.3 Drawing Enthalpy Diagrams and Determining the Sign of ΔH

Problem In each of the following cases, determine the sign of ΔH, state whether the reaction is exothermic or endothermic, and draw an enthalpy diagram:

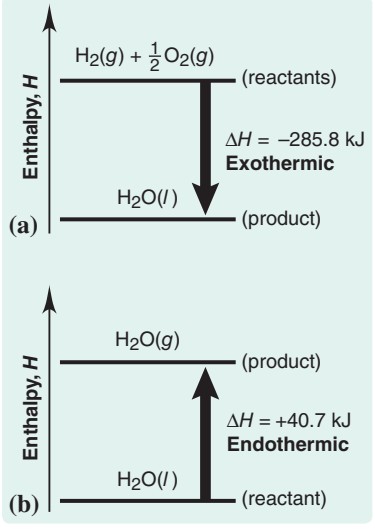
(a) $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) + 285.8\ kJ$

(b) $40.7\ kJ + H_2O(l) \longrightarrow H_2O(g)$

Plan From each equation, we note whether heat is a "product" (exothermic; $\Delta H < 0$) or a "reactant" (endothermic; $\Delta H > 0$). For exothermic reactions, reactants are above products on the enthalpy diagram; for endothermic reactions, reactants are below products. The ΔH arrow *always* points from reactants to products.

Solution **(a)** Heat is a product (on the right), so $\Delta H < 0$ and the reaction is exothermic. The enthalpy diagram appears in the margin *(top)*.

(b) Heat is a reactant (on the left), so $\Delta H > 0$ and the reaction is endothermic. The enthalpy diagram appears in the margin *(bottom)*.



Check Substances that are on the same side of the equation as the heat have less enthalpy than substances on the other side, so make sure those substances are placed on the lower line of the diagram.

FOLLOW-UP PROBLEMS

6.3A Nitroglycerine decomposes through a violent explosion that releases 5.72×10^3 kJ of heat per mole: $C_3H_5(NO_3)_3(l) \longrightarrow 3CO_2(g) + \frac{5}{2}H_2O(g) + \frac{1}{4}O_2(g) + \frac{3}{2}N_2(g)$. Is the decomposition of nitroglycerine exothermic or endothermic? Draw an enthalpy diagram for the process.

6.3B Ammonium nitrate is used in some "instant" cold packs because the salt absorbs 25.7 kJ per mole as it dissolves: $NH_4NO_3(s) \xrightarrow{H_2O} NH_4^+(aq) + NO_3^-(aq)$. Is dissolving ammonium nitrate an exothermic or endothermic process? Draw an enthalpy diagram for the process.

SOME SIMILAR PROBLEMS 6.24–6.29

Summary of Section 6.2

- Enthalpy (H) is a state function, so any change in enthalpy (ΔH) is independent of how the change occurred. At constant P, the value of ΔH equals ΔE plus the PV work, which occurs when the volume of the system changes in the presence of an external pressure.
- ΔH equals q_P, the heat released or absorbed during a chemical or physical change that takes place at constant pressure.
- In most cases, ΔH is equal, or very close, to ΔE.
- A change that releases heat is exothermic ($\Delta H < 0$); a change that absorbs heat is endothermic ($\Delta H > 0$).

6.3 CALORIMETRY: MEASURING THE HEAT OF A CHEMICAL OR PHYSICAL CHANGE

Data about energy content and usage are everywhere, from the caloric value of a slice of pizza to the gas mileage of a car. In this section, we consider the basic ideas behind how these values are determined.

Specific Heat Capacity

To find the energy change during a process, we measure the quantity of heat released or absorbed by relating it to the change in temperature. You know from everyday experience that the more you heat an object, the higher its temperature, and the more you cool it, the lower its temperature; in other words, the quantity of heat (q) absorbed or released by an object is proportional to its temperature change:

$$q \propto \Delta T \qquad \text{or} \qquad q = \text{constant} \times \Delta T \qquad \text{or} \qquad \frac{q}{\Delta T} = \text{constant}$$

What you might not know is that the temperature change depends on the object. Every object has its own **heat capacity,** the quantity of heat required to change its temperature by 1 K. Heat capacity is the proportionality constant in the preceding equation:

$$\text{Heat capacity} = \frac{q}{\Delta T} \quad [\text{in units of J/K}]$$

A related property is **specific heat capacity (*c*),** the quantity of heat required to change the temperature of 1 *gram* of a substance or material by 1 K:

$$\text{Specific heat capacity } (c) = \frac{q}{\text{mass} \times \Delta T} \quad [\text{in units of J/g·K}]$$

If we know c of the object being heated (or cooled), we can measure the mass and the temperature change and calculate the heat absorbed (or released):

$$q = c \times \text{mass} \times \Delta T \tag{6.7}$$

Equation 6.7 says that when an object gets hotter, that is, when ΔT ($T_{\text{final}} - T_{\text{initial}}$) is positive, $q > 0$ (the object absorbs heat). And when an object gets cooler, that is, when ΔT is negative, $q < 0$ (the object releases heat). Table 6.2 lists the specific heat capacities of some representative substances and materials. Notice that metals have relatively low values of c and water has a very high value: for instance, it takes over 30 times as much energy to increase the temperature of a gram of water by 1 K as it does a gram of gold!

Closely related to the specific heat capacity (but reserved for substances) is the **molar heat capacity** (***C;*** note the capital letter), the quantity of heat required to change the temperature of 1 *mole* of a substance by 1 K:

$$\text{Molar heat capacity } (C) = \frac{q}{\text{amount (mol)} \times \Delta T} \quad [\text{in units of J/mol·K}]$$

Table 6.2 Specific Heat Capacities (*c*) of Some Elements, Compounds, and Materials

Substance	*c* (J/g·K)*
Elements	
Aluminum, Al	0.900
Graphite, C	0.711
Iron, Fe	0.450
Copper, Cu	0.387
Gold, Au	0.129
Compounds	
Water, $H_2O(l)$	4.184
Ethyl alcohol, $C_2H_5OH(l)$	2.46
Ethylene glycol, $(CH_2OH)_2(l)$	2.42
Carbon tetrachloride, $CCl_4(l)$	0.862
Materials	
Wood	1.76
Cement	0.88
Glass	0.84
Granite	0.79
Steel	0.45

*At 298 K (25°C)

Earth without oceans.

To find C of liquid H_2O, we multiply c of liquid H_2O (4.184 J/g·K) by the molar mass of H_2O (18.02 g/mol):

$$C \text{ of } H_2O(l) = 4.184 \frac{\text{J}}{\text{g·K}} \times \frac{18.02 \text{ g}}{1 \text{ mol}} = 75.40 \frac{\text{J}}{\text{mol·K}}$$

Liquid water has a *very* high specific heat capacity (~4.2 J/g·K), about six times that of rock (~0.7 J/g·K). If Earth had no oceans *(see margin),* it would take one-sixth as much energy for the Sun to heat the rocky surface, and the surface would give off six times as much heat after sundown. Days would be scorching and nights frigid.

SAMPLE PROBLEM 6.4 Finding the Quantity of Heat from a Temperature Change

Problem A layer of copper welded to the bottom of a skillet weighs 125 g. How much heat is needed to raise the temperature of the copper layer from 25°C to 300.°C? The specific heat capacity (c) of Cu is given in Table 6.2.

Plan We know the mass (125 g) and c (0.387 J/g·K) of Cu and can find ΔT in °C, which equals ΔT in K. We then use Equation 6.7 to calculate the heat.

Solution Calculating ΔT and then q:

$$\Delta T = T_{\text{final}} - T_{\text{initial}} = 300.°\text{C} - 25°\text{C} = 275°\text{C} = 275 \text{ K}$$

$$q = c \times \text{mass (g)} \times \Delta T = 0.387 \text{ J/g·K} \times 125 \text{ g} \times 275 \text{ K} = 1.33\times10^4 \text{ J}$$

Check Heat is absorbed by the copper bottom (system), so q is positive. Rounding shows the arithmetic is reasonable: $q \approx 0.4 \text{ J/g·K} \times 100 \text{ g} \times 300 \text{ K} = 1.2\times10^4$ J.

FOLLOW-UP PROBLEMS

6.4A Before baking a pie, you line the bottom of an oven with a 7.65-g piece of aluminum foil and then raise the oven temperature from 18°C to 375°C. Use Table 6.2 to find the heat (in J) absorbed by the foil.

6.4B Find the heat released (in kJ) when 5.50 L of ethylene glycol (d = 1.11 g/mL; see Table 6.2) in a car radiator cools from 37.0°C to 25.0°C.

SOME SIMILAR PROBLEMS 6.37–6.40

The Two Major Types of Calorimetry

How do we know the heat of an acid-base reaction or the Calories in a teaspoon of sugar? In the lab, we construct "surroundings" that retain the heat as reactants change to products, and then note the temperature change. These "surroundings" take the form of a **calorimeter,** a device used to measure the heat released (or absorbed) by a physical or chemical process. Let's look at two types of calorimeter—one designed to measure the heat at constant pressure and the other at constant volume.

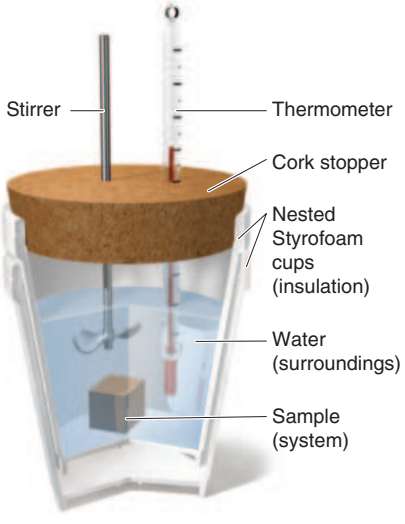


Figure 6.9 Coffee-cup calorimeter. This device measures the heat transferred at constant pressure (q_P).

Constant-Pressure Calorimetry For processes that take place at constant pressure, the heat transferred (q_P) is often measured in a *coffee-cup calorimeter* (Figure 6.9). This simple apparatus can be used to find the heat of an aqueous reaction, the heat accompanying the dissolving of a salt, or even the specific heat capacity of a solid that does not react with or dissolve in water.

Let's examine the third application first. The solid (the system) is weighed, heated to some known temperature, and added to a known mass and temperature of water (surroundings) in the calorimeter. After stirring, the final water temperature is measured, which is also the final temperature of the solid. Assuming no heat escapes the calorimeter, the heat released by the system ($-q_{\text{sys}}$, or $-q_{\text{solid}}$) is equal in magnitude but opposite in sign to the heat absorbed by the surroundings ($+q_{\text{surr}}$, or $+q_{H_2O}$):

$$-q_{\text{solid}} = q_{H_2O}$$

Substituting from Equation 6.7 on each side of this equation gives

$$-(c_{\text{solid}} \times \text{mass}_{\text{solid}} \times \Delta T_{\text{solid}}) = c_{H_2O} \times \text{mass}_{H_2O} \times \Delta T_{H_2O}$$

All the quantities are known or measured except c_{solid}:

$$c_{solid} = -\frac{c_{H_2O} \times mass_{H_2O} \times \Delta T_{H_2O}}{mass_{solid} \times \Delta T_{solid}}$$

SAMPLE PROBLEM 6.5 Determining the Specific Heat Capacity of a Solid

Problem You heat 22.05 g of a solid in a test tube to 100.00°C and add it to 50.00 g of water in a coffee-cup calorimeter. The water temperature changes from 25.10°C to 28.49°C. Find the specific heat capacity of the solid.

Plan We are given the masses of the solid (22.05 g) and of H_2O (50.00 g), and we can find the temperature changes of the water and of the solid by subtracting the given values, always using $T_{final} - T_{initial}$. Using Equation 6.7, we set the heat released by the solid ($-q_{solid}$) equal to the heat absorbed by the water (q_{H_2O}). The specific heat of water is known, and we solve for c_{solid}.

Solution Finding ΔT_{solid} and ΔT_{H_2O}:

$$\Delta T_{H_2O} = T_{final} - T_{initial} = (28.49°C - 25.10°C) = 3.39°C = 3.39\ K$$
$$\Delta T_{solid} = T_{final} - T_{initial} = (28.49°C - 100.00°C) = -71.51°C = -71.51\ K$$

Solving for c_{solid}:

$$c_{solid} = -\frac{c_{H_2O} \times mass_{H_2O} \times \Delta T_{H_2O}}{mass_{solid} \times \Delta T_{solid}} = -\frac{4.184\ J/g\cdot K \times 50.00\ g \times 3.39\ K}{22.05\ g \times (-71.51\ K)} = 0.450\ J/g\cdot K$$

Check Rounding gives $-4\ J/g\cdot K \times 50\ g \times 3\ K/[20\ g \times (-70°C)] = 0.4\ J/g\cdot K$, so the answer seems correct.

FOLLOW-UP PROBLEMS

6.5A A 12.18-g sample of a shiny, orange-brown metal is heated to 65.00°C and then added to 25.00 g of water in a coffee-cup calorimeter. The water temperature changes from 25.55°C to 27.25°C. What is the unknown metal (see Table 6.2)?

6.5B A 33.2-g titanium bicycle part is added to 75.0 g of water in a coffee-cup calorimeter at 50.00°C, and the temperature drops to 49.30°C. What was the initial temperature (in °C) of the metal part (c of titanium is 0.228 J/g·K)?

SOME SIMILAR PROBLEMS 6.41–6.46

In the next sample problem, the calorimeter is used to study the transfer of heat during an aqueous acid-base reaction. Recall that, if a reaction takes place at constant pressure, the heat of the reaction (q_{rxn}) is equal to its enthalpy change (ΔH).

SAMPLE PROBLEM 6.6 Determining the Enthalpy Change of an Aqueous Reaction

Problem You place 50.0 mL of 0.500 *M* NaOH in a coffee-cup calorimeter at 25.00°C and add 25.0 mL of 0.500 *M* HCl, also at 25.00°C. After stirring, the final temperature is 27.21°C. [Assume that the total volume is the sum of the individual volumes and that the final solution has the same density (1.00 g/mL) and specific heat capacity (Table 6.2) as water.] **(a)** Calculate q_{soln} (in J). **(b)** Calculate the change in enthalpy, ΔH, of the reaction (in kJ/mol of H_2O formed).

(a) Calculate q_{soln}

Plan The solution is the surroundings, and as the reaction takes place, heat flows into the solution. To find q_{soln}, we use Equation 6.7, so we need the mass of solution, the change in temperature, and the specific heat capacity. We know the solutions' volumes (25.0 mL and 50.0 mL), so we find their masses with the given density (1.00 g/mL). Then, to find q_{soln}, we multiply the total mass by the given c (4.184 J/g·K) and the change in T, which we find from $T_{final} - T_{initial}$.

Solution Finding mass_{soln} and ΔT_{soln}:

$$\text{Total mass (g) of solution} = (25.0\ \text{mL} + 50.0\ \text{mL}) \times 1.00\ \text{g/mL} = 75.0\ \text{g}$$

$$\Delta T = 27.21°\text{C} - 25.00°\text{C} = 2.21°\text{C} = 2.21\ \text{K}$$

Finding q_{soln}:

$$q_{soln} = c_{soln} \times \text{mass}_{soln} \times \Delta T_{soln} = (4.184\ \text{J/g·K})(75.0\ \text{g})(2.21\ \text{K}) = 693\ \text{J}$$

Check The value of q_{soln} is positive because the reaction releases heat to the solution. Rounding to check the size of q_{soln} gives 4 J/g·K × 75 g × 2 K = 600 J, which is close to the answer.

(b) Calculate the change in enthalpy (ΔH)

Plan To find ΔH, we write the balanced equation for the acid-base reaction and use the volumes and the concentrations (0.500 *M*) to find amount (mol) of each reactant (H^+ and OH^-). Since the amounts of two reactants are given, we determine which is limiting, that is, which gives less product (H_2O). The heat of the surroundings is q_{soln}, and it is the negative of the heat of the reaction (q_{rxn}), which equals ΔH. And dividing q_{rxn} by the amount (mol) of water formed gives ΔH in kJ/mol of water formed.

Solution Writing the balanced equation:

$$HCl(aq) + NaOH(aq) \longrightarrow H_2O(l) + NaCl(aq)$$

Finding amount (mol) of reactants:

$$\text{Amount (mol) of HCl} = 0.500\ \text{mol HCl/L} \times 0.0250\ \text{L} = 0.0125\ \text{mol HCl}$$

$$\text{Amount (mol) of NaOH} = 0.500\ \text{mol NaOH/L} \times 0.0500\ \text{L} = 0.0250\ \text{mol NaOH}$$

Finding the amount (mol) of product: All the coefficients in the equation are 1, which means that the amount (mol) of reactant yields that amount of product. Therefore, HCl is limiting because it yields less product: 0.0125 mol of H_2O.

Finding ΔH: Heat absorbed by the solution was released by the reaction; that is,

$$q_{soln} = -q_{rxn} = 693\ \text{J} \qquad \text{so} \qquad q_{rxn} = -693\ \text{J}$$

$$\Delta H\,(\text{kJ/mol}) = \frac{q_{rxn}}{\text{mol } H_2O} \times \frac{1\ \text{kJ}}{1000\ \text{J}} = \frac{-693\ \text{J}}{0.0125\ \text{mol } H_2O} \times \frac{1\ \text{kJ}}{1000\ \text{J}} = -55.4\ \text{kJ/mol } H_2O$$

Check We check for the limiting reactant: The volume of H^+ is half the volume of OH^-, but they have the same concentration and a 1/1 stoichiometric ratio. Therefore, the amount (mol) of H^+ determines the amount of product. Rounding and taking the negative of q_{soln} to find ΔH gives $-600\ \text{J}/0.012\ \text{mol} = -5\times10^4\ \text{J/mol}$, or -50 kJ/mol, so the answer seems correct.

FOLLOW-UP PROBLEMS

6.6A When 25.0 mL of 2.00 *M* HNO_3 and 50.0 mL of 1.00 *M* KOH, both at 21.90°C, are mixed, a reaction causes the temperature of the mixture to rise to 27.05°C. (**a**) Write balanced molecular and net ionic equations for the reaction. (**b**) Calculate q_{rxn} (in kJ). (Assume that the final volume is the sum of the volumes being mixed and that the final solution has $d = 1.00$ g/mL and $c = 4.184$ J/g·K.)

6.6B After 50.0 mL of 0.500 *M* $Ba(OH)_2$ and the same volume and concentration of HCl react in a coffee-cup calorimeter, you find q_{soln} to be 1.386 kJ. Calculate ΔH of the reaction in kJ/mol of H_2O formed.

A SIMILAR PROBLEM 6.50

Constant-Volume Calorimetry Constant-volume calorimetry is carried out in a *bomb calorimeter,* a device commonly used to measure the heat of combustion reactions, such as for fuels and foods. With a coffee-cup calorimeter, we simply assume that all the heat is absorbed by the water, but in reality, some is absorbed by the stirrer, thermometer, cups, and so forth. With the much more precise bomb calorimeter, the *heat capacity of the entire calorimeter* is known (or can be determined).

Figure 6.10 depicts the preweighed combustible sample in a metal-walled chamber (the bomb), which is filled with oxygen gas and immersed in an insulated water bath fitted with motorized stirrer and thermometer. A heating coil connected to an electrical source ignites the sample, and the heat released raises the temperature of the bomb, water, and other calorimeter parts. Because we know the mass of the

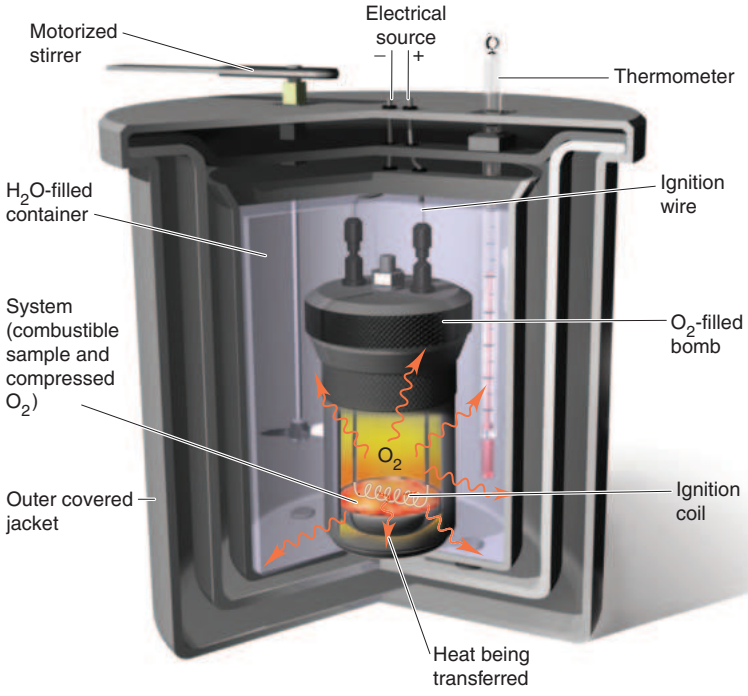

Figure 6.10 **A bomb calorimeter.** This device measures the heat released at constant volume (q_V).

sample and the heat capacity of the entire calorimeter, we can use the measured ΔT to calculate the heat released.

Note that the steel bomb is tightly sealed, not open to the atmosphere as is the coffee cup, so the pressure is *not* constant. And the volume of the bomb is fixed, so $\Delta V = 0$, and thus $P\Delta V = 0$. Thus, the energy change measured is the *heat released at constant volume (q_V),* which equals ΔE, not ΔH:

$$\Delta E = q + w = q_V + 0 = q_V$$

Recall from Section 6.2, however, that even though the number of moles of gas may change, $P\Delta V$ is usually *much* less than ΔE, so ΔH is very close to ΔE. For example, ΔH is only 0.5% larger than ΔE for the combustion of H_2 and only 0.2% smaller than ΔE for the combustion of octane.

SAMPLE PROBLEM 6.7 Calculating the Heat of a Combustion Reaction

Problem A manufacturer claims that its new dietetic dessert has "fewer than 10 Calories per serving." To test the claim, a chemist at the Department of Consumer Affairs places one serving in a bomb calorimeter and burns it in O_2. The initial temperature is 21.862°C and the temperature rises to 26.799°C. If the heat capacity of the calorimeter is 8.151 kJ/K, is the manufacturer's claim correct?

Plan When the dessert (system) burns, the heat released is absorbed by the calorimeter:

$$-q_{system} = q_{calorimeter}$$

The claim is correct if the heat of the system is less than 10 Calories. To find the heat, we find ΔT, multiply it by the given heat capacity of the calorimeter (8.151 kJ/K), and then convert to Calories.

Solution Finding ΔT:

$$\Delta T = T_{final} - T_{initial} = 26.799°C - 21.862°C = 4.937°C = 4.937\ K$$

Calculating the heat absorbed by the calorimeter:

$$q_{calorimeter} = \text{heat capacity} \times \Delta T = 8.151\ kJ/K \times 4.937\ K = 40.24\ kJ$$

Recall that 1 Calorie = 1 kcal = 4.184 kJ. Therefore, 10 Calories = 41.84 kJ, so the claim is correct.

Check A quick math check shows that the answer is reasonable: 8 kJ/K × 5 K = 40 kJ.

FOLLOW-UP PROBLEMS

6.7A A chemist burns 0.8650 g of graphite (a form of carbon) in a new bomb calorimeter, and CO_2 forms. If 393.5 kJ of heat is released per mole of graphite and ΔT is 2.613 K, what is the heat capacity of the bomb calorimeter?

6.7B Oxyacetylene torches reach such high temperatures that they are often used to weld and cut metal. When 2.50 g of acetylene (C_2H_2) is burned in the bomb calorimeter used in Follow-up Problem 6.7A, the temperature increases 11.50°C. What is ΔE (in kJ/mol) for this combustion reaction?

SOME SIMILAR PROBLEMS 6.47 and 6.49

Summary of Section 6.3

- We calculate ΔH of a process by measuring the energy transferred as heat at constant pressure (q_P). To do this, we determine ΔT and multiply it by the mass of the substance and by its specific heat capacity (c), which is the quantity of energy needed to raise the temperature of 1 g of the substance by 1 K.
- Calorimeters measure the heat released (or absorbed) during a process either at constant pressure (coffee cup; $q_P = \Delta H$) or at constant volume (bomb; $q_V = \Delta E$).

6.4 STOICHIOMETRY OF THERMOCHEMICAL EQUATIONS

A **thermochemical equation** is a balanced equation that includes the enthalpy change of the reaction (ΔH). Keep in mind that a given ΔH refers only to the *amounts (mol) of substances* ***and*** *their states of matter in that equation.* The enthalpy change of any process has two aspects:

- *Sign.* The sign of ΔH depends on whether the reaction is exothermic (−) or endothermic (+). A forward reaction has the *opposite* sign of the reverse reaction. Decomposition of 2 mol of water to its elements (endothermic):

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g) \qquad \Delta H = 572 \text{ kJ}$$

  Formation of 2 mol of water from its elements (exothermic):

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l) \qquad \Delta H = -572 \text{ kJ}$$

- *Magnitude.* The magnitude of ΔH is *proportional to the amount of substance*. Formation of 1 mol of water from its elements (half the preceding amount):

$$H_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H = -286 \text{ kJ}$$

Two key points to understand about thermochemical equations are

1. *Balancing coefficients*. When necessary, we use fractional coefficients to balance an equation, because we are specifying the magnitude of ΔH for a *particular amount,* often 1 mol, *of a substance,* for example, gaseous SO_2:

$$\tfrac{1}{8}S_8(s) + O_2(g) \longrightarrow SO_2(g) \qquad \Delta H = -296.8 \text{ kJ}$$

2. *Thermochemical equivalence.* For a *particular reaction,* a certain amount of substance is thermochemically equivalent to a certain quantity of energy. Just as we use stoichiometrically equivalent molar ratios to find amounts of substances, we use thermochemically equivalent quantities to find the ΔH of a reaction for a given amount of substance. Some examples from the previous two reactions are

296.8 kJ is thermochemically equivalent to $\frac{1}{8}$ mol of $S_8(s)$
286 kJ is thermochemically equivalent to $\frac{1}{2}$ mol of $O_2(g)$
286 kJ is thermochemically equivalent to 1 mol of $H_2O(l)$

Also, just as we use molar mass (in g/mol) to convert an amount (mol) of a substance to mass (g), we use the ΔH (in kJ/mol) to convert an amount (mol) of a substance to an equivalent quantity of heat (in kJ). Figure 6.11 shows this new relationship, and Sample Problem 6.8 applies it.

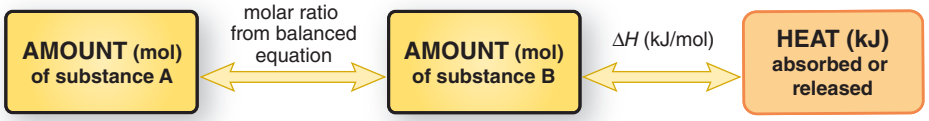

Figure 6.11 The relationship between amount (mol) of substance and the energy (kJ) transferred as heat during a reaction.

SAMPLE PROBLEM 6.8 **Using the Enthalpy Change of a Reaction (ΔH) to Find the Amount of a Substance**

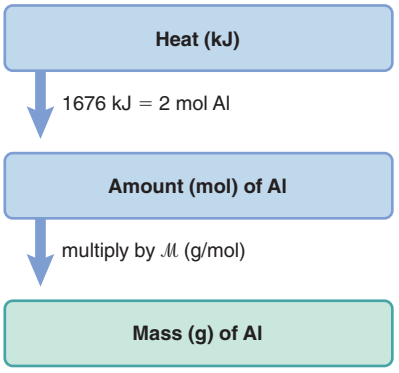
Problem The major source of aluminum in the world is bauxite (mostly aluminum oxide). Its thermal decomposition can be written as

$$Al_2O_3(s) \xrightarrow{\Delta} 2Al(s) + \tfrac{3}{2}O_2(g) \qquad \Delta H = 1676\ kJ$$

If aluminum is produced this way (see Comment), how many grams of aluminum can form when 1.000×10^3 kJ of heat is transferred (see the road map)?

Plan From the balanced equation and the enthalpy change, we see that 1676 kJ of heat is thermochemically equivalent to 2 mol of Al. With this equivalent quantity, we convert the given number of kJ to amount (mol) formed and then convert amount to mass (g).

Road Map



Solution Combining steps to convert from heat transferred to mass of Al:

$$\text{Mass (g) of Al} = (1.000\times10^3\ \text{kJ}) \times \frac{2\ \text{mol Al}}{1676\ \text{kJ}} \times \frac{26.98\ \text{g Al}}{1\ \text{mol Al}} = 32.20\ \text{g Al}$$

Check The mass of aluminum seems correct: ~1700 kJ forms about 2 mol of Al (54 g), so 1000 kJ should form a bit more than half that amount (27 g).

Comment In practice, aluminum is not obtained by heating bauxite but by supplying electrical energy (as you'll see in Chapter 22). Because *H* is a state function, however, the total energy required for the change is the same no matter how it occurs.

FOLLOW-UP PROBLEMS

6.8A Hydrogenation reactions, in which H_2 and an "unsaturated" organic compound combine, are used in the food, fuel, and polymer industries. In the simplest case, ethene (C_2H_4) and H_2 form ethane (C_2H_6). If 137 kJ is given off per mole of C_2H_4 reacting, how much heat is released when 15.0 kg of C_2H_6 forms?

6.8B In the searing temperatures reached in a lightning bolt, nitrogen and oxygen form nitrogen monoxide, NO. If 180.58 kJ of heat is absorbed per mole of N_2 reacting, how much heat is absorbed when 3.50 metric tons (t; 1 t = 10^3 kg) of NO forms?

SOME SIMILAR PROBLEMS 6.54–6.57

Summary of Section 6.4

- A thermochemical equation shows a balanced reaction *and* its ΔH value. The sign of ΔH for a forward reaction is opposite that for the reverse reaction. The magnitude of ΔH is specific for the given equation.
- The amount of a substance and the quantity of heat specified by the balanced equation are thermochemically equivalent and act as a conversion factor to find the quantity of heat transferred when any amount of the substance reacts.

6.5 HESS'S LAW: FINDING ΔH OF ANY REACTION

In some cases, a reaction is difficult, even impossible, to carry out individually: it may be part of a complex biochemical process, or take place under extreme conditions, or require a change in conditions to occur. Even if we can't run a reaction in the lab, we can still find its enthalpy change. In fact, the state-function property of enthalpy (*H*) allows us to find ΔH of *any* reaction for which we can write an equation.

This application is based on **Hess's law:** *the enthalpy change of an overall process is the sum of the enthalpy changes of its individual steps:*

$$\Delta H_{\text{overall}} = \Delta H_1 + \Delta H_2 + \cdots + \Delta H_n \qquad \textbf{(6.8)}$$

This law follows from the fact that ΔH for a process depends only on the difference between the final and initial states. To apply Hess's law, we

- Imagine that an overall (target) reaction occurs through a series of individual reaction steps, whether or not it actually does. (Adding the steps must give the overall reaction.)
- Choose individual reaction steps that each has a known ΔH.
- Adjust, as needed, the equations for the individual steps, as well as their ΔH values, to obtain the overall equation.
- Add the ΔH values for the steps to get the unknown ΔH of the overall reaction. We can also find an unknown ΔH of any step by subtraction, if we know the ΔH values for the overall reaction and all the other steps.

Let's apply Hess's law to the oxidation of sulfur to sulfur trioxide, the key change in the industrial production of sulfuric acid and in the formation of acid rain. (To introduce this approach, we'll use S as the formula for sulfur, rather than the more correct S_8.) When we burn S in an excess of O_2, sulfur dioxide (SO_2) forms (equation 1), *not* sulfur trioxide (SO_3). After a change in conditions, we add more O_2 and oxidize SO_2 to SO_3 (equation 2). Thus, we cannot put S and O_2 in a calorimeter and find ΔH for the overall reaction of S to SO_3 (equation 3). But, we *can* find it with Hess's law.

$$\begin{aligned}
&\text{Equation 1:} && S(s) + O_2(g) \longrightarrow SO_2(g) && \Delta H_1 = -296.8\ \text{kJ}\\
&\text{Equation 2:} && 2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g) && \Delta H_2 = -198.4\ \text{kJ}\\
&\text{Equation 3:} && S(s) + \tfrac{3}{2}O_2(g) \longrightarrow SO_3(g) && \Delta H_3 = \ ?
\end{aligned}$$

If we can adjust equation 1 and/or equation 2, *along with their ΔH value(s),* so these equations add up to equation 3, their ΔH values will add up to the unknown ΔH_3.

First, we identify our "target" equation, the one whose ΔH we want to find, and note the amount (mol) of each reactant and product; our "target" is equation 3. Then, we adjust equations 1 and/or 2 to make them add up to equation 3:

- Equations 3 and 1 have the same amount of S, so we don't change equation 1.
- Equation 3 has half as much SO_3 as equation 2, so we multiply equation 2, ***and ΔH_2,*** by $\frac{1}{2}$; that is, we always treat the equation and its ΔH value the same.
- With the targeted amounts of reactants and products present, we add equation 1 to the halved equation 2 and cancel terms that appear on both sides:

$$\begin{aligned}
&\text{Equation 1:} && S(s) + O_2(g) \longrightarrow SO_2(g) && \Delta H_1 = -296.8\ \text{kJ}\\
&\tfrac{1}{2}(\text{Equation 2}): && SO_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow SO_3(g) && \tfrac{1}{2}(\Delta H_2) = -99.2\ \text{kJ}\\
&\text{Equation 3:} && S(s) + O_2(g) + \cancel{SO_2(g)} + \tfrac{1}{2}O_2(g) \longrightarrow \cancel{SO_2(g)} + SO_3(g)
\end{aligned}$$

$$\text{or,} \qquad S(s) + \tfrac{3}{2}O_2(g) \longrightarrow SO_3(g) \qquad \Delta H_3 = -396.0\ \text{kJ}$$

Because ΔH depends only on the difference between H_{final} and H_{initial}, Hess's law tells us that the difference between the enthalpies of the reactants (1 mol of S and $\frac{3}{2}$ mol of O_2) and the product (1 mol of SO_3) is the same, whether S is oxidized directly to SO_3 (impossible) or through the intermediate formation of SO_2 (actual).

To summarize, calculating an unknown ΔH involves three steps:

1. Identify the target equation, the step whose ΔH is unknown, and note the amount (mol) of each reactant and product.
2. Adjust each equation with known ΔH values so that the target amount (mol) of each substance is on the correct side of the equation. Remember to:
   - Change the sign of ΔH when you reverse an equation.
   - Multiply amount (mol) and ΔH by the same factor.
3. Add the adjusted equations and their resulting ΔH values to get the target equation and its ΔH. All substances except those in the target equation must cancel.

SAMPLE PROBLEM 6.9 Using Hess's Law to Calculate an Unknown ΔH

Problem Two pollutants that form in automobile exhaust are CO and NO. An environmental chemist must convert these pollutants to less harmful gases through the following:

$$CO(g) + NO(g) \longrightarrow CO_2(g) + \tfrac{1}{2}N_2(g) \qquad \Delta H = ?$$

Given the following information, calculate the unknown ΔH:

$$\text{Equation A:} \quad CO(g) + \tfrac{1}{2}O_2(g) \longrightarrow CO_2(g) \qquad \Delta H = -283.0 \text{ kJ}$$
$$\text{Equation B:} \quad N_2(g) + O_2(g) \longrightarrow 2NO(g) \qquad \Delta H = 180.6 \text{ kJ}$$

Plan We note the amount (mol) of each substance and on which side each appears in the target equation. We adjust equations A and/or B *and* their ΔH values as needed and add them together to obtain the target equation and the unknown ΔH.

Solution Noting substances in the target equation: For reactants, there are 1 mol of CO and 1 mol of NO; for products, there are 1 mol of CO_2 and $\frac{1}{2}$ mol of N_2. Adjusting the given equations:

- Equation A has the same amounts of CO and CO_2 on the same sides of the arrow as in the target, so we leave it as written.
- Equation B has twice as much N_2 and NO as the target, and they are on the opposite sides in the target. Thus, we reverse equation B, change the sign of its ΔH, and multiply both by $\frac{1}{2}$:

$$\tfrac{1}{2}[2NO(g) \longrightarrow N_2(g) + O_2(g)] \qquad \Delta H = -\tfrac{1}{2}(\Delta H) = -\tfrac{1}{2}(180.6 \text{ kJ})$$

or

$$NO(g) \longrightarrow \tfrac{1}{2}N_2(g) + \tfrac{1}{2}O_2(g) \qquad \Delta H = -90.3 \text{ kJ}$$

Adding the adjusted equations to obtain the target equation:

Equation A:	$CO(g) + \cancel{\tfrac{1}{2}O_2(g)} \longrightarrow CO_2(g)$	$\Delta H = -283.0$ kJ
$\frac{1}{2}$(Equation B reversed)	$NO(g) \longrightarrow \tfrac{1}{2}N_2(g) + \cancel{\tfrac{1}{2}O_2(g)}$	$\Delta H = -90.3$ kJ
Target equation:	$CO(g) + NO(g) \longrightarrow CO_2(g) + \tfrac{1}{2}N_2(g)$	$\Delta H = -373.3$ kJ

Check Obtaining the desired target equation is a sufficient check. Be sure to remember to change the *sign* of ΔH for any equation you reverse.

FOLLOW-UP PROBLEMS

6.9A Nitrogen oxides undergo many reactions in the environment and in industry. Given the following information, calculate ΔH for the overall equation, $2NO_2(g) + \frac{1}{2}O_2(g) \longrightarrow N_2O_5(s)$:

$$N_2O_5(s) \longrightarrow 2NO(g) + \tfrac{3}{2}O_2(g) \qquad \Delta H = 223.7 \text{ kJ}$$
$$NO(g) + \tfrac{1}{2}O_2(g) \longrightarrow NO_2(g) \qquad \Delta H = -57.1 \text{ kJ}$$

6.9B Use the following reactions to find ΔH when 1 mol of HCl gas forms from its elements:

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g) \qquad \Delta H = -91.8 \text{ kJ}$$
$$N_2(g) + 4H_2(g) + Cl_2(g) \longrightarrow 2NH_4Cl(s) \qquad \Delta H = -628.8 \text{ kJ}$$
$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s) \qquad \Delta H = -176.2 \text{ kJ}$$

SOME SIMILAR PROBLEMS 6.67 and 6.68

Summary of Section 6.5

- Because H is a state function, we can use Hess's law to determine ΔH of any reaction by assuming that it is the sum of other reactions.
- After adjusting the equations of the other reactions and their ΔH values to match the substances in the target equation, we add the adjusted ΔH values to find the unknown ΔH.

6.6 STANDARD ENTHALPIES OF REACTION (ΔH°_{rxn})

In this section, we see how Hess's law is used to determine the ΔH values of an enormous number of reactions. Thermodynamic variables, such as ΔH, vary somewhat with conditions. Therefore, in order to study and compare reactions, chemists have established a set of specific conditions called **standard states:**

- For a *gas,* the standard state is 1 atm* and ideal behavior.
- For a substance in *aqueous solution,* the standard state is 1 *M* concentration.
- For a *pure substance* (element or compound), the standard state is usually the most stable form of the substance at 1 atm and the temperature of interest. In this text (and in most thermodynamic tables), that temperature is usually 25°C (298 K).

The standard-state symbol (shown as a degree sign) indicates that the variable has been measured with *all the substances in their standard states*. For example, when the enthalpy change of a reaction is measured at the standard state, it is the **standard enthalpy of reaction, ΔH°_{rxn}** (also called *standard heat of reaction*).

Formation Equations and Their Standard Enthalpy Changes

In a **formation equation,** 1 mol of a compound forms from its elements. The **standard enthalpy of formation (ΔH_f°;** or *standard heat of formation*) is the enthalpy change for the formation equation when all the substances are in their standard states. For instance, the formation equation for methane (CH_4) is

$$C(\text{graphite}) + 2H_2(g) \longrightarrow CH_4(g) \qquad \Delta H_f^\circ = -74.9 \text{ kJ}$$

Fractional coefficients are often used with reactants to obtain 1 mol of the product:

$$Na(s) + \tfrac{1}{2}Cl_2(g) \longrightarrow NaCl(s) \qquad \Delta H_f^\circ = -411.1 \text{ kJ}$$
$$2C(\text{graphite}) + 3H_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow C_2H_5OH(l) \qquad \Delta H_f^\circ = -277.6 \text{ kJ}$$

Standard enthalpies of formation have been tabulated for many substances. The values in Table 6.3 make two points (see Appendix B for a more extensive table):

1. *For an element in its standard state,* $\Delta H_f^\circ = 0$.
   - The standard state for metals, like sodium, is the solid ($\Delta H_f^\circ = 0$); it takes 107.8 kJ of heat to form 1 mol of gaseous Na ($\Delta H_f^\circ = 107.8$ kJ/mol).
   - The standard state for molecular elements, such as the halogens, is the molecular form, not separate atoms: for Cl_2, $\Delta H_f^\circ = 0$, but for Cl, $\Delta H_f^\circ = 121.0$ kJ/mol.
   - Some elements exist in different forms (called *allotropes;* Chapter 14), but only one is the standard state. The standard state of carbon is graphite ($\Delta H_f^\circ = 0$), not diamond ($\Delta H_f^\circ = 1.9$ kJ/mol), the standard state of oxygen is O_2 ($\Delta H_f^\circ = 0$), not ozone (O_3; $\Delta H_f^\circ = 143$ kJ/mol), and the standard state of sulfur is S_8 in its rhombic crystal form ($\Delta H_f^\circ = 0$), not in its monoclinic form ($\Delta H_f^\circ = 0.3$ kJ/mol).
2. *Most compounds have a negative* ΔH_f°. That is, most compounds have exothermic formation reactions: *under standard conditions, heat is released when most compounds form from their elements.*

SAMPLE PROBLEM 6.10 Writing Formation Equations

Problem Write a balanced formation equation for each of the following and include the value of ΔH_f°: **(a)** AgCl(*s*); **(b)** $CaCO_3(s)$; **(c)** HCN(*g*).

Plan We write the elements as the reactants and 1 mol of the compound as the product, being sure all substances are in their standard states. Then, we balance the equations and find the ΔH_f° values in Appendix B.

Solution **(a)** $Ag(s) + \tfrac{1}{2}Cl_2(g) \longrightarrow AgCl(s) \qquad \Delta H_f^\circ = -127.03 \text{ kJ}$

(b) $Ca(s) + C(\text{graphite}) + \tfrac{3}{2}O_2(g) \longrightarrow CaCO_3(s) \qquad \Delta H_f^\circ = -1206.9 \text{ kJ}$

(c) $\tfrac{1}{2}H_2(g) + C(\text{graphite}) + \tfrac{1}{2}N_2(g) \longrightarrow HCN(g) \qquad \Delta H_f^\circ = 135 \text{ kJ}$

*The definition of the standard state for gases has been changed to 1 bar, a slightly lower pressure than the 1 atm standard on which the data in this book are based (1 atm = 101.3 kPa = 1.013 bar). For most purposes, this makes very little difference in the standard enthalpy values.

FOLLOW-UP PROBLEMS

6.10A Write a balanced formation equation for each of the following and include the value of ΔH°_f: **(a)** $CH_3OH(l)$; **(b)** $CaO(s)$; **(c)** $CS_2(l)$.

6.10B Write a balanced formation equation for each of the following and include the value of ΔH°_f: **(a)** $CHCl_3$; **(b)** NH_4Cl; **(c)** $PbSO_4$.

SOME SIMILAR PROBLEMS 6.77 and 6.78

Determining ΔH°_{rxn} from ΔH°_f Values for Reactants and Products

We can use ΔH°_f values to determine ΔH°_{rxn} for any reaction. By applying Hess's law, we can imagine the reaction occurring in two steps (Figure 6.12):

Step 1. Each reactant decomposes to its elements. This is the *reverse* of the formation reaction for the *reactant,* so the standard enthalpy change is $-\Delta H^\circ_f$.

Step 2. Each product forms from its elements. This step *is* the formation reaction for the *product,* so the standard enthalpy change is ΔH°_f.

According to Hess's law, we add the enthalpy changes for these steps to obtain the overall enthalpy change for the reaction (ΔH°_{rxn}). Suppose we want ΔH°_{rxn} for

$$TiCl_4(l) + 2H_2O(g) \longrightarrow TiO_2(s) + 4HCl(g)$$

We write this equation as though it were the sum of four individual equations, one for each compound. The first two show step 1, the decomposition of the reactants to their elements (*reverse* of their formation); the second two show step 2, the formation of the products from their elements:

$$\begin{aligned} TiCl_4(l) &\longrightarrow Ti(s) + 2Cl_2(g) & -\Delta H^\circ_f[TiCl_4(l)] \\ 2H_2O(g) &\longrightarrow 2H_2(g) + O_2(g) & -2\Delta H^\circ_f[H_2O(g)] \\ Ti(s) + O_2(g) &\longrightarrow TiO_2(s) & \Delta H^\circ_f[TiO_2(s)] \\ 2H_2(g) + 2Cl_2(g) &\longrightarrow 4HCl(g) & 4\Delta H^\circ_f[HCl(g)] \end{aligned}$$

$$TiCl_4(l) + 2H_2O(g) + \cancel{Ti(s)} + \cancel{O_2(g)} + \cancel{2H_2(g)} + \cancel{2Cl_2(g)} \longrightarrow \cancel{Ti(s)} + \cancel{2Cl_2(g)} + \cancel{2H_2(g)} + \cancel{O_2(g)} + TiO_2(s) + 4HCl(g)$$

or $$TiCl_4(l) + 2H_2O(g) \longrightarrow TiO_2(s) + 4HCl(g)$$

Note that when titanium(IV) chloride and water react, the reactants don't *actually* decompose to their elements, which then recombine to form the products. But the great usefulness of Hess's law and the state-function concept is that ΔH°_{rxn} is the difference between two state functions, $H^\circ_{products}$ minus $H^\circ_{reactants}$, so it doesn't matter how the reaction *actually* occurs. We add the individual enthalpy changes to find ΔH°_{rxn}:

$$\begin{aligned} \Delta H^\circ_{rxn} &= \Delta H^\circ_f[TiO_2(s)] + 4\Delta H^\circ_f[HCl(g)] + \{-\Delta H^\circ_f[TiCl_4(l)]\} + \{-2\Delta H^\circ_f[H_2O(g)]\} \\ &= \underbrace{\{\Delta H^\circ_f[TiO_2(s)] + 4\Delta H^\circ_f[HCl(g)]\}}_{\text{Products}} - \underbrace{\{\Delta H^\circ_f[TiCl_4(l)] + 2\Delta H^\circ_f[H_2O(g)]\}}_{\text{Reactants}} \end{aligned}$$

For this example, the arithmetic gives $\Delta H^\circ_{rxn} = -25.39$ kJ. When we generalize the pattern, we see that *the standard enthalpy of reaction is the sum of the standard enthalpies of formation of the* ***products*** *minus the sum of the standard enthalpies of formation of the* ***reactants*** (see Figure 6.12):

$$\Delta H^\circ_{rxn} = \Sigma m \Delta H^\circ_{f\,(products)} - \Sigma n \Delta H^\circ_{f\,(reactants)} \qquad \textbf{(6.9)}$$

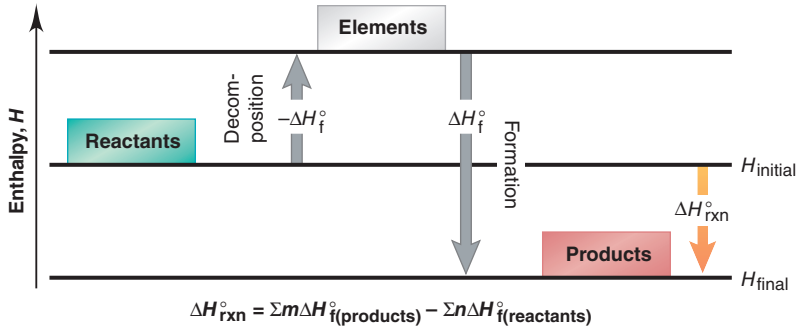

Figure 6.12 The two-step process for determining ΔH°_{rxn} from ΔH°_f values.

where Σ means "sum of," and m and n are the amounts (mol) of the products and reactants given by the coefficients in the balanced equation.

SAMPLE PROBLEM 6.11 Calculating ΔH°_{rxn} from ΔH°_f Values

Problem Nitric acid is used to make many products, including fertilizers, dyes, and explosives. The first step in its production is the oxidation of ammonia:

$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$$

Calculate ΔH°_{rxn} from ΔH°_f values.

Plan We use values from Appendix B and apply Equation 6.9.

Solution Calculating ΔH°_{rxn}:

$$\begin{aligned}\Delta H^\circ_{rxn} &= \Sigma m\Delta H^\circ_{f\,(products)} - \Sigma n\Delta H^\circ_{f\,(reactants)}\\ &= \{4\Delta H^\circ_f[NO(g)] + 6\Delta H^\circ_f[H_2O(g)]\} - \{4\Delta H^\circ_f[NH_3(g)] + 5\Delta H^\circ_f[O_2(g)]\}\\ &= (4\text{ mol})(90.29\text{ kJ/mol}) + (6\text{ mol})(-241.840\text{ kJ/mol})\\ &\quad - [(4\text{ mol})(-45.9\text{ kJ/mol}) + (5\text{ mol})(0\text{ kJ/mol})]\\ &= 361.2\text{ kJ} - 1451.04\text{ kJ} + 184\text{ kJ} - 0\text{ kJ} = -906\text{ kJ}\end{aligned}$$

Check We write formation equations, with ΔH°_f values for the amounts of each compound, in the correct direction (forward for products and reverse for reactants) and find the sum:

$$\begin{aligned}4NH_3(g) &\longrightarrow \cancel{2N_2(g)} + \cancel{6H_2(g)} && -4\Delta H^\circ_f = -4(-45.9\text{ kJ}) = 184\text{ kJ}\\ \cancel{2N_2(g)} + 2O_2(g) &\longrightarrow 4NO(g) && 4\Delta H^\circ_f = 4(90.29\text{ kJ}) = 361.2\text{ kJ}\\ \cancel{6H_2(g)} + 3O_2(g) &\longrightarrow 6H_2O(g) && 6\Delta H^\circ_f = 6(-241.840\text{ kJ}) = -1451.04\text{ kJ}\\ \hline 4NH_3(g) + 5O_2(g) &\longrightarrow 4NO(g) + 6H_2O(g) && \Delta H^\circ_{rxn} = -906\text{ kJ}\end{aligned}$$

Comment In this problem, we know the individual ΔH°_f values and find the sum, ΔH°_{rxn}. In Follow-up Problem 6.11B, we know the sum and want to find one of the ΔH°_f values.

FOLLOW-UP PROBLEMS

6.11A Tetraphosphorus decoxide reacts vigorously with water to form phosphoric acid, one of the top-10 industrial chemicals:

$$P_4O_{10}(s) + 6H_2O(l) \longrightarrow 4H_3PO_4(l)$$

Calculate ΔH°_{rxn} from ΔH°_f values in Appendix B.

6.11B Use the following to find ΔH°_f of methanol [$CH_3OH(l)$]:

$$CH_3OH(l) + \tfrac{3}{2}O_2(g) \longrightarrow CO_2(g) + 2H_2O(g) \quad \Delta H^\circ_{rxn} = -638.6\text{ kJ}$$
$$\Delta H^\circ_f \text{ of } CO_2(g) = -393.5\text{ kJ/mol}$$
$$\Delta H^\circ_f \text{ of } H_2O(g) = -241.826\text{ kJ/mol}$$

SOME SIMILAR PROBLEMS 6.79–6.82

The upcoming Chemical Connections essay applies ideas from this chapter to new approaches for energy utilization.

Summary of Section 6.6

- Standard states are a set of specific conditions used for determining thermodynamic variables for all substances.
- When 1 mol of a compound forms from its elements with all substances in their standard states, the enthalpy change is the stanndard enthalpy of formation, ΔH°_f.
- Hess's law allows us to picture a reaction as the decomposition of the reactants to their elements followed by the formation of the products from their elements.
- We use tabulated ΔH°_f values to find ΔH°_{rxn} or use known ΔH°_{rxn} and ΔH°_f values to find an unknown ΔH°_f.
- Because of major concerns about climate change, chemists are developing energy alternatives, including coal and biomass conversion, hydrogen fuel, and noncombustible energy sources.

The Future of Energy Use

Out of necessity, we are totally rethinking our global use of energy. The dwindling supplies of our most common fuels and the environmental impact of their combustion products threaten human well-being and the survival of many other species. Energy production presents scientists, engineers, and political leaders with some of the greatest challenges of our time.

A changeover in energy sources from wood to coal and then petroleum took place over the 20th century. The **fossil fuels**—coal, petroleum, and natural gas—remain our major sources, but they are *nonrenewable* because natural processes form them many orders of magnitude slower than we consume them. In the United States, ongoing research seeks new approaches to using coal and nuclear energy, and utilizing *renewable* sources—biomass, hydrogen, sunlight, wind, geothermal heat, and tides—is the subject of intensive efforts as well.

In this discussion, we focus on converting coal and biomass to cleaner fuels, understanding the effect of carbon-based fuels on climate, developing hydrogen as a fuel, utilizing solar energy, and conserving energy.

Converting Coal to Cleaner Fuels

U.S. reserves of coal are enormous, but the burning of coal, in addition to forming CO_2, produces SO_2 and particulates, and releases mercury. Exposure to SO_2 and particulates causes respiratory disease, and SO_2 can be oxidized to H_2SO_4, the key component of acid rain (Chapter 19). The trace amounts of Hg, a neurotoxin, spread as Hg vapor and bioaccumulate in fish.

Two processes are used to reduce the amounts of SO_2.

Desulfurization. The removal of sulfur dioxide from flue gases is done with devices called *scrubbers* that heat powdered limestone ($CaCO_3$) or spray lime-water slurries [$Ca(OH)_2$]:

$$CaCO_3(s) + SO_2(g) \xrightarrow{\Delta} CaSO_3(s) + CO_2(g)$$

$$2CaSO_3(s) + O_2(g) + 4H_2O(l) \longrightarrow 2CaSO_4 \cdot 2H_2O(s;\ \text{gypsum})$$

$$2Ca(OH)_2(aq) + 2SO_2(g) + O_2(g) + 2H_2O(l) \longrightarrow 2CaSO_4 \cdot 2H_2O(s)$$

A wallboard (drywall) plant built next to the power plant sells the gypsum (1 ton per customer each year); about 20% of the drywall produced each year is made with synthetic gypsum.

Gasification. In **coal gasification,** solid coal is converted to sulfur-free gaseous fuels. In this process, the sulfur in the coal is reduced to H_2S, which is removed through an acid-base reaction with a base, such as ethanolamine ($HOCH_2CH_2NH_2$). The resulting salt is heated to release H_2S, which is converted to elemental sulfur by the Claus process (Chapter 22) and sold. Several reactions yield mixtures with increasing fuel value, that is, with a lower C/H ratio:

- Pulverized coal reacts with limited O_2 and water at 800–1500°C to form approximately a 2/1 mixture of CO/H_2.
- Alternatively, in the *water-gas reaction* (or *steam-carbon reaction*), an exothermic oxidation of C to CO is followed by the endothermic reaction of C with steam to form a nearly 1/1 mixture of CO/H_2 called *water gas:*

$$C(s) + \tfrac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta H^\circ_{rxn} = -110\ \text{kJ}$$

$$C(s) + H_2O(g) \longrightarrow CO(g) + H_2(g) \qquad \Delta H^\circ_{rxn} = 131\ \text{kJ}$$

However, water gas has a much lower fuel value than methane (CH_4). For example, a mixture of 0.5 mol of CO and 0.5 mol of H_2 releases about one-third as much energy as 1.0 mol of methane ($\Delta H = -802$ kJ/mol):

$$\tfrac{1}{2}H_2(g) + \tfrac{1}{4}O_2(g) \longrightarrow \tfrac{1}{2}H_2O(g) \qquad \Delta H^\circ_{rxn} = -121\ \text{kJ}$$

$$\tfrac{1}{2}CO(g) + \tfrac{1}{4}O_2(g) \longrightarrow \tfrac{1}{2}CO_2(g) \qquad \Delta H^\circ_{rxn} = -142\ \text{kJ}$$

$$\tfrac{1}{2}H_2(g) + \tfrac{1}{2}CO(g) + \tfrac{1}{2}O_2(g) \longrightarrow \tfrac{1}{2}H_2O(g) + \tfrac{1}{2}CO_2(g) \qquad \Delta H^\circ_{rxn} = -263\ \text{kJ}$$

- In the *CO-shift* (or *water-gas shift*) reaction, the H_2 content of water gas is increased to produce synthesis gas *(syngas):*

$$CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g) \qquad \Delta H^\circ_{rxn} = -41\ \text{kJ}$$

- To produce CH_4, a syngas that is a 3/1 mixture of H_2/CO from which the CO_2 has been removed, is employed:

$$CO(g) + 3H_2(g) \longrightarrow CH_4(g) + H_2O(g) \qquad \Delta H^\circ_{rxn} = -206\ \text{kJ}$$

Drying the product gives **synthetic natural gas (SNG).**

Syngas is used in some newer methods as well. In *integrated gasification combined cycle (IGCC),* electricity is produced in two ways—when syngas is burned in a combustion turbine and when the hot product gases generate steam to power a steam turbine. In the *Fischer-Tropsch process,* syngas is used to form liquid hydrocarbon fuels that have higher molar masses than methane:

$$nCO(g) + (2n + 1)H_2(g) \longrightarrow C_nH_{2n+2}(l) + nH_2O(g)$$

Converting Biomass to Fuels

Nearly half the world's people rely on wood for energy. In principle, wood is renewable, but widespread deforestation has resulted from its use for fuel, lumber, and paper. Therefore, great emphasis has been placed on **biomass conversion** of vegetable and animal waste. In one process, chemical and/or microbial methods convert vegetable (sugarcane, corn, switchgrass) and tree waste into fuel, mainly ethanol (C_2H_5OH). In the United States, ethanol is mixed with gasoline to form *gasohol;* in Brazil, it substitutes directly for gasoline.

Methanogenesis forms methane by anaerobic (oxygen-free) biodegradation of organic sources such as manure and vegetable waste or wastewater. China's biogas-generating facilities apply this technique, and similar ones in the United States use garbage and sewage. In addition to producing methane, the process yields residues that improve soil; it also prevents the wastes from polluting natural waters.

Another biomass conversion process changes vegetable oils (soybean, cottonseed, sunflower, canola, and even used cooking oil) into a mixture called *biodiesel,* whose combustion produces

(continued)

less CO, SO_2, and particulate matter than fossil-fuel–based diesel. The CO_2 produced in combustion of biodiesel has minimal impact on the net atmospheric amount because the carbon is taken up by the plants grown as sources of the vegetable oils.

The Greenhouse Effect and Global Warming

Combustion of all carbon-based fuels releases CO_2, and over the past two decades, it has become clear that the atmospheric buildup of this gas from our increased use of these fuels is changing the climate. Let's examine the basis of climate change, its current effects, and the long-term outlook.

The natural greenhouse effect. Throughout Earth's history, CO_2 has played a key temperature-regulating role in the atmosphere. Much of the sunlight that shines on Earth is absorbed by the land and oceans and converted to heat (IR radiation; Figure B6.1). Like the glass of a greenhouse, CO_2 does not absorb visible light from the Sun, but it absorbs and re-emits some of the heat radiating from Earth's surface and, thus, helps warm the atmosphere. This process is called the *natural greenhouse effect* (Figure B6.1, *left*). Over several billion years, due to the spread of plant life, which uses CO_2 in photosynthesis, the amount of CO_2 originally present (from volcanic activity) decreased to 0.028% by volume. With this amount, Earth's average temperature was about 14°C (57°F); without CO_2, it would be −17°C (2°F)!

The enhanced greenhouse effect. As a result of intensive use of fossil fuels for the past 150 years, the amount of CO_2 in the atmosphere increased to 0.040%. Thus, although the same quantity of solar energy passes through the atmosphere, more is being trapped as heat, which has created an *enhanced greenhouse effect* that is changing the climate through *global warming* (Figure B6.1, *right*). Based on current trends, CO_2 amounts will increase to between 0.049% and 0.126% by 2100 (Figure B6.2).

Modeling global warming and its effects. If this projected increase in CO_2 occurs, two closely related questions arise that must be addressed by models: (1) How much will the temperature rise? (2) How will this rise affect life on Earth? Despite constantly improving models, answers are difficult to obtain. Natural fluctuations in temperature must be taken into account, as well as cyclic changes in solar activity. Moreover, as the amount of CO_2 increases from fossil-fuel burning, so do the amounts of particulate matter and SO_2-based aerosols, which may block sunlight and have a cooling effect. Water vapor also traps heat, and as temperatures rise, more water evaporates. The increased amounts of water vapor may thicken the cloud cover and lead to cooling as well.

Despite such opposing factors, all of the best models predict net warming, and we are already observing the effects. The average temperature has increased by 0.6±0.2°C since the late 19th century and 0.2–0.3°C over the past 25 years. Globally, the decade from 2001 to 2010 was the warmest on record and the current decade is continuing this trend. December 2012 was the 334th month in a row with an average temperature above the 20th-century norm, and 2012 was the hottest year on record, with severe droughts and damaging storms in many areas. Snow cover and glacial size in the northern hemisphere and floating ice in the Arctic Ocean have decreased dramatically. Antarctica is also experiencing widespread breakup of icebound regions.

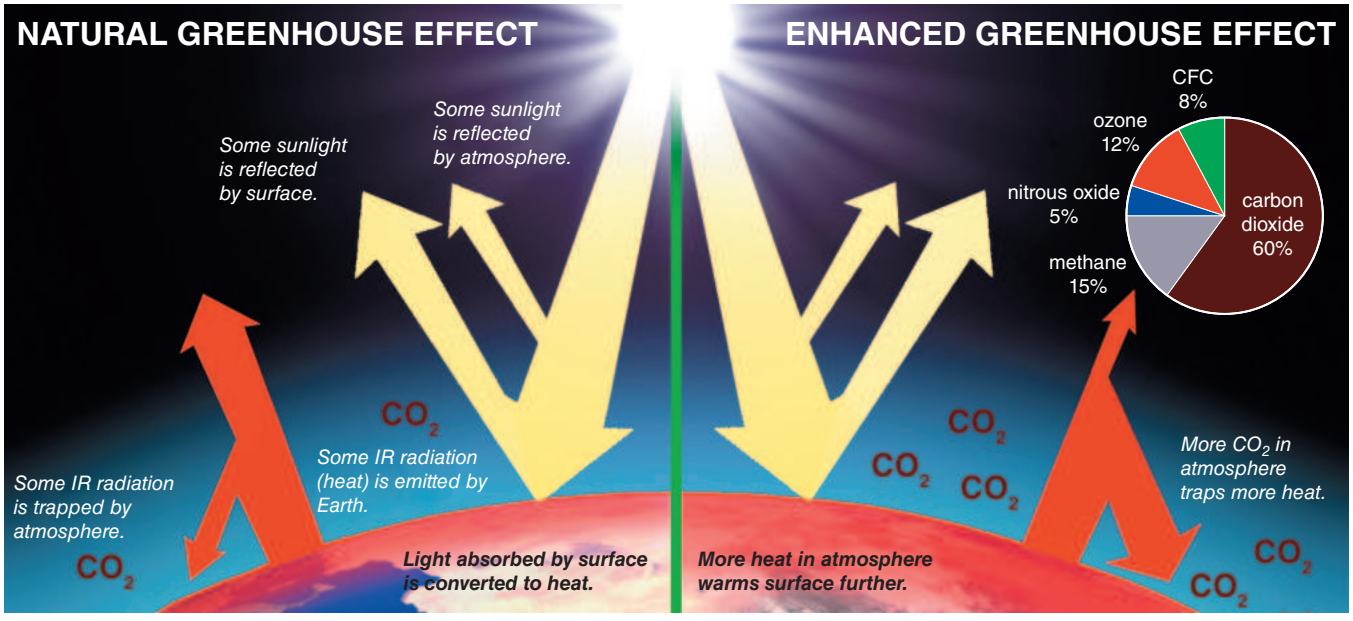

Figure B6.1 The trapping of heat by the atmosphere. Of the total sunlight reaching Earth, some is reflected and some is absorbed and converted to IR radiation (heat). Some heat emitted by the surface is trapped by atmospheric CO_2, creating a *natural* greenhouse effect *(left)* that has been essential to life. But, largely as a result of human activity in the past 150 years, and especially the past several decades, the buildup of CO_2 and several other greenhouse gases (*pie chart*) has created an *enhanced* greenhouse effect *(right)*.

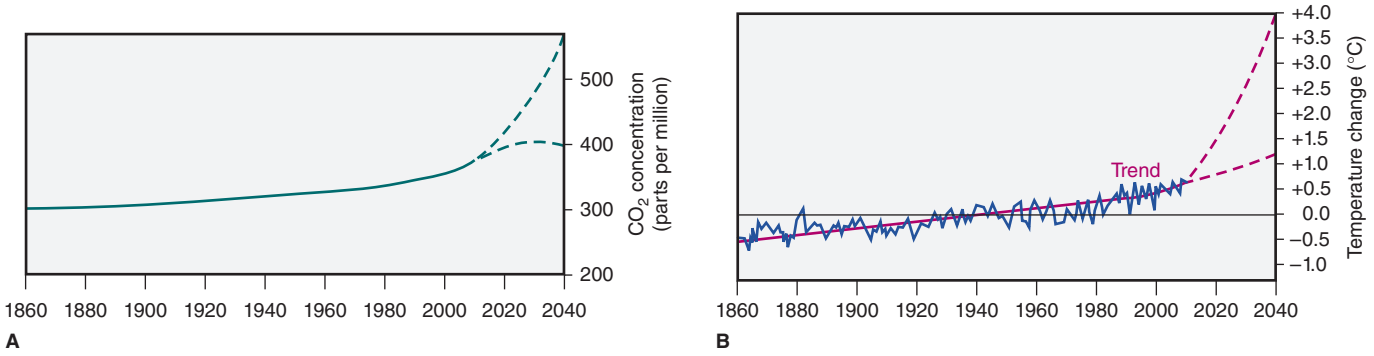

Figure B6.2 Evidence for the enhanced greenhouse effect. A, Since the mid-19th century, atmospheric CO_2 has increased. **B,** Since the mid-19th century, average global temperature has risen 0.6°C. (Zero is the average from 1957 to 1970.) The projections in the graphs *(dashed lines)* assume that current fossil-fuel consumption and deforestation continue *(upper line)* or slow *(lower line)*.

Globally, sea level has risen an average of 17 cm (6.7 in) over the past century, and flooding and other extreme weather events have increased.

Fifteen years ago, the best models predicted a temperature rise of 1.0–3.5°C; today, their predictions are more than 50% higher. Such increases would alter rainfall patterns and crop yields throughout the world and increase sea level as much as 1 meter, thus flooding regions such as the Netherlands, half of Florida, much of southern Asia, coastal New England and New York, and many Pacific island nations. To make matters worse, as we burn fossil fuels that *release* CO_2, we cut down forests that *absorb* it.

Addressing the challenge of climate change. In addition to ways to reduce fossil-fuel consumption, some of which we discuss below, researchers are studying methods of *carbon capture and storage (CCS),* including *CO_2 sequestration,* both naturally by maintaining forests and jungles and industrially by liquefying CO_2 formed and either burying it underground or using it to produce mineral carbonates.

The 1997 United Nations Conference on Climate Change in Kyoto, Japan, created a treaty with legally binding targets to limit greenhouse gases. It was ratified by 189 countries, but not by the United States, then the largest emitter. The 2009 conference in Copenhagen, Denmark, was attended by representatives from 192 countries (including the U.S.), but did not result in legally binding emission targets or financial commitments. In late 2010, however, a conference in Cancun, Mexico, resulted in financial commitments to help developing nations rely on alternative energy sources. Rising standards of living in China and India, the two most populous nations, are leading to a need for more energy, which makes large and sustained global reductions in CO_2 even more urgent.

Hydrogen

The use of H_2 as an energy source holds great promise but presents several problems. The simplest element and most plentiful gas in the universe always occurs on Earth in compounds, most importantly with oxygen in water and carbon in hydrocarbons. Once freed, however, H_2 is an excellent energy source because of several properties:

- It has the highest energy content per *mass* unit of any fuel—nearly three times as much as gasoline.
- Its energy content per *volume* unit is low at STP but increases greatly when the H_2 is liquefied under extremely high P and low T.
- Its combustion does not produce CO_2, particulates, or sulfur oxides. It is such a clean energy source that H_2-fuel cells operate electrical systems aboard the space shuttles, and the crews drink the pure water product.

A hydrogen-based economy is the dream of many because, even though combustion of H_2 ($\Delta H^\circ_{rxn} = -242$ kJ/mol) produces less than one-third as much energy per mole as combustion of CH_4 ($\Delta H^\circ_{rxn} = -802$ kJ/mol), it yields nonpolluting water vapor. The keys to realizing the dream, however, involve major improvements in both production of H_2 and its transportation and storage.

Production of H_2. Hydrogen is produced by a number of methods, some more widely used than others.

- *Fossil-fuel byproduct.* In the United States today, almost all H_2 is produced by the *steam-reforming process,* in which methane or natural gas is treated with steam in high-temperature reactions (Chapter 22).
- *Electrolysis of liquid water.* Formation of H_2 from the decomposition of liquid water is endothermic ($\Delta H^\circ_{rxn} = 286$ kJ/mol), and most direct methods that utilize electricity are costly. However, energy from flowing water, wind, and geothermal sources can provide the needed electricity. An exciting new *photoelectrochemical approach* uses a photovoltaic panel coupled to an electrolysis unit: the energy of sunlight powers the decomposition of water.
- *Biological methods.* Green algae and cyanobacteria store the energy of sunlight in the form of starch or glycogen for their own metabolism. Under certain conditions, however, these microbes can be made to produce H_2 gas instead of these large organic molecules. For example, eliminating sulfur from

(continued)

the diet of green algae activates a long dormant gene and the cells produce H_2. But, major improvements in yields are needed to make this method cost-effective.

Transportation and storage of H_2. The absence of an infrastructure for transporting and storing large quantities of hydrogen is still a roadblock to realizing a hydrogen-based economy. Currently, the cost of energy to cool and compress the gas to liquefy it is very high. Hydrogen is carried in pipelines, but its ability to escape through metals and to make them brittle requires more expensive piping. Storage in the form of solid metal hydrides has been explored, but heating the hydrides to release the stored hydrogen requires energy. Use of H_2 in fuel cells is a major area of electrochemical research (Chapter 21). Tests are underway to commercialize fuel-cell technology using the hydrogen that is a byproduct of the petrochemical and coal industries.

Solar Energy

The Sun's energy drives global winds and ocean currents, the cycle of evaporation and condensation, and many biological processes, especially photosynthesis. More energy falls on Earth's surface as sunlight in 1 h [1.2×10^5 TW (terawatts); 1 TW = 1×10^{12} W] than is used in all human activity in 1 year. Solar energy is, however, a dilute source (only 1 kW/m^2 at noon); in 1 h, about 600–1000 TW strikes land at sites suitable for collecting. Nevertheless, covering 0.16% of that land with today's photovoltaic systems would provide 20 TW/h, equivalent to the output of 20,000 nuclear power plants producing 1 GW (gigawatt) each. Clearly, solar energy is the largest carbon-free option among renewable sources.

Three important ways to utilize solar energy are with electronic materials, biomass, and thermal systems:

Electronic materials. A **photovoltaic cell** converts sunlight directly into electricity by employing certain combinations of elements (usually metalloids; we discuss the behavior of elements with *semiconductor* properties in Chapter 12). Early cells relied primarily on crystalline silicon, but their *yield,* the proportion of electrical energy produced relative to the radiant energy supplied, was only about 10%. More recent devices have achieved much higher yields by using thin films of polycrystalline materials that incorporate combinations of other elements, such as cadmium telluride (CdTe cells, 16%), gallium arsenide (GaAs cells, 18%), and copper indium gallium selenide (CIGS cells, 20%). And ongoing research on nanometer-sized semiconductor devices, called *quantum dots,* suggests yields as high as 70%.

Biomass. Solar energy is used to convert CO_2 and water via photosynthesis to plant material (carbohydrate) and oxygen. Plant biomass can be burned directly as a fuel or converted to other fuels, such as ethanol or hydrogen (see p. 273).

Thermal systems. The operation of a photovoltaic cell creates a buildup of heat, which lowers its efficiency. A *photovoltaic thermal (PVT) hybrid cell* thus combines such a cell with conductive metal piping (filled with water or antifreeze) that transfers the heat from the cell to a domestic hot-water system.

Because sunlight is typically available only 6 to 8 hours a day and is greatly reduced in cloudy weather, another thermal system focuses on storing solar energy during the day and releasing it at night. When an ionic hydrate, such as $Na_2SO_4\cdot10H_2O$, is warmed by sunlight to over 32°C, the 3 mol of ions dissolve in the 10 mol of water in an endothermic process:

$$Na_2SO_4(aq)\cdot10H_2O(s) \xrightarrow{>32^\circ C} Na_2SO_4(aq) \qquad \Delta H^\circ_{rxn} = 354\ kJ$$

When cooled below 32°C after sunset, the solution recrystallizes, releasing the absorbed energy for heating:

$$Na_2SO_4(aq) \xrightarrow{<32^\circ C} Na_2SO_4(aq)\cdot10H_2O(s) \qquad \Delta H^\circ_{rxn} = -354\ kJ$$

Unfortunately, as of the middle of the second decade of the 21st century, solar energy is still not competitive with highly subsidized fossil fuels. Nevertheless, changes in economic policy as well as improvements in photovoltaic technology and biomass processing should greatly increase solar energy's contribution to a carbon-free energy future.

Nuclear Energy

Despite ongoing problems with disposal of radioactive waste, energy from nuclear *fission*—the splitting of large, unstable atomic nuclei—is used extensively, especially in France and other parts of northern Europe. Nuclear *fusion*—the combining of small atomic nuclei—avoids the problems of fission but has been achieved so far only with a net consumption of power. (We'll discuss these processes in detail in Chapter 24.)

Energy Conservation: More from Less

All systems, whether organisms or factories, waste energy, which is, in effect, a waste of fuel. For example, the production of one aluminum beverage can requires energy equivalent to burning 0.25 L of gasoline. Energy conservation lowers costs, extends our fuel supply, and reduces the effects of climate change. Following are three examples of conservation.

Passive solar design. Heating and cooling costs can be reduced by as much as 50% when buildings are constructed with large windows and materials that absorb the Sun's heat in the day and release it slowly at night.

Residential heating systems. A high-efficiency gas-burning furnace channels hot waste gases through a system of baffles to transfer more heat to the room and then to an attached domestic hot-water system. While moving through the system, the gases cool to 100°C, so the water vapor condenses, thus releasing about 10% more heat:

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + \cancel{2H_2O(g)} \qquad \Delta H^\circ_{rxn} = -802\ kJ$$
$$\cancel{2H_2O(g)} \longrightarrow 2H_2O(l) \qquad \Delta H^\circ_{rxn} = -88\ kJ$$
$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l) \qquad \Delta H^\circ_{rxn} = -890\ kJ$$

Modern lighting. Incandescent bulbs give off light when the material in their filament reaches a high temperature. They are very inefficient because less than 7% of the electrical energy is converted to light, the rest being wasted as heat. *Compact fluorescent lamps (CFLs)* have an efficiency of about 18% and are having a major economic impact: in many parts of Europe, incandescent bulbs are no longer sold. *Light-emitting diodes (LEDs)* are even more efficient (about 30%) and are already being used in car indicator lamps and tail lights. Light-emitting devices based on organic semiconductors (OLEDs) are used in flat-panel displays, and recent use of Al-In-Ga-P materials and Ga and In nitrides in LEDs has improved their brightness and color richness. Over 20% of electricity generated in the United States is used for lighting, and burning of fossil fuels in power plants creates smog, particulates, and CO_2. By 2020, use of these devices for lighting can cut electricity usage by 50%, eliminating the emission of 2.8×10^7 metric tons of carbon per year.

Engineers and chemists will continue to explore alternatives for energy production and use, but a more hopeful energy future ultimately depends on our dedication to conserving planetary resources.

Problems

B6.1 To make use of an ionic hydrate for storing solar energy, you place 500.0 kg of sodium sulfate decahydrate on your house roof. Assuming complete reaction and 100% efficiency of heat transfer, how much heat (in kJ) is released to your house at night?

B6.2 In one step of coal gasification, coal reacts with superheated steam:

$$C(coal) + H_2O(g) \longrightarrow CO(g) + H_2(g) \quad \Delta H^\circ_{rxn} = 129.7\ kJ$$

(a) Use this reaction and the following two to write an overall reaction for the production of methane:

$$CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g) \quad \Delta H^\circ_{rxn} = -41\ kJ$$
$$CO(g) + 3H_2(g) \longrightarrow CH_4(g) + H_2O(g) \quad \Delta H^\circ_{rxn} = -206\ kJ$$

(b) Calculate ΔH°_{rxn} for this overall change.
(c) Using the value from part (b) and a calculated value of ΔH°_{rxn} for the combustion of methane, find the total ΔH for gasifying 1.00 kg of coal and burning the methane formed (assume that water forms as a gas and $\mathcal{M}$ of coal is 12.00 g/mol).

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The distinction between a system and its surroundings (§6.1)
2. The transfer of energy to or from a system as heat and/or work (§6.1)
3. The relation of internal energy change, heat, and work (§6.1)
4. The meaning of energy conservation (§6.1)
5. The meaning of a state function and why ΔE is constant even though q and w vary (§6.1)
6. The meaning of enthalpy and the relation between ΔE and ΔH (§6.2)
7. The meaning of ΔH and the distinction between exothermic and endothermic reactions (§6.2)
8. The relation between specific heat capacity and heat (§6.3)
9. How constant-pressure (coffee-cup) and constant-volume (bomb) calorimeters work (§6.3)
10. The relation between ΔH and amount of substance (§6.4)
11. The calculation of ΔH values with Hess's law (§6.5)
12. The meaning of a formation equation and the standard enthalpy of formation (§6.6)
13. How a reaction can be viewed as the decomposition of reactants followed by the formation of products (§6.6)

Master These Skills

1. Determining the change in a system's internal energy in different units (SP 6.1)
2. Calculating PV work done by or on a system (SP 6.2)
3. Drawing enthalpy diagrams for chemical and physical changes (SP 6.3)
4. Solving problems involving specific heat capacity and heat transferred in a reaction (SPs 6.4–6.7)
5. Relating the heat transferred in a reaction to the amounts of substances changing (SP 6.8)
6. Using Hess's law to find an unknown ΔH (SP 6.9)
7. Writing formation equations and using ΔH°_f values to find ΔH°_{rxn} (SPs 6.10, 6.11)

Key Terms

Page numbers appear in parentheses.

thermodynamics (251)
thermochemistry (251)

Section 6.1
system (252)
surroundings (252)
internal energy (E) (252)
heat (q) (252)
work (w) (253)
law of conservation of energy (first law of thermodynamics) (255)
joule (J) (255)
calorie (cal) (255)
state function (256)

Section 6.2
pressure-volume work (PV work) (258)
enthalpy (H) (258)
change in enthalpy (ΔH) (258)
exothermic process (259)
enthalpy diagram (260)
endothermic process (260)

Section 6.3
heat capacity (261)
specific heat capacity (c) (261)
molar heat capacity (C) (261)
calorimeter (262)

thermochemical equation (266)

Section 6.5
Hess's law (268)

Section 6.6
standard state (270)
standard enthalpy of reaction (ΔH°_{rxn}) (270)
formation equation (270)
standard enthalpy of formation (ΔH°_f) (270)
fossil fuel (273)
coal gasification (273)
synthetic natural gas (SNG) (273)
biomass conversion (273)
methanogenesis (273)
photovoltaic cell (276)

Key Equations and Relationships

Page numbers appear in parentheses.

6.1 Defining the change in internal energy (252):

$$\Delta E = E_{final} - E_{initial} = E_{products} - E_{reactants}$$

6.2 Expressing the change in internal energy in terms of heat and work (253):

$$\Delta E = q + w$$

6.3 Stating the first law of thermodynamics (law of conservation of energy) (255):

$$\Delta E_{universe} = \Delta E_{system} + \Delta E_{surroundings} = 0$$

6.4 Determining the work due to a change in volume at constant pressure (PV work) (258):

$$w = -P\Delta V$$

6.5 Relating the enthalpy change to the internal energy change at constant pressure (258):

$$\Delta H = \Delta E + P\Delta V$$

6.6 Identifying the enthalpy change with the heat absorbed or released at constant pressure (259):

$$q_P = \Delta E + P\Delta V = \Delta H$$

6.7 Calculating the heat absorbed or released when a substance undergoes a temperature change or a reaction occurs (261):

$$q = c \times \text{mass} \times \Delta T$$

6.8 Calculating the overall enthalpy change of a reaction (Hess's law) (268):

$$\Delta H_{overall} = \Delta H_1 + \Delta H_2 + \cdots + \Delta H_n$$

6.9 Calculating the standard enthalpy of reaction (271):

$$\Delta H^\circ_{rxn} = \Sigma m\Delta H^\circ_{f\,(products)} - \Sigma n\Delta H^\circ_{f\,(reactants)}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

6.1A $\Delta E = q + w$

$$= [13.5\text{ kJ} + (-1.8\text{ kJ})] \times \frac{1000\text{ J}}{1\text{ kJ}}$$

$$= 1.17\times10^4\text{ J}$$

6.1B $\Delta E = q + w$

$$= \left(-26.0\text{ kcal} \times \frac{4.184\text{ kJ}}{1\text{ kcal}}\right) + \left(15.0\text{ Btu} \times \frac{1.055\text{ kJ}}{1\text{ Btu}}\right)$$

$$= -93\text{ kJ}$$

6.2A $P\text{ (atm)} = 732\text{ torr} \times \frac{1\text{ atm}}{760\text{ torr}} = 0.963\text{ atm}$

$w\text{ (atm·L)} = -P\Delta V = -0.963\text{ atm} \times (2.35\text{ L} - 5.68\text{ L})$

$= 3.21\text{ atm·L}$

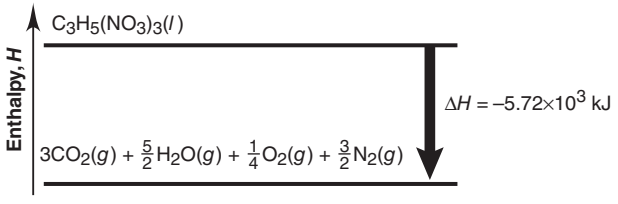
$w\text{ (J)} = 3.21\text{ atm·L} \times \frac{101.3\text{ J}}{1\text{ atm·L}} = 325\text{ J}$

6.2B $w\text{ (atm·L)} = -P\Delta V = -5.5\text{ atm} \times (16.3\text{ L} - 10.5\text{ L})$

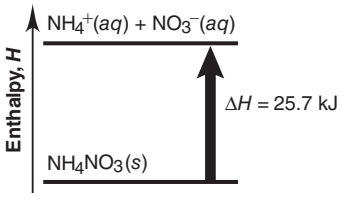
$= -32\text{ atm·L}$

$w\text{ (J)} = -32\text{ atm·L} \times \frac{101.3\text{ J}}{1\text{ atm·L}} = -3.2\times10^3\text{ J}$

6.3A The reaction is exothermic.



6.3B The process is endothermic.



6.4A $\Delta T = 375°\text{C} - 18°\text{C} = 357°\text{C} = 357\text{ K}$

$q = c \times \text{mass} \times \Delta T = (0.900\text{ J/g·K})(7.65\text{ g})(357\text{ K})$

$= 2.46\times10^3\text{ J}$

6.4B $\Delta T = 25.0°C - 37.0°C = -12.0°C = -12.0\ K$

$$\text{Mass (g)} = 1.11\ \text{g/mL} \times \frac{1000\ \text{mL}}{1\ \text{L}} \times 5.50\ \text{L} = 6.10\times10^3\ \text{g}$$

$$q = c \times \text{mass} \times \Delta T$$
$$= (2.42\ \text{J/g·K})\left(\frac{1\ \text{kJ}}{1000\ \text{J}}\right)(6.10\times10^3\ \text{g})(-12.0\ \text{K}) = -177\ \text{kJ}$$

6.5A $$c_{solid} = -\frac{4.184\ \text{J/g·K} \times 25.00\ \text{g} \times 1.70\ \text{K}}{12.18\ \text{g} \times (-37.75\ \text{K})}$$
$$= 0.387\ \text{J/g·K}$$

From Table 6.2, the metal is copper.

6.5B $$-c_{solid} \times \text{mass}_{solid} \times \Delta T_{solid} = c_{H_2O} \times \text{mass}_{H_2O} \times \Delta T_{H_2O}$$
$$-[(0.228\ \text{J/g·K})(33.2\ \text{g})(322.45\ \text{K} - x\ \text{K})] = (4.184\ \text{J/g·K})(75.0\ \text{g})(322.45\ \text{K} - 323.15\ \text{K})$$

Solving for x: $-2440\ \text{J} + 7.57x\ \text{J/K} = -220.\ \text{J}$

$$x = 293\ \text{K} = 20.°C$$

6.6A (a) $HNO_3(aq) + KOH(aq) \longrightarrow KNO_3(aq) + H_2O(l)$

$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$

(b) $$q_{soln} = c_{soln} \times \text{mass}_{soln} \times \Delta T_{soln} = -q_{rxn}$$
$$= (4.184\ \text{J/g·K})(25.0\ \text{g} + 50.0\ \text{g})(300.20\ \text{K} - 295.05\ \text{K})$$
$$= 1620\ \text{J} \times 1\ \text{kJ}/1000\ \text{J} = 1.62\ \text{kJ}$$
$$q_{rxn} = -1.62\ \text{kJ}$$

6.6B $2HCl(aq) + Ba(OH)_2(aq) \longrightarrow 2H_2O(l) + BaCl_2(aq)$

$$\text{Amount (mol) of HCl} = 0.500\ \text{mol HCl/L} \times 0.0500\ \text{L} = 0.0250\ \text{mol HCl}$$

Similarly, we have 0.0250 mol $BaCl_2$.

Finding the limiting reactant from the balanced equation:

$$\text{Amount (mol) of } H_2O = 0.0250\ \text{mol HCl} \times \frac{2\ \text{mol } H_2O}{2\ \text{mol HCl}} = 0.0250\ \text{mol } H_2O$$

$$\text{Amount (mol) of } H_2O = 0.0250\ \text{mol Ba(OH)}_2 \times \frac{2\ \text{mol } H_2O}{1\ \text{mol Ba(OH)}_2} = 0.0500\ \text{mol } H_2O$$

Thus, HCl is limiting.

$$\Delta H\ (\text{kJ/mol } H_2O) = \frac{q_{rxn}}{\text{mol } H_2O} = \frac{-1.386\ \text{kJ}}{0.0250\ \text{mol } H_2O} = -55.4\ \text{kJ/mol } H_2O$$

6.7A $$-q_{sample} = q_{calorimeter}$$
$$-(0.8650\ \text{g C})\left(\frac{1\ \text{mol C}}{12.01\ \text{g C}}\right)(-393.5\ \text{kJ/mol C}) = (2.613\ \text{K})x$$
$$x = 10.85\ \text{kJ/K}$$

6.7B $$-q_{rxn} = q_{calorimeter} = (c_{calorimeter})(\Delta T)$$
$$= (10.85\ \text{kJ/K})(11.50\ \text{K}) = 124.8\ \text{kJ}$$
$$q_{rxn} = -124.8\ \text{J}$$
$$\Delta E = -124.8\ \text{kJ} \times \frac{26.04\ \text{g/mol}}{2.50\ \text{g}} = -1.30\times10^3\ \text{kJ/mol } C_2H_2$$

6.8A $C_2H_4(g) + H_2(g) \longrightarrow C_2H_6(g) + 137\ \text{kJ}$

$$\text{Heat (kJ)} = 15.0\ \text{kg} \times \frac{1000\ \text{g}}{1\ \text{kg}} \times \frac{1\ \text{mol } C_2H_6}{30.07\ \text{g } C_2H_6} \times \frac{137\ \text{kJ}}{1\ \text{mol}} = 6.83\times10^4\ \text{kJ released}$$

6.8B $N_2(g) + O_2(g) + 180.58\ \text{kJ} \longrightarrow 2NO(g)$

$$\text{Heat (kJ)} = 3.50\ \text{t} \times \frac{1000\ \text{kg}}{1\ \text{t}} \times \frac{1000\ \text{g}}{1\ \text{kg}} \times \frac{1\ \text{mol NO}}{30.01\ \text{g}} \times \frac{180.58\ \text{kJ}}{2\ \text{mol NO}}$$
$$= 1.05\times10^7\ \text{kJ absorbed}$$

6.9A Reverse equation 1:

$2NO(g) + \frac{3}{2}O_2(g) \longrightarrow N_2O_5(s) \qquad \Delta H = -223.7\ \text{kJ}$

Reverse equation 2 and multiply by 2:

$2NO_2(g) \longrightarrow 2NO(g) + O_2(g) \qquad \Delta H = 114.2\ \text{kJ}$

$\cancel{2NO(g)} + \frac{1}{2}\cancel{\frac{3}{1}}O_2(g) + 2NO_2(g) \longrightarrow N_2O_5(s) + \cancel{2NO(g)} + \cancel{O_2(g)}$

$2NO_2(g) + \frac{1}{2}O_2(g) \longrightarrow N_2O_5(s) \qquad \Delta H = -109.5\ \text{kJ}$

6.9B Reverse equation 1 and divide by 2:

$NH_3(g) \longrightarrow \frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \quad \Delta H = -\frac{1}{2}(-91.8\ \text{kJ}) = 45.9\ \text{kJ}$

Divide equation 2 by 2:

$\frac{1}{2}N_2(g) + 2H_2(g) + \frac{1}{2}Cl_2(g) \longrightarrow NH_4Cl(s)$

$\Delta H = \frac{1}{2}(-628.8\ \text{kJ}) = -314.4\ \text{kJ}$

Reverse equation 3:

$NH_4Cl(s) \longrightarrow NH_3(g) + HCl(g)$

$\Delta H = -(-176.2\ \text{kJ}) = 176.2\ \text{kJ}$

$\cancel{NH_4Cl(s)} + \frac{1}{2}\cancel{N_2(g)} + \frac{1}{2}\cancel{2}H_2(g) + \frac{1}{2}Cl_2(g) + \cancel{NH_4Cl(s)} \longrightarrow \frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) + \cancel{NH_4Cl(s)} + \cancel{NH_3(g)} + HCl(g)$

$\frac{1}{2}H_2(g) + \frac{1}{2}Cl_2(g) \longrightarrow HCl(g) \qquad \Delta H = -92.3\ \text{kJ}$

6.10A (a) $C(\text{graphite}) + 2H_2(g) + \frac{1}{2}O_2(g) \longrightarrow CH_3OH(l)$

$\Delta H_f^\circ = -238.6\ \text{kJ}$

(b) $Ca(s) + \frac{1}{2}O_2(g) \longrightarrow CaO(s) \qquad \Delta H_f^\circ = -635.1\ \text{kJ}$

(c) $C(\text{graphite}) + \frac{1}{4}S_8(\text{rhombic}) \longrightarrow CS_2(l) \qquad \Delta H_f^\circ = 87.9\ \text{kJ}$

6.10B (a) $C(\text{graphite}) + \frac{1}{2}H_2(g) + \frac{3}{2}Cl_2(g) \longrightarrow CHCl_3(l)$

$\Delta H_f^\circ = -132\ \text{kJ}$

(b) $\frac{1}{2}N_2(g) + 2H_2(g) + \frac{1}{2}Cl_2(g) \longrightarrow NH_4Cl(s)$

$\Delta H_f^\circ = -314.4\ \text{kJ}$

(c) $Pb(s) + \frac{1}{8}S_8(\text{rhombic}) + 2O_2(g) \longrightarrow PbSO_4(s)$

$\Delta H_f^\circ = -918.39\ \text{kJ}$

6.11A $$\Delta H_{rxn}^\circ = 4\Delta H_f^\circ[H_3PO_4(l)] - \{\Delta H_f^\circ[P_4O_{10}(s)] + 6\Delta H_f^\circ[H_2O(l)]\}$$
$$= (4\ \text{mol})(-1271.7\ \text{kJ/mol}) - [(1\ \text{mol})(-2984\ \text{kJ/mol}) + (6\ \text{mol})(-285.840\ \text{kJ/mol})]$$
$$= -5086.8\ \text{kJ} - (-2984\ \text{kJ} - 1715.04\ \text{kJ}) = -387.8\ \text{kJ}$$

6.11B $$\Delta H_f^\circ \text{ of } CH_3OH(l) = -\Delta H_{rxn}^\circ + 2\Delta H_f^\circ[H_2O(g)] + \Delta H_f^\circ[CO_2(g)]$$
$$= 638.6\ \text{kJ} + (2\ \text{mol})(-241.826\ \text{kJ/mol}) + (1\ \text{mol})(-393.5\ \text{kJ/mol})$$
$$= -238.6\ \text{kJ}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Forms of Energy and Their Interconversion

(Sample Problem 6.1)

Concept Review Questions

6.1 Why do heat (q) and work (w) have positive values when entering a system and negative values when leaving?

6.2 If you feel warm after exercising, have you increased the internal energy of your body? Explain.

6.3 An *adiabatic* process is one that involves no heat transfer. What is the relationship between work and the change in internal energy in an adiabatic process?

6.4 State two ways that you increase the internal energy of your body and two ways that you decrease it.

6.5 Name a common device used to accomplish each change:
(a) Electrical energy to thermal energy
(b) Electrical energy to sound energy
(c) Electrical energy to light energy
(d) Mechanical energy to electrical energy
(e) Chemical energy to electrical energy

6.6 In winter, an electric heater uses a certain amount of electrical energy to heat a room to 20°C. In summer, an air conditioner uses the same amount of electrical energy to cool the room to 20°C. Is the change in internal energy of the heater larger, smaller, or the same as that of the air conditioner? Explain.

6.7 You lift your textbook and drop it onto a desk. Describe the energy transformations (from one form to another) that occur, moving backward in time from a moment after impact.

Skill-Building Exercises (grouped in similar pairs)

6.8 A system receives 425 J of heat from and delivers 425 J of work to its surroundings. What is the change in internal energy of the system (in J)?

6.9 A system releases 255 cal of heat to the surroundings and delivers 428 cal of work. What is the change in internal energy of the system (in cal)?

6.10 What is the change in internal energy (in J) of a system that releases 675 J of thermal energy to its surroundings and has 530 cal of work done on it?

6.11 What is the change in internal energy (in J) of a system that absorbs 0.615 kJ of heat from its surroundings and has 0.247 kcal of work done on it?

6.12 Complete combustion of 2.0 metric tons of coal to gaseous carbon dioxide releases 6.6×10^{10} J of heat. Convert this energy to (a) kilojoules; (b) kilocalories; (c) British thermal units.

6.13 Thermal decomposition of 5.0 metric tons of limestone to lime and carbon dioxide absorbs 9.0×10^{6} kJ of heat. Convert this energy to (a) joules; (b) calories; (c) British thermal units.

Problems in Context

6.14 The nutritional calorie (Calorie) is equivalent to 1 kcal. One pound of body fat is equivalent to about 4.1×10^{3} Calories. Express this quantity of energy in joules and kilojoules.

6.15 If an athlete expends 1950 kJ/h, how long does it take her to work off 1.0 lb of body fat? (See Problem 6.14.)

Enthalpy: Changes at Constant Pressure

(Sample Problems 6.2 and 6.3)

Concept Review Questions

6.16 Why is the work done when a system expands against a constant external pressure assigned a negative sign?

6.17 Why is it often more convenient to measure ΔH than ΔE?

6.18 Hot packs used by skiers use the crystallization of sodium acetate from a concentrated solution. What is the sign of ΔH for this crystallization? Is the reaction exothermic or endothermic?

6.19 Classify the following processes as exothermic or endothermic: (a) freezing of water; (b) boiling of water; (c) digestion of food; (d) a person running; (e) a person growing; (f) wood being chopped; (g) heating with a furnace.

6.20 What are the two main components of the internal energy of a substance? On what are they based?

6.21 For each process, state whether ΔH is less than (more negative), equal to, or greater than ΔE of the system. Explain.
(a) An ideal gas is cooled at constant pressure.
(b) A gas mixture reacts exothermically at fixed volume.
(c) A solid reacts exothermically to yield a mixture of gases in a container of variable volume.

Skill-Building Exercises (grouped in similar pairs)

6.22 At constant temperature, a sample of helium gas expands from 922 mL to 1.14 L against a pressure of 2.33 atm. Find w (in J) done by the gas ($1\ \text{J} = 9.87\times10^{-3}$ atm·L).

6.23 The external pressure on a gas sample is 2660 mmHg, and the volume changes from 0.88 L to 0.63 L at constant temperature. Find w (in kJ) done on the gas (1 atm·L = 101.3 J).

6.24 Draw an enthalpy diagram for a general exothermic reaction; label the axis, reactants, products, and ΔH with its sign.

6.25 Draw an enthalpy diagram for a general endothermic reaction; label the axis, reactants, products, and ΔH with its sign.

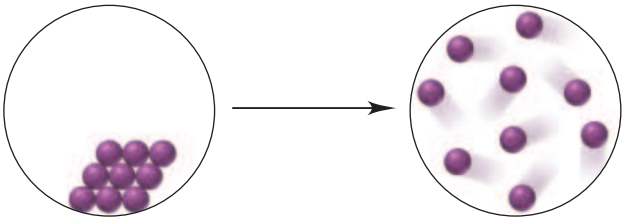
6.26 Write a balanced equation and draw an approximate enthalpy diagram for: (a) combustion of 1 mol of ethane; (b) freezing of liquid water.

6.27 Write a balanced equation and draw an approximate enthalpy diagram for (a) formation of 1 mol of sodium chloride from its elements (heat is released); (b) vaporization of liquid benzene.

6.28 Write a balanced equation and draw an approximate enthalpy diagram for (a) combustion of 1 mol of liquid methanol (CH_3OH); (b) formation of 1 mol of NO_2 from its elements (heat is absorbed).

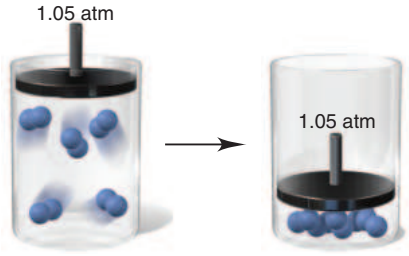
6.29 Write a balanced equation and draw an approximate enthalpy diagram for (a) sublimation of dry ice [conversion of $CO_2(s)$ directly to $CO_2(g)$]; (b) reaction of 1 mol of SO_2 with O_2.

6.30 The circles represent a phase change at constant temperature:



Is the value of each of the following positive (+), negative (−), or zero: (a) q_{sys}; (b) ΔE_{sys}; (c) ΔE_{univ}?

6.31 The scenes below represent a physical change taking place in a piston-cylinder assembly:



(a) Is w_{sys} +, −, or 0? (b) Is ΔH_{sys} +, −, or 0? (c) Can you determine whether ΔE_{surr} is +, −, or 0? Explain.

Calorimetry: Measuring the Heat of a Chemical or Physical Change

(Sample Problems 6.4 to 6.7)

Concept Review Questions

6.32 Which is larger, the specific heat capacity or the molar heat capacity of a substance? Explain.

6.33 What data do you need to determine the specific heat capacity of a substance?

6.34 Is the specific heat capacity of a substance an intensive or extensive property? Explain.

6.35 Distinguish between specific heat capacity, molar heat capacity, and heat capacity.

6.36 Both a coffee-cup calorimeter and a bomb calorimeter can be used to measure the heat transferred in a reaction. Which measures ΔE and which measures ΔH? Explain.

Skill-Building Exercises (grouped in similar pairs)

6.37 Find q when 22.0 g of water is heated from 25.0°C to 100.°C.

6.38 Calculate q when 0.10 g of ice is cooled from 10.°C to −75°C (c_{ice} = 2.087 J/g·K).

6.39 A 295-g aluminum engine part at an initial temperature of 13.00°C absorbs 75.0 kJ of heat. What is the final temperature of the part (c of Al = 0.900 J/g·K)?

6.40 A 27.7-g sample of the radiator coolant ethylene glycol releases 688 J of heat. What was the initial temperature of the sample if the final temperature is 32.5°C (c of ethylene glycol = 2.42 J/g·K)?

6.41 Two iron bolts of equal mass—one at 100.°C, the other at 55°C—are placed in an insulated container. Assuming the heat capacity of the container is negligible, what is the final temperature inside the container (c of iron = 0.450 J/g·K)?

6.42 One piece of copper jewelry at 105°C has twice the mass of another piece at 45°C. Both are placed in a calorimeter of negligible heat capacity. What is the final temperature inside the calorimeter (c of copper = 0.387 J/g·K)?

6.43 When 155 mL of water at 26°C is mixed with 75 mL of water at 85°C, what is the final temperature? (Assume that no heat is released to the surroundings; d of water = 1.00 g/mL.)

6.44 An unknown volume of water at 18.2°C is added to 24.4 mL of water at 35.0°C. If the final temperature is 23.5°C, what was the unknown volume? (Assume that no heat is released to the surroundings; d of water = 1.00 g/mL.)

6.45 A 455-g piece of copper tubing is heated to 89.5°C and placed in an insulated vessel containing 159 g of water at 22.8°C. Assuming no loss of water and a heat capacity of 10.0 J/K for the vessel, what is the final temperature (c of copper = 0.387 J/g·K)?

6.46 A 30.5-g sample of an alloy at 93.0°C is placed into 50.0 g of water at 22.0°C in an insulated coffee cup with a heat capacity of 9.2 J/K. If the final temperature of the system is 31.1°C, what is the specific heat capacity of the alloy?

Problems in Context

6.47 High-purity benzoic acid (C_6H_5COOH; ΔH for combustion = −3227 kJ/mol) is used to calibrate bomb calorimeters. A 1.221-g sample burns in a calorimeter (heat capacity of 1365 J/°C) that contains 1.200 kg of water. What is the temperature change?

6.48 Two aircraft rivets, one iron and the other copper, are placed in a calorimeter that has an initial temperature of 20.°C. The data for the rivets are as follows:

	Iron	Copper
Mass (g)	30.0	20.0
Initial T (°C)	0.0	100.0
c (J/g·K)	0.450	0.387

(a) Will heat flow from Fe to Cu or from Cu to Fe?
(b) What other information is needed to correct any measurements in an actual experiment?
(c) What is the maximum final temperature of the system (assuming the heat capacity of the calorimeter is negligible)?

6.49 A chemical engineer placed 1.520 g of a hydrocarbon in the bomb of a calorimeter (see Figure 6.10, p. 265). The bomb was immersed in 2.550 L of water and the sample was burned. The water temperature rose from 20.00°C to 23.55°C. If the calorimeter (excluding the water) had a heat capacity of 403 J/K, what was the heat released (q_V) per gram of hydrocarbon?

6.50 When 25.0 mL of 0.500 M H_2SO_4 is added to 25.0 mL of 1.00 M KOH in a coffee-cup calorimeter at 23.50°C, the temperature rises to 30.17°C. Calculate ΔH of this reaction. (Assume that the total volume is the sum of the volumes and that the density and specific heat capacity of the solution are the same as for water.)

Stoichiometry of Thermochemical Equations

(Sample Problem 6.8)

Concept Review Questions

6.51 Does a negative ΔH mean that the heat should be treated as a reactant or as a product?

6.52 Would you expect $O_2(g) \longrightarrow 2O(g)$ to have a positive or a negative ΔH? Explain.

6.53 Is ΔH positive or negative when 1 mol of water vapor condenses to liquid water? Why? How does this value compare with ΔH for the vaporization of 2 mol of liquid water to water vapor?

Skill-Building Exercises (grouped in similar pairs)

6.54 Consider the following balanced thermochemical equation for a reaction sometimes used for H_2S production:

$$\tfrac{1}{8}S_8(s) + H_2(g) \longrightarrow H_2S(g) \quad \Delta H = -20.2 \text{ kJ}$$

(a) Is this an exothermic or endothermic reaction?
(b) What is ΔH for the reverse reaction?
(c) What is ΔH when 2.6 mol of S_8 reacts?
(d) What is ΔH when 25.0 g of S_8 reacts?

6.55 Consider the following balanced thermochemical equation for the decomposition of the mineral magnesite:

$$MgCO_3(s) \longrightarrow MgO(s) + CO_2(g) \quad \Delta H = 117.3 \text{ kJ}$$

(a) Is heat absorbed or released in the reaction?
(b) What is ΔH for the reverse reaction?
(c) What is ΔH when 5.35 mol of CO_2 reacts with excess MgO?
(d) What is ΔH when 35.5 g of CO_2 reacts with excess MgO?

6.56 When 1 mol of $NO(g)$ forms from its elements, 90.29 kJ of heat is absorbed. (a) Write a balanced thermochemical equation. (b) What is ΔH when 3.50 g of NO decomposes to its elements?

6.57 When 1 mol of $KBr(s)$ decomposes to its elements, 394 kJ of heat is absorbed. (a) Write a balanced thermochemical equation. (b) What is ΔH when 10.0 kg of KBr forms from its elements?

Problems in Context

6.58 Liquid hydrogen peroxide, an oxidizing agent in many rocket fuel mixtures, releases oxygen gas on decomposition:

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g) \quad \Delta H = -196.1 \text{ kJ}$$

How much heat is released when 652 kg of H_2O_2 decomposes?

6.59 Compounds of boron and hydrogen are remarkable for their unusual bonding (described in Section 14.5) and also for their reactivity. With the more reactive halogens, for example, diborane (B_2H_6) forms trihalides even at low temperatures:

$$B_2H_6(g) + 6Cl_2(g) \longrightarrow 2BCl_3(g) + 6HCl(g) \quad \Delta H = -755.4 \text{ kJ}$$

What is ΔH per kilogram of diborane that reacts?

6.60 Deterioration of buildings, bridges, and other structures through the rusting of iron costs millions of dollars a day. The actual process requires water, but a simplified equation is

$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s) \quad \Delta H = -1.65\times10^3 \text{ kJ}$$

(a) How much heat is released when 0.250 kg of iron rusts?
(b) How much rust forms when 4.85×10^3 kJ of heat is released?

6.61 A mercury mirror forms inside a test tube as a result of the thermal decomposition of mercury(II) oxide:

$$2HgO(s) \longrightarrow 2Hg(l) + O_2(g) \quad \Delta H = 181.6 \text{ kJ}$$

(a) How much heat is absorbed to decompose 555 g of the oxide?
(b) If 275 kJ of heat is absorbed, how many grams of Hg form?

6.62 Most ethylene (C_2H_4), the starting material for producing polyethylene, comes from petroleum processing. It also occurs naturally as a fruit-ripening hormone and as a component of natural gas. (a) The heat transferred during combustion of C_2H_4 is -1411 kJ/mol. Write a balanced thermochemical equation. (b) How many grams of C_2H_4 must burn to give 70.0 kJ of heat?

6.63 Sucrose ($C_{12}H_{22}O_{11}$, table sugar) is oxidized in the body by O_2 via a complex set of reactions that produces $CO_2(g)$ and $H_2O(g)$ and releases 5.64×10^3 kJ/mol of sucrose. (a) Write a balanced thermochemical equation for the overall process. (b) How much heat is released per gram of sucrose oxidized?

Hess's Law: Finding ΔH of Any Reaction

(Sample Problem 6.9)

Concept Review Questions

6.64 Express Hess's law in your own words.

6.65 What is the main application of Hess's law?

6.66 When carbon burns in a deficiency of O_2, a mixture of CO and CO_2 forms. Carbon burns in excess O_2 to form only CO_2, and CO burns in excess O_2 to form only CO_2. Use ΔH values of the latter two reactions (from Appendix B) to calculate ΔH for

$$C(\text{graphite}) + \tfrac{1}{2}O_2(g) \longrightarrow CO(g)$$

Skill-Building Exercises (grouped in similar pairs)

6.67 Calculate ΔH for

$$Ca(s) + \tfrac{1}{2}O_2(g) + CO_2(g) \longrightarrow CaCO_3(s)$$

given the following reactions:

$$Ca(s) + \tfrac{1}{2}O_2(g) \longrightarrow CaO(s) \quad \Delta H = -635.1 \text{ kJ}$$
$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g) \quad \Delta H = 178.3 \text{ kJ}$$

6.68 Calculate ΔH for

$$2NOCl(g) \longrightarrow N_2(g) + O_2(g) + Cl_2(g)$$

given the following reactions:

$$\tfrac{1}{2}N_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow NO(g) \quad \Delta H = 90.3 \text{ kJ}$$
$$NO(g) + \tfrac{1}{2}Cl_2(g) \longrightarrow NOCl(g) \quad \Delta H = -38.6 \text{ kJ}$$

6.69 Write the balanced overall equation (equation 3) for the following process, calculate $\Delta H_{overall}$, and match the number of each equation with the letter of the appropriate arrow in Figure P6.69:

(1) $N_2(g) + O_2(g) \longrightarrow 2NO(g)$ $\quad \Delta H = 180.6$ kJ
(2) $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$ $\quad \Delta H = -114.2$ kJ
(3) $\quad \Delta H_{overall} = ?$

6.70 Write the balanced overall equation (equation 3) for the following process, calculate $\Delta H_{overall}$, and match the number of each equation with the letter of the appropriate arrow in Figure P6.70:

(1) $P_4(s) + 6Cl_2(g) \longrightarrow 4PCl_3(g)$ $\quad \Delta H = -1148$ kJ
(2) $4PCl_3(g) + 4Cl_2(g) \longrightarrow 4PCl_5(g)$ $\quad \Delta H = -460$ kJ
(3) $\quad \Delta H_{overall} = ?$

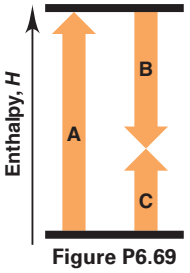


Figure P6.69

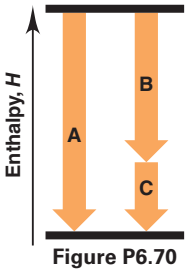

Figure P6.70

6.71 At a given set of conditions, 241.8 kJ of heat is released when 1 mol of $H_2O(g)$ forms from its elements. Under the same conditions, 285.8 kJ is released when 1 mol of $H_2O(l)$ forms from its elements. Find ΔH for the vaporization of water at these conditions.

6.72 When 1 mol of $CS_2(l)$ forms from its elements at 1 atm and 25°C, 89.7 kJ of heat is absorbed, and it takes 27.7 kJ to vaporize

1 mol of the liquid. How much heat is absorbed when 1 mol of $CS_2(g)$ forms from its elements at these conditions?

Problems in Context

6.73 Diamond and graphite are two crystalline forms of carbon. At 1 atm and 25°C, diamond changes to graphite so slowly that the enthalpy change of the process must be obtained indirectly. Using equations from the numbered list below, determine ΔH for

$$\text{C(diamond)} \longrightarrow \text{C(graphite)}$$

(1) $C(diamond) + O_2(g) \longrightarrow CO_2(g)$ $\quad \Delta H = -395.4$ kJ
(2) $2CO_2(g) \longrightarrow 2CO(g) + O_2(g)$ $\quad \Delta H = 566.0$ kJ
(3) $C(graphite) + O_2(g) \longrightarrow CO_2(g)$ $\quad \Delta H = -393.5$ kJ
(4) $2CO(g) \longrightarrow C(graphite) + CO_2(g)$ $\quad \Delta H = -172.5$ kJ

Standard Enthalpies of Reaction (ΔH°_{rxn})

(Sample Problems 6.10 and 6.11)

Concept Review Questions

6.74 What is the difference between the standard enthalpy of formation and the standard enthalpy of reaction?

6.75 How are ΔH°_f values used to calculate ΔH°_{rxn}?

6.76 Make any changes needed in each of the following equations to make the enthalpy change equal to ΔH°_f for the compound:
(a) $Cl(g) + Na(s) \longrightarrow NaCl(s)$
(b) $H_2O(g) \longrightarrow 2H(g) + \frac{1}{2}O_2(g)$
(c) $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \longrightarrow NH_3(g)$

Skill-Building Exercises (grouped in similar pairs)

6.77 Use Table 6.3 or Appendix B to write a balanced formation equation at standard conditions for each of the following compounds: (a) $CaCl_2$; (b) $NaHCO_3$; (c) CCl_4; (d) HNO_3.

6.78 Use Table 6.3 or Appendix B to write a balanced formation equation at standard conditions for each of the following compounds: (a) HI; (b) SiF_4; (c) O_3; (d) $Ca_3(PO_4)_2$.

6.79 Calculate ΔH°_{rxn} for each of the following:
(a) $2H_2S(g) + 3O_2(g) \longrightarrow 2SO_2(g) + 2H_2O(g)$
(b) $CH_4(g) + Cl_2(g) \longrightarrow CCl_4(l) + HCl(g)$ [unbalanced]

6.80 Calculate ΔH°_{rxn} for each of the following:
(a) $SiO_2(s) + 4HF(g) \longrightarrow SiF_4(g) + 2H_2O(l)$
(b) $C_2H_6(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$ [unbalanced]

6.81 Copper(I) oxide can be oxidized to copper(II) oxide:

$$Cu_2O(s) + \tfrac{1}{2}O_2(g) \longrightarrow 2CuO(s) \quad \Delta H^\circ_{rxn} = -146.0 \text{ kJ}$$

Given ΔH°_f of $Cu_2O(s) = -168.6$ kJ/mol, find ΔH°_f of $CuO(s)$.

6.82 Acetylene burns in air by the following equation:

$$C_2H_2(g) + \tfrac{5}{2}O_2(g) \longrightarrow 2CO_2(g) + H_2O(g) \quad \Delta H^\circ_{rxn} = -1255.8 \text{ kJ}$$

Given ΔH°_f of $CO_2(g) = -393.5$ kJ/mol and ΔH°_f of $H_2O(g) = -241.8$ kJ/mol, find ΔH°_f of $C_2H_2(g)$.

Problems in Context

6.83 The common lead-acid car battery produces a large burst of current, even at low temperatures, and is rechargeable. The reaction that occurs while recharging a "dead" battery is

$$2PbSO_4(s) + 2H_2O(l) \longrightarrow Pb(s) + PbO_2(s) + 2H_2SO_4(l)$$

(a) Use ΔH°_f values from Appendix B to calculate ΔH°_{rxn}.
(b) Use the following equations to check your answer to part (a):

(1) $Pb(s) + PbO_2(s) + 2SO_3(g) \longrightarrow 2PbSO_4(s)$ $\quad \Delta H^\circ_{rxn} = -768$ kJ
(2) $SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(l)$ $\quad \Delta H^\circ_{rxn} = -132$ kJ

Comprehensive Problems

6.84 Stearic acid ($C_{18}H_{36}O_2$) is a fatty acid, a molecule with a long hydrocarbon chain and an organic acid group (COOH) at the end. It is used to make cosmetics, ointments, soaps, and candles and is found in animal tissue as part of many saturated fats. In fact, when you eat meat, you are ingesting some fats containing stearic acid.
(a) Write a balanced equation for the combustion of stearic acid to gaseous products.
(b) Calculate ΔH°_{rxn} for this combustion (ΔH°_f of $C_{18}H_{36}O_2 = -948$ kJ/mol).
(c) Calculate the heat (q) released in kJ and kcal when 1.00 g of stearic acid is burned completely.
(d) A candy bar contains 11.0 g of fat and provides 100. Cal from fat; is this consistent with your answer for part (c)?

6.85 Diluting sulfuric acid with water is highly exothermic:

$$H_2SO_4(l) \xrightarrow{H_2O} H_2SO_4(aq) + heat$$

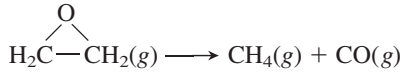
(a) Use Appendix B to find ΔH°_{rxn} for diluting 1.00 mol of $H_2SO_4(l)$ ($d = 1.83$ g/mL) to 1 L of 1.00 M $H_2SO_4(aq)$ ($d = 1.060$ g/mL).
(b) Suppose you carry out the dilution in a calorimeter. The initial T is 25.0°C, and the specific heat capacity of the final solution is 3.50 J/g·K. What is the final T?
(c) Use the ideas of density and heat capacity to explain why you should add acid to water rather than water to acid.

6.86 A balloonist begins a trip in a helium-filled balloon in early morning when the temperature is 15°C. By mid-afternoon, the temperature is 30.°C. Assuming the pressure remains at 1.00 atm, for each mole of helium, calculate the following:
(a) The initial and final volumes
(b) The change in internal energy, ΔE (*Hint:* Helium behaves like an ideal gas, so $E = \frac{3}{2}nRT$. Be sure the units of R are consistent with those of E.)
(c) The work (w) done by the helium (in J)
(d) The heat (q) transferred (in J)
(e) ΔH for the process (in J)
(f) Explain the relationship between the answers to parts (d) and (e).

6.87 In winemaking, the sugars in grapes undergo *fermentation* by yeast to yield CH_3CH_2OH and CO_2. During cellular *respiration* (combustion), sugar and ethanol yield water vapor and CO_2.
(a) Using $C_6H_{12}O_6$ for sugar, calculate ΔH°_{rxn} of fermentation and of respiration.
(b) Write a combustion reaction for ethanol. Which has a higher ΔH°_{rxn} for combustion per mole of C, sugar or ethanol?

6.88 Three of the reactions that occur when the paraffin of a candle (typical formula $C_{21}H_{44}$) burns are as follows:
(1) Complete combustion forms CO_2 and water vapor.
(2) Incomplete combustion forms CO and water vapor.
(3) Some wax is oxidized to elemental C (soot) and water vapor.
(a) Find ΔH°_{rxn} of each reaction (ΔH°_f of $C_{21}H_{44} = -476$ kJ/mol; use graphite for elemental carbon).
(b) Find q (in kJ) when a 254-g candle burns completely.
(c) Find q (in kJ) when 8.00% by mass of the candle burns incompletely and 5.00% by mass of it undergoes soot formation.

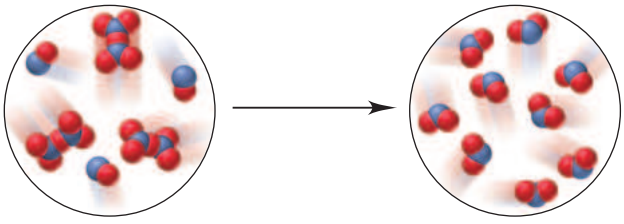
6.89 Ethylene oxide (EO) is prepared by the vapor-phase oxidation of ethylene. Its main uses are in the preparation of the antifreeze ethylene glycol and in the production of poly(ethylene terephthalate), which is used to make beverage bottles and fibers. Pure EO vapor can decompose explosively:



$$H_2C\text{—}CH_2(g) \longrightarrow CH_4(g) + CO(g)$$

Liquid EO has $\Delta H_f^\circ = -77.4$ kJ/mol and ΔH° for its vaporization = 569.4 J/g. (a) Calculate ΔH_{rxn}° for the gas-phase reaction. (b) External heating causes the vapor to decompose at 10 bar and 93°C in a distillation column. What is the final temperature if the average specific heat capacity of the products is 2.5 J/g·°C?

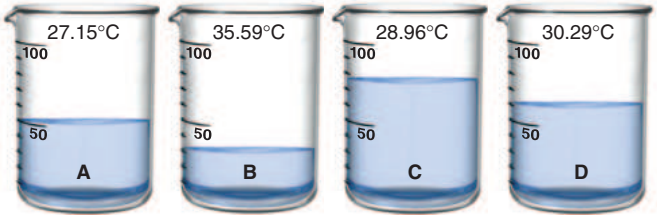
6.90 The following scenes represent a gaseous reaction between compounds of nitrogen *(blue)* and oxygen *(red)* at 298 K:



(a) Write a balanced equation and use Appendix B to calculate ΔH_{rxn}°.
(b) If each molecule of product represents 1.50×10^{-2} mol, what quantity of heat (in J) is released or absorbed?

6.91 Isooctane (C_8H_{18}; $d = 0.692$ g/mL) is used as the fuel in a test of a new automobile drive train.
(a) How much energy (in kJ) is released by combustion of 20.4 gal of isooctane to gases ($\Delta H_{rxn}^\circ = -5.44\times10^3$ kJ/mol)?
(b) The energy delivered to the wheels at 65 mph is 5.5×10^4 kJ/h. Assuming *all* the energy is transferred as work to the wheels, how far (in km) can the car travel on the 20.4 gal of fuel?
(c) If the actual range is 455 mi, explain your answer to (b).

6.92 Four 50.-g samples of different colorless liquids are placed in beakers at $T_{initial} = 25.00$°C. Each liquid is heated until 450. J of heat has been absorbed; T_{final} is shown on each beaker below. Rank the liquids in order of increasing specific heat capacity.



6.93 Reaction of gaseous ClF with F_2 yields liquid ClF_3, an important fluorinating agent. Use the following thermochemical equations to calculate ΔH_{rxn}° for this reaction:

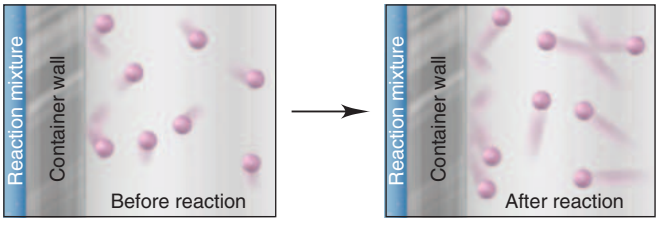
(1) $2ClF(g) + O_2(g) \longrightarrow Cl_2O(g) + OF_2(g)$ $\Delta H_{rxn}^\circ = 167.5$ kJ
(2) $2F_2(g) + O_2(g) \longrightarrow 2OF_2(g)$ $\Delta H_{rxn}^\circ = -43.5$ kJ
(3) $2ClF_3(l) + 2O_2(g) \longrightarrow Cl_2O(g) + 3OF_2(g)$ $\Delta H_{rxn}^\circ = 394.1$ kJ

6.94 Silver bromide is used to coat ordinary black-and-white photographic film, while high-speed film uses silver iodide.
(a) When 50.0 mL of 5.0 g/L $AgNO_3$ is added to a coffee-cup calorimeter containing 50.0 mL of 5.0 g/L NaI, with both solutions at 25°C, what mass of AgI forms?
(b) Use Appendix B to find ΔH_{rxn}°.
(c) What is ΔT_{soln} (assuming the volumes are additive and the solution has the density and specific heat capacity of water)?

6.95 The calorie (4.184 J) is defined as the quantity of energy needed to raise the temperature of 1.00 g of liquid water by 1.00°C. The British thermal unit (Btu) is defined as the quantity of energy needed to raise the temperature of 1.00 lb of liquid water by 1.00°F.
(a) How many joules are in 1.00 Btu (1 lb = 453.6 g; 1.0°C = 1.8°F)?
(b) The *therm* is a unit of energy consumption and is defined as 100,000 Btu. How many joules are in 1.00 therm?
(c) How many moles of methane must be burned to give 1.00 therm of energy? (Assume that water forms as a gas.)
(d) If natural gas costs $0.66 per therm, what is the cost per mole of methane? (Assume that natural gas is pure methane.)
(e) How much would it cost to warm 318 gal of water in a hot tub from 15.0°C to 42.0°C by burning methane (1 gal = 3.78 L)?

6.96 When organic matter decomposes under oxygen-free (anaerobic) conditions, methane is one of the products. Thus, enormous deposits of natural gas, which is almost entirely methane, serve as a major source of fuel for home and industry.
(a) Known deposits of natural gas can produce 5600 EJ of energy (1 EJ = 10^{18} J). Current total global energy usage is 4.0×10^2 EJ per year. Find the mass (in kg) of known deposits of natural gas (ΔH_{rxn}° for the combustion of $CH_4 = -802$ kJ/mol).
(b) At current rates of usage, for how many years could these deposits supply the world's total energy needs?
(c) What volume (in ft^3) of natural gas, measured at STP, is required to heat 1.00 qt of water from 25.0°C to 100.0°C (d of $H_2O = 1.00$ g/mL; d of CH_4 at STP = 0.72 g/L)?
(d) The fission of 1 mol of uranium (about 4×10^{-4} ft^3) in a nuclear reactor produces 2×10^{13} J. What volume (in ft^3) of natural gas would produce the same amount of energy?

6.97 A reaction takes place in a steel vessel within a chamber filled with argon gas. Shown below are atomic-scale views of the argon adjacent to the surface of the container wall of the reaction vessel before and after the reaction. Was the reaction exothermic or endothermic? Explain.



6.98 An aqueous waste stream with a maximum concentration of 0.50 M H_2SO_4 ($d = 1.030$ g/mL at 25°C) is neutralized by controlled addition of 40% NaOH ($d = 1.430$ g/L) before it goes to the process sewer and then to the chemical plant waste treatment facility. A safety review finds that the waste stream could meet a small stream of an immiscible organic compound, which could form a flammable vapor in air at 40.°C. The maximum temperature reached by the NaOH solution and the waste stream is 31°C.

Could the temperature increase due to the heat transferred by the neutralization cause the organic vapor to explode? Assume that the specific heat capacity of each solution is 4.184 J/g·K.

6.99 Kerosene, a common space-heater fuel, is a mixture of hydrocarbons whose "average" formula is $C_{12}H_{26}$.
(a) Write a balanced equation, using the simplest whole-number coefficients, for the complete combustion of kerosene to gases.
(b) If $\Delta H^\circ_{rxn} = -1.50\times10^4$ kJ for the combustion equation as written in part (a), determine ΔH°_f of kerosene.
(c) Calculate the heat released by combustion of 0.50 gal of kerosene (d of kerosene = 0.749 g/mL).
(d) How many gallons of kerosene must be burned for a kerosene furnace to produce 1250. Btu (1 Btu = 1.055 kJ)?

6.100 Silicon tetrachloride is produced annually on the multikiloton scale and used in making transistor-grade silicon. It can be produced directly from the elements (reaction 1) or, more cheaply, by heating sand and graphite with chlorine gas (reaction 2). If water is present in reaction 2, some tetrachloride may be lost in an unwanted side reaction (reaction 3):

(1) $Si(s) + 2Cl_2(g) \longrightarrow SiCl_4(g)$
(2) $SiO_2(s) + 2C(\text{graphite}) + 2Cl_2(g) \longrightarrow SiCl_4(g) + 2CO(g)$
(3) $SiCl_4(g) + 2H_2O(g) \longrightarrow SiO_2(s) + 4HCl(g)$

$$\Delta H^\circ_{rxn} = -139.5 \text{ kJ}$$

(a) Use reaction 3 to calculate the standard enthalpies of reaction of reactions 1 and 2.
(b) What is the standard enthalpy of reaction for a fourth reaction that is the sum of reactions 2 and 3?

6.101 One mole of nitrogen gas confined within a cylinder by a piston is heated from 0°C to 819°C at 1.00 atm.
(a) Calculate the work done by the expanding gas in joules (1 J = 9.87×10^{-3} atm·L). Assume that all the energy is used to do work.
(b) What would be the temperature change if the gas were heated using the same amount of energy in a container of fixed volume? (Assume that the specific heat capacity of N_2 is 1.00 J/g·K.)

6.102 The chemistry of nitrogen oxides is very versatile. Given the following reactions and their standard enthalpy changes,

(1) $NO(g) + NO_2(g) \longrightarrow N_2O_3(g)$ $\quad \Delta H^\circ_{rxn} = -39.8$ kJ
(2) $NO(g) + NO_2(g) + O_2(g) \longrightarrow N_2O_5(g)$ $\quad \Delta H^\circ_{rxn} = -112.5$ kJ
(3) $2NO_2(g) \longrightarrow N_2O_4(g)$ $\quad \Delta H^\circ_{rxn} = -57.2$ kJ
(4) $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$ $\quad \Delta H^\circ_{rxn} = -114.2$ kJ
(5) $N_2O_5(s) \longrightarrow N_2O_5(g)$ $\quad \Delta H^\circ_{rxn} = 54.1$ kJ

calculate the standard enthalpy of reaction for

$$N_2O_3(g) + N_2O_5(s) \longrightarrow 2N_2O_4(g)$$

6.103 Electric generating plants transport large amounts of hot water through metal pipes, and oxygen dissolved in the water can cause a major corrosion problem. Hydrazine (N_2H_4) added to the water avoids the problem by reacting with the oxygen:

$$N_2H_4(aq) + O_2(g) \longrightarrow N_2(g) + 2H_2O(l)$$

About 4×10^7 kg of hydrazine is produced every year by reacting ammonia with sodium hypochlorite in the *Raschig process:*

$$2NH_3(aq) + NaOCl(aq) \longrightarrow N_2H_4(aq) + NaCl(aq) + H_2O(l)$$
$$\Delta H^\circ_{rxn} = -151 \text{ kJ}$$

(a) If ΔH°_f of $NaOCl(aq) = -346$ kJ/mol, find ΔH°_f of $N_2H_4(aq)$.
(b) What is the heat released when aqueous N_2H_4 is added to 5.00×10^3 L of water that is 2.50×10^{-4} M O_2?

6.104 Liquid methanol (CH_3OH) can be used as an alternative fuel in pickup and SUV engines. An industrial method for preparing it involves the catalytic hydrogenation of carbon monoxide:

$$CO(g) + 2H_2(g) \xrightarrow{\text{catalyst}} CH_3OH(l)$$

How much heat (in kJ) is released when 15.0 L of CO at 85°C and 112 kPa reacts with 18.5 L of H_2 at 75°C and 744 torr?

6.105 (a) How much heat is released when 25.0 g of methane burns in excess O_2 to form gaseous CO_2 and H_2O?
(b) Calculate the temperature of the product mixture if the methane and air are both at an initial temperature of 0.0°C. Assume a stoichiometric ratio of methane to oxygen from the air, with air being 21% O_2 by volume (c of CO_2 = 57.2 J/mol·K; c of $H_2O(g)$ = 36.0 J/mol·K; c of N_2 = 30.5 J/mol·K).

Concepts and Skills to Review Before You Study This Chapter

- discovery of the electron and atomic nucleus (Section 2.4)
- major features of atomic structure (Section 2.5)
- changes in the energy state of a system (Section 6.1)

After studying at the library into the night, you might appreciate the yellow glow of sodium-vapor streetlights that illuminate your way across a dark campus. Scientists in the early 20th century were fascinated by the phenomenon of vaporized sodium emitting light, one of several observations that led to a new view of matter and energy. That view is also essential for understanding neon signs, TV screens, and fireworks, not to mention the structure of the atom! New ideas about atomic structure were some of many revolutions that took place in Western science (and culture) from around 1890 to 1930.

But revolutions in science are not the violent upheavals of political overthrow. Flaws appear in a model due to conflicting evidence, a startling discovery widens the flaws into cracks, and the theoretical structure crumbles. Then, new insight, verified by experiment, builds a model more consistent with reality. So it was when Lavoisier's theory of combustion overthrew the phlogiston model, when Dalton's atomic theory established the idea of individual units of matter, and when Rutherford's model substituted nuclear atoms for "billiard balls" or "plum puddings." You will see this process unfold again as we discuss the development of modern atomic theory.

IN THIS CHAPTER . . . *We discuss quantum mechanics, the theory that explains the fundamental nature of energy and matter and accounts for atomic structure.*

- We consider the classical distinction between the wave properties of energy and the particle properties of matter.
- We then examine two observations—blackbody radiation and the photoelectric effect—whose explanations led to a *quantized*, or particulate, model of light.
- We see that light emitted by excited atoms—an *atomic spectrum*—suggests an atom with distinct energy levels, and we apply spectra to chemical analysis.
- We see how wave-particle duality, which shows that matter and energy have similar properties, and the uncertainty principle, which proposes that electron behavior can never be known exactly, led to the current model of the H atom.
- We present quantum numbers, which specify the size, shape, and orientation of atomic orbitals, the regions an electron occupies in the H atom. (In Chapter 8, we'll examine quantum numbers for atoms with more than one electron.)

A Time of Revolution

Here are some of the revolutionary discoveries and events occurring in the Western world during those decades:

1895 Röntgen: discovery of x-rays
1896 Becquerel: discovery of radioactivity
1897 Thomson: discovery of the electron
1900 Freud: theory of the unconscious
1900 Planck: quantum theory
1901 Marconi: invention of the radio
1903 Wright brothers: flight of a plane
1905 Ford: assembly line to build cars
1905 Rutherford: radioactivity explained
1905 Einstein: relativity/photon theories
1906 St. Denis: modern dance
1908 Matisse/Picasso: modern art
1909 Schoenberg/Berg: modern music
1911 Rutherford: nuclear model
1913 Bohr: atomic spectra and new model
1914–1918: World War I
1923 Compton: photon momentum
1924 De Broglie: wave theory of matter
1926 Schrödinger: wave equation
1927 Heisenberg: uncertainty principle

7.1 THE NATURE OF LIGHT

To understand current atomic theory, you need to know about **electromagnetic radiation** (also called *electromagnetic energy,* or *radiant energy*). Visible light, x-rays, radio waves, and microwaves are some of the types of electromagnetic radiation, all of which consist of energy propagated by electric and magnetic fields that increase and decrease in intensity as they move, wavelike, through space. This *classical wave model* explains why rainbows form, how magnifying glasses work, and many other familiar observations. But it cannot explain observations on the very *un*familiar atomic scale. In this section, we describe some properties of electromagnetic radiation and note how they are distinguished from the properties of matter. But, we will see that some properties blur the distinction between energy and matter, requiring a new model to explain them.

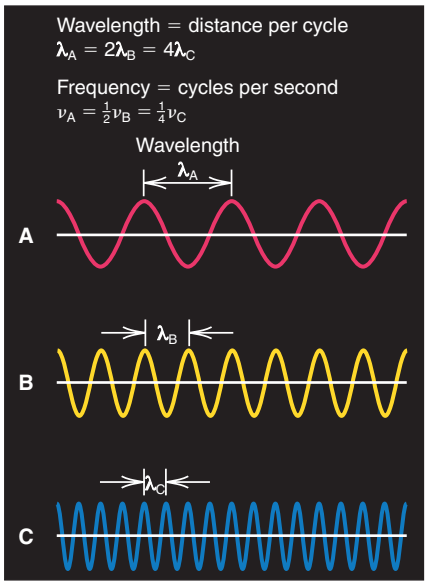

Figure 7.1 The inverse relationship of frequency and wavelength.

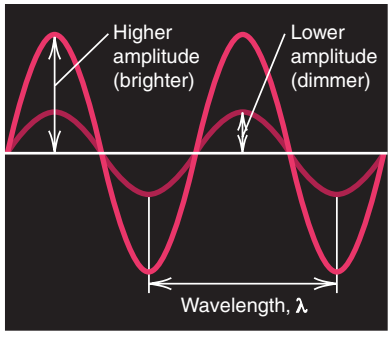

Figure 7.2 Differing amplitude (brightness, or intensity) of a wave.

The Wave Nature of Light

The wave properties of electromagnetic radiation are described by three variables and one constant (Figure 7.1):

1. *Frequency* (ν, Greek *nu*). The **frequency** of electromagnetic radiation is the number of complete waves, or cycles, that pass a given point per second, expressed by the unit 1/second [s^{-1}; also called a *hertz* (Hz)]. An FM radio station's channel is the frequency, in MHz, at which it broadcasts.
2. *Wavelength* (λ, Greek *lambda*). The **wavelength** is the distance between any point on a wave and the corresponding point on the next crest (or trough) of the wave, that is, the distance the wave travels during one cycle. Wavelength has units of meters or, for very short wavelengths, nanometers (nm, 10^{-9} m), picometers (pm, 10^{-12} m), or the non-SI unit angstroms (Å, 10^{-10} m).
3. *Speed*. The speed of a wave is the distance it moves per unit time (meters per second), the product of its frequency (cycles per second) and wavelength (meters per cycle):

$$\text{Units for speed of wave:} \quad \frac{\cancel{\text{cycles}}}{\text{s}} \times \frac{\text{m}}{\cancel{\text{cycle}}} = \frac{\text{m}}{\text{s}}$$

In a vacuum, electromagnetic radiation moves at 2.99792458×10^8 m/s (3.00×10^8 m/s to three significant figures), a *physical constant* called the **speed of light (c):**

$$c = \nu \times \lambda \qquad (7.1)$$

Since the product of ν and λ is a constant, they have an inverse relationship—*radiation with a high frequency has a short wavelength, and vice versa*:

$$\nu\uparrow\lambda\downarrow \qquad \text{and} \qquad \nu\downarrow\lambda\uparrow$$

4. *Amplitude.* The **amplitude** of a wave is the height of the crest (or depth of the trough). For an electromagnetic wave, the amplitude is related to the *intensity* of the radiation, or its brightness in the case of visible light. Light of a particular color has a specific frequency (and thus, wavelength) but, as Figure 7.2 shows, it can be dimmer (lower amplitude, less intense) or brighter (higher amplitude, more intense).

The Electromagnetic Spectrum *All waves of electromagnetic radiation travel at the same speed through a vacuum but differ in frequency and, therefore, wavelength.* The types of radiation are arranged in order of increasing wavelength (decreasing frequency) in the **electromagnetic spectrum** (Figure 7.3). As a *continuum of radiant energy,* the spectrum is broken down into regions according to wavelength and frequency, with each region adjoining the next.

Visible light represents just a small region of the spectrum. We perceive different wavelengths (or frequencies) of visible light as different colors, from violet

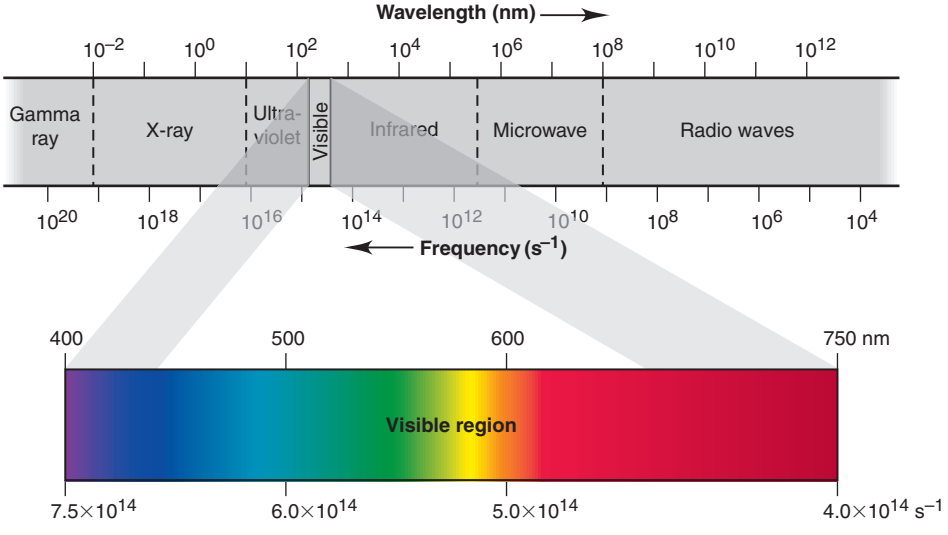

Figure 7.3 Regions of the electromagnetic spectrum. The visible region is expanded (and the scale made linear) to show the component colors.

($\lambda \approx 400$ nm) to red ($\lambda \approx 750$ nm). Light of a single wavelength is called *monochromatic* (Greek, "one color"), whereas light of many wavelengths is *polychromatic*. White light, composed of all of the colors of visible light, is polychromatic. The region adjacent to visible light on the short-wavelength (high-frequency) end consists of **ultraviolet (UV)** radiation (also called *ultraviolet light*); still shorter wavelengths make up the x-ray and gamma (γ) ray regions. The region adjacent to visible light on the long-wavelength (low-frequency) end consists of **infrared (IR)** radiation; still longer wavelengths make up the microwave and radio wave regions.

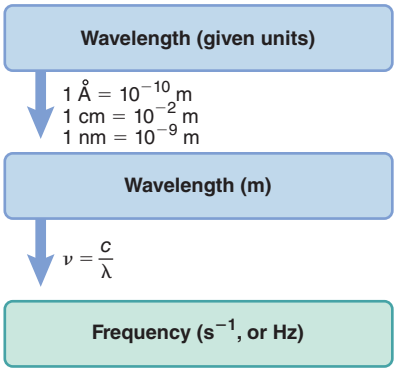
Some types of electromagnetic radiation are utilized by familiar devices; for example, long-wavelength, low-frequency radiation is used by microwave ovens, radios, and cell phones. But electromagnetic emissions are everywhere: coming from human artifacts such as lightbulbs, x-ray equipment, and car motors, and from natural sources such as the Sun, lightning, radioactivity, and even the glow of fireflies! Our knowledge of the universe comes from radiation that enters our eyes and our light, x-ray, and radio telescopes.

SAMPLE PROBLEM 7.1 Interconverting Wavelength and Frequency

Problem A dental hygienist uses x-rays ($\lambda = 1.00$ Å) to take a series of dental radiographs while the patient listens to a radio station ($\lambda = 325$ cm) and looks out the window at the blue sky ($\lambda = 473$ nm). What is the frequency (in s^{-1}) of the electromagnetic radiation from each source? (Assume that the radiation travels at the speed of light, 3.00×10^8 m/s.)

Plan We are given the wavelengths, so we use Equation 7.1 to find the frequencies. However, we must first convert the wavelengths to meters because c has units of m/s (see the road map).

Road Map



Solution For the x-rays: Converting from angstroms to meters,

$$\lambda = 1.00 \text{ Å} \times \frac{10^{-10} \text{ m}}{1 \text{ Å}} = 1.00\times10^{-10} \text{ m}$$

Calculating the frequency:

$$\nu = \frac{c}{\lambda} = \frac{3.00\times10^8 \text{ m/s}}{1.00\times10^{-10} \text{ m}} = 3.00\times10^{18} \text{ s}^{-1}$$

For the radio signal: Combining steps to calculate the frequency,

$$\nu = \frac{c}{\lambda} = \frac{3.00\times10^8 \text{ m/s}}{325 \text{ cm} \times \dfrac{10^{-2} \text{ m}}{1 \text{ cm}}} = 9.23\times10^7 \text{ s}^{-1}$$

For the blue sky: Combining steps to calculate the frequency,

$$\nu = \frac{c}{\lambda} = \frac{3.00\times10^8 \text{ m/s}}{473 \text{ nm} \times \dfrac{10^{-9} \text{ m}}{1 \text{ nm}}} = 6.34\times10^{14} \text{ s}^{-1}$$

Check The orders of magnitude are correct for the regions of the electromagnetic spectrum (see Figure 7.3): x-rays (10^{19} to 10^{16} s^{-1}), radio waves (10^9 to 10^4 s^{-1}), and visible light (7.5×10^{14} to 4.0×10^{14} s^{-1}).

Comment The radio station here is broadcasting at 92.3×10^6 s^{-1}, or 92.3 million Hz (92.3 MHz), about midway in the FM range.

FOLLOW-UP PROBLEMS

*Brief Solutions to **all** Follow-up Problems appear at the end of the chapter.*

7.1A Some diamonds appear yellow because they contain nitrogen compounds that absorb purple light of frequency 7.23×10^{14} Hz. Calculate the wavelength (in nm and Å) of the absorbed light.

7.1B A typical television remote control emits radiation with a wavelength of 940 nm. What is the frequency (in s^{-1}) of this radiation? What type of electromagnetic radiation is this?

SOME SIMILAR PROBLEMS 7.7, 7.8, 7.13, and 7.14

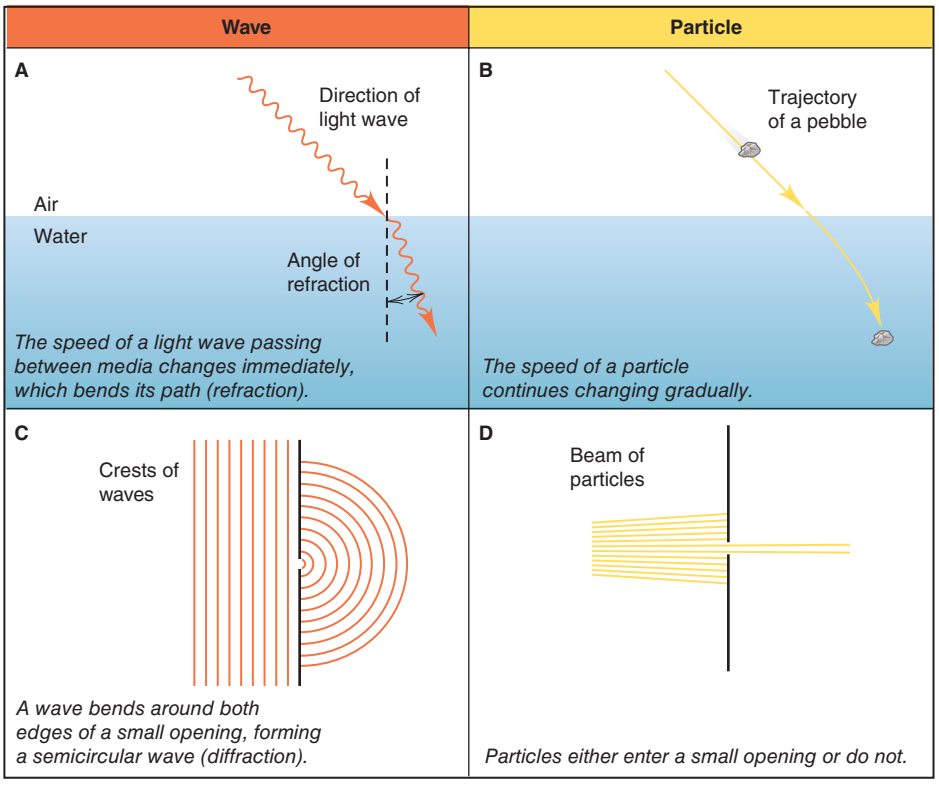


Figure 7.4 Different behaviors of waves and particles.

The Classical Distinction Between Energy and Matter In our everyday world, matter comes in chunks you can hold, weigh, and change the quantity of, piece by piece. In contrast, energy is "massless," and its quantity can change continuously. Matter moves in specific paths, whereas radiant energy (light) travels in diffuse waves. Let's examine some distinctions between the behavior of waves of energy and particles of matter.

1. *Refraction and dispersion.* Light of a given wavelength travels at different speeds through various transparent media—vacuum, air, water, quartz, and so forth. Therefore, when a light wave passes from one medium into another, the speed of the wave changes. Figure 7.4A shows the phenomenon known as **refraction.** If the wave strikes the boundary between media, say, between air and water, at an angle other than 90°, the change in speed causes a change in direction, and the wave continues at a different angle. The angle of refraction depends on the two media and the wavelength of the light. In the related process of *dispersion,* white light separates (disperses) into its component colors when it passes through a prism (or other refracting object) because each incoming wave is refracted at a slightly different angle.

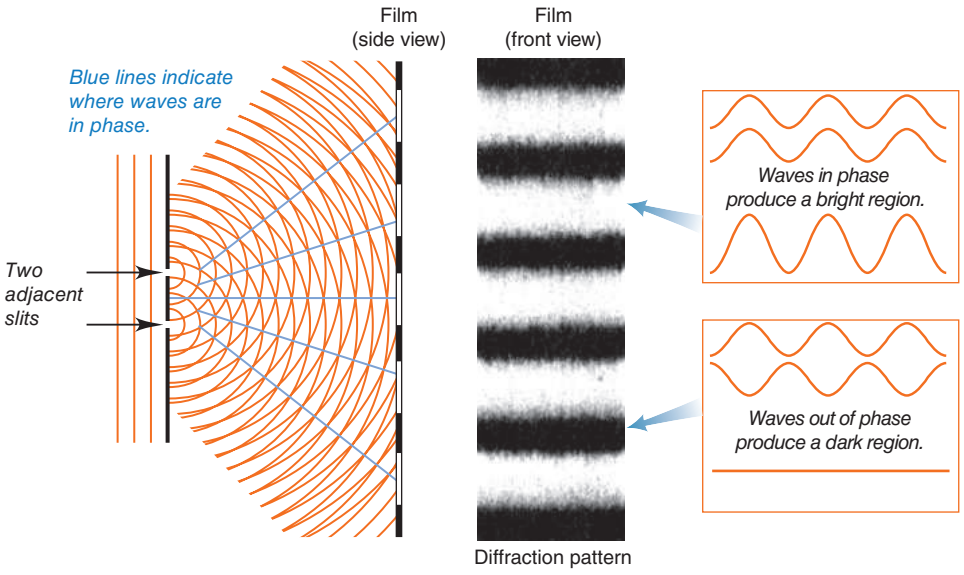
Two of many familiar applications of refraction and dispersion involve rainbows and diamonds. You see a rainbow when sunlight entering the near surface of countless droplets is dispersed and reflected off the far surface. Red light is bent least, so it appears higher in the sky and violet lower *(see photo)*. A diamond sparkles with various colors because its facets disperse and reflect the incoming light.

In contrast to a wave of light, a particle of matter, like a pebble, does not undergo refraction. If you throw a pebble through the air into a pond, it continues to slow down gradually along a curved path after entering the water (Figure 7.4B).

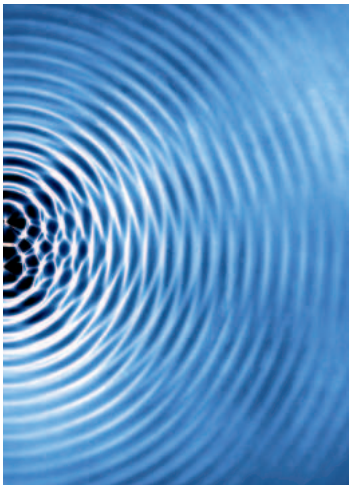
2. *Diffraction and interference*. When a wave strikes the edge of an object, it bends around it in a phenomenon called **diffraction.** If the wave passes through a slit about as wide as its wavelength, it bends around both edges of the slit and forms a semicircular wave on the other side of the opening (Figure 7.4C).

In contrast, when you throw a collection of particles, like a handful of sand, at a small opening, some particles hit the edge, while others go through the opening and continue in a narrower group (Figure 7.4D).

Wave theory explains the colors of a rainbow.



Light waves passing through two slits emerge as circular waves; constructive and destructive interference result in a diffraction pattern.



Constructive and destructive interference occur as water waves pass through two adjacent slits.

Figure 7.5 **Formation of a diffraction pattern.**

When waves of light pass through two adjacent slits, the nearby emerging circular waves interact through the process of *interference.* If the crests of the waves coincide *(in phase),* they interfere *constructively*—the amplitudes add together to form a brighter region. If crests coincide with troughs *(out of phase),* they interfere *destructively*—the amplitudes cancel to form a darker region. The result is a *diffraction pattern* (Figure 7.5).

In contrast, particles passing through adjacent openings continue in straight paths, some colliding and moving at different angles.

The Particle Nature of Light

Three observations involving matter and light confounded physicists at the turn of the 20th century: blackbody radiation, the photoelectric effect, and atomic spectra. Explaining these phenomena required a radically new picture of energy. We discuss the first two of them here and the third in Section 7.2.

Blackbody Radiation and the Quantum Theory of Energy The first of the puzzling observations involved the light given off by an object being heated.

1. *Observation: blackbody radiation.* When a solid object is heated to about 1000 K, it begins to emit visible light, as you can see in the red glow of smoldering coal (Figure 7.6A). At about 1500 K, the light is brighter and more orange, like that from an electric heating coil (Figure 7.6B). At temperatures greater than 2000 K, the light is still brighter and whiter, like that emitted by the filament of a lightbulb (Figure 7.6C).

Figure 7.6 **Familiar examples of light emission related to blackbody radiation.**

A Smoldering coal

B Electric heating element

C Lightbulb filament

These changes in intensity and wavelength of emitted light as an object is heated are characteristic of *blackbody radiation,* light given off by a hot *blackbody.** Attempts that applied the classical wave model to explain the relationship between the energy given off by a hot object and the wavelength of the emitted radiation failed.

2. *Explanation: the quantum theory.* In 1900, the German physicist Max Planck (1858–1947) developed a formula that fit the data perfectly. To find a physical explanation for his formula, Planck assumed, in a self-proclaimed "act of despair," that the hot, glowing object could emit (or absorb) only *certain* quantities of energy:

$$E = nh\nu$$

where E is the energy of the radiation, ν is its frequency, n is a positive integer (1, 2, 3, and so on) called a **quantum number,** and h is **Planck's constant.** With energy in joules (J) and frequency in s^{-1}, h has units of J·s:

$$h = 6.62606876\times10^{-34}\ \text{J·s} = 6.626\times10^{-34}\ \text{J·s} \quad (4\ \text{sf})$$

Since the hot object emits only certain quantities of energy, and the energy must be emitted by the object's atoms, this means that each atom *emits* only certain quantities of energy. It follows, then, that each atom *has* only certain quantities of energy. Thus, the energy of an atom is *quantized:* it occurs in fixed quantities, rather than being continuous. Each change in an atom's energy occurs when the atom absorbs or emits one or more "packets," or definite amounts, of energy. Each energy packet is called a **quantum** ("fixed quantity"; plural, *quanta*). A quantum of energy is equal to $h\nu$. Thus, *an atom changes its energy state by emitting (or absorbing) one or more quanta,* and the energy of the emitted (or absorbed) radiation is equal to the *difference in the atom's energy states:*

$$\Delta E_{\text{atom}} = E_{\text{emitted (or absorbed) radiation}} = \Delta nh\nu$$

Because the atom can change its energy only by integer multiples of $h\nu$, the smallest change occurs when an atom in a given energy state changes to an adjacent state, that is, when $\Delta n = 1$:

$$\Delta E = h\nu \qquad \textbf{(7.2)}$$

Rearranging Equation 7.1 (p. 288) and combining it with Equation 7.2 gives the direct relationship between wavelength and energy:

$$\Delta E = h\nu = \frac{hc}{\lambda} \qquad \textbf{(7.3)}$$

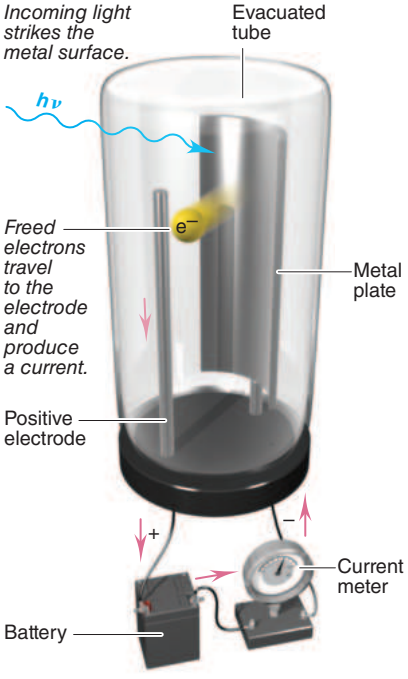


Figure 7.7 **The photoelectric effect.**

The Photoelectric Effect and the Photon Theory of Light Despite the idea of quantization, physicists still pictured energy as traveling in waves. But, the wave model could not explain the second confusing observation, the flow of current when light strikes a metal.

1. *Observation: the* ***photoelectric effect.*** When monochromatic light of sufficient frequency shines on a metal plate, a current flows (Figure 7.7). It was thought that the current arises because light transfers energy that frees electrons from the metal surface. However, the effect had two confusing features, the presence of a threshold frequency and the absence of a time lag:

- *Presence of a threshold frequency.* For current to flow, the light shining on the metal must have a minimum, or threshold, *frequency,* and different metals have different minimum frequencies. But, the wave theory associates the energy of light with its *amplitude* (intensity), not its frequency (color). Thus, the theory predicts that an electron would break free when it absorbed enough energy from light of *any* color.
- *Absence of a time lag.* Current flows the moment light of the minimum frequency shines on the metal, regardless of the light's intensity. But the wave theory predicts that with dim light there would be a time lag before the current flows, because the electrons would have to absorb enough energy to break free.

*A blackbody is an idealized object that absorbs all the radiation incident on it. A hollow cube with a small hole in one wall approximates a blackbody.

2. *Explanation: the photon theory.* Building on Planck's ideas, Einstein proposed that light itself is particulate, quantized into tiny "bundles" of energy, later called **photons.** Each atom changes its energy by an amount ΔE_{atom} when it absorbs or emits one photon, one "particle" of light, whose energy is related to its *frequency,* not its amplitude:

$$E_{photon} = h\nu = \Delta E_{atom}$$

Let's see how the photon theory explains the two features of the photoelectric effect:

- *Why there is a threshold frequency.* A beam of light consists of an enormous number of photons. The intensity (brightness) is related to the *number* of photons, but *not* to the energy of each. Therefore, a photon of a certain *minimum* energy must be absorbed to free an electron from the surface (see Figure 7.7). Since energy depends on frequency ($h\nu$), the theory predicts a threshold frequency.
- *Why there is no time lag.* An electron breaks free when it absorbs a photon of *enough* energy; it cannot break free by "saving up" energy from several photons, each having less than the minimum energy. The current is weak in dim light because fewer photons of enough energy can free fewer electrons per unit time, but some current flows *as soon as* light of sufficient energy (frequency) strikes the metal. ›

Ping-Pong Photons

This analogy helps explain why light of *insufficient* energy *cannot* free an electron from the metal surface. If one Ping-Pong ball doesn't have enough energy to knock a book off a shelf, neither does a series of Ping-Pong balls, because the book can't save up the energy from the individual impacts. But one baseball traveling at the same speed does have enough energy.

SAMPLE PROBLEM 7.2 Interconverting Energy, Wavelength, and Frequency

Problem A student uses a microwave oven to heat a meal. The wavelength of the radiation is 1.20 cm. What is the energy of one photon of this microwave radiation?

Plan We know λ in centimeters (1.20 cm) so we convert to meters and then find the energy of one photon with Equation 7.3.

Solution Combining steps to find the energy of a photon:

$$E = \frac{hc}{\lambda} = \frac{(6.626\times10^{-34}\ \text{J·s})(3.00\times10^{8}\ \text{m/s})}{(1.20\ \text{cm})\left(\dfrac{10^{-2}\ \text{m}}{1\ \text{cm}}\right)} = 1.66\times10^{-23}\ \text{J}$$

Check Checking the order of magnitude gives

$$\frac{10^{-33}\ \text{J·s}\times10^{8}\ \text{m/s}}{10^{-2}\ \text{m}} = 10^{-23}\ \text{J}$$

FOLLOW-UP PROBLEMS

7.2A Calculate the wavelength (in nm) and the frequency of a photon with an energy of 8.2×10^{-19} J, the minimum amount of energy required to dislodge an electron from the metal gold.

7.2B Calculate the energy of one photon of **(a)** ultraviolet light ($\lambda = 1\times10^{-8}$ m); **(b)** visible light ($\lambda = 5\times10^{-7}$ m); and **(c)** infrared light ($\lambda = 1\times10^{-4}$ m). What do the answers indicate about the relationship between light's wavelength and energy?

SOME SIMILAR PROBLEMS 7.9–7.12

Summary of Section 7.1

- Electromagnetic radiation travels in waves characterized by a given wavelength (λ) and frequency (ν).
- Electromagnetic waves travel through a vacuum at the speed of light, c (3.00×10^{8} m/s), which equals $\nu \times \lambda$. Therefore, wavelength and frequency are inversely proportional to each other.
- The intensity (brightness) of light is related to the amplitude of its waves.
- The electromagnetic spectrum ranges from very long radio waves to very short gamma rays and includes the visible region between wavelengths 750 nm (red) and 400 nm (violet).

- Refraction (change in a wave's speed when entering a different medium) and diffraction (bend of a wave around an edge of an object) indicate that energy is wavelike, with properties distinct from those of particles of mass.
- Blackbody radiation and the photoelectric effect, however, are consistent with energy occurring in discrete packets, like particles.
- Light exists as photons (quanta) whose energy is directly proportional to the frequency.
- According to quantum theory, an atom has only certain quantities of energy ($E = nh\nu$), and it can change its energy only by absorbing or emitting a photon whose energy equals the change in the atom's energy.

7.2 ATOMIC SPECTRA

The third confusing observation about matter and energy involved the light emitted when an element is vaporized and then excited electrically. In this section, we discuss the nature of that light and see why it created a problem for the existing atomic model and how a new model solved the problem.

Line Spectra and the Rydberg Equation

When light from electrically excited gaseous atoms passes through a slit and is refracted by a prism, it does not create a *continuous spectrum,* or rainbow, as sunlight does. Instead, it creates a **line spectrum,** a series of fine lines at specific frequencies separated by black spaces. Figure 7.8A shows the apparatus and the line spectrum of atomic hydrogen. Figure 7.8B shows that each spectrum is *characteristic* of the element producing it.

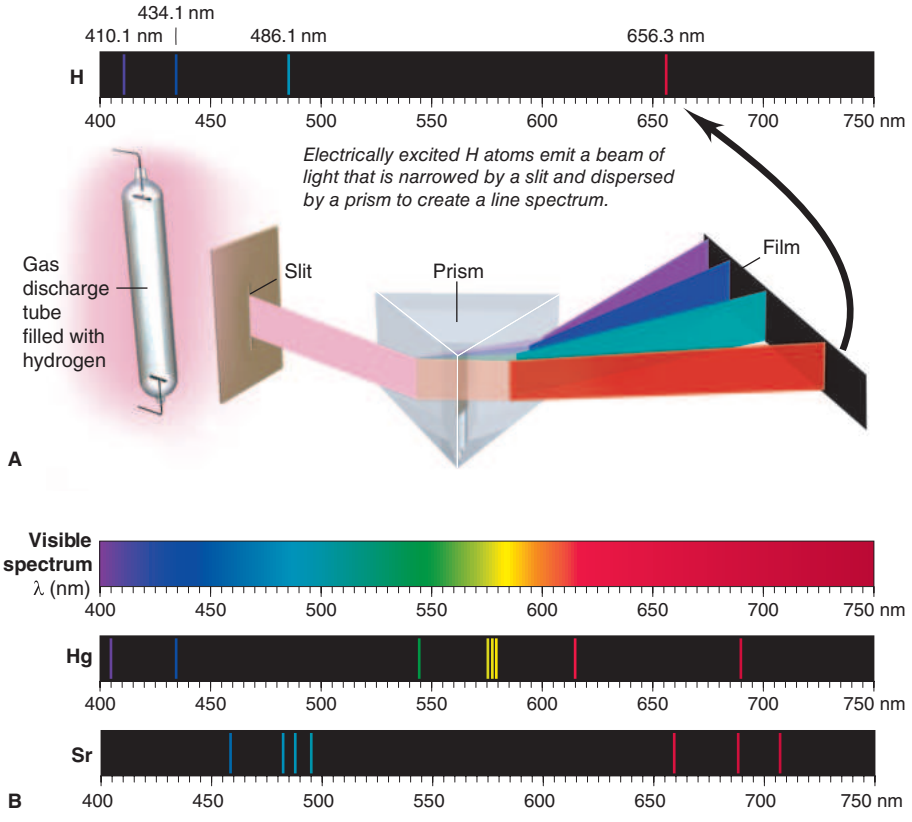

Figure 7.8 The line spectra of several elements. A, The line spectrum of atomic hydrogen. **B,** Unlike the continuous spectrum of white light, emission spectra of elements, such as mercury and strontium, appear as characteristic series of colored lines.

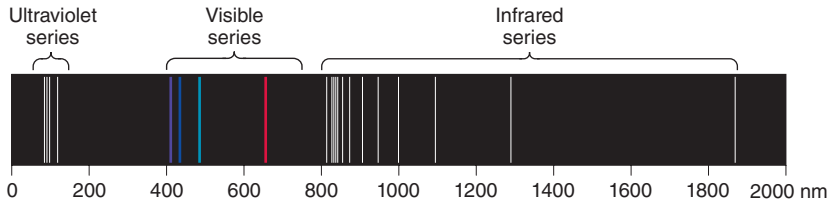

Figure 7.9 Three series of spectral lines of atomic hydrogen.

Features of the Rydberg Equation Spectroscopists studying atomic hydrogen identified several series of spectral lines in different regions of the electromagnetic spectrum. Figure 7.9 shows three of them. Using data, not theory, the Swedish physicist Johannes Rydberg developed a relationship, called the *Rydberg equation,* that predicted the position and wavelength of any line in a given series:

$$\frac{1}{\lambda} = R\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right) \tag{7.4}$$

where λ is the wavelength of the line, n_1 and n_2 are positive integers with $n_2 > n_1$, and R is the Rydberg constant ($1.096776 \times 10^7\ m^{-1}$). For the visible series, $n_1 = 2$:

$$\frac{1}{\lambda} = R\left(\frac{1}{2^2} - \frac{1}{n_2^2}\right), \quad \text{with } n_2 = 3, 4, 5, \ldots$$

For the ultraviolet series, $n_1 = 1$, and for the infrared series, $n_1 = 3$. While the Rydberg equation predicts the wavelengths in the line spectrum of hydrogen, it does not explain why line spectra occur.

Problems with Rutherford's Nuclear Model Almost as soon as Rutherford proposed his nuclear model (described in Chapter 2), a major problem arose. A positive nucleus and a negative electron attract each other, and for them to stay apart, the kinetic energy of the electron's motion must counterbalance the potential energy of attraction. However, the laws of classical physics say that a negative particle moving in a curved path around a positive particle *must* emit radiation and thus lose energy. If the orbiting electrons behaved in that way, they would spiral into the nucleus, and all atoms would collapse! The laws of classical physics also say that the frequency of the emitted radiation should change smoothly as the negative particle spirals inward and, thus, create a continuous spectrum, not a line spectrum. The behavior of subatomic particles seemed to violate real-world experience and accepted principles.

The Bohr Model of the Hydrogen Atom

Two years after the nuclear model was proposed, Niels Bohr (1885–1962), a young Danish physicist working in Rutherford's laboratory, suggested a model for the H atom that *did* predict the existence of line spectra.

Postulates of the Model In his model, Bohr used Planck's and Einstein's ideas about quantized energy and proposed three postulates:

1. *The H atom has only certain energy levels,* which Bohr called **stationary states.** Each state is associated with a fixed circular orbit of the electron around the nucleus. The higher the energy level, the farther the orbit is from the nucleus.
2. *The atom does **not** radiate energy while in one of its stationary states.* Even though it violates principles of classical physics, the atom does not change its energy while the electron moves *within* an orbit.
3. *The atom changes to another stationary state* (the electron moves to another orbit) *only by absorbing or emitting a photon. The energy of the photon ($h\nu$) equals the difference in the energies of the two states:*

$$E_{photon} = \Delta E_{atom} = E_{final} - E_{initial} = h\nu$$

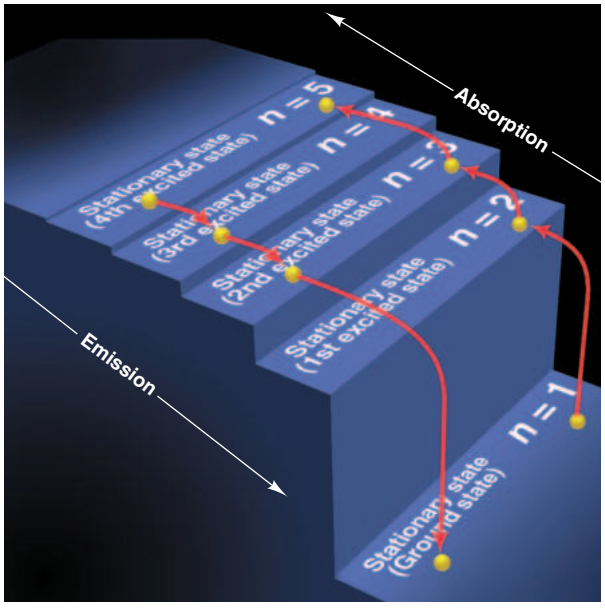

Figure 7.10 A quantum "staircase" as an analogy for atomic energy levels. Note that the electron can move up or down one or more steps at a time but cannot lie *between* steps.

Features of the Model The model has several key features:

- *Quantum numbers and electron orbit*. The quantum number n is a positive integer (1, 2, 3, . . .) associated with the radius of an electron orbit, which is directly related to the electron's energy: *the lower the n value, the smaller the radius of the orbit, and the lower the energy level.* Thus, when the electron is in an orbit closer to the nucleus (lower n), more energy is required to move it out of that orbit than when it is in an orbit farther from the nucleus (higher n).
- *Ground state.* When the electron is in the first orbit ($n = 1$), it is closest to the nucleus, and the H atom is in its lowest (first) energy level, called the **ground state.**
- *Excited states.* If the electron is in any orbit farther from the nucleus, the atom is in an **excited state.** With the electron in the second orbit ($n = 2$), the atom is in the first excited state; when the electron is in the third orbit ($n = 3$), the atom is in the second excited state, and so forth.
- *Absorption*. If an H atom *absorbs* a photon whose energy equals the *difference* between lower and higher energy levels, the electron moves to the outer (higher energy) orbit.
- *Emission*. If an H atom in a higher energy level (electron in a farther orbit) returns to a lower energy level (electron in a closer orbit), the atom *emits* a photon whose energy equals the difference between the two levels. Figure 7.10 shows a staircase analogy that illustrates absorption and emission. Once again, note that the energy difference between two consecutive orbits decreases as n increases.

How the Model Explains Line Spectra When an electron moves to an orbit closer to the nucleus, the atom's energy changes from a higher state to a lower state, resulting in a loss of a specific quantity of energy; that energy is *emitted* as a photon of a specific wavelength, producing a line in the atom's line spectrum. Since there are only certain energy levels in the atom, only certain quantities of energy (and photons of certain wavelengths) can be emitted as the electron transitions from one orbit to another. *Since an atom's energy is not continuous, but rather has only certain states, an atomic spectrum is not continuous.*

Figure 7.11A shows how Bohr's model accounts for three series of spectral lines of hydrogen. When a sample of gaseous H atoms is excited, the atoms absorb different quantities of energy. Each atom has one electron, but there are so many atoms in the whole sample that all the energy levels (orbits) have electrons. When electrons drop from outer orbits ($n = 4, 5, \ldots$) to the $n = 3$ orbit (second excited state), photons with the energy of infrared radiation are emitted, creating the *infrared* series of lines. When electrons drop to the $n = 2$ orbit (first excited state), photons of higher energy (shorter wavelength) visible radiation are emitted, creating the *visible* series of lines. The energy emitted when electrons drop to the $n = 1$ orbit (ground state) corresponds to ultraviolet radiation, resulting in the *ultraviolet* series of lines. Figure 7.11B shows how the specific lines in the ultraviolet series appear.

Limitations of the Model Despite its great success in accounting for the spectral lines of the H atom, the Bohr model failed to predict the spectrum of any other atom. The reason is that it is a *one-electron model:* it works beautifully for the H atom and for other one-electron species, such as He^+ ($Z = 2$), Li^{2+} ($Z = 3$), and Be^{3+} ($Z = 4$). It fails completely for atoms with more than one electron because the electron-electron repulsions and additional nucleus-electron attractions that are present create much more complex interactions. But, even more fundamentally, as we'll see in Section 7.4, *electrons do not move in fixed, defined orbits*. Even though, as a picture of the atom, the Bohr model is incorrect, we still use the terms "ground state" and "excited state" and retain the central idea that *the energy of an atom occurs in discrete levels and it changes when the atom absorbs or emits a photon of specific energy.*

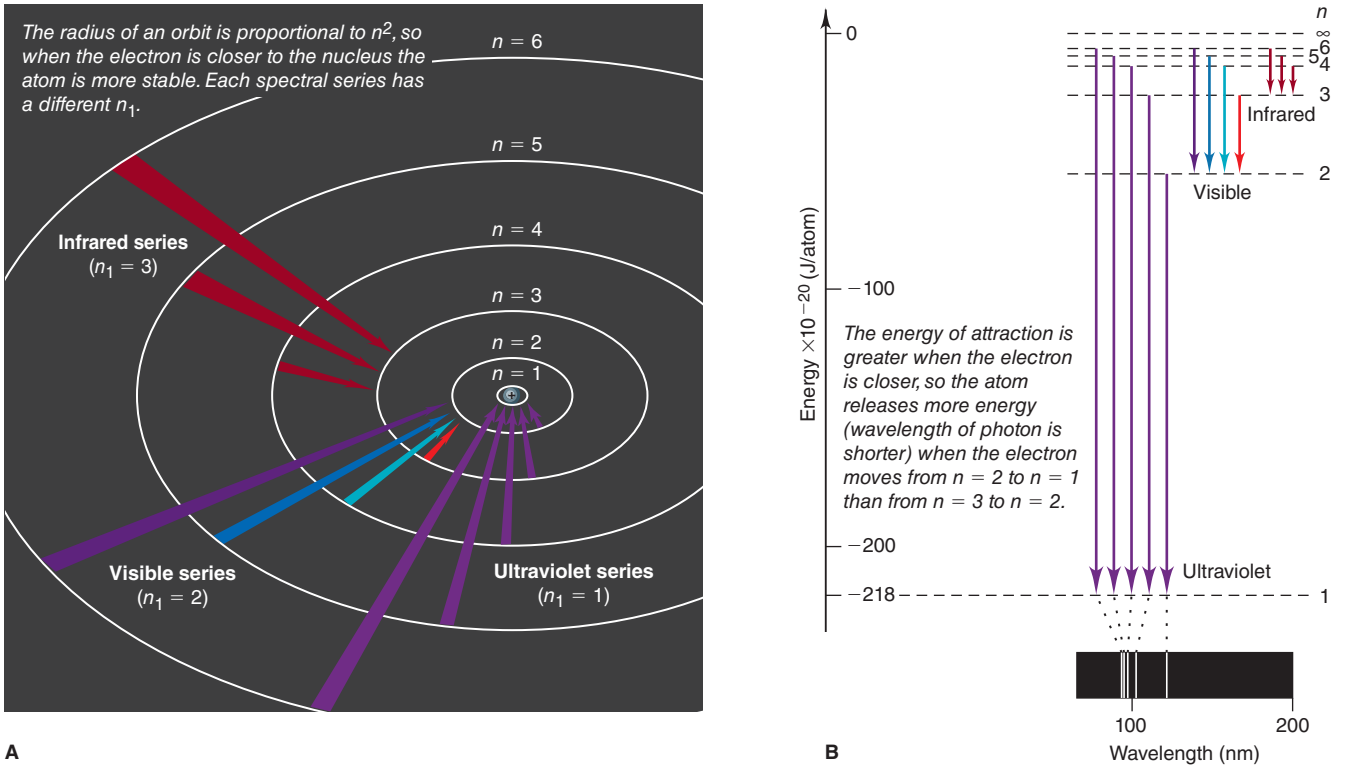

Figure 7.11 **The Bohr explanation of three series of spectral lines emitted by the H atom. A,** In a given series, the outer electron drops to the same inner orbit (the same value of n_1 in the Rydberg equation). **B,** An energy diagram shows how the ultraviolet series arises.

The Energy Levels of the Hydrogen Atom

Bohr's work leads to an equation for calculating the energy levels of an atom:

$$E = -2.18\times10^{-18}\ \text{J}\left(\frac{Z^2}{n^2}\right)$$

where Z is the charge of the nucleus. For the H atom, $Z = 1$, so we have

$$E = -2.18\times10^{-18}\ \text{J}\left(\frac{1^2}{n^2}\right)$$

$$= -2.18\times10^{-18}\ \text{J}\left(\frac{1}{n^2}\right)$$

Therefore, the energy of the ground state ($n = 1$) of the H atom is

$$E = -2.18\times10^{-18}\ \text{J}\left(\frac{1}{1^2}\right)$$

$$= -2.18\times10^{-18}\ \text{J}$$

The negative sign for the energy (also used on the axis in Figure 7.11B) appears because we *define* the zero point of the atom's energy when *the electron is completely removed from the nucleus.* Thus, $E = 0$ when $n = \infty$, so $E < 0$ for any smaller n. ❯

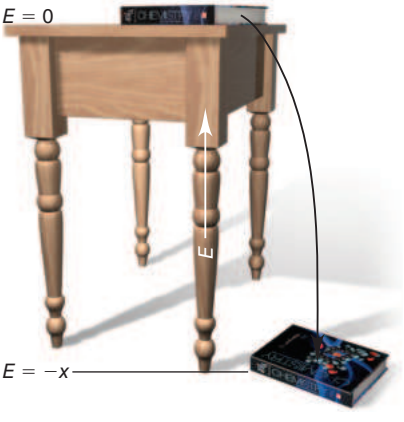
Applying Bohr's Equation for the Energy Levels of an Atom We can use the equation for the energy levels in several ways:

1. *Finding the difference in energy between two levels.* By subtracting the initial energy level of the atom from its final energy level, we find the change in energy when the electron moves between the two levels:

$$\Delta E = E_{\text{final}} - E_{\text{initial}} = -2.18\times10^{-18}\ \text{J}\left(\frac{1}{n^2_{\text{final}}} - \frac{1}{n^2_{\text{initial}}}\right) \qquad (7.5)$$

A Tabletop Analogy for Defining the Energy of a System

If you define the zero point of your textbook's potential energy when the book is on a table, the energy is negative when it's on the floor.



Note that, since n is in the denominator,

- *When the atom emits energy,* the electron moves closer to the nucleus ($n_{final} < n_{initial}$), so the atom's final energy is a *larger* negative number and ΔE is negative.
- *When the atom absorbs energy,* the electron moves away from the nucleus ($n_{final} > n_{initial}$), so the atom's final energy is a *smaller* negative number and ΔE is positive. (Analogously, in Chapter 6, you saw that, when the system releases heat, ΔH is negative, and when it absorbs heat, ΔH is positive.)

2. *Finding the energy needed to ionize the H atom.* We can also find the energy needed to remove the electron completely, that is, find ΔE for the following change:

$$H(g) \longrightarrow H^+(g) + e^-$$

We substitute $n_{final} = \infty$ and $n_{initial} = 1$ into Equation 7.5 and obtain

$$\Delta E = E_{final} - E_{initial} = -2.18\times10^{-18}\ J\left(\frac{1}{\infty^2} - \frac{1}{1^2}\right)$$
$$= -2.18\times10^{-18}\ J\,(0 - 1) = 2.18\times10^{-18}\ J$$

Energy must be *absorbed* to remove the electron from the nucleus, so ΔE is positive.

The *ionization energy* of hydrogen is the energy required to form 1 mol of gaseous H^+ ions from 1 mol of gaseous H atoms. Thus, for 1 mol of H atoms,

$$\Delta E = \left(2.18\times10^{-18}\ \frac{J}{atom}\right)\left(6.022\times10^{23}\ \frac{atoms}{mol}\right)\left(\frac{1\ kJ}{10^3\ J}\right) = 1.31\times10^3\ kJ/mol$$

Ionization energy is a key atomic property, and we'll return to it in Chapter 8.

3. *Finding the wavelength of a spectral line.* Once we know ΔE from Equation 7.5, we find the wavelengths of the spectral lines of the H atom from Equation 7.3:

$$\lambda = \frac{hc}{\Delta E}$$

Alternatively, we combine Equation 7.3 with 7.5 and use Bohr's model to derive Rydberg's equation (Equation 7.4):

$$\frac{hc}{\lambda} = \Delta E = -2.18\times10^{-18}\ J\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right)$$
$$\frac{1}{\lambda} = \frac{-2.18\times10^{-18}\ J}{hc}\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right)$$
$$= \frac{-2.18\times10^{-18}\ J}{(6.626\times10^{-34}\ J\cdot s)(3.00\times10^8\ m/s)}\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right)$$
$$= 1.0967\times10^7\ m^{-1}\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)$$

SAMPLE PROBLEM 7.3 Determining ΔE and λ of an Electron Transition

Problem A hydrogen atom absorbs a photon of UV light (see Figure 7.11), and its electron enters the $n = 4$ energy level. Calculate **(a)** the change in energy of the atom and **(b)** the wavelength (in nm) of the photon.

Plan **(a)** The H atom absorbs energy, so $E_{final} > E_{initial}$. We are given $n_{final} = 4$, and Figure 7.11 shows that $n_{initial} = 1$ because a UV photon is absorbed. We apply Equation 7.5 to find ΔE. **(b)** Once we know ΔE, we find the wavelength (in m) with Equation 7.3. Then we convert from meters to nanometers.

Solution **(a)** Substituting the known values into Equation 7.5:

$$\Delta E = -2.18\times10^{-18}\ J\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right) = -2.18\times10^{-18}\ J\left(\frac{1}{4^2} - \frac{1}{1^2}\right)$$
$$= -2.18\times10^{-18}\ J\left(\frac{1}{16} - \frac{1}{1}\right) = \boxed{2.04\times10^{-18}\ J}$$

(b) Using Equation 7.3 to solve for λ:

$$\Delta E = \frac{hc}{\lambda}$$

therefore,

$$\lambda = \frac{hc}{\Delta E} = \frac{(6.626\times10^{-34}\ \text{J·s})(3.00\times10^{8}\ \text{m/s})}{2.04\times10^{-18}\ \text{J}} = 9.74\times10^{-8}\ \text{m}$$

Converting m to nm:

$$\lambda = 9.74\times10^{-8}\ \text{m} \times \frac{1\ \text{nm}}{10^{-9}\ \text{m}}$$

$$= \boxed{97.4\ \text{nm}}$$

Check **(a)** The energy change is positive, which is consistent with absorption of a photon. **(b)** The wavelength is within the UV region (about 10–380 nm).

Comment **1.** We could instead use Equation 7.4 to find the wavelength:

$$\frac{1}{\lambda} = R\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)$$

$$= 1.096776\times10^{7}\ \text{m}^{-1}\left(\frac{1}{1^2} - \frac{1}{4^2}\right)$$

$$= 1.028228\times10^{7}\ \text{m}^{-1}$$

$$\lambda = 9.73\times10^{-8}\ \text{m} = 97.3\ \text{nm}$$

2. In Follow-up Problem 7.3A, note that if ΔE is negative (the atom loses energy), we use its absolute value, $|\Delta E|$, because λ must have a positive value.

FOLLOW-UP PROBLEMS

7.3A A hydrogen atom with its electron in the $n = 6$ energy level emits a photon of IR light. Calculate **(a)** the change in energy of the atom and **(b)** the wavelength (in Å) of the photon.

7.3B An electron in the $n = 6$ energy level of an H atom drops to a lower energy level; the atom emits a photon of wavelength 410. nm. (**a**) What is ΔE for this transition in 1 mol of H atoms? (**b**) To what energy level did the electron move?

SOME SIMILAR PROBLEMS 7.23–7.28, 7.31, and 7.32

Spectrometric analysis of the H atom led to the Bohr model, the first step toward our current model of the atom. From its use by 19th-century chemists as a means of identifying elements and compounds, spectrometry has developed into a major tool of modern chemistry (see Tools of the Laboratory).

Summary of Section 7.2

- Unlike sunlight, light emitted by electrically excited atoms of elements appears as separate spectral lines.
- Spectroscopists use an empirical formula (the Rydberg equation) to determine the wavelength of a spectral line. Atomic hydrogen displays several series of spectral lines.
- To explain the existence of line spectra, Bohr proposed that an electron moves in fixed orbits. It moves from one orbit to another when the atom absorbs or emits a photon whose energy equals the difference in energy levels (orbits).
- Bohr's model predicts only the spectrum of the H atom and other one-electron species. Despite this, Bohr was correct that an atom's energy is quantized.
- Spectrometry is an instrumental technique that uses emission and absorption spectra to identify substances and measure their concentrations.

Spectrometry in Chemical Analysis

The use of spectral data to identify and quantify substances is essential to modern chemical analysis. The terms *spectroscopy* and **spectrometry** refer to a large group of instrumental techniques that obtain spectra to gather data on a substance's atomic and molecular energy levels.

Types of Spectra

Emission and absorption spectra occur in two important types:

1. An **emission spectrum,** such as the H atom line spectrum, occurs when atoms in an excited state *emit* photons as they return to a lower energy state. Some elements produce an intense spectral line (or several closely spaced ones) that is evidence of their presence. **Flame tests,** performed by placing a granule of an ionic compound or a drop of its solution in a flame, rely on these intense emissions (Figure B7.1, part A), and some colors of fireworks are due to the same elements (Figure B7.1, part B). The colors of sodium-vapor and mercury-vapor streetlamps are due to intense emissions lines in these elements' spectra.

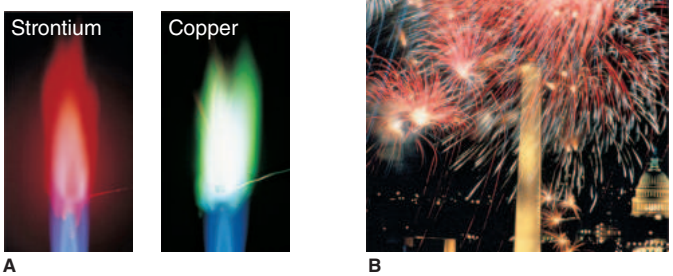


Figure B7.1 **Flame tests and fireworks. A,** The flame's color is due to intense emission by the element of light of a particular wavelength. **B,** Fireworks display emissions similar to those seen in flame tests.

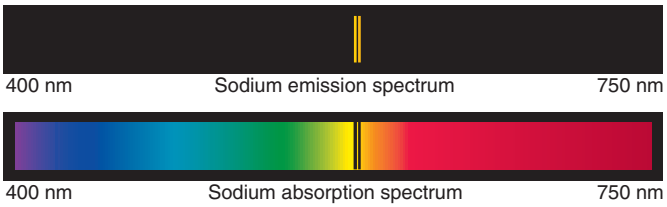

Figure B7.2 **Emission and absorption spectra of sodium atoms.** The wavelengths of the bright emission lines correspond to those of the dark absorption lines because both are created by the same energy change: $\Delta E_{emission} = -\Delta E_{absorption}$. (Only the two most intense lines in the Na spectra are shown.)

2. An **absorption spectrum** is produced when atoms *absorb* photons of certain wavelengths and become excited. When white light passes through sodium vapor, for example, the absorption spectrum shows dark lines at the same wavelengths as the yellow-orange lines in sodium's emission spectrum (Figure B7.2).

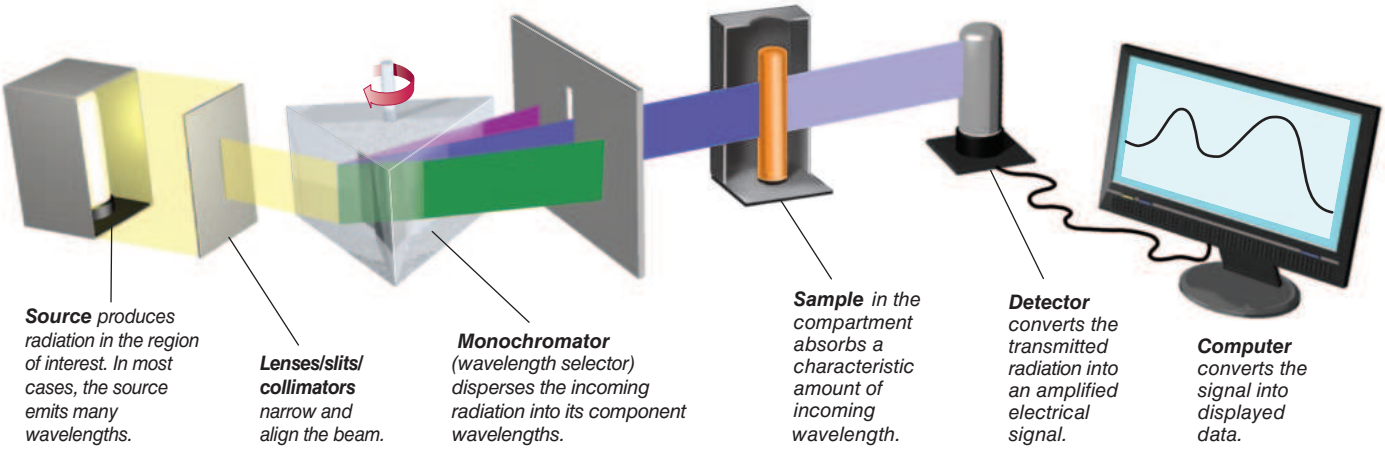
Because elements and compounds have unique line spectra, astronomers can use such spectra to determine the composition of the Sun, planets, stars, comets, and other celestial bodies.

Basic Instrumentation

Instruments that are based on absorption spectra are much more common than those based on emission spectra because many substances absorb relatively few wavelengths so their spectra are more characteristic, and absorption is less destructive of fragile molecules.

Design differences depend on the region of the electromagnetic spectrum used to irradiate the sample, but all modern spectrometers have components that perform the same basic functions (Figure B7.3). (We discuss infrared spectroscopy and nuclear magnetic resonance spectroscopy in later chapters.)

Figure B7.3 **Components of a typical spectrometer.**



Identifying and Quantifying a Substance

In chemical analysis, spectra are used to identify a substance and/or quantify the amount in a sample. Visible light is often used for colored substances, because they absorb only some of the wavelengths. A leaf looks green, for example, because its chlorophyll absorbs red and blue light strongly but green light weakly, so most of the green light is reflected.

Figure B7.4 shows the visible absorption spectrum of chlorophyll *a* in ether solution. The shape of the curve and the wavelengths of the major peaks are characteristic of chlorophyll *a*. The curve varies in height because chlorophyll *a* absorbs light of different wavelengths to different extents. The absorptions appear as broad bands, rather than as the distinct lines seen on absorption spectra of elements, because there are greater numbers and types of energy levels within a molecule as well as interactions between molecules and solvent.

In addition to identifying a substance, a spectrometer can be used to measure its concentration because *absorbance,* the quantity of light of a given wavelength absorbed by a substance, is *proportional to the number of molecules.* Suppose you want to determine the concentration of chlorophyll *a* in a leaf extract. You select a strongly absorbed wavelength from the compound's spectrum (such as 663 nm in Figure B7.4, part A), measure the absorbance of the *unknown* solution, and compare it with the absorbances of a series of solutions of *known* concentration (Figure B7.4, part B).

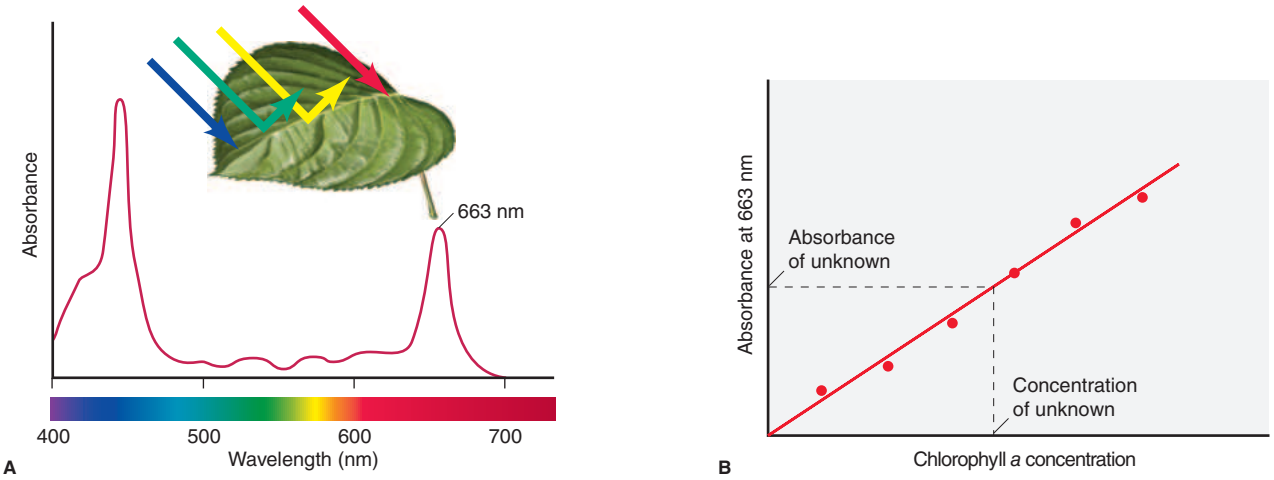


Figure B7.4 Measuring chlorophyll *a* concentration in leaf extract. **A,** The spectrometer is set to measure the strong absorption at 663 nm in the chlorophyll *a* spectrum. **B,** The absorbance from the leaf extract is compared to a series of known standards.

Problems

B7.1 The sodium salt of 2-quinizarinsulfonic acid forms a complex with Al^{3+} that absorbs strongly at 560 nm.

(a) Use the data below to draw a plot of absorbance vs. concentration of the complex in solution and find the slope and *y*-intercept:

Concentration (*M*)	Absorbance (560 nm)
1.0×10^{-5}	0.131
1.5×10^{-5}	0.201
2.0×10^{-5}	0.265
2.5×10^{-5}	0.329
3.0×10^{-5}	0.396

(b) When 20.0 mL of a solution of this complex is diluted with water to 150. mL, its absorbance is 0.236. Find the concentrations of the diluted solution and of the original solution.

B7.2 In fireworks displays, flame tests, and other emission events, light of a given wavelength may indicate the presence of a particular element or ion. What are the frequency and color of the light associated with each of the following?

(a) Li, $\lambda = 671$ nm

(b) Cs^+, $\lambda = 453$ nm

(c) Na, $\lambda = 589$ nm

7.3 THE WAVE-PARTICLE DUALITY OF MATTER AND ENERGY

The year 1905 was a busy one for Albert Einstein. He had just presented the photon theory and explained the photoelectric effect. A friend remembered him in his small apartment, rocking his baby in its carriage with one hand, while scribbling with the other ideas for a new branch of physics—the theory of relativity. One of its revelations was that *matter and energy are alternate forms of the same entity*. This idea is embodied in his famous equation $E = mc^2$, relating the quantity of energy equivalent to a given mass. Some results that showed energy to be particle-like had to coexist with others that showed matter to be wavelike. These remarkable ideas are the key to understanding our modern atomic model.

The Wave Nature of Electrons and the Particle Nature of Photons

Bohr's model was a perfect case of fitting theory to data: he *assumed* that an atom has only certain energy levels in order to *explain* line spectra. However, Bohr had no theoretical basis for the assumption. Several breakthroughs in the early 1920s provided that basis and blurred the distinction between matter (chunky and massive) and energy (diffuse and massless).

The Wave Nature of Electrons Attempting to explain why an atom has fixed energy levels, a French physics student, Louis de Broglie, considered other systems that display only certain allowed motions, such as the vibrations of a plucked guitar string. Figure 7.12 shows that, because the end of the string is fixed, only certain vibrational frequencies (and wavelengths) are allowable when the string is plucked. De Broglie proposed that *if energy is particle-like, perhaps matter is wavelike.* He reasoned that *if electrons have wavelike motion* in orbits of fixed radii, they would have only certain allowable frequencies and energies.

Combining the equations for mass-energy equivalence ($E = mc^2$) and energy of a photon ($E = h\nu = hc/\lambda$), de Broglie derived an equation for the wavelength of any particle of mass m—whether planet, baseball, or electron—moving at speed u:

$$\lambda = \frac{h}{mu} \qquad (7.6)$$

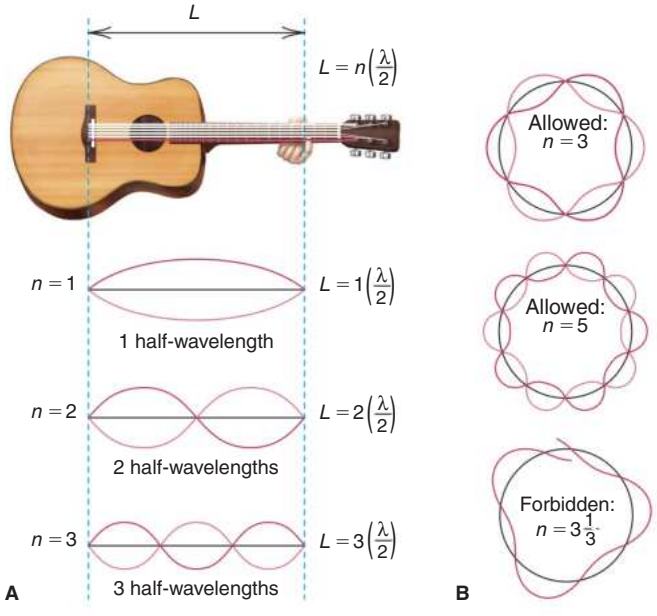

Figure 7.12 Wave motion in restricted systems. A, One half-wavelength ($\lambda/2$) is the "quantum" of the guitar string's vibration. With string length L fixed by a finger on the fret, allowed vibrations occur when L is a whole-number multiple (n) of $\lambda/2$. **B,** In a circular electron orbit, only whole numbers of wavelengths are allowed ($n = 3$ and $n = 5$ are shown). A wave with a fractional number of wavelengths (such as $n = 3\frac{1}{3}$) is "forbidden" because it dies out through overlap of crests and troughs.

According to this equation for the **de Broglie wavelength,** *matter behaves as though it moves in a wave.* An object's wavelength is *inversely* proportional to its mass, so heavy objects such as planets and baseballs have wavelengths *many* orders of magnitude smaller than the objects themselves, too small to be detected, in fact (Table 7.1).

Table 7.1 The de Broglie Wavelengths of Several Objects

Substance	Mass (g)	Speed (m/s)	λ (m)
Slow electron	9×10^{-28}	1.0	7×10^{-4}
Fast electron	9×10^{-28}	5.9×10^{6}	1×10^{-10}
Alpha particle	6.6×10^{-24}	1.5×10^{7}	7×10^{-15}
1-gram mass	1.0	0.01	7×10^{-29}
Baseball	142	40.0	1×10^{-34}
Earth	6.0×10^{27}	3.0×10^{4}	4×10^{-63}

SAMPLE PROBLEM 7.4 Calculating the de Broglie Wavelength of an Electron

Problem Find the de Broglie wavelength of an electron with a speed of 1.00×10^{6} m/s (electron mass = 9.11×10^{-31} kg; $h = 6.626\times10^{-34}$ kg·m²/s).

Plan We know the speed (1.00×10^{6} m/s) and mass (9.11×10^{-31} kg) of the electron, so we substitute these into Equation 7.6 to find λ.

Solution

$$\lambda = \frac{h}{mu} = \frac{6.626\times10^{-34}\ \text{kg}\cdot\text{m}^2/\text{s}}{(9.11\times10^{-31}\ \text{kg})(1.00\times10^{6}\ \text{m/s})} = 7.27\times10^{-10}\ \text{m}$$

Check The order of magnitude and the unit seem correct:

$$\lambda \approx \frac{10^{-33}\ \text{kg}\cdot\text{m}^2/\text{s}}{(10^{-30}\ \text{kg})(10^{6}\ \text{m/s})} = 10^{-9}\ \text{m}$$

Comment As you'll see in the upcoming discussion, such fast-moving electrons, with wavelengths in the range of atomic sizes, exhibit remarkable properties.

FOLLOW-UP PROBLEMS

7.4A (**a**) What is the speed of an electron that has a de Broglie wavelength of 100. nm (electron mass = 9.11×10^{-31} kg)?
(**b**) At what speed would a 45.9-g golf ball need to move to have a de Broglie wavelength of 100. nm?

7.4B Find the de Broglie wavelength of a 39.7-g racquetball traveling at a speed of 55 mi/h.

SOME SIMILAR PROBLEMS 7.39(a), 7.40(a), and 7.41–7.42

If electrons travel in waves, they should exhibit diffraction and interference. A fast-moving electron has a wavelength of about 10^{-10} m, so a beam of such electrons should be diffracted by the spaces between atoms in a crystal—which measure about 10^{-10} m. In 1927, C. Davisson and L. Germer guided a beam of x-rays and then a beam of electrons at a nickel crystal and obtained two diffraction patterns; Figure 7.13 shows such patterns for aluminum. Thus, electrons—particles with mass and charge—create diffraction patterns, just as electromagnetic waves do.

A major application of electrons traveling in waves is the *electron microscope*. Its great advantage over light microscopes is that high-speed electrons have much smaller wavelengths than visible light, which allow much higher resolution. A transmission electron microscope focuses a beam of electrons through a lens, and the beam then passes through a thin section of the specimen to a second and then third lens. In this instrument, these "lenses" are electromagnetic fields, which can result in up to 200,000-fold magnification. In a scanning electron microscope, the beam scans the

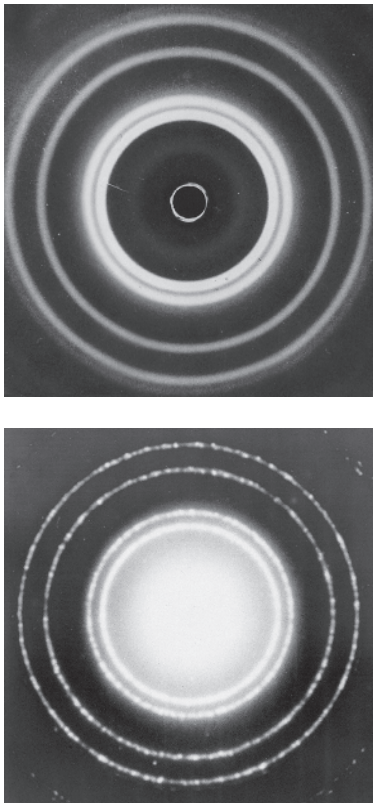

Figure 7.13 Diffraction patterns of aluminum with x-rays *(top)* and electrons *(bottom).*

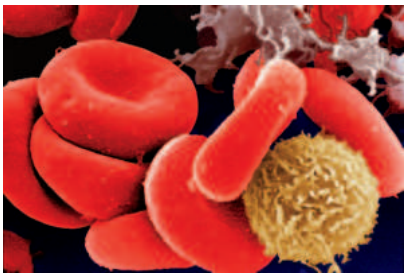

Figure 7.14 False-color scanning electron micrograph of blood cells (×1200).

specimen, knocking electrons from it that create a current, which generates an image that looks like the object's surface (Figure 7.14).

The Particle Nature of Photons If electrons have properties of energy, do photons have properties of matter? The de Broglie equation suggests that we can calculate the momentum (p), the product of mass and speed, for a photon. Substituting the speed of light (c) for speed u in Equation 7.6 and solving for p gives

$$\lambda = \frac{h}{mc} = \frac{h}{p} \qquad \text{and} \qquad p = \frac{h}{\lambda}$$

The inverse relationship between p and λ in this equation means that shorter wavelength (higher energy) photons have greater momentum. Thus, a decrease in a photon's momentum should appear as an increase in its wavelength. In 1923, Arthur Compton directed a beam of x-ray photons at graphite and observed an increase in the wavelength of the reflected photons. Thus, just as billiard balls transfer momentum when they collide, the photons transferred momentum to the electrons in the carbon atoms of the graphite. In this experiment, photons behaved as particles.

Wave-Particle Duality Classical experiments had shown matter to be particle-like and energy to be wavelike. But, results on the atomic scale show electrons moving in waves and photons having momentum. Thus, every property of matter was also a property of energy. The truth is that *both* matter and energy show *both* behaviors: each possesses both "faces." In some experiments, we observe one face; in other experiments, we observe the other face. Our everyday distinction between matter and energy is meaningful in the macroscopic world, *not* in the atomic world. The distinction is in our minds and the limited definitions we have created, not inherent in nature. This dual character of matter and energy is known as the **wave-particle duality.** Figure 7.15 summarizes the theories and observations that led to this new understanding.

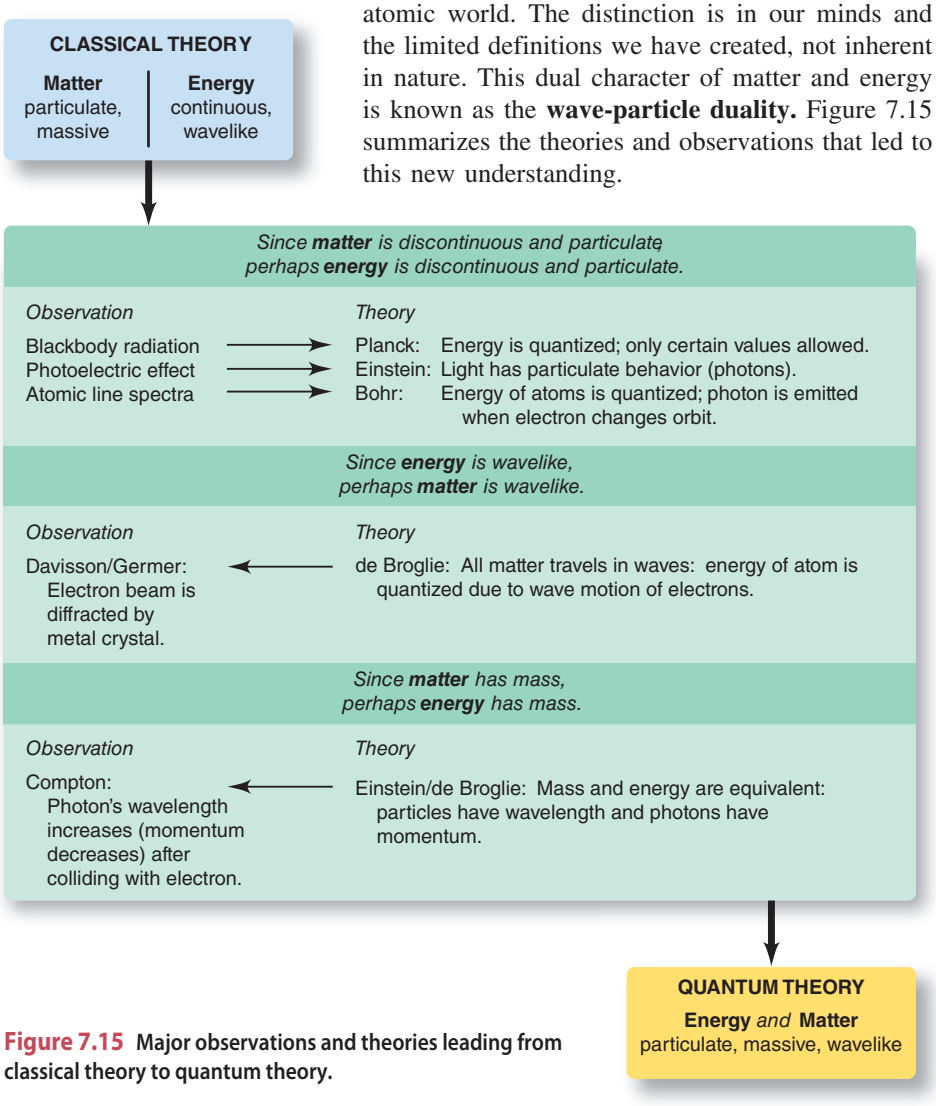

Figure 7.15 Major observations and theories leading from classical theory to quantum theory.

Heisenberg's Uncertainty Principle

In classical physics, a moving particle has a definite location at any instant, whereas a wave is spread out in space. If an electron has the properties of *both* a particle and a wave, can we determine its position in the atom? In 1927, the German physicist Werner Heisenberg (1901–1976) postulated the **uncertainty principle,** which states that it is impossible to know simultaneously the position *and* momentum (mass times speed) of a particle. For a particle with constant mass m, the principle is expressed mathematically as

$$\Delta x \cdot m\Delta u \geq \frac{h}{4\pi} \qquad (7.7)$$

where Δx is the uncertainty in position, Δu is the uncertainty in speed, and h is Planck's constant. The more accurately we know the position of the particle (smaller Δx), the less accurately we know its speed (larger Δu), and vice versa. The best-case scenario is that we know the product of these uncertainties, which is equal to $h/4\pi$.

For a macroscopic object like a baseball, Δx and Δu are insignificant because the mass is enormous compared with $h/4\pi$. Thus, if we know the position and speed of a pitched baseball, we can use the laws of motion to predict its trajectory and whether it will be a ball or a strike. However, using the position and speed of an electron to find its trajectory is a very different proposition, as Sample Problem 7.5 demonstrates.

SAMPLE PROBLEM 7.5 Applying the Uncertainty Principle

Problem An electron moving near an atomic nucleus has a speed of 6×10^6 m/s ± 1%. What is the uncertainty in its position (Δx)?

Plan The uncertainty in the speed (Δu) is given as 1%, so we multiply u (6×10^6 m/s) by 0.01 to calculate the value of Δu, substitute it into Equation 7.7, and solve for the uncertainty in position (Δx).

Solution Finding the uncertainty in speed, Δu:

$$\Delta u = 1\% \text{ of } u = 0.01(6\times10^6 \text{ m/s}) = 6\times10^4 \text{ m/s}$$

Calculating the uncertainty in position, Δx:

$$\Delta x \cdot m\Delta u \geq \frac{h}{4\pi}$$

Thus,

$$\Delta x \geq \frac{h}{4\pi m\Delta u} \geq \frac{6.626\times10^{-34}\ \text{kg}\cdot\text{m}^2/\text{s}}{4\pi(9.11\times10^{-31}\ \text{kg})(6\times10^4\ \text{m/s})} \geq 1\times10^{-9}\ \text{m}$$

Check Be sure to round off and check the order of magnitude of the answer:

$$\Delta x \geq \frac{10^{-33}\ \text{kg}\cdot\text{m}^2/\text{s}}{(10^1)(10^{-30}\ \text{kg})(10^5\ \text{m/s})} = 10^{-9}\ \text{m}$$

Comment The uncertainty in the electron's position is about 10 times greater than the diameter of the entire atom (10^{-10} m)! Therefore, we have no precise idea where in the atom the electron is located. In Follow-up Problem 7.5A, you'll see whether an umpire has any better idea about the position of a baseball.

FOLLOW-UP PROBLEMS

7.5A How accurately can an umpire know the position of a baseball (mass = 0.142 kg) moving at 100.0 mi/h ± 1.00% (44.7 m/s ± 1.00%)?

7.5B A neutron has a speed of 8×10^7 m/s ± 1%. What is the uncertainty in its position? The mass of a neutron is 1.67×10^{-27} kg.

SOME SIMILAR PROBLEMS 7.39(b) and 7.40(b)

Summary of Section 7.3

- As a result of Planck's quantum theory and Einstein's theory of relativity, we no longer view matter and energy as distinct entities.
- The de Broglie wavelength is based on the idea that an electron (or any object) has wavelike motion. Allowed atomic energy levels are related to allowed wavelengths of the electron's motion.
- Electrons exhibit diffraction, just as light waves do, and photons exhibit transfer of momentum, just as objects do. This wave-particle duality of matter and energy is observable only on the atomic scale.
- According to the uncertainty principle, we can never know the position and speed of an electron simultaneously.

7.4 THE QUANTUM-MECHANICAL MODEL OF THE ATOM

Acceptance of the dual nature of matter and energy and of the uncertainty principle culminated in the field of **quantum mechanics,** which examines the wave nature of objects on the atomic scale. In 1926, Erwin Schrödinger (1887–1961) derived an equation that is the basis for the *quantum-mechanical model* of the H atom. The model describes an atom with specific quantities of energy that result from allowed frequencies of its electron's wavelike motion. The electron's position can only be known within a certain probability. Key features of the model are described in the following subsections.

The Atomic Orbital and the Probable Location of the Electron

Two central aspects of the quantum-mechanical model concern the atomic orbital and the electron's probable location.

The Schrödinger Equation and the Atomic Orbital The electron's matter-wave occupies the space near the nucleus and is continuously influenced by it. The **Schrödinger equation** is quite complex but can be represented in simpler form as

$$\hat{\mathcal{H}}\psi = E\psi$$

where E is the energy of the atom. The symbol ψ (Greek *psi,* pronounced "sigh") is called a **wave function** (or **atomic orbital**), a mathematical description of the electron's matter-wave in three dimensions. The symbol $\hat{\mathcal{H}}$, called the Hamiltonian operator, represents a set of mathematical operations that, when carried out with a particular ψ, yields one of the allowed energy states of the atom.* Thus, *each solution of the equation gives an energy state associated with a given atomic orbital.*

An important point to keep in mind throughout this discussion is that an "orbital" in the quantum-mechanical model *bears no resemblance* to an "orbit" in the Bohr model: an *orbit* is an electron's actual path around the nucleus, whereas an *orbital* is a mathematical function that describes the electron's matter-wave but has no physical meaning.

The Probable Location of the Electron While we cannot know *exactly* where the electron is at any moment, we can know where it *probably* is, that is, where it spends most of its time. We get this information by squaring the wave function. Thus, even though ψ has no physical meaning, ψ^2 does and is called the *probability density,* a

*The complete form of the Schrödinger equation in terms of the three linear axes is

$$\left[-\frac{h^2}{8\pi^2 m_e}\left(\frac{d^2}{dx^2}+\frac{d^2}{dy^2}+\frac{d^2}{dz^2}\right)+V(x,y,z)\right]\psi(x,y,z)=E\psi(x,y,z)$$

where ψ is the wave function, m_e is the electron's mass, E is the total quantized energy of the atomic system, and V is the potential energy at point (x, y, z).

measure of the probability of finding the electron in some tiny volume of the atom. We depict the electron's probable location in several ways, which we'll look at first for the H atom's *ground state:*

1. *Probability of the electron being in some tiny volume of the atom.* For each energy level, we can create an *electron probability density diagram,* or more simply, an **electron density diagram.** The value of ψ^2 for a given volume is shown with dots: the greater the density of dots, the higher the probability of finding the electron in that volume. Note, that for the ground state of the H atom, *the electron probability density decreases with distance from the nucleus* along a line, *r* (Figure 7.16A).

These diagrams are also called **electron cloud depictions** because, if we *could* take a time-exposure photograph of the electron in wavelike motion around the nucleus, it would appear as a "cloud" of positions. The electron cloud is an *imaginary* picture of the electron changing its position rapidly over time; it does *not* mean that an electron is a diffuse cloud of charge.

Figure 7.16B shows a plot of ψ^2 vs. *r*. Due to the thickness of the printed line, the curve appears to touch the axis; however, in the blow-up circle, we see that *the probability of the electron being far from the nucleus is very small, but not zero.*

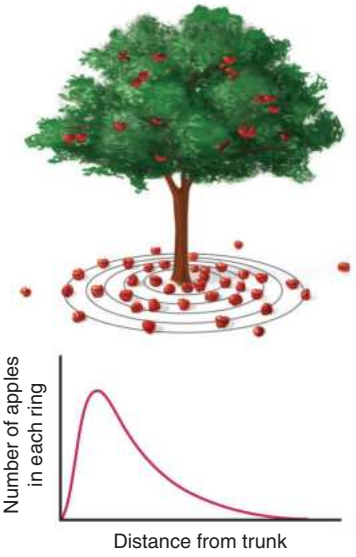
2. *Total probability density at some distance from the nucleus.* To find *radial probability distribution,* that is, the *total* probability of finding the electron at some distance *r* from the nucleus, we first mentally divide the volume around the nucleus into thin, concentric, spherical layers, like the layers of an onion (shown in cross section in Figure 7.16C). Then, we find the *sum of* ψ^2 *values* in each layer to see which is most likely to contain the electron.

The falloff in probability density with distance has an important effect. Near the nucleus, *the volume of each layer increases faster than its density of dots decreases.* The result of these opposing effects is that the *total* probability peaks in a layer *near,* but not *at,* the nucleus. For example, the total probability in the second layer is higher than in the first, but this result disappears with greater distance. Figure 7.16D shows this result as a **radial probability distribution plot.**

3. *Probability contour and the size of the atom.* How far away from the nucleus can we find the electron? This is the same as asking "How big is the H atom?" Recall from Figure 7.16B that the probability of finding the electron far from the nucleus is not zero. Therefore, we *cannot* assign a definite volume to an atom. However, we can visualize an atom with a 90% **probability contour:** the electron is somewhere within that volume 90% of the time (Figure 7.16E).

A Radial Probability Distribution of Apples

An analogy might clarify why the curve in the radial probability distribution plot peaks and then falls off. Picture fallen apples around the base of an apple tree: the density of apples is greatest near the trunk and decreases with distance. Divide the ground under the tree into foot-wide concentric rings and collect the apples within each ring. Apple density is greatest in the first ring, but the area of the second ring is larger, and so it contains a greater *total* number of apples. Farther out near the edge of the tree, rings have more area but lower apple "density," so the total number of apples decreases. A plot of "number of apples in each ring" vs. "distance from trunk" shows a peak at some distance close to the trunk, as in Figure 7.16D.



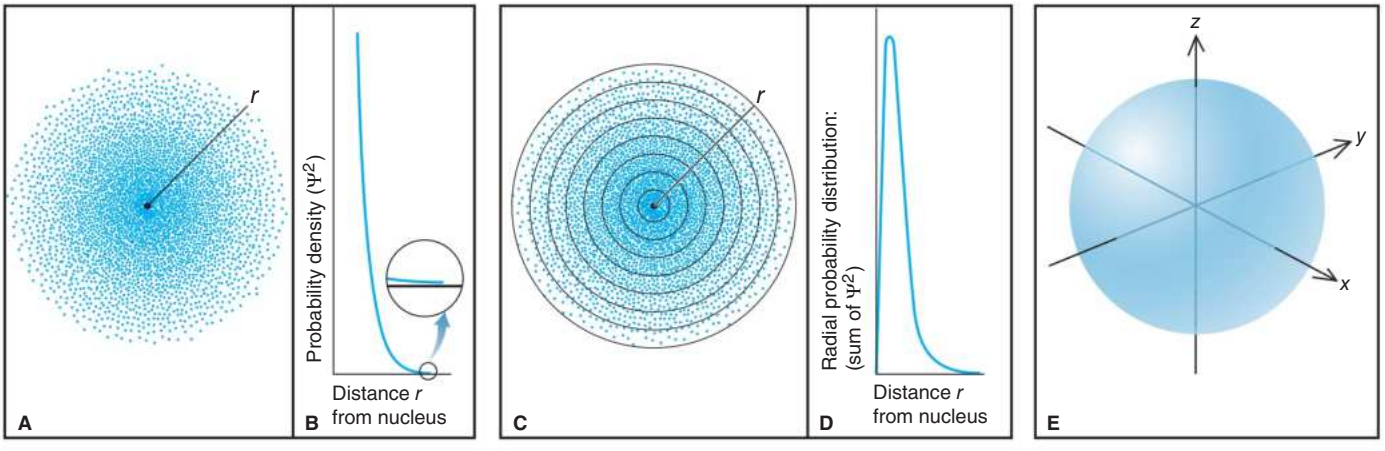


Figure 7.16 Electron probability density in the ground-state H atom. **A,** In the electron density diagram, the density of dots represents the probability of the electron being within a tiny volume and decreases with distance, *r*, from the nucleus. **B,** The probability density (ψ^2) decreases with *r* but does not reach zero *(blow-up circle).* **C,** Counting dots within each layer gives the total probability of the electron being in that layer. **D,** A radial probability distribution plot shows that total electron density peaks *near,* but not *at,* the nucleus. **E,** A 90% probability contour for the ground state of the H atom.

As you'll see later in this section, each atomic orbital has a distinctive radial probability distribution and 90% probability contour.

Quantum Numbers of an Atomic Orbital

An atomic orbital is specified by three quantum numbers (Table 7.2) that are part of the solution of the Schrödinger equation and indicate the size, shape, and orientation in space of the orbital.*

1. The **principal quantum number (n)** *is a positive integer* (1, 2, 3, and so forth). It indicates the relative *size* of the orbital and therefore the relative *distance from the nucleus* of the peak in the radial probability distribution plot. The principal quantum number specifies the *energy level* of the H atom: *the higher the n value, the higher the energy level.* When the electron occupies an orbital with $n = 1$, the H atom is in its ground state and has its lowest energy. When the electron occupies an orbital with $n = 2$ (first excited state), the atom has more energy.

2. The **angular momentum quantum number (l)** *is an integer from 0 to* $n - 1$. It is related to the *shape* of the orbital. Note that the principal quantum number sets a limit on the angular momentum quantum number: n limits l. For example:

$$n = 1 \longrightarrow l = 0 \text{ (1 value)}$$
$$n = 2 \longrightarrow l = 0, 1 \text{ (2 values)}$$
$$n = 3 \longrightarrow l = 0, 1, 2 \text{ (3 values)}$$

Thus, the number of possible l values equals the value of n.

3. The **magnetic quantum number (m_l)** *is an integer from* $-l$ *through 0 to* $+l$. It prescribes the three-dimensional *orientation* of the orbital in the space around the nucleus. The angular momentum quantum number sets a limit on the magnetic quantum number: l limits m_l. An orbital with $l = 0$ can have only $m_l = 0$. However, an orbital with $l = 1$ can have one of three m_l values, -1, 0, or $+1$; that is, there are three possible orbitals with $l = 1$, each with its own orientation. Note that

- the number of m_l values $= 2l + 1 =$ the number of orbitals for a given l, and
- the total number of m_l values for a given n value $= n^2 =$ the total number of orbitals in that energy level.

*For ease in discussion, chemists often refer to the size, shape, and orientation of an "atomic orbital," although we really mean the size, shape, and orientation of an "atomic orbital's radial probability distribution."

Table 7.2 The Hierarchy of Quantum Numbers for Atomic Orbitals

Name, Symbol (Property)	Allowed Values	Quantum Numbers
Principal, n (size, energy)	Positive integer (1, 2, 3, ...)	1 | 2 | 3
Angular momentum, l (shape)	0 to $n - 1$	0 | 0 1 | 0 1 2
Magnetic, m_l (orientation)	$-l, \ldots, 0, \ldots, +l$	0 | 0 −1 0 +1 | 0 −1 0 +1 −2 −1 0 +1 +2

SAMPLE PROBLEM 7.6 **Determining Quantum Numbers for an Energy Level**

Problem What values of the angular momentum (l) and magnetic (m_l) quantum numbers are allowed for a principal quantum number (n) of 3? How many orbitals are there in this energy level?

Plan We determine allowable quantum numbers with the rules from the text: l values are integers from 0 to $n - 1$, and m_l values are integers from $-l$ to 0 to $+l$. One m_l value is assigned to each orbital, so the number of m_l values gives the number of orbitals.

Solution Determining l values: for $n = 3$, $l = 0, 1, 2$.
Determining m_l for each l value:

For $l = 0$, $m_l = 0$

For $l = 1$, $m_l = -1, 0, +1$

For $l = 2$, $m_l = -2, -1, 0, +1, +2$

There are nine m_l values, so there are nine orbitals with $n = 3$.

Check Table 7.2 shows that we are correct. As we saw, the total number of orbitals for a given n value is n^2, and for $n = 3$, $n^2 = 9$.

FOLLOW-UP PROBLEMS

7.6A What are the possible l and m_l values for $n = 4$?

7.6B For what value of the principal quantum number n are there five allowed values of l? What are the allowed m_l values for this n?

SOME SIMILAR PROBLEMS 7.51 and 7.52

Quantum Numbers and Energy Levels

The energy states and orbitals of the atom are described with specific terms and are associated with one or more quantum numbers:

1. *Level.* The atom's energy **levels,** or *shells,* are given by the n value: the smaller the n value, the lower the energy level and the greater the probability that the electron is closer to the nucleus.

2. *Sublevel.* The atom's levels are divided into **sublevels,** or *subshells,* that are given by the l value. Each l value is designated by a letter:

$l = 0$ is an *s* sublevel.
$l = 1$ is a *p* sublevel.
$l = 2$ is a *d* sublevel.
$l = 3$ is an *f* sublevel.

(The letters derive from names of spectroscopic lines: *s*harp, *p*rincipal, *d*iffuse, and *f*undamental.) Sublevels with l values greater than 3 are designated by consecutive letters after *f*: *g* sublevel, *h* sublevel, and so on. A sublevel is named with its n value and letter designation; for example, the sublevel (subshell) with $n = 2$ and $l = 0$ is called the 2*s* sublevel. We discuss orbital shapes below.

3. *Orbital.* Each combination of *n, l,* and m_l specifies the size (energy), shape, and spatial orientation of one of the atom's orbitals. We know the quantum numbers of the orbitals in a sublevel from the sublevel name and the quantum-number hierarchy. For example,

- For the 2*s* sublevel: $n = 2$, $l = 0$, $m_l = 0$; **one** value of m_l indicates **one** orbital in this sublevel.
- For the 3*p* sublevel: $n = 3$, $l = 1$, $m_l = -1, 0, +1$; **three** values of m_l indicate **three** orbitals in this sublevel, one with $m_l = -1$, one with $m_l = 0$, and one with $m_l = +1$.

SAMPLE PROBLEM 7.7 Determining Sublevel Names and Orbital Quantum Numbers

Problem Give the name, magnetic quantum numbers, and number of orbitals for the sublevel that has the given n and l quantum numbers:
(a) $n = 3, l = 2$ **(b)** $n = 2, l = 0$ **(c)** $n = 5, l = 1$ **(d)** $n = 4, l = 3$

Plan We name the sublevel (subshell) with the n value and the letter designation of the l value. From the l value, we find the number of possible m_l values, which equals the number of orbitals in that sublevel.

Solution

	n	l	Sublevel Name	Possible m_l Values	No. of Orbitals
(a)	3	2	$3d$	$-2, -1, 0, +1, +2$	5
(b)	2	0	$2s$	0	1
(c)	5	1	$5p$	$-1, 0, +1$	3
(d)	4	3	$4f$	$-3, -2, -1, 0, +1, +2, +3$	7

Check Check the number of orbitals in each sublevel using

$$\text{No. of orbitals} = \text{no. of } m_l \text{ values} = 2l + 1$$

FOLLOW-UP PROBLEMS

7.7A What are the n, l, and possible m_l values for the $2p$ and $5f$ sublevels?

7.7B What are the n, l, and possible m_l values for the $4d$ and $6s$ sublevels? How many orbitals are in these sublevels of an atom?

SOME SIMILAR PROBLEMS 7.49, 7.50, and 7.55–7.58

SAMPLE PROBLEM 7.8 Identifying Incorrect Quantum Numbers

Problem What is wrong with each quantum number designation and/or sublevel name?

	n	l	m_l	Name
(a)	1	1	0	$1p$
(b)	4	3	$+1$	$4d$
(c)	3	1	-2	$3p$

Solution **(a)** A sublevel with $n = 1$ can only have $l = 0$, not $l = 1$. The correct sublevel name is $1s$.
(b) A sublevel with $l = 3$ is an f sublevel, not a d sublevel. The name should be $4f$.
(c) A sublevel with $l = 1$ can have only -1, 0, or $+1$ for m_l, not -2.

Check Check that l is always less than n, and m_l is always $\geq -l$ and $\leq +l$.

FOLLOW-UP PROBLEMS

7.8A Supply the missing quantum numbers and sublevel names.

	n	l	m_l	Name
(a)	?	?	0	$4p$
(b)	2	1	0	?
(c)	3	2	-2	?
(d)	?	?	?	$2s$

7.8B What is wrong with each quantum number designation and/or sublevel name?

	n	l	m_l	Name
(a)	5	3	4	$5f$
(b)	2	2	1	$2d$
(c)	6	1	-1	$6s$

SOME SIMILAR PROBLEMS 7.59, 7.60, and 7.72

Shapes of Atomic Orbitals

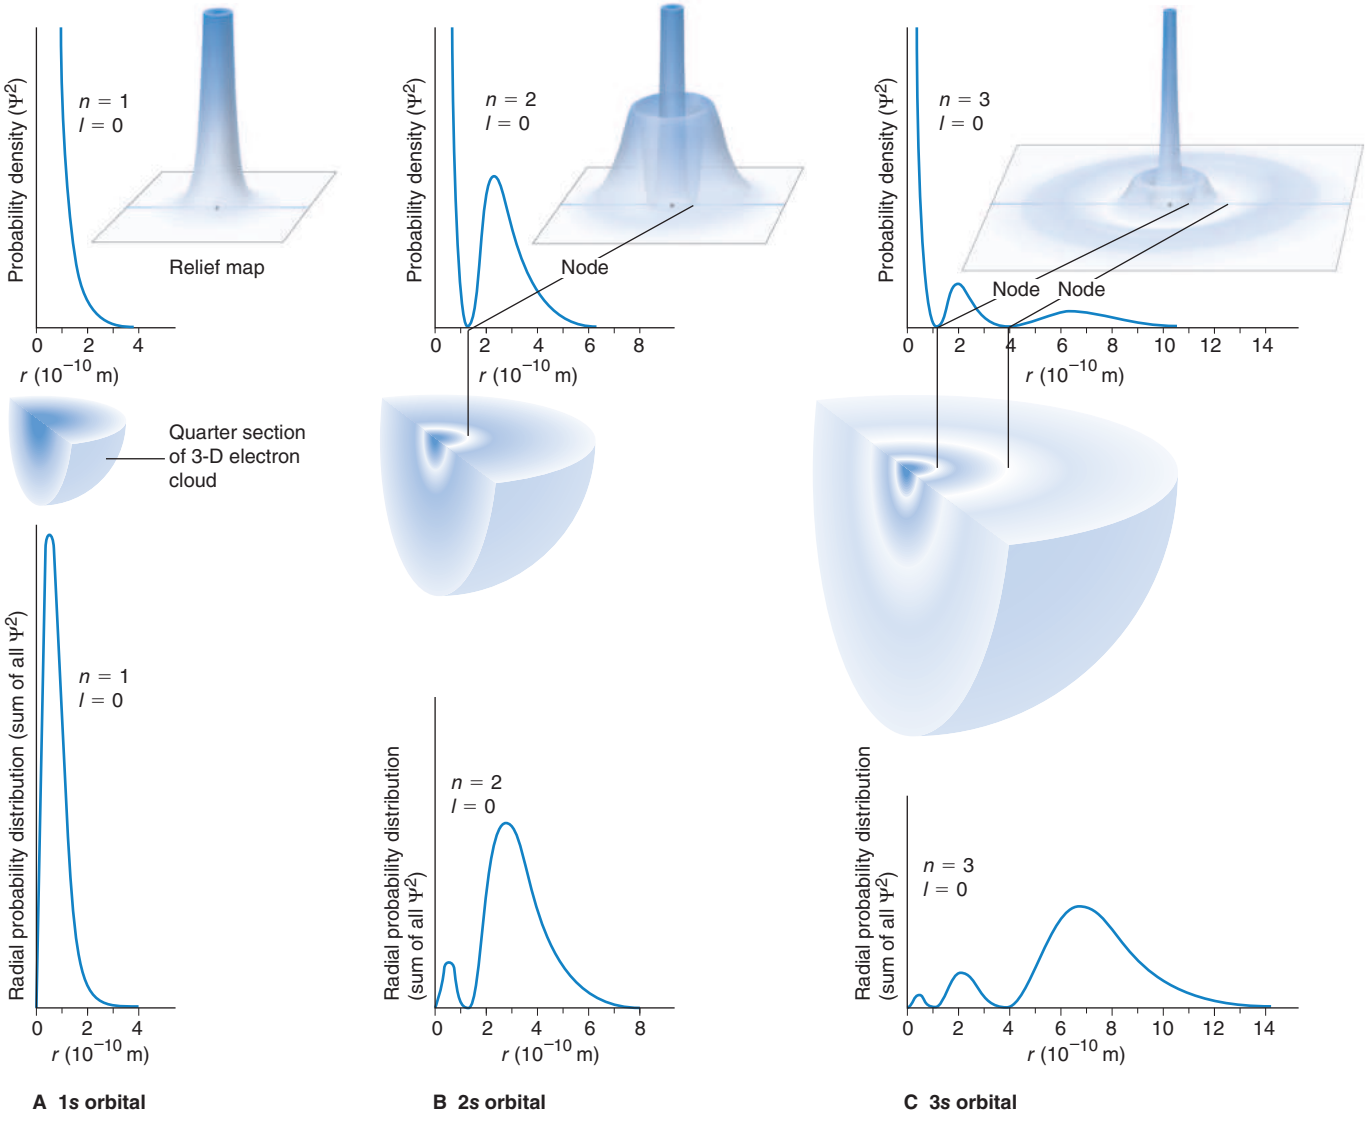
Each sublevel of the H atom consists of a set of orbitals with characteristic shapes. As you'll see in Chapter 8, orbitals for the other atoms have similar shapes.

The *s* Orbital An orbital with $l = 0$ has a *spherical* shape with the nucleus at its center and is called an ***s* orbital.** Because a sphere has only one orientation, an *s* orbital has only one m_l value: for any *s* orbital, $m_l = 0$.

1. *The 1s orbital* holds the electron in the H atom's ground state. *The electron probability density is highest at the nucleus.* Figure 7.17A shows this graphically *(top),* and an electron density *relief map (inset)* depicts the graph's curve in three dimensions. Note the quarter-section of a three-dimensional electron cloud depiction *(middle)* has the darkest shading at the nucleus. For reasons discussed earlier (see Figure 7.16D and the margin note, p. 307), the radial probability distribution plot *(bottom)* is highest slightly out from the nucleus. Both plots fall off smoothly with distance from the nucleus.

2. *The 2s orbital* (Figure 7.17B) has two regions of higher electron density. The radial probability distribution (Figure 7.17B, *bottom*) of the more distant region is *higher* than that of the closer one because the sum of ψ^2 for it is taken over a much larger volume. Between the two regions is a spherical **node,** where the probability of finding the electron drops to zero ($\psi^2 = 0$ at the node, analogous to zero amplitude

Figure 7.17 The 1*s*, 2*s*, and 3*s* orbitals. For each of the *s* orbitals, a plot of probability density vs. distance (*top*, with the relief map, *inset*, showing the plot in three dimensions) lies above a quarter section of an electron cloud depiction of the 90% probability contour *(middle),* which lies above a radial probability distribution plot *(bottom).* **A,** The 1*s* orbital. **B,** The 2*s* orbital. **C,** The 3*s* orbital.



of a wave exactly between the peak and trough). Because the 2*s* orbital is larger than the 1*s*, an electron in the 2*s* spends more time farther from the nucleus (in the larger of the two regions) than it does when it occupies the 1*s*.

3. *The 3s orbital* (Figure 7.17C) has three regions of high electron density and two nodes. Here again, the highest radial probability is at the greatest distance from the nucleus. This pattern of more nodes and higher probability with distance from the nucleus continues with the 4*s*, 5*s*, and so forth.

The *p* Orbital An orbital with $l = 1$ is called a ***p* orbital** and has two regions (lobes) of high probability, one on *either side* of the nucleus (Figure 7.18). The *nucleus lies at the nodal plane* of this dumbbell-shaped orbital. Since the maximum value of l is $n - 1$, only levels with $n = 2$ or higher have a *p* orbital: the lowest energy *p* orbital (the one closest to the nucleus) is the 2*p*. *One p* orbital consists of *two* lobes, and the electron spends *equal* time in both. Similar to the pattern for *s* orbitals, a 3*p* orbital is larger than a 2*p*, a 4*p* is larger than a 3*p*, and so forth.

Unlike *s* orbitals, *p* orbitals *have* different spatial orientations. The three possible m_l values of -1, 0, and $+1$ refer to three *mutually perpendicular* orientations; that is, while identical in size, shape, and energy, the three *p* orbitals differ in orientation. We associate *p* orbitals with the *x*, *y*, and *z* axes: the p_x orbital lies along the *x* axis, the p_y along the *y* axis, and the p_z along the *z* axis. (There is no relationship between a particular axis and a given m_l value.)

The *d* Orbital An orbital with $l = 2$ is called a ***d* orbital.** There are five possible m_l values for $l = 2$: -2, -1, 0, $+1$, and $+2$. Thus, a *d* orbital has any one of five orientations (Figure 7.19). Four of the five *d* orbitals have four lobes (a cloverleaf shape) with two mutually perpendicular nodal planes between them and the nucleus at the junction of the lobes (Figure 7.19C). (The orientation of the nodal planes always lies between the orbital lobes.) Three of these orbitals lie in the *xy, xz,* and *yz* planes, with their lobes *between* the axes, and are called the d_{xy}, d_{xz}, and d_{yz} orbitals. A fourth, the $d_{x^2-y^2}$ orbital, also lies in the *xy* plane, but its lobes are *along* the axes. The fifth

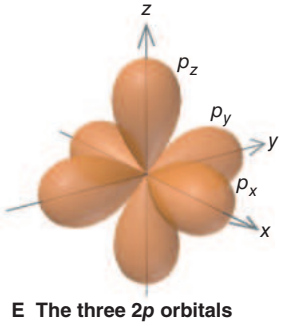
D Stylized probability contour, $2p_z$



E The three 2*p* orbitals

Figure 7.18 The 2*p* orbitals. A, A radial probability distribution plot of the 2*p* orbital shows a peak much farther from the nucleus than for the 1*s*. **B,** Cross section of an electron cloud depiction of the 90% probability contour of the $2p_z$ orbital shows a nodal plane. **C,** An accurate representation of the $2p_z$ probability contour. **D,** The stylized depiction of the $2p_z$ probability contour used in the text. **E,** The three (stylized) 2*p* orbitals occupy mutually perpendicular regions of space, contributing to the atom's overall spherical shape.

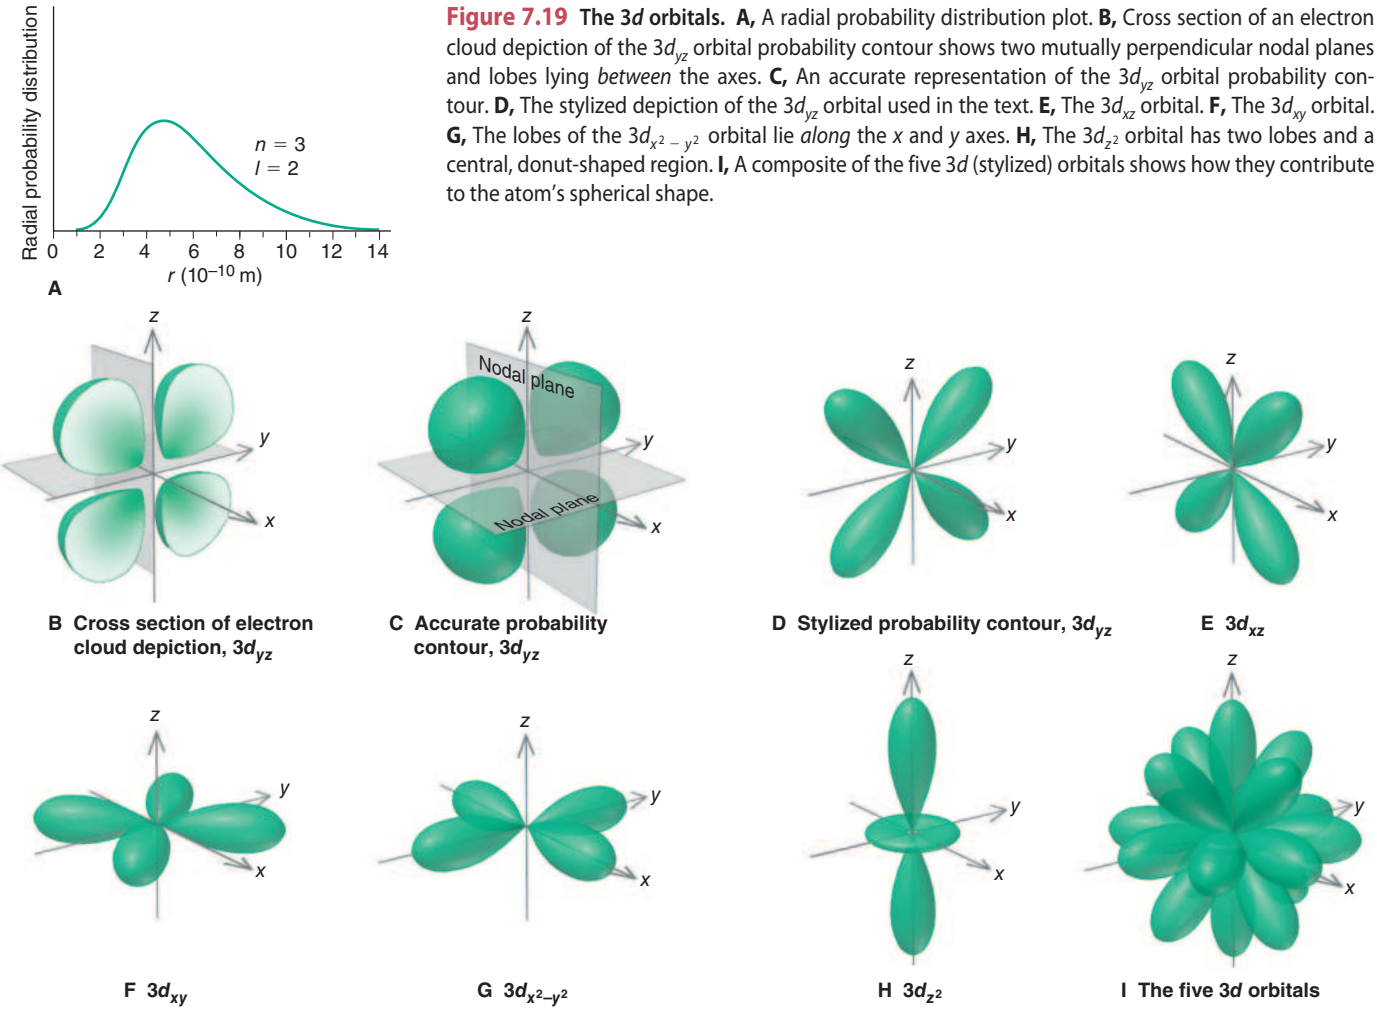


Figure 7.19 **The 3*d* orbitals. A,** A radial probability distribution plot. **B,** Cross section of an electron cloud depiction of the $3d_{yz}$ orbital probability contour shows two mutually perpendicular nodal planes and lobes lying *between* the axes. **C,** An accurate representation of the $3d_{yz}$ orbital probability contour. **D,** The stylized depiction of the $3d_{yz}$ orbital used in the text. **E,** The $3d_{xz}$ orbital. **F,** The $3d_{xy}$ orbital. **G,** The lobes of the $3d_{x^2-y^2}$ orbital lie *along* the *x* and *y* axes. **H,** The $3d_{z^2}$ orbital has two lobes and a central, donut-shaped region. **I,** A composite of the five 3*d* (stylized) orbitals shows how they contribute to the atom's spherical shape.

d orbital, the d_{z^2}, has two major lobes *along* the *z* axis, and a donut-shaped region girdles the center. An electron in a *d* orbital spends equal time in all of its lobes.

In keeping with the quantum-number hierarchy, a *d* orbital ($l = 2$) must have a principal quantum number of $n = 3$ or higher, so 3*d* is the lowest energy *d* sublevel. Orbitals in the 4*d* sublevel are larger (extend farther from the nucleus) than those in the 3*d,* and the 5*d* orbitals are larger still.

Orbitals with Higher *l* Values Orbitals with $l = 3$ are *f* orbitals and have a principal quantum number of at least $n = 4$. Figure 7.20 shows one of the seven *f* orbitals ($2l + 1 = 7$); each *f* orbital has a complex, multilobed shape with several nodal planes. Orbitals with $l = 4$ are *g* orbitals, but they play no known role in chemical bonding.

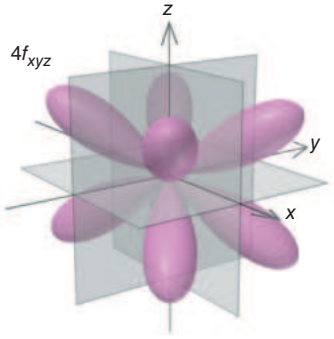

Figure 7.20 **The $4f_{xyz}$ orbital, one of the seven 4*f* orbitals.**

The Special Case of Energy Levels in the Hydrogen Atom

With regard to energy levels and sublevels, the H atom is a special case. When an H atom gains energy, its electron occupies an orbital of higher *n* value, which is (on average) farther from the nucleus. But, because it has just one electron, *hydrogen is the only atom whose energy state depends completely on the principal quantum number, n.* As you'll see in Chapter 8, because of additional nucleus-electron attractions and electron-electron repulsions, the energy states of all other atoms depend on the

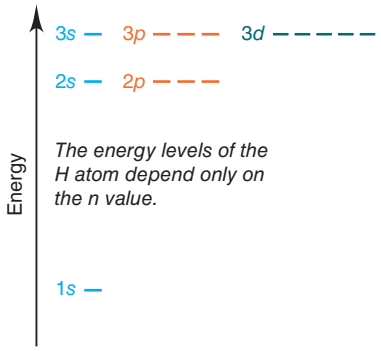

Figure 7.21 Energy levels of the H atom.

n and l values of the occupied orbitals. Thus, *for the H atom only,* all four $n = 2$ orbitals (one 2*s* and three 2*p*) have the same energy, all nine $n = 3$ orbitals (one 3*s,* three 3*p,* and five 3*d*) have the same energy (Figure 7.21), and so forth.

Summary of Section 7.4

- The atomic orbital (ψ, wave function) is a mathematical description of the electron's wavelike behavior in an atom. The Schrödinger equation converts each allowed wave function to one of the atom's energy states.
- The probability density of finding the electron at a particular location is represented by ψ^2. For a given energy level, an electron density diagram and a radial probability distribution plot show how the electron occupies the space near the nucleus.
- An atomic orbital is described by three quantum numbers: size (n), shape (l), and orientation (m_l): n limits l to $n - 1$ values, and l limits m_l to $2l + 1$ values.
- An energy level has sublevels with the same n value; a sublevel has orbitals with the same n and l values but differing m_l values.
- A sublevel with $l = 0$ has a spherical (*s*) orbital; a sublevel with $l = 1$ has three, two-lobed (*p*) orbitals; and a sublevel with $l = 2$ has five multilobed (*d*) orbitals.
- In the special case of the H atom, the energy levels depend only on the n value.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The wave characteristics of light (the interrelations of frequency, wavelength, and speed; the meaning of amplitude) and the general regions of the electromagnetic spectrum (§7.1)
2. How particles and waves differ in terms of the phenomena of refraction, diffraction, and interference (§7.1)
3. The quantization of energy and how an atom changes its energy by emitting or absorbing quanta of radiation (§7.1)
4. How the photon theory explains the photoelectric effect (§7.1)
5. How Bohr's theory explained the line spectra of the H atom; why the theory is wrong and which ideas we retain (§7.2)
6. The wave-particle duality of matter and energy and the relevant theories and experiments that led to it (de Broglie wavelength, electron diffraction, and photon momentum) (§7.3)
7. The meaning of the uncertainty principle and how uncertainty limits our knowledge of electron properties (§7.3)
8. The distinction between ψ (wave function, or atomic orbital) and ψ^2 (probability density) (§7.4)
9. How electron density diagrams and radial probability distribution plots depict the electron's location within the atom (§7.4)
10. The hierarchy of the quantum numbers that describe the size (n, energy), shape (l), and orientation (m_l) of an orbital (§7.4)
11. The distinction between energy level (shell), sublevel (subshell), and orbital (§7.4)
12. The shapes of *s, p,* and *d* orbitals (§7.4)

Master These Skills

Key Equations and Relationships

Page numbers appear in parentheses.

7.1 Relating the speed of light to its frequency and wavelength (288):

$$c = \nu \times \lambda$$

7.2 Relating energy change and frequency (292):

$$\Delta E = h\nu$$

7.3 Relating energy change and wavelength (292):

$$\Delta E = \frac{hc}{\lambda}$$

7.4 Calculating the wavelength of any line in the H atom spectrum (Rydberg equation) (295):

$$\frac{1}{\lambda} = R\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)$$

where n_1 and n_2 are positive integers and $n_2 > n_1$

7.5 Finding the difference between two energy levels in the H atom (297):

$$\Delta E = E_{final} - E_{initial} = -2.18\times10^{-18}\ \text{J}\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right)$$

7.6 Calculating the wavelength of any moving particle (de Broglie wavelength) (302):

$$\lambda = \frac{h}{mu}$$

7.7 Finding the uncertainty in position or speed of a particle (Heisenberg's uncertainty principle) (305):

$$\Delta x \cdot m\Delta u \geq \frac{h}{4\pi}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

7.1A $\lambda(\text{nm}) = \dfrac{3.00\times10^8\ \text{m/s}}{7.23\times10^{14}\ \text{s}^{-1}} \times \dfrac{10^9\ \text{nm}}{1\ \text{m}} = 415\ \text{nm}$

$$\lambda\ (\text{Å}) = 415\ \text{nm} \times \frac{10\ \text{Å}}{1\ \text{nm}} = 4150\ \text{Å}$$

7.1B $\nu = \dfrac{3.00\times10^8\ \text{m/s}}{940\ \text{nm}} \times \dfrac{10^9\ \text{nm}}{1\ \text{m}} = 3.2\times10^{14}\ \text{s}^{-1}$

This is infrared radiation.

7.2A $\lambda = \dfrac{hc}{E} = \dfrac{(6.626\times10^{-34}\ \text{J·s})(3.00\times10^8\ \text{m/s})}{8.2\times10^{-19}\ \text{J}} \times \dfrac{10^9\ \text{nm}}{1\ \text{m}}$

$= 240\ \text{nm}$

$$\nu = \frac{E}{h} = \frac{8.2\times10^{-19}\ \text{J}}{6.626\times10^{-34}\ \text{J·s}} = 1.2\times10^{15}\ \text{s}^{-1}$$

7.2B (a) UV: $E = hc/\lambda$

$$= \frac{(6.626\times10^{-34}\ \text{J·s})(3.00\times10^8\ \text{m/s})}{1\times10^{-8}\ \text{m}}$$

$= 2\times10^{-17}\ \text{J}$

(b) Visible: $E = 4\times10^{-19}$ J; (c) IR: $E = 2\times10^{-21}$ J

As λ increases, E decreases.

7.3A (a) With $n_{final} = 3$ for an IR photon:

$$\Delta E = -2.18\times10^{-18}\ \text{J}\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right)$$

$$= -2.18\times10^{-18}\ \text{J}\left(\frac{1}{3^2} - \frac{1}{6^2}\right)$$

$$= -2.18\times10^{-18}\ \text{J}\left(\frac{1}{9} - \frac{1}{36}\right) = -1.82\times10^{-19}\ \text{J}$$

(b) $\lambda = \dfrac{hc}{|\Delta E|} = \dfrac{(6.626\times10^{-34}\ \text{J·s})(3.00\times10^8\ \text{m/s})}{1.82\times10^{-19}\ \text{J}} \times \dfrac{1\ \text{Å}}{10^{-10}\ \text{m}}$

$= 1.09\times10^4\ \text{Å}$

7.3B

(a) $\Delta E\ (\text{J/atom}) = \dfrac{hc}{\lambda}$

$$= \frac{(6.626\times10^{-34}\ \text{J·s})(3.00\times10^8\ \text{m/s})}{410\ \text{nm}} \times \frac{10^9\ \text{nm}}{1\ \text{m}}$$

$= 4.85\times10^{-19}\ \text{J} = -4.85\times10^{-19}\ \text{J}$

(ΔE is negative since the photon is emitted.)

$$\Delta E\ (\text{kJ/mol}) = \frac{-4.85\times10^{-19}\ \text{J}}{\text{atom}} \times \frac{6.022\times10^{23}\ \text{atoms}}{\text{mol}} \times \frac{1\ \text{kJ}}{10^3\ \text{J}}$$

$= -292\ \text{kJ/mol}$

(b) $\dfrac{1}{n_{final}^2} = \dfrac{\Delta E}{-2.18\times10^{-18}\ \text{J}} + \dfrac{1}{n_{initial}^2}$

$$= \frac{-4.85\times10^{-19}\ \text{J}}{-2.18\times10^{-18}\ \text{J}} + \frac{1}{6^2}$$

$= 0.25025$

$$n_{final}^2 = \frac{1}{0.25025} = 4$$

$n_{final} = 2$

7.4A (a) $u = \dfrac{h}{m\lambda} = \dfrac{6.626\times10^{-34}\ \text{kg·m}^2\text{/s}}{(9.11\times10^{-31}\ \text{kg})\left(100\ \text{nm} \times \dfrac{1\ \text{m}}{10^9\ \text{nm}}\right)}$

$= 7.27\times10^3\ \text{m/s}$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

(b) $u = \dfrac{h}{m\lambda} = \dfrac{6.626\times10^{-34}\ \text{kg·m}^2/\text{s}}{(0.0459\ \text{kg})\left(100.\ \text{nm} \times \dfrac{1\ \text{m}}{10^9\ \text{nm}}\right)}$

$= 1.44\times10^{-25}\ \text{m/s}$

7.4B $u\ (\text{m/s}) = \dfrac{55\ \text{mi}}{1\ \text{h}} \times \dfrac{1\ \text{h}}{3600\ \text{s}} \times \dfrac{1.609\ \text{km}}{1\ \text{mi}} \times \dfrac{10^3\ \text{m}}{1\ \text{km}}$

$= 25\ \text{m/s}$

$\lambda = \dfrac{h}{mu} = \dfrac{6.626\times10^{-34}\ \text{kg·m}^2/\text{s}}{(0.0397\ \text{kg})(25\ \text{m/s})}$

$= 6.7\times10^{-34}\ \text{m}$

7.5A $\Delta x \geq \dfrac{6.626\times10^{-34}\ \text{kg·m}^2/\text{s}}{4\pi(0.142\ \text{kg})(0.447\ \text{m/s})} \geq 8.31\times10^{-34}\ \text{m}$

7.5B $\Delta x \geq \dfrac{6.626\times10^{-34}\ \text{kg·m}^2/\text{s}}{4\pi\ (1.67\times10^{-27}\ \text{kg})(8\times10^5\ \text{m/s})} \geq 4\times10^{-14}\ \text{m}$

7.6A $n = 4$, so $l = 0, 1, 2, 3$. In addition to the nine m_l values given in Sample Problem 7.6 there are those for $l = 3$:
$m_l = -3, -2, -1, 0, +1, +2, +3$

7.6B For $l = 0, 1, 2, 3, 4$, $n = 5$. In addition to the nine m_l values listed in Sample Problem 7.6 and the seven m_l values listed in Follow-up Problem 7.6A, there are those for $l = 4$: $m_l = -4, -3, -2, -1, 0, +1, +2, +3, +4$.

7.7A For $2p$: $n = 2$, $l = 1$, $m_l = -1, 0, +1$
For $5f$: $n = 5$, $l = 3$, $m_l = -3, -2, -1, 0, +1, +2, +3$

7.7B For $4d$: $n = 4$, $l = 2$, $m_l = -2, -1, 0, +1, +2$; there are five $4d$ orbitals.
For $6s$: $n = 6$, $l = 0$, $m_l = 0$; there is one $6s$ orbital.

7.8A (a) $n = 4$, $l = 1$; (b) name is $2p$; (c) name is $3d$; (d) $n = 2$, $l = 0$, $m_l = 0$

7.8B (a) For $l = 3$, the allowed values for m_l are -3, -2, -1, 0, $+1$, $+2$, $+3$, not 4.
(b) For $n = 2$, $l = 0$ or 1 only, not 2; the sublevel is $2p$, since $m_l = 1$.
(c) The value $l = 1$ indicates the p sublevel, not the s; the sublevel name is $6p$.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. Comprehensive Problems are based on material from any section or previous chapter.

The Nature of Light

(Sample Problems 7.1 and 7.2)

Concept Review Questions

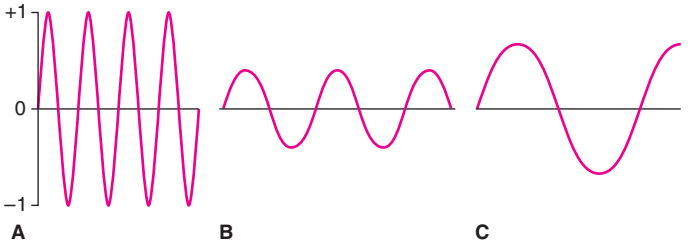
7.1 In what ways are microwave and ultraviolet radiation the same? In what ways are they different?

7.2 Consider the following types of electromagnetic radiation:
(1) Microwave (2) Ultraviolet (3) Radio waves
(4) Infrared (5) X-ray (6) Visible
(a) Arrange them in order of increasing wavelength.
(b) Arrange them in order of increasing frequency.
(c) Arrange them in order of increasing energy.

7.3 Define each of the following wave phenomena, and give an example of where each occurs: (a) refraction; (b) diffraction; (c) dispersion; (d) interference.

7.4 In the 17th century, Newton proposed that light was a stream of particles. The wave-particle debate continued for over 250 years until Planck and Einstein presented their ideas. Give two pieces of evidence for the wave model and two for the particle model.

7.5 Portions of electromagnetic waves A, B, and C are represented by the following (not drawn to scale):



Rank them in order of (a) increasing frequency; (b) increasing energy; (c) increasing amplitude. (d) If wave B just barely fails to cause a current when shining on a metal, is wave A or C more likely to do so? (e) If wave B represents visible radiation, is wave A or C more likely to be IR radiation?

7.6 What new idea about light did Einstein use to explain the photoelectric effect? Why does the photoelectric effect exhibit a threshold frequency but not a time lag?

Skill-Building Exercises (grouped in similar pairs)

7.7 An AM station broadcasts rock music at "950 on your radio dial." Units for AM frequencies are given in kilohertz (kHz). Find the wavelength of the station's radio waves in meters (m), nanometers (nm), and angstroms (Å).

7.8 An FM station broadcasts music at 93.5 MHz (megahertz, or 10^6 Hz). Find the wavelength (in m, nm, and Å) of these waves.

7.9 A radio wave has a frequency of 3.8×10^{10} Hz. What is the energy (in J) of one photon of this radiation?

7.10 An x-ray has a wavelength of 1.3 Å. Calculate the energy (in J) of one photon of this radiation.

7.11 Rank these photons in terms of increasing energy: (a) blue ($\lambda = 453$ nm); (b) red ($\lambda = 660$ nm); (c) yellow ($\lambda = 595$ nm).

7.12 Rank these photons in terms of decreasing energy: (a) IR ($\nu = 6.5\times10^{13}$ s^{-1}); (b) microwave ($\nu = 9.8\times10^{11}$ s^{-1}); (c) UV ($\nu = 8.0\times10^{15}$ s^{-1}).

Problems in Context

7.13 Police often monitor traffic with "K-band" radar guns, which operate in the microwave region at 22.235 GHz (1 GHz = 10^9 Hz). Find the wavelength (in nm and Å) of this radiation.

7.14 Covalent bonds in a molecule absorb radiation in the IR region and vibrate at characteristic frequencies.
(a) The C—O bond absorbs radiation of wavelength 9.6 μm. What frequency (in s^{-1}) corresponds to that wavelength?
(b) The H—Cl bond has a frequency of vibration of 8.652×10^{13} Hz. What wavelength (in μm) corresponds to that frequency?

7.15 Cobalt-60 is a radioactive isotope used to treat cancers. A gamma ray emitted by this isotope has an energy of 1.33 MeV (million electron volts; 1 eV = 1.602×10^{-19} J). What is the frequency (in Hz) and the wavelength (in m) of this gamma ray?

7.16 (a) Ozone formation in the upper atmosphere starts when oxygen molecules absorb UV radiation of wavelengths ≤ 242 nm. Find the frequency and energy of the least energetic of these photons. (b) Ozone absorbs radiation of wavelengths 2200–2900 Å, thus protecting organisms from this radiation. Find the frequency and energy of the most energetic of these photons.

Atomic Spectra

(Sample Problem 7.3)

Concept Review Questions

7.17 How is n_1 in the Rydberg equation (Equation 7.4) related to the quantum number n in the Bohr model?

7.18 What key assumption of Bohr's model would a "Solar System" model of the atom violate? What was the theoretical basis for this assumption?

7.19 Distinguish between an absorption spectrum and an emission spectrum. With which did Bohr work?

7.20 Which of these electron transitions correspond to absorption of energy and which to emission?
(a) $n = 2$ to $n = 4$ (b) $n = 3$ to $n = 1$
(c) $n = 5$ to $n = 2$ (d) $n = 3$ to $n = 4$

7.21 Why couldn't the Bohr model predict spectra for atoms other than hydrogen?

7.22 The H atom and the Be^{3+} ion each have one electron. Would you expect the Bohr model to predict their spectra accurately? Would you expect their spectra to be identical? Explain.

Skill-Building Exercises (grouped in similar pairs)

7.23 Use the Rydberg equation to find the wavelength (in nm) of the photon emitted when an electron in an H atom undergoes a transition from $n = 5$ to $n = 2$.

7.24 Use the Rydberg equation to find the wavelength (in Å) of the photon absorbed when an electron in an H atom undergoes a transition from $n = 1$ to $n = 3$.

7.25 What is the wavelength (in nm) of the least energetic spectral line in the infrared series of the H atom?

7.26 What is the wavelength (in nm) of the least energetic spectral line in the visible series of the H atom?

7.27 Calculate the energy difference (ΔE) for the transition in Problem 7.23 for 1 mol of H atoms.

7.28 Calculate the energy difference (ΔE) for the transition in Problem 7.24 for 1 mol of H atoms.

7.29 Arrange the following H atom electron transitions in order of *increasing* frequency of the photon absorbed or emitted:
(a) $n = 2$ to $n = 4$ (b) $n = 2$ to $n = 1$
(c) $n = 2$ to $n = 5$ (d) $n = 4$ to $n = 3$

7.30 Arrange the following H atom electron transitions in order of *decreasing* wavelength of the photon absorbed or emitted:
(a) $n = 2$ to $n = \infty$ (b) $n = 4$ to $n = 20$
(c) $n = 3$ to $n = 10$ (d) $n = 2$ to $n = 1$

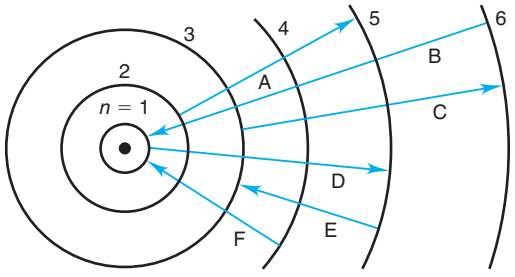
7.31 The electron in a ground-state H atom absorbs a photon of wavelength 97.20 nm. To what energy level does it move?

7.32 An electron in the $n = 5$ level of an H atom emits a photon of wavelength 1281 nm. To what energy level does it move?

Problems in Context

7.33 In addition to continuous radiation, fluorescent lamps emit some visible lines from mercury. A prominent line has a wavelength of 436 nm. What is the energy (in J) of one photon of it?

7.34 A Bohr-model representation of the H atom is shown below with several electron transitions depicted by arrows:



(a) Which transitions are absorptions and which are emissions? (b) Rank the emissions in terms of increasing energy. (c) Rank the absorptions in terms of increasing wavelength of light absorbed.

The Wave-Particle Duality of Matter and Energy

(Sample Problems 7.4 and 7.5)

Concept Review Questions

7.35 In what sense is the wave motion of a guitar string analogous to the motion of an electron in an atom?

7.36 What experimental support did de Broglie's concept receive?

7.37 If particles have wavelike motion, why don't we observe that motion in the macroscopic world?

7.38 Why can't we overcome the uncertainty predicted by Heisenberg's principle by building more precise instruments to reduce the error in measurements below the $h/4\pi$ limit?

Skill-Building Exercises (grouped in similar pairs)

7.39 A 232-lb fullback runs 40 yd at 19.8 ± 0.1 mi/h.
(a) What is his de Broglie wavelength (in meters)?
(b) What is the uncertainty in his position?

7.40 An alpha particle (mass = 6.6×10^{-24} g) emitted by a radium isotope travels at $3.4\times10^{7} \pm 0.1\times10^{7}$ mi/h.
(a) What is its de Broglie wavelength (in meters)?
(b) What is the uncertainty in its position?

7.41 How fast must a 56.5-g tennis ball travel to have a de Broglie wavelength equal to that of a photon of green light (5400 Å)?

7.42 How fast must a 142-g baseball travel to have a de Broglie wavelength equal to that of an x-ray photon with $\lambda = 100.$ pm?

7.43 A sodium flame has a characteristic yellow color due to emissions of wavelength 589 nm. What is the mass equivalence of one photon with this wavelength (1 J = 1 kg·m^2/s^2)?

7.44 A lithium flame has a characteristic red color due to emissions of wavelength 671 nm. What is the mass equivalence of 1 mol of photons with this wavelength (1 J = 1 kg·m^2/s^2)?

The Quantum-Mechanical Model of the Atom
(Sample Problems 7.6 to 7.8)

Concept Review Questions

7.45 What physical meaning is attributed to ψ^2?

7.46 What does "electron density in a tiny volume of space" mean?

7.47 Explain what it means for the peak in the radial probability distribution plot for the $n = 1$ level of an H atom to be at 0.529 Å. Is the probability of finding an electron at 0.529 Å from the nucleus greater for the 1*s* or the 2*s* orbital?

7.48 What feature of an orbital is related to each of the following?
(a) Principal quantum number (n)
(b) Angular momentum quantum number (l)
(c) Magnetic quantum number (m_l)

Skill-Building Exercises (grouped in similar pairs)

7.49 How many orbitals in an atom can have each of the following designations: (a) 1*s;* (b) 4*d;* (c) 3*p;* (d) $n = 3$?

7.50 How many orbitals in an atom can have each of the following designations: (a) 5*f;* (b) 4*p;* (c) 5*d;* (d) $n = 2$?

7.51 Give all possible m_l values for orbitals that have each of the following: (a) $l = 2$; (b) $n = 1$; (c) $n = 4$, $l = 3$.

7.52 Give all possible m_l values for orbitals that have each of the following: (a) $l = 3$; (b) $n = 2$; (c) $n = 6$, $l = 1$.

7.53 Draw 90% probability contours (with axes) for each of the following orbitals: (a) *s;* (b) p_x.

7.54 Draw 90% probability contours (with axes) for each of the following orbitals: (a) p_z; (b) d_{xy}.

7.55 For each of the following, give the sublevel designation, the allowable m_l values, and the number of orbitals:
(a) $n = 4$, $l = 2$ (b) $n = 5$, $l = 1$ (c) $n = 6$, $l = 3$

7.56 For each of the following, give the sublevel designation, the allowable m_l values, and the number of orbitals:
(a) $n = 2$, $l = 0$ (b) $n = 3$, $l = 2$ (c) $n = 5$, $l = 1$

7.57 For each of the following sublevels, give the n and l values and the number of orbitals: (a) 5*s;* (b) 3*p;* (c) 4*f.*

7.58 For each of the following sublevels, give the n and l values and the number of orbitals: (a) 6*g;* (b) 4*s;* (c) 3*d.*

7.59 Are the following combinations allowed? If not, show two ways to correct them:
(a) $n = 2$; $l = 0$; $m_l = -1$ (b) $n = 4$; $l = 3$; $m_l = -1$
(c) $n = 3$; $l = 1$; $m_l = 0$ (d) $n = 5$; $l = 2$; $m_l = +3$

7.60 Are the following combinations allowed? If not, show two ways to correct them:
(a) $n = 1$; $l = 0$; $m_l = 0$ (b) $n = 2$; $l = 2$; $m_l = +1$
(c) $n = 7$; $l = 1$; $m_l = +2$ (d) $n = 3$; $l = 1$; $m_l = -2$

Comprehensive Problems

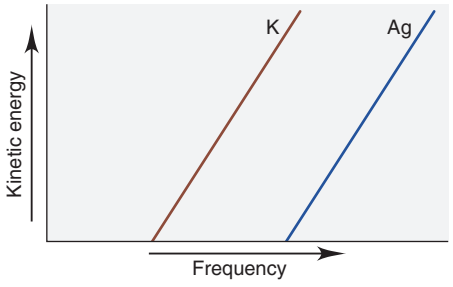
7.61 The orange color of carrots and orange peel is due mostly to β-carotene, an organic compound insoluble in water but soluble in benzene and chloroform. Describe an experiment to determine the concentration of β-carotene in the oil from orange peel.

7.62 The quantum-mechanical treatment of the H atom gives the energy, E, of the electron as a function of n:

$$E = -\frac{h^2}{8\pi^2 m_e a_0^2 n^2} \qquad (n = 1, 2, 3, \ldots)$$

where h is Planck's constant, m_e is the electron mass, and a_0 is 52.92×10^{-12} m.
(a) Write the expression in the form $E = -(\text{constant})(1/n^2)$, evaluate the constant (in J), and compare it with the corresponding expression from Bohr's theory.
(b) Use the expression from part (a) to find ΔE between $n = 2$ and $n = 3$.
(c) Calculate the wavelength of the photon that corresponds to this energy change.

7.63 The photoelectric effect is illustrated in a plot of the kinetic energies of electrons ejected from the surface of potassium metal or silver metal at different frequencies of incident light.



(a) Why don't the lines begin at the origin? (b) Why don't the lines begin at the same point? (c) From which metal will light of shorter wavelength eject an electron? (d) Why are the slopes equal?

7.64 The optic nerve needs a minimum of 2.0×10^{-17} J of energy to trigger a series of impulses that eventually reach the brain. (a) How many photons of red light (700. nm) are needed? (b) How many photons of blue light (475 nm)?

7.65 One reason carbon monoxide (CO) is toxic is that it binds to the blood protein hemoglobin more strongly than oxygen does. The bond between hemoglobin and CO absorbs radiation of 1953 cm^{-1}. (The units are the reciprocal of the wavelength in centimeters.) Calculate the wavelength (in nm and Å) and the frequency (in Hz) of the absorbed radiation.

7.66 A metal ion M^{n+} has a single electron. The highest energy line in its emission spectrum has a frequency of 2.961×10^{16} Hz. Identify the ion.

7.67 Compare the wavelengths of an electron (mass = 9.11×10^{-31} kg) and a proton (mass = 1.67×10^{-27} kg), each having (a) a speed of 3.4×10^{6} m/s; (b) a kinetic energy of 2.7×10^{-15} J.

7.68 Five lines in the H atom spectrum have these wavelengths (in Å): (a) 1212.7; (b) 4340.5; (c) 4861.3; (d) 6562.8; (e) 10,938. Three lines result from transitions to $n_{final} = 2$ (visible series). The other two result from transitions in different series, one with $n_{final} = 1$ and the other with $n_{final} = 3$. Identify $n_{initial}$ for each line.

7.69 In his explanation of the threshold frequency in the photoelectric effect, Einstein reasoned that the absorbed photon must have a minimum energy to dislodge an electron from the metal surface. This energy is called the *work function* (ϕ) of the metal. What is the longest wavelength of radiation (in nm) that could cause the photoelectric effect in each of these metals: (a) calcium, $\phi = 4.60\times10^{-19}$ J; (b) titanium, $\phi = 6.94\times10^{-19}$ J; (c) sodium, $\phi = 4.41\times10^{-19}$ J?

7.70 Refractometry is based on the difference in the speed of light through a substance (v) and through a vacuum (c). In the procedure, light of known wavelength passes through a fixed thickness of the substance at a known temperature. The index of refraction equals c/v. Using yellow light ($\lambda = 589$ nm) at 20°C, for example, the index of refraction of water is 1.33 and that of diamond is 2.42. Calculate the speed of light in (a) water and (b) diamond.

7.71 A laser (*l*ight *a*mplification by *s*timulated *e*mission of *r*adiation) provides nearly monochromatic high-intensity light. Lasers are used in eye surgery, CD/DVD players, basic research, and many other areas. Some dye lasers can be "tuned" to emit a desired wavelength. Fill in the blanks in the following table of the properties of some common types of lasers:

Type	λ (nm)	ν (s^{-1})	E (J)	Color
He-Ne	632.8	?	?	?
Ar	?	6.148×10^{14}	?	?
Ar-Kr	?	?	3.499×10^{-19}	?
Dye	663.7	?	?	?

7.72 The following combinations are not allowed. If n and m_l are correct, change the l value to create an allowable combination:
(a) $n = 3; l = 0; m_l = -1$ (b) $n = 3; l = 3; m_l = +1$
(c) $n = 7; l = 2; m_l = +3$ (d) $n = 4; l = 1; m_l = -2$

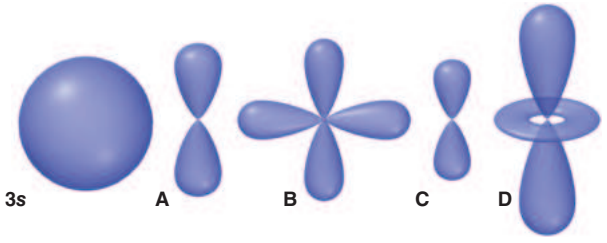
7.73 A ground-state H atom absorbs a photon of wavelength 94.91 nm, and its electron attains a higher energy level. The atom then emits two photons: one of wavelength 1281 nm to reach an intermediate energy level, and a second to return to the ground state.
(a) What higher level did the electron reach?
(b) What intermediate level did the electron reach?
(c) What was the wavelength of the second photon emitted?

7.74 Ground-state ionization energies of some one-electron species are

$H = 1.31\times10^{3}$ kJ/mol $He^{+} = 5.24\times10^{3}$ kJ/mol
$Li^{2+} = 1.18\times10^{4}$ kJ/mol

(a) Write a general expression for the ionization energy of any one-electron species. (b) Use your expression to calculate the ionization energy of B^{4+}. (c) What is the minimum wavelength required to remove the electron from the $n = 3$ level of He^{+}? (d) What is the minimum wavelength required to remove the electron from the $n = 2$ level of Be^{3+}?

7.75 Use the relative size of the 3*s* orbital below to answer the following questions about orbitals A–D.



(a) Which orbital has the highest value of n? (b) Which orbital(s) have a value of $l = 1$? $l = 2$? (c) How many other orbitals with the same value of n have the same shape as orbital B? Orbital C? (d) Which orbital has the highest energy? Lowest energy?

7.76 In the course of developing his model, Bohr arrived at the following formula for the radius of the electron's orbit: $r_n = n^2h^2\epsilon_0/\pi m_e e^2$, where m_e is the electron mass, e is its charge, and ϵ_0 is a constant related to charge attraction in a vacuum. Given that $m_e = 9.109\times10^{-31}$ kg, $e = 1.602\times10^{-19}$ C, and $\epsilon_0 = 8.854\times10^{-12}$ $C^2/J\cdot m$, calculate the following:
(a) The radius of the first ($n = 1$) orbit in the H atom
(b) The radius of the tenth ($n = 10$) orbit in the H atom

7.77 (a) Find the Bohr radius of an electron in the $n = 3$ orbit of an H atom (see Problem 7.76). (b) What is the energy (in J) of the atom in (a)? (c) What is the energy of an Li^{2+} ion with its electron in the $n = 3$ orbit? (d) Why are the answers to (b) and (c) different?

7.78 Enormous numbers of microwave photons are needed to warm macroscopic samples of matter. A portion of soup containing 252 g of water is heated in a microwave oven from 20.°C to 98°C, with radiation of wavelength 1.55×10^{-2} m. How many photons are absorbed by the water in the soup?

7.79 The quantum-mechanical treatment of the hydrogen atom gives this expression for the wave function, ψ, of the 1*s* orbital:

$$\psi = \frac{1}{\sqrt{\pi}}\left(\frac{1}{a_0}\right)^{3/2} e^{-r/a_0}$$

where r is the distance from the nucleus and a_0 is 52.92 pm. The probability of finding the electron in a tiny volume at distance r from the nucleus is proportional to ψ^2. The total probability of finding the electron at all points at distance r from the nucleus is proportional to $4\pi r^2\psi^2$. Calculate the values (to three significant figures) of ψ, ψ^2, and $4\pi r^2\psi^2$ to fill in the following table and sketch a plot of each set of values versus r. Compare the latter two plots with those in Figure 7.17A, p. 311:

r (pm)	ψ ($pm^{-3/2}$)	ψ^2 (pm^{-3})	$4\pi r^2\psi^2$ (pm^{-1})
0			
50			
100			
200			

7.80 Lines in one spectral series can overlap lines in another.
(a) Does the range of wavelengths in the $n_1 = 1$ series for the H atom overlap the range in the $n_1 = 2$ series?
(b) Does the range in the $n_1 = 3$ series overlap the range in the $n_1 = 4$ series?
(c) How many lines in the $n_1 = 4$ series lie in the range of the $n_1 = 5$ series?
(d) What does this overlap imply about the H atom line spectrum at longer wavelengths?

7.81 The following values are the only energy levels of a hypothetical one-electron atom:

$$E_6 = -2\times10^{-19}\ \text{J} \qquad E_5 = -7\times10^{-19}\ \text{J}$$
$$E_4 = -11\times10^{-19}\ \text{J} \qquad E_3 = -15\times10^{-19}\ \text{J}$$
$$E_2 = -17\times10^{-19}\ \text{J} \qquad E_1 = -20\times10^{-19}\ \text{J}$$

(a) If the electron were in the $n = 3$ level, what would be the highest frequency (and minimum wavelength) of radiation that could be emitted?
(b) What is the ionization energy (in kJ/mol) of the atom in its ground state?
(c) If the electron were in the $n = 4$ level, what would be the shortest wavelength (in nm) of radiation that could be absorbed without causing ionization?

7.82 Photoelectron spectroscopy applies the principle of the photoelectric effect to study orbital energies of atoms and molecules. High-energy radiation (usually UV or x-ray) is absorbed by a sample and an electron is ejected. The orbital energy can be calculated from the known energy of the radiation and the measured energy of the electron lost. The following energy differences were determined for several electron transitions:

$$\Delta E_{2\longrightarrow1} = 4.098\times10^{-17}\ \text{J} \qquad \Delta E_{3\longrightarrow1} = 4.854\times10^{-17}\ \text{J}$$
$$\Delta E_{5\longrightarrow1} = 5.242\times10^{-17}\ \text{J} \qquad \Delta E_{4\longrightarrow2} = 1.024\times10^{-17}\ \text{J}$$

Calculate ΔE and λ of a photon emitted in the following transitions: (a) level $3 \longrightarrow 2$; (b) level $4 \longrightarrow 1$; (c) level $5 \longrightarrow 4$.

7.83 Horticulturists know that, for many plants, dark green leaves are associated with low light levels and pale green with high levels. (a) Use the photon theory to explain this behavior. (b) What change in leaf composition might account for this difference?

7.84 In order to comply with the requirement that energy be conserved, Einstein showed in the photoelectric effect that the energy of a photon ($h\nu$) absorbed by a metal is the sum of the work function (ϕ), the minimum energy needed to dislodge an electron from the metal's surface, and the kinetic energy (E_k) of the electron: $h\nu = \phi + E_k$. When light of wavelength 358.1 nm falls on the surface of potassium metal, the speed (u) of the dislodged electron is 6.40×10^5 m/s. (a) What is E_k ($\frac{1}{2}mu^2$) of the dislodged electron? (b) What is ϕ (in J) of potassium?

7.85 For any microscope, the size of the smallest observable object is one-half the wavelength of the radiation used. For example, the smallest object observable with 400-nm light is 2×10^{-7} m. (a) What is the smallest observable object for an electron microscope using electrons moving at 5.5×10^4 m/s? (b) At 3.0×10^7 m/s?

7.86 In fireworks, the heat of the reaction of an oxidizing agent, such as $KClO_4$, with an organic compound excites certain salts, which emit specific colors. Strontium salts have an intense emission at 641 nm, and barium salts have one at 493 nm.
(a) What colors do these emissions produce?
(b) What is the energy (in kJ) of these emissions for 5.00 g each of the chloride salts of Sr and Ba? (Assume that all the heat produced is converted to emitted light.)

7.87 Atomic hydrogen produces several series of spectral lines. Each series fits the Rydberg equation with its own particular n_1 value. Calculate the value of n_1 (by trial and error if necessary) that would produce a series of lines in which:
(a) The *highest* energy line has a wavelength of 3282 nm.
(b) The *lowest* energy line has a wavelength of 7460 nm.

7.88 Fish-liver oil is a good source of vitamin A, whose concentration is measured spectrometrically at a wavelength of 329 nm.
(a) Suggest a reason for using this wavelength.
(b) In what region of the spectrum does this wavelength lie?
(c) When 0.1232 g of fish-liver oil is dissolved in 500. mL of solvent, the absorbance is 0.724 units. When 1.67×10^{-3} g of vitamin A is dissolved in 250. mL of solvent, the absorbance is 1.018 units. Calculate the vitamin A concentration in the fish-liver oil.

7.89 Many calculators use photocells as their energy source. Find the maximum wavelength needed to remove an electron from silver ($\phi = 7.59\times10^{-19}$ J). Is silver a good choice for a photocell that uses visible light? [The concept of the work function (ϕ) is explained in Problem 7.69.]

7.90 In a game of "Clue," Ms. White is killed in the conservatory. A spectrometer in each room records who is present to help find the murderer. For example, if someone wearing yellow is in a room, light at 580 nm is reflected. The suspects are Col. Mustard, Prof. Plum, Mr. Green, Ms. Peacock (blue), and Ms. Scarlet. At the time of the murder, the spectrometer in the dining room shows a reflection at 520 nm, those in the lounge and the study record lower frequencies, and the one in the library records the shortest possible wavelength. Who killed Ms. White? Explain.

7.91 Technetium (Tc; $Z = 43$) is a synthetic element used as a radioactive tracer in medical studies. A Tc atom emits a beta particle (electron) with a kinetic energy ($E_k = \frac{1}{2}mv^2$) of 4.71×10^{-15} J. What is the de Broglie wavelength of this electron?

7.92 Electric power is measured in watts (1 W = 1 J/s). About 95% of the power output of an incandescent bulb is converted to heat and 5% to light. If 10% of that light shines on your chemistry textbook, how many photons per second shine on the book from a 75-W bulb? (Assume that the photons have a wavelength of 550 nm.)

7.93 The flame tests for sodium and potassium are based on the emissions at 589 nm and 404 nm, respectively. When both elements are present, the Na^+ emission is so strong that the K^+ emission can be seen only by looking through a cobalt-glass filter.
(a) What are the colors of these Na^+ and K^+ emissions?
(b) What does the cobalt-glass filter do?
(c) Why is $KClO_4$ used as an oxidizing agent in fireworks rather than $NaClO_4$?

7.94 The net change during photosynthesis involves CO_2 and H_2O forming glucose ($C_6H_{12}O_6$) and O_2. Chlorophyll absorbs light in the 600–700 nm region.

(a) Write a balanced thermochemical equation for formation of 1.00 mol of glucose.
(b) What is the minimum number of photons with $\lambda = 680.$ nm needed to form 1.00 mol of glucose?

7.95 Only certain transitions are allowed from one energy level to another. In one-electron species, the change in l of an allowed transition is ± 1. For example, a $3p$ electron can move to a $2s$ orbital but not to a $2p$. Thus, in the UV series, where $n_{final} = 1$, allowed transitions can start in a p orbital ($l = 1$) of $n = 2$ or higher, not in an s ($l = 0$) or d ($l = 2$) orbital of $n = 2$ or higher. From what orbital do each of the allowed transitions start for the first four emission lines in the visible series ($n_{final} = 2$)?

7.96 The discharge of phosphate in detergents to the environment has led to imbalances in the life cycle of freshwater lakes. A chemist uses a spectrometric method to measure total phosphate and obtains the following data for known standards:

Absorbance (880 nm)	Concentration (mol/L)
0	0.0×10^{-5}
0.10	2.5×10^{-5}
0.16	3.2×10^{-5}
0.20	4.4×10^{-5}
0.25	5.6×10^{-5}
0.38	8.4×10^{-5}
0.48	10.5×10^{-5}
0.62	13.8×10^{-5}
0.76	17.0×10^{-5}
0.88	19.4×10^{-5}

(a) Draw a curve of absorbance vs. phosphate concentration.
(b) If a sample of lake water has an absorbance of 0.55, what is its phosphate concentration?

Concepts and Skills to Review Before You Study This Chapter

- format of the periodic table (Section 2.6)
- characteristics of metals and nonmetals (Section 2.6)
- attractions, repulsions, and Coulomb's law (Section 2.7)
- characteristics of acids and bases (Section 4.4)
- rules for assigning quantum numbers (Section 7.4)

We have become expert at measuring recurring patterns in nature—day and night, the seasons, the rhythm of a heartbeat, lunar phases—patterns that allow us to predict events such as the date of the next solar eclipse. Elements exhibit recurring patterns in properties because their atoms do, and we can use these patterns to make predictions, too.

The outpouring of scientific creativity by early 20th-century physicists that led to the new quantum-mechanical model of the atom was preceded by countless hours of laboratory work by 19th-century chemists who were exploring the nature of electrolytes, the kinetic-molecular theory, and chemical thermodynamics. The fields of organic chemistry and biochemistry were born in the 19th century, as were the fertilizer, explosives, glassmaking, soapmaking, bleaching, and dyestuff industries. And, for the first time, chemistry became a subject in universities in Europe and America.

Condensed from all these efforts was an enormous body of facts about the elements, which became organized into the periodic table:

- *The original periodic table.* In 1870, the Russian chemist Dmitri Mendeleev arranged the 65 elements known at the time into a table and summarized their behavior in the **periodic law:** when arranged by *atomic mass,* the elements exhibit a periodic recurrence of similar properties. Mendeleev left blank spaces in his table and was even able to *predict* the properties of several elements, for example, germanium, that were not discovered until later.
- *The modern periodic table.* Today's table *(inside front cover)* includes 53 elements not known in 1870 and, most importantly, arranges the elements by *atomic number* (number of protons) *not* atomic mass. This change is based on the work of the British physicist Henry G. J. Moseley, who obtained x-ray spectra of various metals by bombarding the metals with electrons. Moseley found that the largest x-ray peak for each metal was related to the nuclear charge, which increased by 1 for each successive element.

The great test for the new atomic model was to answer one of the central questions in chemistry: *why* do the elements behave as they do? Or, rephrasing to fit the main topic of this chapter, how does the **electron configuration** of an element—*the distribution of electrons within the levels and sublevels of its atoms*—relate to its chemical and physical properties?

IN THIS CHAPTER . . . *We explore recurring patterns of electron distributions in atoms to see how they account for the recurring behavior of the elements.*

- We describe a new quantum number and a restriction on the number of electrons in an orbital, which allows us to define a unique set of quantum numbers for each electron in an atom of any element.
- We explore electrostatic effects that lead to splitting of atomic energy levels into sublevels and give rise to the order in which orbitals fill with electrons. This filling order correlates with the order of elements in the periodic table.
- We examine the reasons for periodic trends in three atomic properties.
- We see how these trends account for chemical reactivity with regard to metallic and redox behavior, oxide acidity, ion formation, and magnetic behavior.

8.1 CHARACTERISTICS OF MANY-ELECTRON ATOMS

The Schrödinger equation (introduced in Chapter 7) does not give *exact* solutions for the energy levels of *many-electron atoms,* those with more than one electron—that is, all atoms except hydrogen. However, unlike the Bohr model, it gives excellent *approximate* solutions. Three additional features become important in many-electron atoms: (1) a fourth quantum number, (2) a limit on the number of electrons in an orbital, and (3) a splitting of energy levels into sublevels.

The Electron-Spin Quantum Number

The three quantum numbers n, l, and m_l describe the size (energy), shape, and orientation in space, respectively, of an atomic orbital. A fourth quantum number describes a property called *spin,* which is a property of the electron and not the orbital.

When a beam of atoms that have one or more lone electrons passes through a nonuniform magnetic field (created by magnet faces with different shapes), it splits into two beams; Figure 8.1 shows this for a beam of H atoms. Each electron behaves as if it were spinning on its axis in one of two opposite directions, and each spinning charge generates a tiny magnetic field, which can have one of two values of *spin*. The two electron fields have opposing directions, so half of the electrons are *attracted* by the large external magnetic field while the other half are *repelled* by it.

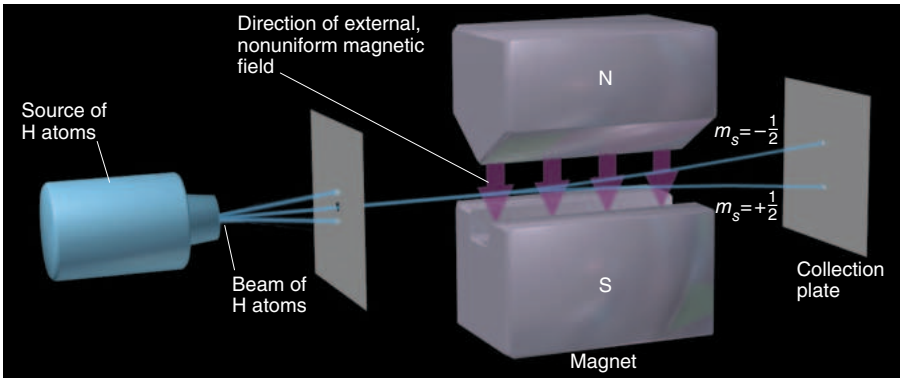

Figure 8.1 The effect of electron spin. A beam of H atoms splits because each atom's electron has one of the two possible values of spin.

Corresponding to the two directions of the electron's field, the **spin quantum number (m_s)** has two possible values, $+\frac{1}{2}$ or $-\frac{1}{2}$. Thus, *each electron in an atom is described completely by a set of* ***four*** *quantum numbers: the first three describe its orbital, and the fourth describes its spin.* The quantum numbers are summarized in Table 8.1.

Now we can write a set of four quantum numbers for any electron in the ground state of any atom. For example, the set of quantum numbers for the lone electron in

Table 8.1 Summary of Quantum Numbers of Electrons in Atoms

Name	Symbol	Permitted Values	Property
Principal	n	Positive integers (1, 2, 3, . . .)	Orbital energy (size)
Angular momentum	l	Integers from 0 to $n - 1$	Orbital shape (The l values 0, 1, 2, and 3 correspond to *s, p, d,* and *f* orbitals, respectively.)
Magnetic	m_l	Integers from $-l$ to 0 to $+l$	Orbital orientation
Spin	m_s	$+\frac{1}{2}$ or $-\frac{1}{2}$	Direction of e^- spin

hydrogen (H; $Z = 1$) is $n = 1$, $l = 0$, $m_l = 0$, and $m_s = +\frac{1}{2}$. (The spin quantum number could just as well have been $-\frac{1}{2}$, but by convention, we assign $+\frac{1}{2}$ to the first electron in an orbital.)

The Exclusion Principle

The element after hydrogen is helium (He; $Z = 2$), the first with atoms having more than one electron. The first electron in the He ground state has the same set of quantum numbers as the electron in the H atom, but the second He electron does not. Based on observations of excited states, the Austrian physicist Wolfgang Pauli formulated the **exclusion principle:** *no two electrons in the same atom can have the same four quantum numbers.* Therefore, the second He electron occupies the same 1*s* orbital as the first but has an opposite spin: $n = 1$, $l = 0$, $m_l = 0$, and $m_s = -\frac{1}{2}$.

The major consequence of the exclusion principle is that *an atomic orbital can hold a maximum of two electrons, which must have opposing spins.* We say that the 1*s* orbital in He is *filled* and that the electrons have *paired spins.* Thus, a beam of He atoms is not split in an experiment like that in Figure 8.1.

Baseball Quantum Numbers

The unique set of quantum numbers that describes an electron is analogous to the unique location of a box seat at a baseball game. The stadium (atom) is divided into section (n, level), box (l, sublevel), row (m_l, orbital), and seat (m_s, spin). Only one person (electron) can have this particular set of stadium "quantum numbers."

Electrostatic Effects and Energy-Level Splitting

Electrostatic effects—attraction of opposite charges and repulsion of like charges—play a major role in determining the energy states of many-electron atoms. Unlike the H atom, in which there is only the attraction between nucleus and electron and the energy state is determined *only* by the n value, the energy states of many-electron atoms are also affected by electron-electron repulsions. You'll see shortly how these additional interactions give rise to *the splitting of energy levels into sublevels of differing energies: the energy of an orbital in a many-electron atom depends mostly on its n value (size) and to a lesser extent on its l value (shape).*

Our first encounter with energy-level splitting occurs with lithium (Li; $Z = 3$). The first two electrons of Li fill its 1*s* orbital, so the third Li electron must go into the $n = 2$ level. But, this level has 2*s and* 2*p* sublevels: which does the third electron enter? For reasons we discuss below, the 2*s* is lower in energy than the 2*p,* so the ground state of Li has its third electron in the 2*s*.

This energy difference arises from three factors—*nuclear attraction, electron repulsions,* and *orbital shape* (i.e., radial probability distribution). Their interplay leads to two phenomena—*shielding* and *penetration*—that occur in all atoms *except* hydrogen. [In the following discussion, keep in mind that more energy is needed to remove an electron from a more stable (lower energy) sublevel than from a less stable (higher energy) sublevel.]

The Effect of Nuclear Charge (*Z*) on Sublevel Energy

Higher charges interact more strongly than lower charges (Coulomb's law, Section 2.7). Therefore, *a higher nuclear charge (more protons in the nucleus) increases nucleus-electron attractions and, thus, lowers sublevel energy (stabilizes the atom).* We see this effect by comparing the 1*s* sublevel energies of three species with one electron—H atom ($Z = 1$), He^+ ion ($Z = 2$), and Li^{2+} ion ($Z = 3$). Figure 8.2 shows that the 1*s* sublevel in H is the least stable (highest energy), so the least energy is needed to remove its electron; and the 1*s* sublevel in Li^{2+} is the most stable, so the most energy is needed to remove its electron.

Shielding: The Effect of Electron Repulsions on Sublevel Energy

In many-electron atoms, each electron "feels" not only the attraction to the nucleus but also repulsions from other electrons. Repulsions counteract the nuclear attraction somewhat, making each electron easier to remove by, in effect, helping to push it away. We speak of each electron "shielding" the other electrons to some extent from the nuclear charge. **Shielding** (also called *screening*) reduces the full nuclear charge to an **effective nuclear charge (Z_{eff}),** the nuclear charge an electron *actually experiences, and this lower nuclear charge makes the electron easier to remove.*

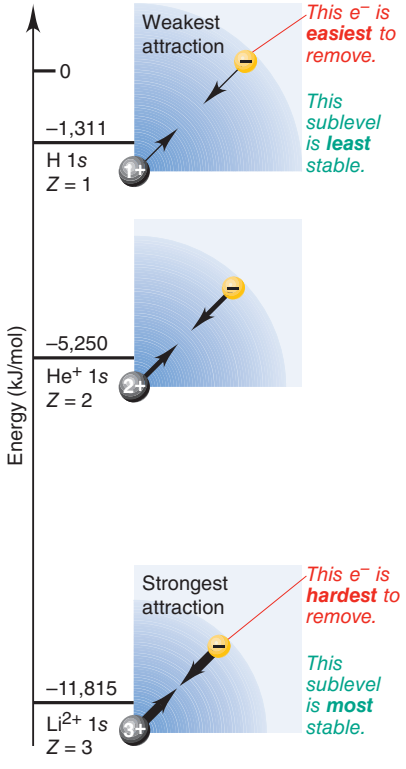

Figure 8.2 The effect of nuclear charge on sublevel energy. Greater nuclear charge lowers sublevel energy (to a more negative number), which makes the electron harder to remove. (The strength of attraction is indicated by the thickness of the black arrows.)

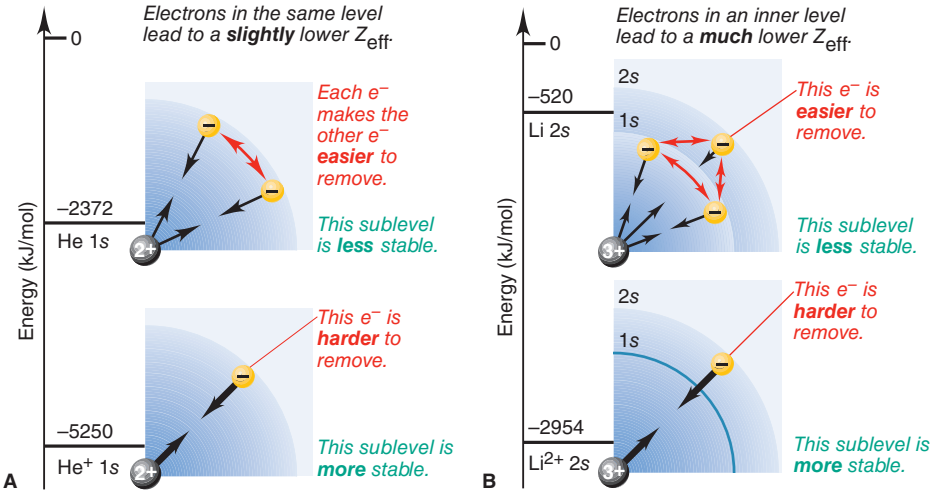

Figure 8.3 **Shielding and energy levels.** **A,** Within an energy level, each electron shields *(red arrows)* other electrons from the full nuclear charge *(black arrows)*, so they experience a lower Z_{eff}. **B,** Inner electrons shield outer electrons *much* more effectively than electrons in the same energy level.

1. *Shielding by other electrons in a given energy level.* Electrons in the *same* energy level shield each other somewhat. Compare the He atom and He^+ ion: both have a 2+ nuclear charge, but He has two electrons in the 1*s* sublevel and He^+ has only one (Figure 8.3A). It takes less than half as much energy to remove an electron from He (2372 kJ/mol) than from He^+ (5250 kJ/mol) because the second electron in He repels the first, in effect causing a lower Z_{eff}.

2. *Shielding by electrons in inner energy levels.* Because inner electrons spend nearly all their time *between* the outer electrons and the nucleus, they cause a *much* lower Z_{eff} than do electrons in the same level. We can see this by comparing two atomic systems with the same nucleus, one *with* inner electrons and the other *without.* The ground-state Li atom has two inner (1*s*) electrons and one outer (2*s*) electron, while the Li^{2+} ion has only one electron, which occupies the 2*s* orbital in the first excited state (Figure 8.3B). It takes about one-sixth as much energy to remove the 2*s* electron from the Li atom (520 kJ/mol) as it takes to remove it from the Li^{2+} ion (2954 kJ/mol), because the *inner electrons shield very effectively.*

Table 8.2 **Values of Z_{eff} for the Sublevels in Potassium ($Z = 19$)**

Sublevel	Z_{eff}
1*s*	18.49
2*s*	13.01
2*p*	15.03
3*s*	8.68
3*p*	7.73
4*s*	3.50

Table 8.2 lists the values of Z_{eff} for the electrons in a potassium atom. Although K ($Z = 19$) has a nuclear charge of 19+, all of its electrons have $Z_{eff} < 19$. The two innermost (1*s*) electrons have a slightly lower Z_{eff} of 18.49 because they shield each other. The outermost (4*s*) electron has a much lower Z_{eff} of 3.50, as a result of the effective shielding by the 18 inner electrons.

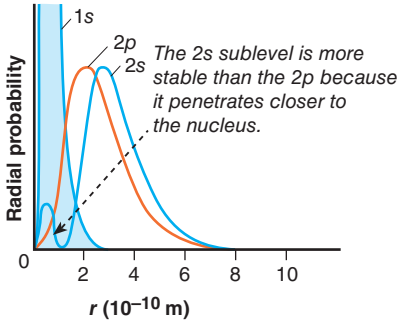

Figure 8.4 **Penetration and sublevel energy.**

Penetration: The Effect of Orbital Shape on Sublevel Energy To see why the third Li electron occupies the 2*s* sublevel rather than the 2*p*, we have to consider orbital shapes, that is, radial probability distributions (Figure 8.4). A 2*p* orbital *(orange curve)* is slightly closer to the nucleus, on average, than the major portion of the 2*s* orbital *(blue curve).* But a small portion of the 2*s* radial probability distribution peaks within the 1*s* region. Thus, an electron in the 2*s* orbital spends part of its time "penetrating" very close to the nucleus. **Penetration** has two effects:

- It *increases the nuclear attraction* for a 2*s* electron over that for a 2*p* electron.
- It *decreases the shielding* of a 2*s* electron by the 1*s* electrons.

Thus, since it takes more energy to remove a 2*s* electron (520 kJ/mol) than a 2*p* (341 kJ/mol), the 2*s* sublevel is lower in energy than the 2*p*.

Splitting of Levels into Sublevels In general, *penetration and the resulting effects on shielding split an energy level into sublevels of differing energy.* The lower the *l* value of a sublevel, the more its electrons penetrate, and so the greater their attraction to the nucleus. Therefore, *for a given n value, a lower l value indicates a more stable (lower energy) sublevel:*

Order of sublevel energies: $s < p < d < f$ **(8.1)**

Thus, the 2*s* ($l = 0$) is lower in energy than the 2*p* ($l = 1$), the 3*p* ($l = 1$) is lower than the 3*d* ($l = 2$), and so forth.

Figure 8.5 shows the general energy order of levels (n value) and how they are split into sublevels (l values) of differing energies. (Compare this with the H atom energy levels in Figure 7.21, p. 314.) Next, we'll use this energy order to construct a periodic table of ground-state atoms.

Summary of Section 8.1

- Identifying electrons in many-electron atoms requires four quantum numbers: three (n, l, m_l) describe the orbital, and a fourth (m_s) describes the electron's spin.
- The exclusion principle requires each electron to have a unique set of four quantum numbers; therefore, an orbital can hold no more than two electrons, and their spins must be paired (opposite).
- Electrostatic interactions determine sublevel energies as follows:
  1. Greater nuclear charge lowers sublevel energy, making electrons harder to remove.
  2. Electron-electron repulsions raise sublevel energy, making electrons easier to remove. Repulsions shield electrons from the full nuclear charge, reducing it to an effective nuclear charge, Z_{eff}. Inner electrons shield outer electrons very effectively.
  3. Penetration makes an electron harder to remove because nuclear attraction increases and shielding decreases. As a result, an energy level is split into sublevels with the energy order $s < p < d < f$.

8.2 THE QUANTUM-MECHANICAL MODEL AND THE PERIODIC TABLE

Quantum mechanics provides the theoretical foundation for the experimentally based periodic table. In this section, we fill the table by determining the *ground-state* electron configuration of each element—*the lowest-energy distribution of electrons in the sublevels of its atoms*. Note especially the *recurring pattern in electron configurations, which is the basis for recurring patterns in chemical behavior.*

A useful way to determine electron configurations is based on the **aufbau principle** (German *aufbauen,* "to build up"). We start at the beginning of the periodic table and add one proton to the nucleus and one electron to the *lowest energy sublevel available.* (Of course, one or more neutrons are also added to the nucleus.)

There are two common ways to indicate the distribution of electrons:

- *The electron configuration.* This shorthand notation consists of the principal energy level (n value), the letter designation of the sublevel (l value), and the number of electrons (#) in the sublevel, written as a superscript: $\boldsymbol{nl^{\#}}$**.**
- *The orbital diagram.* An **orbital diagram** consists of a box (or just a line) for each orbital in a given energy level, grouped by sublevel (with *nl* designation shown beneath), with an arrow representing an electron *and* its spin: ↑ is $+\frac{1}{2}$ and ↓ is $-\frac{1}{2}$. (Throughout the text, orbital occupancy is also indicated by color intensity: no color is empty, pale color is half-filled, and full color is filled.)

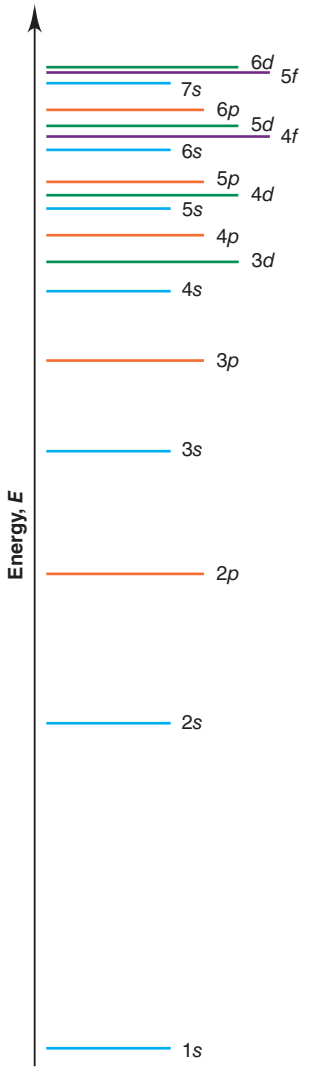

Figure 8.5 Order for filling energy sublevels with electrons. In general, energies of sublevels increase with the principal quantum number n ($1 < 2 < 3$, etc.) and the angular momentum quantum number l ($s < p < d < f$). As n increases, some sublevels overlap; for example, the 4*s* sublevel is lower in energy than the 3*d*. (Line color indicates sublevel type.)

Building Up Period 1

Let's begin by applying the aufbau principle to Period 1, whose ground-state elements have only the $n = 1$ level and, thus, only the 1*s* sublevel, which consists of only the 1*s* orbital. We'll also assign a set of four quantum numbers to each element's *last added* electron.

1. *Hydrogen.* For the electron in H, as you've seen, the set of quantum numbers is H ($Z = 1$): $n = 1, l = 0, m_l = 0, m_s = +\frac{1}{2}$. The electron configuration (spoken "one-ess-one") and orbital diagram are

$$\text{H}\,(Z = 1)\quad 1s^1 \qquad \underset{1s}{\boxed{\uparrow}}$$

2. *Helium.* Recall that the first electron in He has the same quantum numbers as the electron in H, but the second He electron has opposing spin (exclusion principle), giving He ($Z = 2$): $n = 1$, $l = 0$, $m_l = 0$, $m_s = -\frac{1}{2}$. The electron configuration (spoken "one-ess-two," *not* "one-ess-squared") and orbital diagram are

e ($Z = 2$) $1s^2$ ↑↓ (1*s*)

Building Up Period 2

The exclusion principle says an orbital can hold no more than two electrons. Therefore, with He, the 1*s* orbital, the 1*s* sublevel, the $n = 1$ level, and Period 1 are filled. Filling the $n = 2$ level builds up Period 2 and begins with the 2*s* sublevel, which is the next lowest in energy (see Figure 8.4) and consists of only the 2*s* orbital. When the 2*s* sublevel is filled, we proceed to fill the 2*p*.

1. *Lithium.* The first two electrons in Li fill the 1*s* sublevel, so the last added Li electron enters the 2*s* sublevel and has quantum numbers $n = 2$, $l = 0$, $m_l = 0$, $m_s = +\frac{1}{2}$. The electron configuration and orbital diagram are

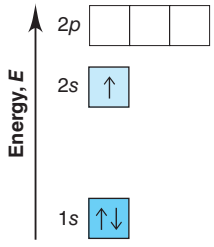

Figure 8.6 A vertical orbital diagram for the Li ground state.

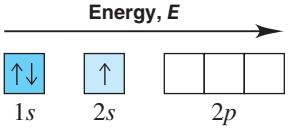
Li ($Z = 3$) $1s^2 2s^1$



(Note that a complete orbital diagram shows all the orbitals for the given *n* value, whether or not they are occupied.) To save space on a page, orbital diagrams are written horizontally, with *the sublevel energy increasing left to right*. But Figure 8.6 highlights the energy increase with a vertical orbital diagram for lithium.

2. *Beryllium.* The 2*s* orbital is only half-filled in Li, so the fourth electron of beryllium fills it with the electron's spin paired: $n = 2$, $l = 0$, $m_l = 0$, $m_s = -\frac{1}{2}$.

Be ($Z = 4$) $1s^2 2s^2$ ↑↓ ↑↓ | | | (1*s*, 2*s*, 2*p*)

3. *Boron.* The next lowest energy sublevel is the 2*p*. A *p* sublevel has $l = 1$, so the m_l (orientation) values can be -1, 0, or $+1$. The three orbitals in the 2*p* sublevel have *equal energy* (same *n* and *l* values), which means that the fifth electron of boron can go into *any one of the 2p orbitals.* For convenience, let's label the boxes from left to right: -1, 0, $+1$. By convention, we start on the left and place the fifth electron in the $m_l = -1$ orbital: $n = 2$, $l = 1$, $m_l = -1$, $m_s = +\frac{1}{2}$.

B ($Z = 5$) $1s^2 2s^2 2p^1$ ↑↓ ↑↓ | ↑ | | (−1 0 +1; 1*s*, 2*s*, 2*p*)

4. *Carbon.* To minimize electron-electron repulsions, the sixth electron of carbon enters one of the *unoccupied* 2*p* orbitals; by convention, we place it in the $m_l = 0$ orbital. Experiment shows that the spin of this electron is *parallel* to (the same as) the spin of the other 2*p* electron. This fact exemplifies **Hund's rule:** *when orbitals of equal energy are available, the electron configuration of lowest energy has the maximum number of unpaired electrons with parallel spins*. Thus, the sixth electron of carbon has $n = 2$, $l = 1$, $m_l = 0$, and $m_s = +\frac{1}{2}$.

C ($Z = 6$) $1s^2 2s^2 2p^2$ ↑↓ ↑↓ | ↑ | ↑ | (1*s*, 2*s*, 2*p*)

5. *Nitrogen.* Based on Hund's rule, nitrogen's seventh electron enters the last empty 2*p* orbital, with its spin parallel to the other two: $n = 2$, $l = 1$, $m_l = +1$, $m_s = +\frac{1}{2}$.

N ($Z = 7$) $1s^2 2s^2 2p^3$ ↑↓ ↑↓ | ↑ | ↑ | ↑ | (1*s*, 2*s*, 2*p*)

6. *Oxygen.* The eighth electron in oxygen must enter one of the three half-filled $2p$ orbitals and "pair up" with (oppose the spin of) the electron present. We place the electron in the first half-filled $2p$ orbital: $n = 2$, $l = 1$, $m_l = -1$, $m_s = -\frac{1}{2}$.

O ($Z = 8$) $1s^2 2s^2 2p^4$

7. *Fluorine.* Fluorine's ninth electron enters the next of the two remaining half-filled $2p$ orbitals: $n = 2$, $l = 1$, $m_l = 0$, $m_s = -\frac{1}{2}$.

F ($Z = 9$) $1s^2 2s^2 2p^5$

8. *Neon.* Only one half-filled $2p$ orbital remains, so the tenth electron of neon occupies it: $n = 2$, $l = 1$, $m_l = +1$, $m_s = -\frac{1}{2}$. With neon, the $n = 2$ level is filled.

Ne ($Z = 10$) $1s^2 2s^2 2p^6$

SAMPLE PROBLEM 8.1 Correlating Quantum Numbers and Orbital Diagrams

Problem Use the orbital diagram shown above to write sets of quantum numbers for the third and eighth electrons of the F atom.

Plan Referring to the orbital diagram, we identify the electron of interest and note its level (n), sublevel (l), orbital (m_l), and spin (m_s).

Solution The third electron is in the $2s$ orbital. The upward arrow indicates a spin of $+\frac{1}{2}$:

$$n = 2, l = 0, m_l = 0, m_s = +\tfrac{1}{2}$$

The eighth electron is in the first $2p$ orbital, which is designated $m_l = -1$, and has a downward arrow:

$$n = 2, l = 1, m_l = -1, m_s = -\tfrac{1}{2}$$

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

8.1A Use the periodic table to identify the element with the electron configuration $1s^2 2s^2 2p^4$. Write its orbital diagram and the set of quantum numbers for its sixth electron.

8.1B The last electron added to an atom has the following set of quantum numbers: $n = 2$, $l = 1$, $m_l = 0$, $m_s = +\frac{1}{2}$. Identify the element, and write its electron configuration and orbital diagram.

SOME SIMILAR PROBLEMS 8.21(d) and 8.22(a) and (d)

With our attention on these notations, it's easy to forget that atoms are real objects and electrons occupy volumes with specific shapes and orientations. Figure 8.7 on the next page shows orbital contours for the first 10 elements arranged in periodic table format.

Even now, we can make an important correlation: *elements in the same group have similar outer electron configurations and similar patterns of reactivity*. As an example, helium (He) and neon (Ne) in Group 8A(18) both have filled outer sublevels—$1s^2$ for helium and $2s^2 2p^6$ for neon—and neither element forms compounds. In general, we find that filled outer sublevels make elements much more stable and unreactive.

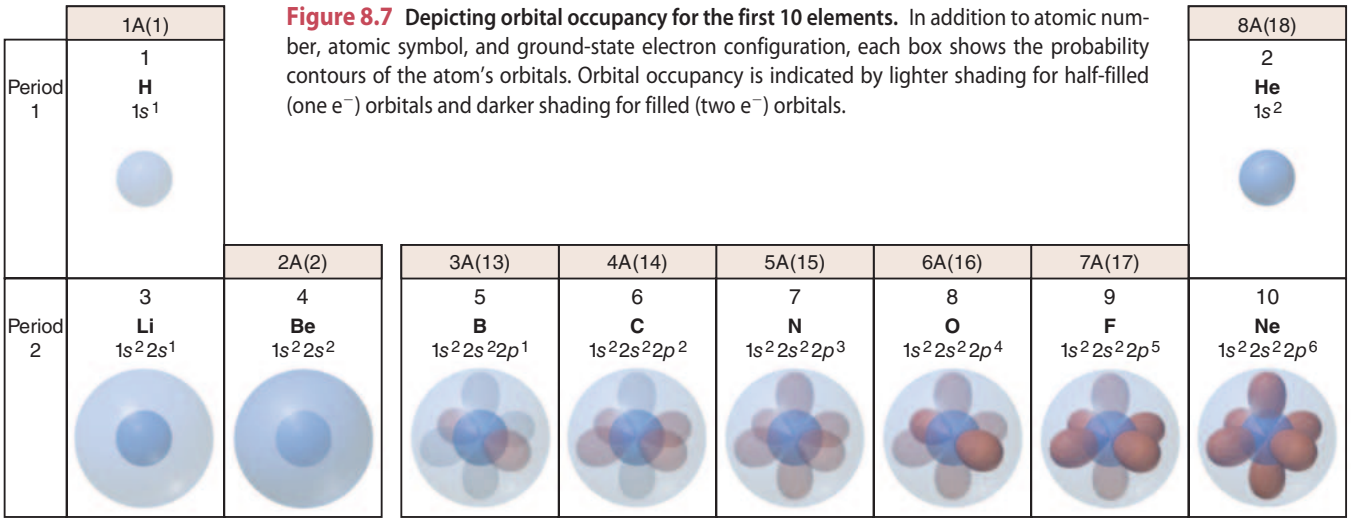


Figure 8.7 Depicting orbital occupancy for the first 10 elements. In addition to atomic number, atomic symbol, and ground-state electron configuration, each box shows the probability contours of the atom's orbitals. Orbital occupancy is indicated by lighter shading for half-filled (one e^-) orbitals and darker shading for filled (two e^-) orbitals.

Building Up Period 3

The Period 3 elements, Na through Ar, lie directly under the Period 2 elements, Li through Ne. That is, even though the $n = 3$ level splits into 3*s*, 3*p*, and 3*d* sublevels, Period 3 fills only 3*s* and 3*p*; as you'll see shortly, the 3*d* is filled in Period 4. Table 8.3 introduces two ways to present electron distributions more concisely:

- *Partial orbital diagrams* show only the sublevels being filled, here the 3*s* and 3*p*.
- *Condensed electron configurations (rightmost column)* have the element symbol of the previous noble gas in brackets, to stand for its configuration, followed by the electron configuration of filled inner sublevels and the energy level being filled. For example, the condensed electron configuration of sulfur is [Ne] $3s^2 3p^4$, where [Ne] stands for $1s^2 2s^2 2p^6$.

In Na (the second alkali metal) and Mg (the second alkaline earth metal), electrons are added to the 3*s* sublevel, which contains only the 3*s* orbital; this is directly comparable to the filling of the 2*s* sublevel in Li and Be in Period 2. Then, in the same

Figure 8.8 Condensed electron configurations in the first three periods. Elements in a group have similar outer electron configurations (*color*).

way as the 2*p* orbitals of B, C, and N in Period 2 are half-filled, the last electrons added to Al, Si, and P in Period 3 half-fill successive 3*p* orbitals with spins parallel (Hund's rule). The last electrons added to S, Cl, and Ar then successively pair up to fill those 3*p* orbitals, and thus the 3*p* sublevel.

Similar Electron Configurations Within Groups

One of the central points in chemistry is that *similar outer electron configurations correlate with similar chemical behavior.* Figure 8.8 shows the condensed electron configurations of the first 18 elements. Note the similarity within each group. Here are examples from three of the groups:

- In Group 1A(1), Li and Na have the outer electron configuration ns^1 (where n is the quantum number of the highest energy level), as do the other alkali metals (K, Rb, Cs, and Fr). All are highly reactive metals whose atoms lose the outer electron when they form ionic compounds with nonmetals, and all react vigorously with water to displace H_2 (Figure 8.9A).
- In Group 7A(17), F and Cl have the outer electron configuration ns^2np^5, as do the other halogens (Br, I, and At). All are reactive nonmetals that occur as diatomic molecules (X_2), and all form ionic compounds with metals (KX, MgX_2) in which their ionic charge is 1− (Figure 8.9B), covalent compounds with hydrogen (HX) that yield acidic solutions in water, and covalent compounds with carbon (CX_4).
- In Group 8A(18), He has the electron configuration ns^2, and all the other elements in the group have the outer configuration ns^2np^6. Consistent with their *filled* energy levels, all the members are very unreactive monatomic gases.

To summarize the major connection between quantum mechanics and chemical periodicity: *sublevels are filled in order of increasing energy, which leads to outer electron configurations that recur periodically, which leads to chemical properties that recur periodically.*

Building Up Period 4: The First Transition Series

Period 4 contains the first series of **transition elements,** those in which *d* orbitals are being filled. Let's examine three factors that affect the filling pattern in a period with a transition series; we focus on Period 4, but similar effects occur in Periods 5–7.

1. *Effects of shielding and penetration on sublevel energy.* The 3*d* sublevel is filled in Period 4, but *the 4s sublevel is filled first.* This switch in filling order is due to shielding and penetration effects. Based on the 3*d* radial probability distribution (see Figure 7.19, p. 313), a 3*d* electron spends most of the time outside the filled inner $n = 1$ and $n = 2$ levels, so it is shielded very effectively from the nuclear charge. However, the outermost 4*s* electron penetrates close to the nucleus part of the time, so it is subject to a greater attraction. As a result, the 4*s* orbital is slightly *lower* in energy than the 3*d* and fills first. In any period, *the ns sublevel fills before the* $(n - 1)d$ *sublevel.* Other variations in the filling pattern occur at higher values of *n* because sublevel energies become very close together (see Figure 8.5).

2. *Filling the 4s and 3d sublevels.* Table 8.4 shows the partial orbital diagrams and full and condensed electron configurations for the 18 elements in Period 4. The first two elements, K and Ca, are the next alkali and alkaline earth metals, respectively; the last electron of K half-fills and that of Ca fills the 4*s* sublevel. The last electron of

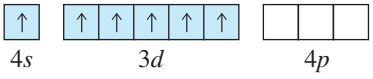
*Colored type indicates sublevel(s) whose occupancy changes when the last electron is added.

scandium (Sc; $Z = 21$), the first transition element, occupies any one of the five $3d$ orbitals because they are equal in energy; Sc has the electron configuration [Ar] $4s^2 3d^1$. Filling of the $3d$ orbitals proceeds one electron at a time, as with the p orbitals, except in two cases, chromium (Cr; $Z = 24$) and copper (Cu; $Z = 29$), discussed next.

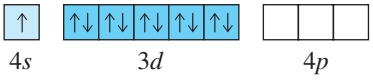
3. *Stability of half-filled and filled sublevels.* Vanadium (V; $Z = 23$) has three half-filled d orbitals ([Ar] $4s^2 3d^3$). However, the last electron of the next element, Cr, does not enter a fourth empty d orbital to give [Ar] $4s^2 3d^4$; instead, Cr has one electron in the $4s$ sublevel and five in the $3d$ sublevel, making both sublevels half-filled: [Ar] $4s^1 3d^5$ *(see margin).* In the next element, manganese (Mn; $Z = 25$), the $4s$ sublevel is filled again ([Ar] $4s^2 3d^5$).

Cr ($Z = 24$) [Ar] $4s^1 3d^5$



Because it follows nickel (Ni; [Ar] $4s^2 3d^8$), copper would be expected to have the configuration [Ar] $4s^2 3d^9$. Instead, the $4s$ sublevel of Cu is *half-filled* with 1 electron, and the $3d$ sublevel is *filled* with 10 *(see margin)*. From these two exceptions, Cr and Cu, we conclude that *half-filled and filled sublevels are unexpectedly stable (low in energy);* we see this pattern with many other elements.

Cu ($Z = 29$) [Ar] $4s^1 3d^{10}$



With zinc (Zn; $Z = 30$), the $4s$ sublevel is filled ([Ar] $4s^2 3d^{10}$), and the first transition series ends. The $4p$ sublevel is filled in the next six elements, and Period 4 ends with the noble gas krypton (Kr; $Z = 36$).

General Principles of Electron Configurations

Figure 8.10 shows the partial (highest energy sublevels being filled) ground-state electron configurations of the 118 known elements. Let's highlight some key relationships among them.

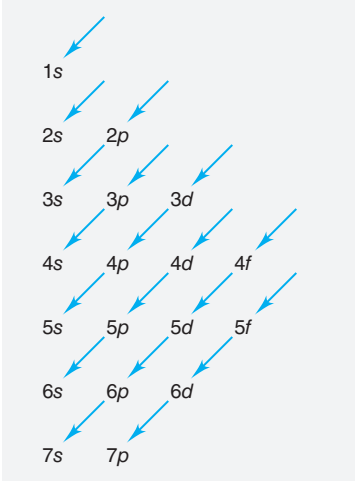
Similar Outer Electron Configurations Within a Group Among the main-group elements (A groups)—the *s*-block and *p*-block elements—outer electron configurations within a group are identical. Some variations in the transition elements (B groups, *d* block) and inner transition elements (*f* block) occur, as we'll see.

Orbital Filling Order When the elements are "built up" by filling levels and sublevels in order of increasing energy, we obtain the sequence in the periodic table. Reading the table from left to right, like words on a page, gives the energy order of levels and sublevels (Figure 8.11); the margin note shows a memory aid for recalling sublevel filling order when a periodic table is not available.

Aid to Memorizing Sublevel Filling Order

List the sublevels as shown, and read from 1*s*, following the direction of the arrows. Note that the

- *n* value is constant horizontally
- *l* value is constant vertically
- $n + l$ is constant diagonally



Categories of Electrons Atoms have three categories of electrons:

1. **Inner (core) electrons** are those an atom has in common with the previous noble gas and any *completed* transition series. They fill all the *lower energy levels* of an atom.
2. **Outer electrons** are those in the *highest energy level* (highest *n* value). They spend most of their time farthest from the nucleus.
3. **Valence electrons** are those involved in forming compounds:
   - For main-group elements, the *valence electrons* ***are*** *the outer electrons*.
   - For transition elements, in addition to the outer *ns* electrons, the $(n - 1)d$ electrons are also valence electrons, though the metals Fe ($Z = 26$) through Zn ($Z = 30$) may use only a few, if any, of their *d* electrons in bonding.

Group and Period Numbers Key information is embedded in the periodic table:

- Among the main-group elements (A groups), *the A number equals the number of outer electrons* (those with the highest *n*); thus, chlorine (Cl; Group **7**A) has 7 outer electrons, and so forth.
- *The period number is the n value of the highest energy level.*
- For an energy level, the *n* value squared (n^2) is the number of *orbitals,* and $2n^2$ is the maximum number of *electrons* (or elements). For example, consider the $n = 3$ level. The number of orbitals is $n^2 = 9$: one 3*s,* three 3*p,* and five 3*d*. The number of electrons is $2n^2 = 18$: two 3*s* and six 3*p* electrons for the eight elements of Period 3, and ten 3*d* electrons for the ten transition elements of Period 4.

Intervening Series: Transition and Inner Transition Elements

As Figure 8.11 shows, the *d* block and *f* block occur between the main-group *s* and *p* blocks.

1. *Transition series.* Periods 4, 5, 6, and 7 incorporate the 3*d,* 4*d,* 5*d,* and 6*d* sublevels, respectively. As you've seen, the general pattern is that the $(n - 1)d$ sublevel is filled between the *ns* and *np* sublevels. Thus, in Period 5, the filling order is 5*s,* then 4*d,* and then 5*p*.

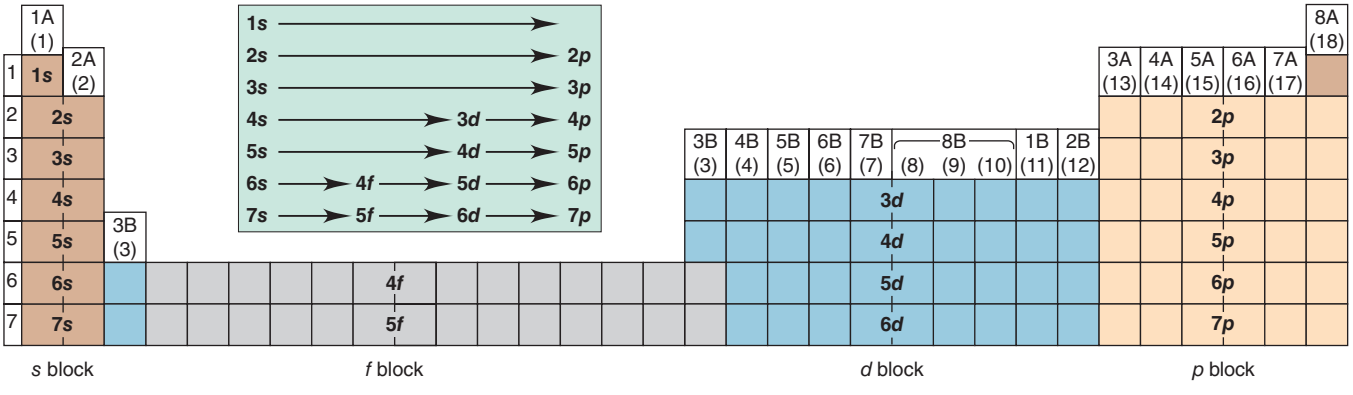


Figure 8.11 Orbital filling and the periodic table. This form of the periodic table shows the sublevel blocks. *Pale green inset:* A summary of the sublevel filling order.

2. *Inner transition series.* Period 6 contains the first of two series of **inner transition elements,** those in which *f* orbitals are being filled (Figure 8.11). The *f* orbitals have $l = 3$, so the possible m_l values are -3, -2, -1, 0, $+1$, $+2$, and $+3$; that is, there are seven *f* orbitals, for a total of 14 elements in *each* of the two inner transition series:

- The Period 6 inner transition series, called the **lanthanides** (or **rare earths**), occurs after lanthanum (La; $Z = 57$), and in it the 4*f* orbitals are filled.
- The Period 7 inner transition series, called the **actinides,** occurs after actinium (Ac; $Z = 89$), and in it the 5*f* orbitals are filled.

Thus, in Periods 6 and 7, the filling sequence is

ns, first of the $(n - 1)d$, all $(n - 2)f$, remainder of the $(n - 1)d$, and *np*

Period 6 ends with the 6*p* sublevel, and Period 7 ends with the 7*p* sublevel.

3. *Irregular filling patterns.* Irregularities in the filling pattern, such as those for Cr and Cu in Period 4, occur in the *d* and *f* blocks because the sublevel energies in these larger atoms differ very little. Even though occasional deviations occur in the *d* block, the sum of *ns* electrons and $(n - 1)d$ electrons always equals the new group number (in parentheses). For instance, despite variations in Group 6B(**6**)—Cr, Mo, W, and Sg—the sum of *ns* and $(n - 1)d$ electrons is 6; for Group 8B(**10**)—Ni, Pd, Pt, and Ds—the sum is 10.

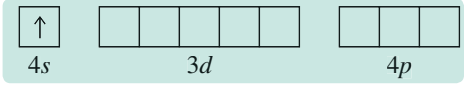
SAMPLE PROBLEM 8.2 Determining Electron Configurations

Problem Using only the periodic table (not Figure 8.10 or Table 8.4) and assuming a regular filling pattern, give the full and condensed electron configurations, partial orbital diagrams showing valence electrons only, and number of inner electrons for the following elements:

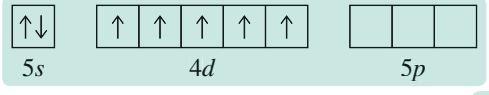
(a) Potassium (K; $Z = 19$) **(b)** Technetium (Tc; $Z = 43$) **(c)** Lead (Pb; $Z = 82$)

Plan The atomic number tells us the number of electrons, and the periodic table shows the order for filling sublevels. In the partial orbital diagrams, we include all electrons added after the previous noble gas *except* those in *filled* inner sublevels. The number of inner electrons is the sum of those in the previous noble gas and in filled *d* and *f* sublevels.

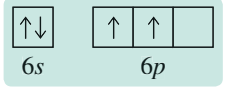
Solution **(a)** For K ($Z = 19$), the full electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$.
The condensed configuration is [Ar] $4s^1$.
The partial orbital diagram showing valence electrons is



K is a main-group element in Group 1A(1) and Period 4, so there are 18 inner electrons.
(b) For Tc ($Z = 43$), assuming the expected pattern, the full electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^5$.
The condensed electron configuration is [Kr] $5s^2 4d^5$.
The partial orbital diagram showing valence electrons is



Tc is a transition element in Group 7B(7) and Period 5, so there are 36 inner electrons.
(c) For Pb ($Z = 82$), the full electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6 6s^2 4f^{14} 5d^{10} 6p^2$.
The condensed electron configuration is [Xe] $6s^2 4f^{14} 5d^{10} 6p^2$.
The partial orbital diagram showing valence electrons (no filled inner sublevels) is



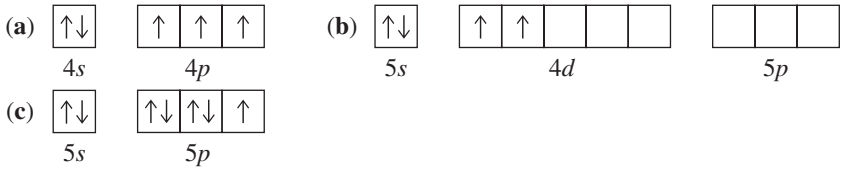
Pb is a main-group element in Group 4A(14) and Period 6, so there are 54 (in Xe) + 14 (in the 4*f* sublevel) + 10 (in the 5*d* sublevel) = 78 inner electrons.

Check Be sure that the sum of the superscripts (numbers of electrons) in the full electron configuration equals the atomic number and that the number of *valence* electrons in the condensed configuration equals the number of electrons in the partial orbital diagram.

FOLLOW-UP PROBLEMS

8.2A Without referring to Table 8.4 or Figure 8.10, give full and condensed electron configurations, partial orbital diagrams showing valence electrons only, and the number of inner electrons for the following elements:
(a) Ni ($Z = 28$) **(b)** Sr ($Z = 38$) **(c)** Po ($Z = 84$)

8.2B From each partial orbital diagram (valence electrons only), identify the element and give its full and condensed electron configuration and the number of inner electrons. Use only the periodic table, without referring to Table 8.4 or Figure 8.10.



SOME SIMILAR PROBLEMS 8.23–8.36

Summary of Section 8.2

- By the aufbau principle, one electron is added to an atom of each successive element in accord with the exclusion principle (no two electrons can have the same set of quantum numbers) and Hund's rule (orbitals of equal energy become half-filled, with electron spins parallel, before any pairing of spins occurs).
- The elements of a group have similar outer electron configurations and similar chemical behavior.
- For the main-group elements, valence electrons (those involved in reactions) are in the outer (highest energy) level only. For transition elements, $(n - 1)d$ electrons are also considered valence electrons.
- Because of shielding of *d* electrons by electrons in inner sublevels and penetration by the *ns* electron, the $(n - 1)d$ sublevel fills after the *ns* and before the *np* sublevels.
- In Periods 6 and 7, $(n - 2)f$ orbitals fill between the first and second $(n - 1)d$ orbitals.

8.3 TRENDS IN THREE ATOMIC PROPERTIES

In this section, we focus on three atomic properties directly influenced by electron configuration and effective nuclear charge: atomic size, ionization energy, and electron affinity. Most importantly, these properties are *periodic,* which means they generally exhibit consistent changes, or *trends,* within a group or period.

Trends in Atomic Size

Recall from Chapter 7 that we often represent atoms with spherical contours in which the electrons spend 90% of their time. We *define* **atomic size** (the extent of the contour) in terms of how closely one atom lies next to another. But, in practice, as we discuss in Chapter 12, we measure the distance between atomic nuclei in a sample of an element and divide that distance in half. Because atoms do not have hard surfaces, the size of an atom in a given compound depends somewhat on the atoms near it. In other words, *atomic size varies slightly from substance to substance.*

Figure 8.12 shows two common definitions of atomic size:

1. **Metallic radius.** Used mostly for *metals,* it is one-half the shortest distance between nuclei of adjacent, individual atoms in a crystal of the element (Figure 8.12A).
2. **Covalent radius.** Used for elements occurring as molecules, mostly *nonmetals,* it is one-half the shortest distance between nuclei of bonded atoms (Figure 8.12B).

Radii measured for some elements are used to determine the radii of other elements from the distances between the atoms in compounds. For instance, in a carbon-chlorine compound, the distance between nuclei in a C—Cl bond is 177 pm. Using the known covalent radius of Cl (100 pm), we find the covalent radius of C (177 pm − 100 pm = 77 pm) (Figure 8.12C).

Main-Group Elements Figure 8.13 shows the atomic radii of the main-group elements and most of the transition elements. Among the main-group elements, atomic size varies within both groups and periods as a result of two opposing influences:

1. *Changes in n.* As the principal quantum number (n) increases, the probability that outer electrons spend most of their time farther from the nucleus increases as well; thus, *atomic size increases.*
2. *Changes in* Z_{eff}. As the effective nuclear charge (Z_{eff}) increases, outer electrons are pulled closer to the nucleus; thus, *atomic size decreases.*

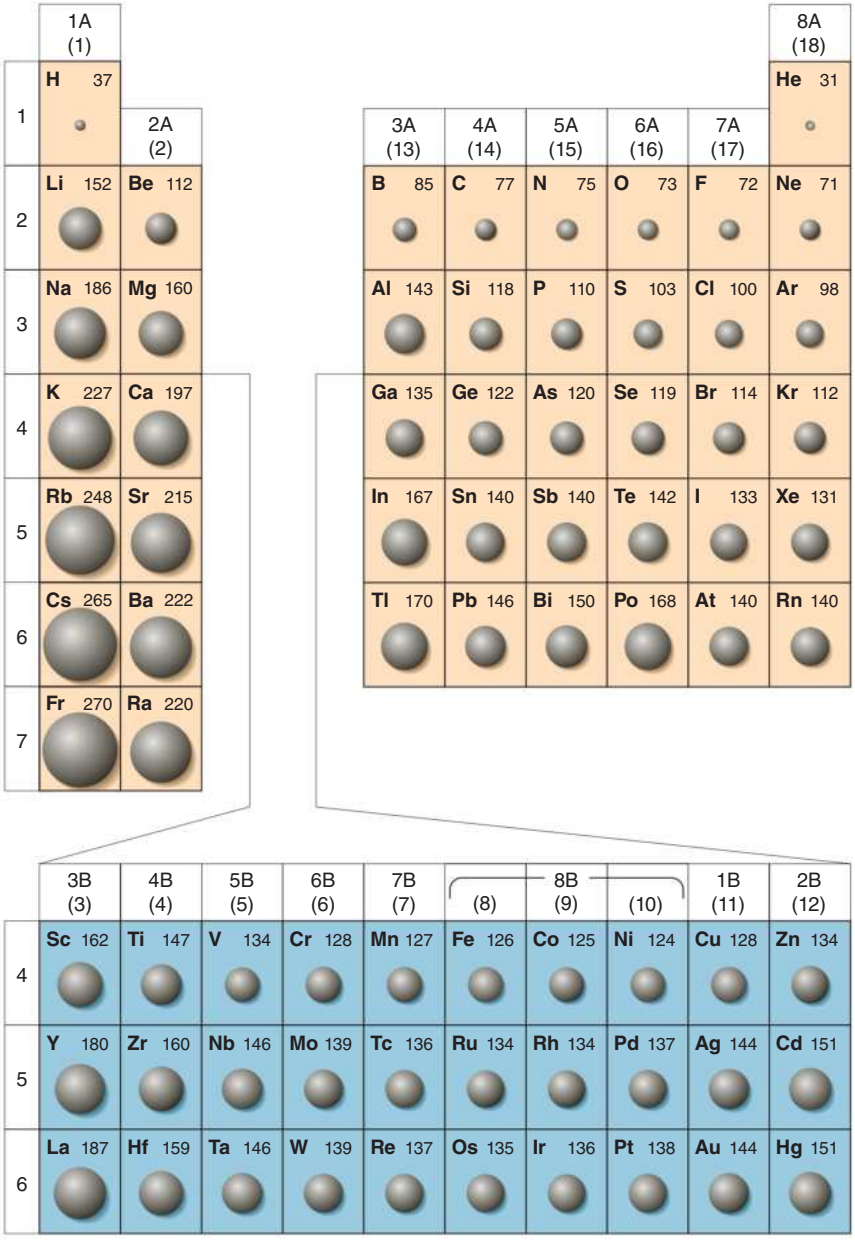

Figure 8.13 Atomic radii of the main-group and transition elements. Atomic radii (in picometers) are shown for the main-group elements *(tan)* and the transition elements *(blue)*. (Values for the noble gases are calculated.)

The net effect of these influences depends on how effectively the inner electrons shield the increasing nuclear charge:

1. *Down a group, n dominates.* As we move down a main group, each member has *one more level of inner electrons that shield the outer electrons very effectively*. Even though additional protons do moderately increase Z_{eff} for the outer electrons, the atoms get larger as a result of the increasing n value:

Atomic radius generally ***increases*** *down a group.*

2. *Across a period, Z_{eff} dominates.* Across a period from left to right, electrons are added to the *same* outer level, so the shielding by inner electrons does not change. Despite greater electron repulsions, outer electrons shield each other only slightly, so Z_{eff} rises significantly, and the outer electrons are pulled closer to the nucleus:

Atomic radius generally ***decreases*** *across a period.*

Transition Elements As Figure 8.13 shows, size trends are *not* as consistent for the transition elements:

1. *Down a transition group, n* increases, but shielding by an additional level of inner electrons results in only a small size increase from Period 4 to 5 and none from 5 to 6.

2. *Across a transition series*, atomic size shrinks through the first two or three elements because of the increasing nuclear charge. But, from then on, *size remains relatively constant* because shielding by the inner *d* electrons counteracts the increase in Z_{eff}. Thus, for example, in Period 4, the third transition element, vanadium (V; $Z = 23$), has the same radius as the last, zinc (Zn; $Z = 30$). This pattern also appears in Periods 5 and 6 in the transition and both inner transition series.

3. *A transition series affects atomic size in neighboring main groups*. Shielding by *d* electrons causes a *major size decrease from Group 2A(2) to Group 3A(13)* in Periods 4 through 6. Because the *np* sublevel has more penetration than the $(n - 1)d$, the first *np* electron [added in Group 3A(13)] "feels" a much greater Z_{eff}, due to all the protons added in the intervening transition elements. The greatest decrease occurs in Period 4: calcium (Ca; $Z = 20$) in Group 2A(2) is nearly 50% larger than gallium (Ga; $Z = 31$) in 3A(13). In fact, *d*-orbital shielding causes gallium to be slightly *smaller* than aluminum (Al; $Z = 13$), the element above it!

SAMPLE PROBLEM 8.3 Ranking Elements by Atomic Size

Problem Using only the periodic table (not Figure 8.13), rank each set of main-group elements in order of *decreasing* atomic size:
(a) Ca, Mg, Sr **(b)** K, Ga, Ca **(c)** Br, Rb, Kr **(d)** Sr, Ca, Rb

Plan To rank the elements by atomic size, we find them in the periodic table. They are main-group elements, so size increases down a group and decreases across a period.

Solution **(a)** Sr > Ca > Mg. These three elements are in Group 2A(2), and size decreases up the group.
(b) K > Ca > Ga. These three elements are in Period 4, and size decreases across a period.
(c) Rb > Br > Kr. Rb is largest because it has one more energy level (Period 5) and is farthest to the left. Kr is smaller than Br because Kr is farther to the right in Period 4.
(d) Rb > Sr > Ca. Ca is smallest because it has one fewer energy level. Sr is smaller than Rb because it is farther to the right.

Check From Figure 8.13, we see that the rankings are correct.

FOLLOW-UP PROBLEMS

8.3A Using only the periodic table, rank the elements in each set in order of *increasing* size: **(a)** Se, Br, Cl; **(b)** I, Xe, Ba.

8.3B Using only the periodic table, rank the elements in each set in order of *decreasing* size: **(a)** As, Cs, S; **(b)** F, P, K.

SOME SIMILAR PROBLEMS 8.53 and 8.54

Periodicity of Atomic Size Figure 8.14 shows the variation in atomic size with atomic number. Note the up-and-down pattern as size drops across a period to the noble gas *(purple)* and then leaps up to the alkali metal *(brown)* that begins the next period. Also note the deviations from the smooth size decrease in each transition *(blue)* and inner transition *(green)* series.

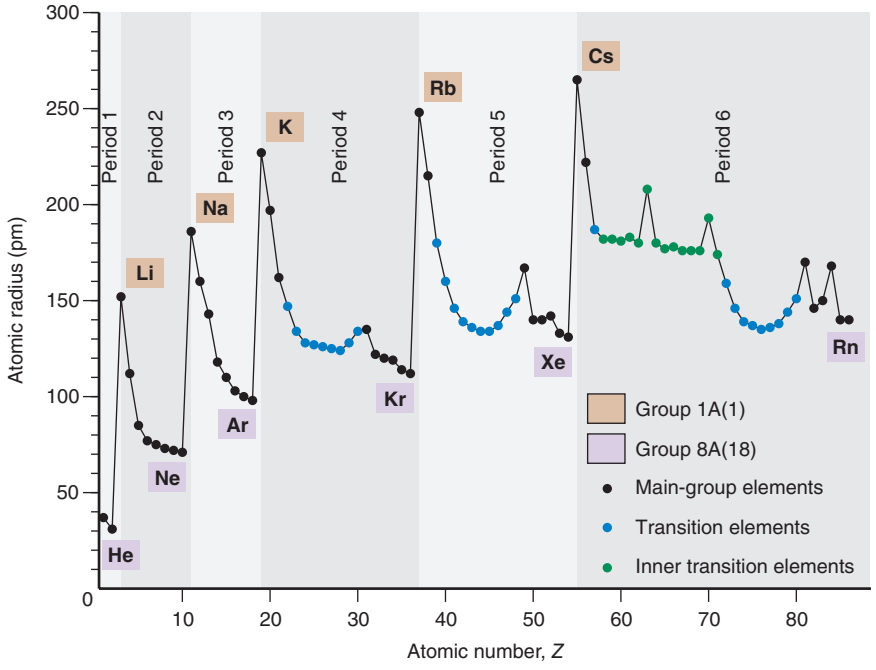

Figure 8.14 Periodicity of atomic radius.

Trends in Ionization Energy

The **ionization energy (IE)** is the energy required for the *complete removal* of 1 mol of electrons from 1 mol of gaseous atoms or ions. Pulling an electron away from a nucleus *requires* energy to overcome their electrostatic attraction. Because energy flows *into* the system, the ionization energy is always positive (like ΔH of an endothermic reaction). (Chapter 7 viewed the ionization energy of the H atom as the energy difference between $n = 1$ and $n = \infty$, where the electron is completely removed.) The ionization energy is a key factor in an element's reactivity:

- *Atoms with a low IE tend to form cations during reactions.*
- *Atoms with a high IE (except the noble gases) tend to form anions.*

Many-electron atoms can lose more than one electron. The *first* ionization energy (IE_1) removes an outermost electron (highest energy sublevel) from a gaseous atom:

$$\text{Atom}(g) \longrightarrow \text{ion}^+(g) + e^- \qquad \Delta E = IE_1 > 0 \tag{8.2}$$

The *second* ionization energy (IE_2) removes a second electron. Since this electron is pulled away from a positive ion, IE_2 is always larger than IE_1:

$$\text{Ion}^+(g) \longrightarrow \text{ion}^{2+}(g) + e^- \qquad \Delta E = IE_2 \,(\text{always} > IE_1)$$

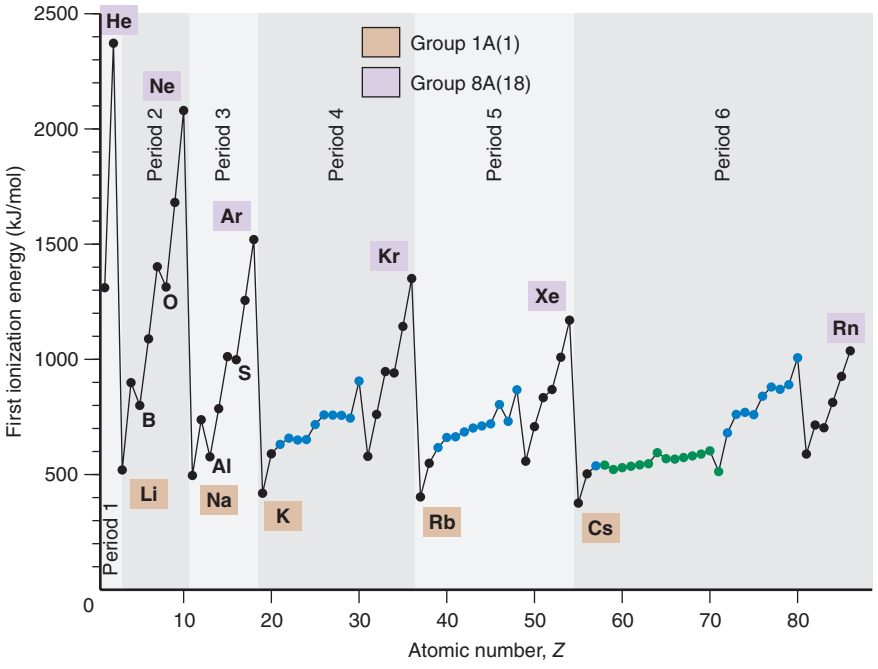

Figure 8.15 Periodicity of first ionization energy (IE_1). This trend is the *inverse* of the trend in atomic size (see Figure 8.14).

Periodicity of First Ionization Energy Figure 8.15 shows the variation in first ionization energy with atomic number. This up-and-down pattern—IE_1 rising across a period to the noble gas *(purple)* and then dropping down to the next alkali metal *(brown)*—is the *inverse* of the variation in atomic size (Figure 8.14): *as size decreases, it takes more energy to remove an electron because the nucleus is closer, so IE_1 increases.*

Let's examine the group and period trends and their exceptions:

1. *Down a group.* As we move *down* a main group, the *n* value increases, so atomic size does as well. As the distance from nucleus to outer electron increases, their attraction lessens, so the electron is easier to remove (Figure 8.16):

Ionization energy generally ***decreases*** *down a group.*

The only significant exception occurs in Group 3A(13): IE_1 decreases from boron (B) to aluminum (Al), but not for the rest of the group. Filling the transition series in Periods 4, 5, and 6 causes a much higher Z_{eff} and an unusually small change in size, so outer electrons in the larger Group 3A members are held tighter.

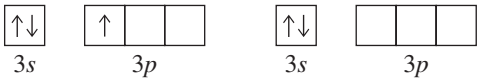
2. *Across a period.* As we move left to right across a period, Z_{eff} increases and atomic size decreases. The attraction between nucleus and outer electron increases, so the electron is harder to remove:

Ionization energy generally ***increases*** *across a period.*

There are two exceptions to the otherwise smooth increase in IE_1 across periods:

- In Periods 2 and 3, there are dips at the Group 3A(13) elements, B and Al. These elements have the first *np* electrons, which are removed more easily because the resulting ion has a filled (stable) *ns* sublevel. For Al, for example,

$$\text{Al ([Ne] } 3s^2 3p^1) \longrightarrow \text{Al}^+ \text{ ([Ne] } 3s^2) + e^-$$



- In Periods 2 and 3, once again, there are dips at the Group 6A(16) elements, O and S. These elements have a fourth *np* electron, the first to pair up with another *np* electron, and electron-electron repulsions raise the orbital energy. The fourth *np* electron is easier to remove because doing so relieves the repulsions and leaves a half-filled (stable) *np* sublevel. For S, for example,

$$\text{S ([Ne] } 3s^2 3p^4) \longrightarrow \text{S}^+ \text{ ([Ne] } 3s^2 3p^3) + e^-$$

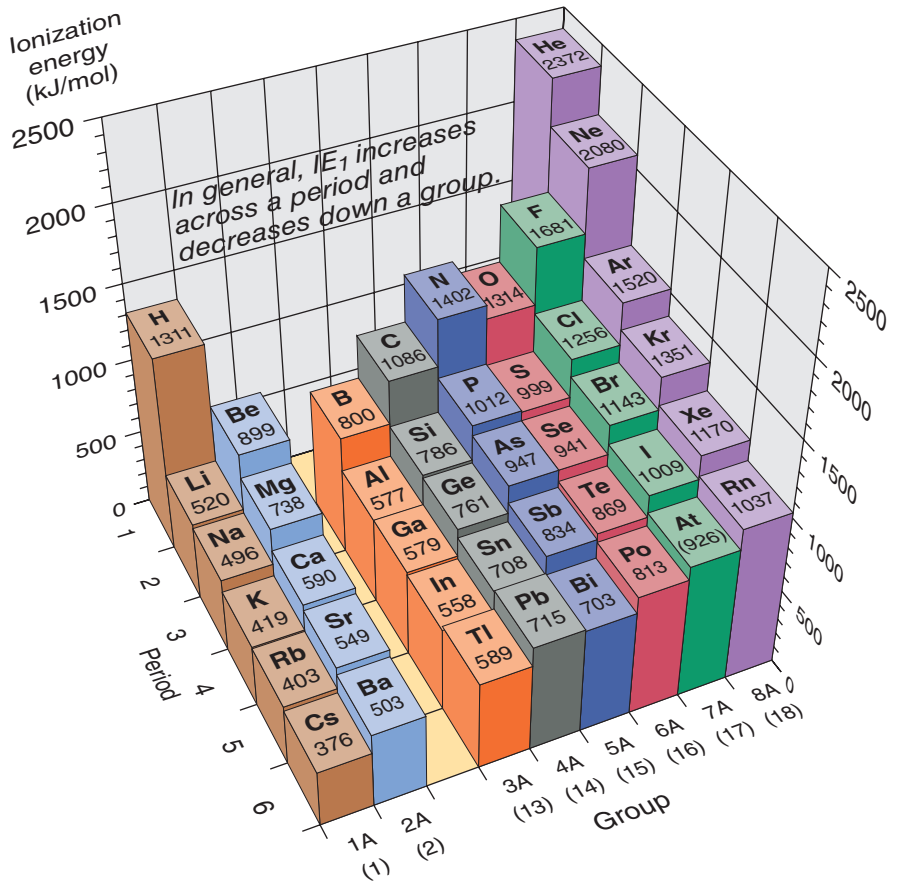


Figure 8.16 First ionization energies of the main-group elements.

SAMPLE PROBLEM 8.4 Ranking Elements by First Ionization Energy

Problem Using the periodic table only, rank the elements in each set in order of *decreasing* IE_1:

(a) Kr, He, Ar **(b)** Sb, Te, Sn
(c) K, Ca, Rb **(d)** I, Xe, Cs

Plan We find the elements in the periodic table and then apply the general trends of decreasing IE_1 down a group and increasing IE_1 across a period.

Solution **(a)** He > Ar > Kr. These are in Group 8A(18), and IE_1 decreases down a group.

(b) Te > Sb > Sn. These are in Period 5, and IE_1 increases across a period.

(c) Ca > K > Rb. IE_1 of K is larger than IE_1 of Rb because K is higher in Group 1A(1). IE_1 of Ca is larger than IE_1 of K because Ca is farther to the right in Period 4.

(d) Xe > I > Cs. IE_1 of I is smaller than IE_1 of Xe because I is farther to the left. IE_1 of I is larger than IE_1 of Cs because I is farther to the right and in the previous period.

Check Because trends in IE_1 are generally the opposite of the trends in size, you can rank the elements by size and check that you obtain the reverse order.

FOLLOW-UP PROBLEMS

8.4A Rank the elements in each set in order of *increasing* IE_1:
(a) Sb, Sn, I; **(b)** Na, Mg, Cs.

8.4B Rank the elements in each set in order of *decreasing* IE_1:
(a) O, As, Rb; **(b)** Sn, Cl, Si.

SOME SIMILAR PROBLEMS 8.55 and 8.56

Table 8.5 Successive Ionization Energies of the Elements Lithium Through Sodium

Z	Element	Number of Valence Electrons	Ionization Energy (MJ/mol)*									
			IE_1	IE_2	IE_3	IE_4	IE_5	IE_6	IE_7	IE_8	IE_9	IE_{10}
3	Li	1	0.52	7.30	11.81							
4	Be	2	0.90	1.76	14.85	21.01			CORE ELECTRONS

9	F	7	1.68	3.37	6.05	8.41	11.02	15.16	17.87	92.04	106.43	
10	Ne	8	2.08	3.95	6.12	9.37	12.18	15.24	20.00	23.07	115.38	131.43
11	Na	1	0.50	4.56	6.91	9.54	13.35	16.61	20.11	25.49	28.93	141.37

*MJ/mol, or megajoules per mole = 10^3 kJ/mol.

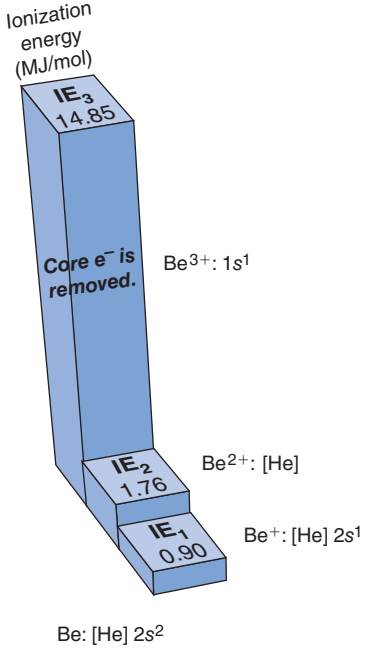

Figure 8.17 The first three ionization energies of beryllium. Beryllium has two valence electrons, so IE_3 is much larger than IE_2.

Successive Ionization Energies For a given element, IE_1, IE_2, and so on, increase because each electron is pulled away from a species with a higher positive charge. This increase includes an enormous jump *after* the outer (valence) electrons have been removed because *much* more energy is needed to remove an inner (core) electron (Figure 8.17).

Table 8.5 shows successive ionization energies for Period 2 and the first element in Period 3. Move across the row of values for any element, and you reach a point that separates relatively low from relatively high IE values *(shaded area)*. For example, follow the values for boron (B): IE_1 (0.80 MJ) is lower than IE_2 (2.43 MJ), which is lower than IE_3 (3.66 MJ), which is *much* lower than IE_4 (25.02 MJ). From this jump, we know that boron has three electrons in the highest energy level ($1s^2 2s^2 2p^1$). Because they are so difficult to remove, *core electrons are not involved in reactions*.

SAMPLE PROBLEM 8.5 Identifying an Element from Its Ionization Energies

Problem Name the Period 3 element with the following ionization energies (kJ/mol), and write its full electron configuration:

IE_1	IE_2	IE_3	IE_4	IE_5	IE_6
1012	1903	2910	4956	6278	22,230

Plan We look for a large jump in the IE values, which occurs after all valence electrons have been removed. Then we refer to the periodic table to find the Period 3 element with this number of valence electrons and write its electron configuration.

Solution The large jump occurs after IE_5, indicating that the element has five valence electrons and, thus, is in Group 5A(15). This Period 3 element is phosphorus (P; $Z = 15$). Its electron configuration is $1s^2 2s^2 2p^6 3s^2 3p^3$.

FOLLOW-UP PROBLEMS

8.5A Element Q is in Period 3 and has the following ionization energies (in kJ/mol):

IE_1	IE_2	IE_3	IE_4	IE_5	IE_6
577	1816	2744	11,576	14,829	18,375

Name element Q, and write its full electron configuration.

8.5B Write the condensed electron configurations of the elements Rb, Sr, and Y. Which has the *highest* IE_2? Which has the highest IE_3?

SOME SIMILAR PROBLEMS 8.57–8.60

Trends in Electron Affinity

The **electron affinity (EA)** is the energy change (kJ/mol) accompanying the *addition* of 1 mol of electrons to 1 mol of gaseous atoms or ions. The *first electron affinity* (EA_1) refers to the formation of 1 mol of monovalent (1−) gaseous anions:

$$\text{Atom}(g) + e^- \longrightarrow \text{ion}^-(g) \qquad \Delta E = EA_1$$

As with ionization energy, there is a first electron affinity, a second, and so forth. The first electron is *attracted* by the atom's nucleus, so in most cases, *EA_1 is negative* (energy is released), analogous to the negative ΔH for an exothermic reaction.* But, the second electron affinity (EA_2) is always positive because energy must be *absorbed* to overcome electrostatic repulsions and add another electron to a negative ion.

Factors other than Z_{eff} and atomic size affect electron affinities, so trends are not regular, as are those for size and IE_1. The many exceptions arise from changes in sublevel energy and electron-electron repulsion:

- *Down a group.* We might expect a smooth decrease (smaller negative number) down a group because atomic size increases, and the nucleus is farther away from an electron being added. But only Group 1A(1) exhibits this behavior (Figure 8.18).
- *Across a period.* We might expect a regular increase (larger negative number) across a period because atomic size decreases, and higher Z_{eff} should attract the electron being added more strongly. There is an overall left-to-right increase, but it is not at all regular.

Despite these irregularities, relative values of IE and EA show three general behavior patterns:

1. *Reactive nonmetals.* Members of Group 6A(16) and especially Group 7A(17) (the halogens) have high IEs and highly negative (exothermic) EAs: these elements lose electrons with difficulty but attract them strongly. Therefore, *in their ionic compounds, they form negative ions.*
2. *Reactive metals.* Members of Groups 1A(1) and 2A(2) have low IEs and slightly negative (exothermic) EAs: they lose electrons easily but attract them weakly, if at all. Therefore, *in their ionic compounds, they form positive ions.*
3. *Noble gases.* Members of Group 8A(18) have very high IEs and slightly positive (endothermic) EAs: *they tend **not** to lose or gain electrons.* In fact, only the larger members of the group (Kr, Xe, and Rn) form compounds at all.

*Some tables of EA_1 list them as positive values because that quantity of energy would be *absorbed* to remove an electron from the anion.

Figure 8.18 Electron affinities of the main-group elements (in kJ/mol). Values for Group 8A(18) are estimates, which is indicated by parentheses.

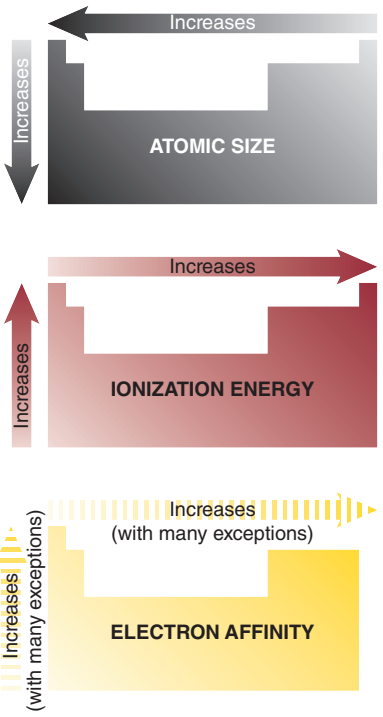

Figure 8.19 Trends in three atomic properties. For electron affinity, the dashed arrows indicate that there are numerous exceptions to expected trends.

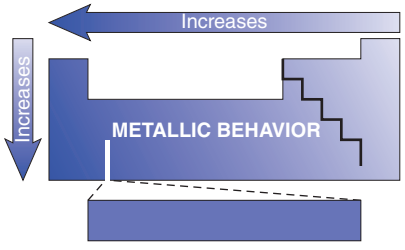

Figure 8.20 Trends in metallic behavior. (Hydrogen appears next to helium.)

Summary of Section 8.3

- Trends in three atomic properties are summarized in Figure 8.19.
- Atomic size (half the distance between nuclei of adjacent atoms) increases down a main group and decreases across a period. In a transition series, size remains relatively constant.
- First ionization energy (the energy required to remove the outermost electron from a mole of gaseous atoms) is inversely related to atomic size: IE_1 decreases down a main group and increases across a period.
- Successive ionization energies of an element show a very large increase after all valence electrons have been removed, because the first inner (core) electron is in an orbital of much lower energy and so is held very tightly.
- Electron affinity (the energy involved in adding an electron to a mole of gaseous atoms) shows many variations from expected trends.
- Based on the relative sizes of IEs and EAs, Group 1A(1) and 2A(2) elements tend to form cations and Group 6A(16) and 7A(17) elements tend to form anions in ionic compounds. Group 8A(18) elements are very unreactive.

8.4 ATOMIC PROPERTIES AND CHEMICAL REACTIVITY

All physical and chemical behaviors of the elements and their compounds are based on electron configuration and effective nuclear charge. In this section, you'll see how atomic properties determine metallic behavior and the properties of ions.

Trends in Metallic Behavior

The three general classes of elements have distinguishing properties:

- *Metals,* found in the left and lower three-quarters of the periodic table, are typically shiny solids, have moderate to high melting points, are good conductors of heat and electricity, can be machined into wires and sheets, and lose electrons to nonmetals.
- *Nonmetals,* found in the upper right quarter of the table, are typically not shiny, have relatively low melting points, are poor conductors, are mostly crumbly solids or gases, and tend to gain electrons from metals.
- *Metalloids,* found between the other two classes, have intermediate properties.

Thus, *metallic behavior decreases left-to-right across a period and increases down a group in the periodic table* (Figure 8.20).

Remember, though, that some elements don't fit these categories: as graphite, nonmetallic carbon is a good electrical conductor; the nonmetal iodine is shiny; metallic gallium melts in your hand; mercury is a liquid; and iron is brittle. Despite such exceptions, in this discussion, we'll make several generalizations about metallic behavior and its applications to redox behavior and the acid-base properties of oxides.

Relative Tendency to Lose or Gain Electrons Metals tend to lose electrons to nonmetals during reactions:

1. *Down a main group*. The increase in metallic behavior down a group is consistent with an increase in size and a decrease in IE and is most obvious in groups with more than one class of element, such as Group 5A(15) (Figure 8.21, *vertical*): *elements at the top can form anions, and those at the bottom can form cations.* Nitrogen (N) is a gaseous nonmetal, and phosphorus (P) is a soft nonmetal; both occur occasionally as $3-$ anions in their compounds. Arsenic (As) and antimony (Sb) are metalloids, with Sb the more metallic, and neither forms ions readily. Bismuth (Bi) is a typical metal, forming a $3+$ cation in its mostly ionic compounds. Groups 3A(13), 4A(14), and 6A(16) show a similar trend. But even in Group 2A(2), which contains

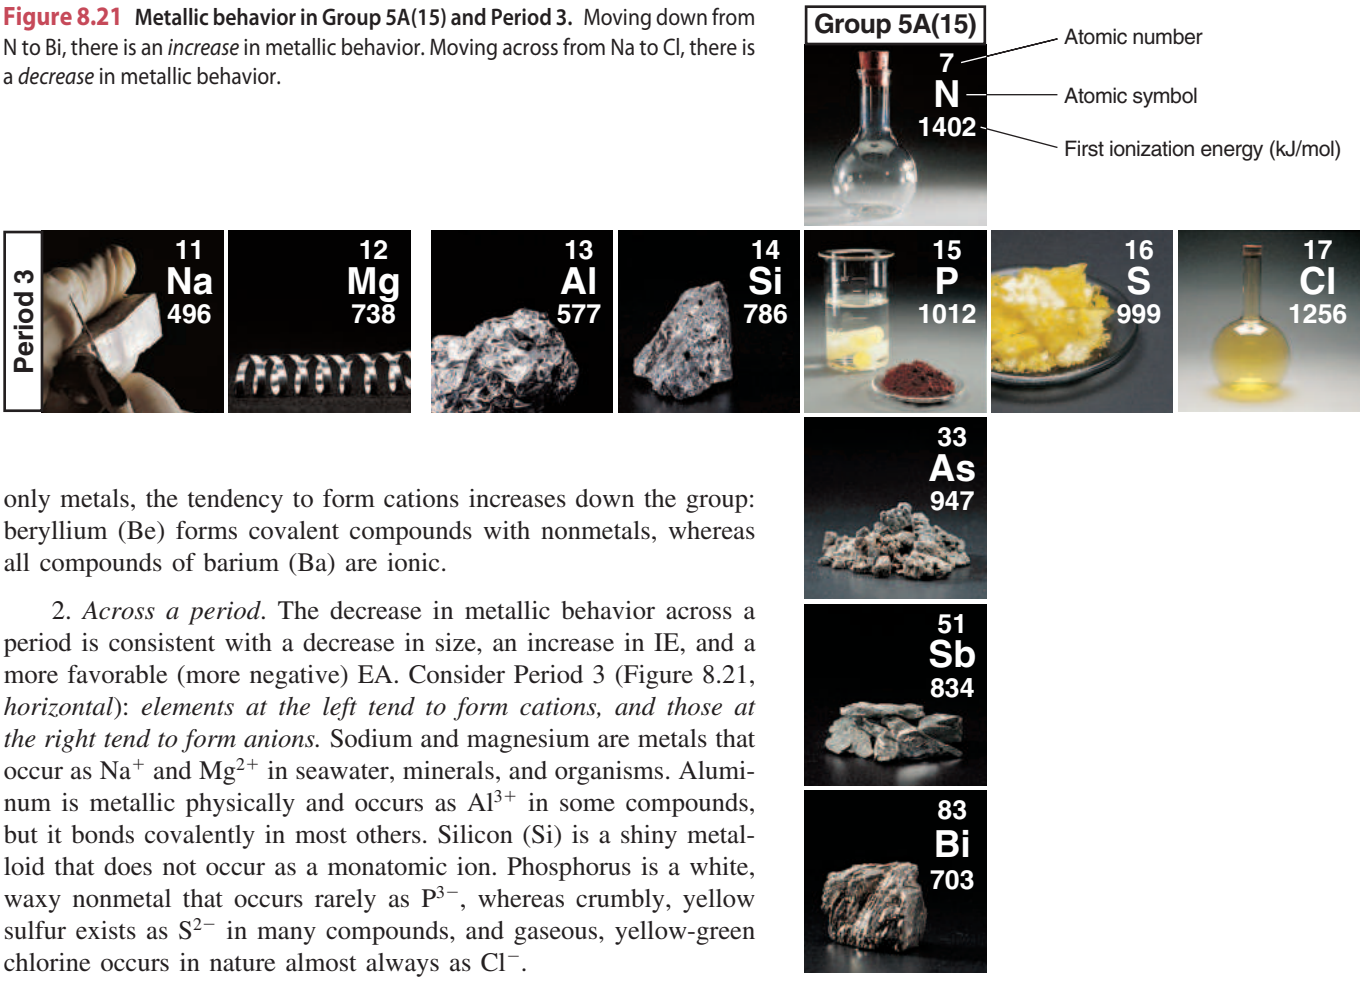

Figure 8.21 **Metallic behavior in Group 5A(15) and Period 3.** Moving down from N to Bi, there is an *increase* in metallic behavior. Moving across from Na to Cl, there is a *decrease* in metallic behavior.

only metals, the tendency to form cations increases down the group: beryllium (Be) forms covalent compounds with nonmetals, whereas all compounds of barium (Ba) are ionic.

2. *Across a period.* The decrease in metallic behavior across a period is consistent with a decrease in size, an increase in IE, and a more favorable (more negative) EA. Consider Period 3 (Figure 8.21, *horizontal*): *elements at the left tend to form cations, and those at the right tend to form anions.* Sodium and magnesium are metals that occur as Na^+ and Mg^{2+} in seawater, minerals, and organisms. Aluminum is metallic physically and occurs as Al^{3+} in some compounds, but it bonds covalently in most others. Silicon (Si) is a shiny metalloid that does not occur as a monatomic ion. Phosphorus is a white, waxy nonmetal that occurs rarely as P^{3-}, whereas crumbly, yellow sulfur exists as S^{2-} in many compounds, and gaseous, yellow-green chlorine occurs in nature almost always as Cl^-.

Redox Behavior of the Main-Group Elements Closely related to an element's tendency to lose or gain electrons is its redox behavior—that is, whether it behaves as an oxidizing or reducing agent and the associated changes in its oxidation number (O.N.). You can find the highest and lowest oxidation numbers of many main-group elements from the periodic table (Figure 8.22):

- For most elements, the A-group number is the *highest* oxidation number (always positive) of any element in the group. The exceptions are O and F (see Table 4.4).
- For nonmetals and some metalloids, the A-group number minus 8 is the *lowest* oxidation number (always negative) of any element in the group.

For example, the highest oxidation number of S (Group 6A) is +6, as in SF_6, and the lowest is 6 − 8, or −2, as in FeS and other metal sulfides.

Redox behavior is closely related to atomic properties:

- With their low IEs and small EAs, the members of Groups 1A(1) and 2A(2) lose electrons readily, so they are *strong reducing agents* and become oxidized.
- With their high IEs and large EAs, nonmetals in Groups 6A(16) and 7A(17) gain electrons readily, so they are *strong oxidizing agents* and become reduced.

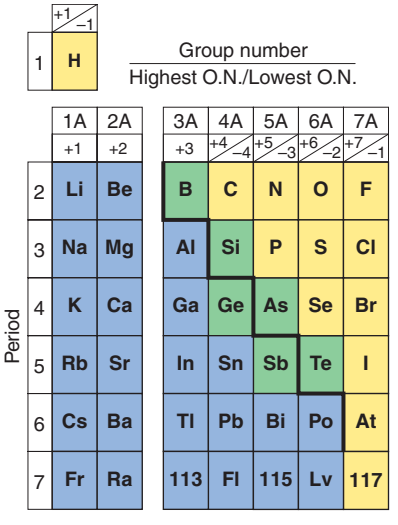

Figure 8.22 **Highest and lowest O.N.s of reactive main-group elements.**

Acid-Base Behavior of Oxides Metals are also distinguished from nonmetals by the acid-base behavior of their oxides in water:

- Most main-group metals *transfer* electrons to oxygen, so their *oxides are ionic. In water, these oxides act as bases,* producing OH^- ions from O^{2-} and reacting with acids. Calcium oxide is an example (Figure 8.23, *left, next page*).

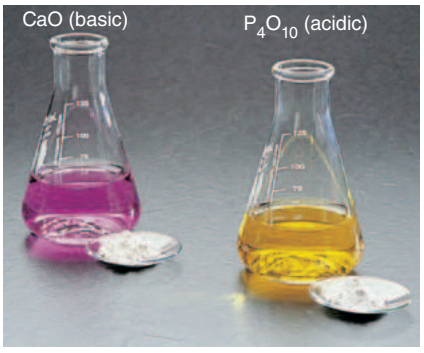

Figure 8.23 **Oxide acidity.** In water, metal oxides are basic *(left),* and nonmetal oxides are acidic *(right).* The colors are due to the presence of acid-base indicators.

- Nonmetals *share* electrons with oxygen, so *nonmetal oxides are covalent. They react with water to form acids,* producing H^+ ions and reacting with bases. Tetraphosphorus decoxide is an example (Figure 8.23, *right*).

Some metals and many metalloids form oxides that are **amphoteric:** they can act as acids *or* bases in water.

In Figure 8.24, the acid-base behavior of some common oxides of elements in Group 5A(15) and Period 3 is shown, with a gradient from blue (basic) to red (acidic):

1. *As elements become more metallic down a group (larger size and smaller IE), their oxides become more basic.* In Group 5A(15), dinitrogen pentoxide, N_2O_5, forms the strong acid HNO_3:

$$N_2O_5(s) + H_2O(l) \longrightarrow 2HNO_3(aq)$$

Tetraphosphorus decoxide, P_4O_{10}, forms the weaker acid H_3PO_4:

$$P_4O_{10}(s) + 6H_2O(l) \longrightarrow 4H_3PO_4(aq)$$

The oxide of the metalloid arsenic is weakly acidic, whereas that of the metalloid antimony is weakly basic. Bismuth, the most metallic of the group, forms a basic oxide that is insoluble in water but reacts with acid to yield a salt and water:

$$Bi_2O_3(s) + 6HNO_3(aq) \longrightarrow 2Bi(NO_3)_3(aq) + 3H_2O(l)$$

2. *As the elements become less metallic across a period (smaller size and higher IE), their oxides become more acidic.* In Period 3, Na_2O and MgO are strongly basic, and amphoteric aluminum oxide (Al_2O_3) reacts with acid or with base:

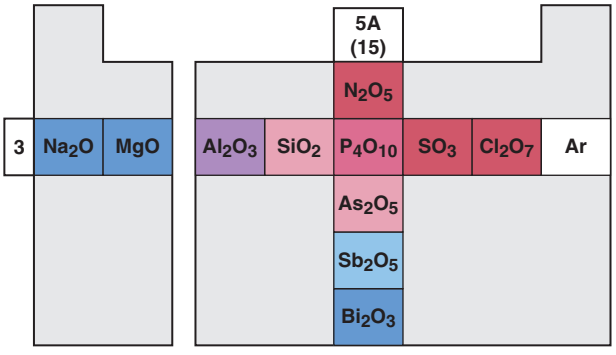
$$Al_2O_3(s) + 6HCl(aq) \longrightarrow 2AlCl_3(aq) + 3H_2O(l)$$
$$Al_2O_3(s) + 2NaOH(aq) + 3H_2O(l) \longrightarrow 2NaAl(OH)_4(aq)$$

Silicon dioxide is weakly acidic, forming a salt and water with base:

$$SiO_2(s) + 2NaOH(aq) \longrightarrow Na_2SiO_3(aq) + H_2O(l)$$

The common oxides of phosphorus, sulfur, and chlorine form acids of increasing strength: H_3PO_4, H_2SO_4, and $HClO_4$.

Figure 8.24 **Acid-base behavior of some element oxides.**



Properties of Monatomic Ions

So far we have focused on the reactants—the atoms—in the process of electron loss and gain. Now we focus on the products—the ions—considering their electron configurations, magnetic properties, and sizes.

Electron Configurations of Main-Group Ions Why does an ion have a particular charge: Na^+ not Na^{2+}, or F^- not F^{2-}? Why do some metals form two ions, such as Sn^{2+} and Sn^{4+}? The answer relates to the location of the element in the periodic table and the energy associated with losing or gaining electrons:

1. *Ions with a noble gas configuration.* Atoms of the noble gases have very low reactivity because their highest energy level is *filled* (ns^2np^6). Thus, *when elements at either end of a period form ions, they attain a filled outer level—a noble gas configuration.* These elements lie on either side of Group 8A(18), and their ions are

isoelectronic (Greek *iso,* "same") with the nearest noble gas (Figure 8.25; see also Figure 2.13, p. 62).

- Elements in Groups 1A(1) and 2A(2) *lose* electrons and become isoelectronic with the *previous* noble gas. The Na^+ ion, for example, is isoelectronic with neon (Ne):

  Na ($1s^22s^22p^63s^1$) $\longrightarrow$ e^- + Na^+([He] $2s^22p^6$) [isoelectronic with Ne ([He] $2s^22p^6$)]

- Elements in Groups 6A(16) and 7A(17) *gain* electrons and become isoelectronic with the *next* noble gas. The Br^- ion, for example, is isoelectronic with krypton (Kr):

  Br ([Ar] $4s^23d^{10}4p^5$) + e^- $\longrightarrow$ Br^- ([Ar] $4s^23d^{10}4p^6$)

  [isoelectronic with Kr ([Ar] $4s^23d^{10}4p^6$)]

The energy needed to remove electrons from metals or add them to nonmetals determines the charges of the resulting ions:

- *Cations*. Removing another electron from Na^+ or from Mg^{2+} means removing a core electron, which requires too much energy: thus, $NaCl_2$ and MgF_3 do *not* exist.
- *Anions*. Similarly, adding another electron to F^- or to O^{2-} means putting it into the next higher energy level ($n = 3$). With 10 electrons ($1s^22s^22p^6$) acting as inner electrons, the nuclear charge would be shielded very effectively, and adding an outer electron would require too much energy: thus, we never see Na_2F or Mg_3O_2.

2. *Ions without a noble gas configuration*. Except for aluminum, the metals of Groups 3A(13) to 5A(15) do not form ions with noble gas configurations. Instead, they form cations with two different stable configurations:

- *Pseudo–noble gas configuration.* If the metal atom empties its highest energy level, it attains the stability of empty *ns* and *np* sublevels and filled inner $(n - 1)d$ sublevel. This $(n - 1)d^{10}$ configuration is called a **pseudo–noble gas configuration.** For example, tin (Sn; $Z = 50$) loses four electrons to form the tin(IV) ion (Sn^{4+}), which has empty 5*s* and 5*p* sublevels and a filled inner 4*d* sublevel:

  Sn ([Kr] $5s^24d^{10}5p^2$) $\longrightarrow$ Sn^{4+} ([Kr] $4d^{10}$) + $4e^-$

- *Inert pair configuration*. Alternatively, the metal atom loses just its *np* electrons and attains a stable configuration with filled *ns* and $(n - 1)d$ sublevels. The retained ns^2 electrons are sometimes called an *inert pair*. For example, in the more common tin(II) ion (Sn^{2+}), the atom loses the two 5*p* electrons and has filled 5*s* and 4*d* sublevels:

  Sn ([Kr] $5s^24d^{10}5p^2$) $\longrightarrow$ Sn^{2+} ([Kr] $5s^24d^{10}$) + $2e^-$

  Thallium, lead, and bismuth, the largest and, thus, most metallic members of Groups 3A(13) to 5A(15), form ions that retain the ns^2 pair: Tl^+, Pb^{2+}, and Bi^{3+}.

Once again, energy considerations explain these configurations. It would be energetically impossible for metals in Groups 3A(13) to 5A(15) to achieve noble gas configurations: tin, for example, would have to lose 14 electrons—ten 4*d* in addition to the two 5*p* and two 5*s*—to be isoelectronic with krypton (Kr; $Z = 36$), the previous noble gas.

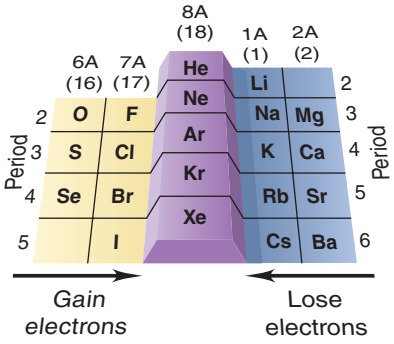


Figure 8.25 Main-group elements whose ions have noble gas electron configurations.

SAMPLE PROBLEM 8.6 Writing Electron Configurations of Main-Group Ions

Problem Using condensed electron configurations, write equations representing the formation of the ion(s) of the following elements:
(a) Iodine ($Z = 53$) **(b)** Potassium ($Z = 19$) **(c)** Indium ($Z = 49$)

Plan We identify the element's position in the periodic table and recall that

- Ions of elements in Groups 1A(1), 2A(2), 6A(16), and 7A(17) are isoelectronic with the nearest noble gas.
- Metals in Groups 3A(13) to 5A(15) lose the *ns* and *np* electrons or just the *np*.

Solution **(a)** Iodine is in Group 7A(17), so it gains one electron, and I^- is isoelectronic with xenon:

I ([Kr] $5s^24d^{10}5p^5$) + e^- $\longrightarrow$ I^- ([Kr] $5s^24d^{10}5p^6$) (same as Xe)

(b) Potassium is in Group 1A(1), so it loses one electron; K^+ is isoelectronic with argon:

K ([Ar] $4s^1$) $\longrightarrow$ K^+ ([Ar]) + e^-

(c) Indium is in Group 3A(13), so it loses either three electrons to form In^{3+} (with a pseudo–noble gas configuration) or one to form In^{+} (with an inert pair):

$$In\ ([Kr]\ 5s^2 4d^{10} 5p^1) \longrightarrow In^{3+}\ ([Kr]\ 4d^{10}) + 3e^-$$

$$In\ ([Kr]\ 5s^2 4d^{10} 5p^1) \longrightarrow In^{+}\ ([Kr]\ 5s^2 4d^{10}) + e^-$$

Check Be sure that the number of electrons in the ion's electron configuration, plus the number gained or lost to form the ion, equals *Z*.

FOLLOW-UP PROBLEMS

8.6A Using condensed electron configurations, write equations representing the formation of the ion(s) of the following elements:
(a) Ba ($Z = 56$) **(b)** O ($Z = 8$) **(c)** Pb ($Z = 82$)

8.6B Using condensed electron configurations, write equations representing the formation of the ion(s) of the following elements:
(a) F ($Z = 9$) **(b)** Tl ($Z = 81$) **(c)** Mg ($Z = 12$)

SOME SIMILAR PROBLEMS 8.75–8.78

Electron Configurations of Transition Metal Ions In contrast to many main-group ions, *transition metal ions rarely attain a noble gas configuration.* Aside from the Period 4 elements scandium, which forms Sc^{3+}, and titanium, which occasionally forms Ti^{4+}, *a transition element typically forms more than one cation by losing all of its ns and some of its* $(n - 1)d$ *electrons.*

The reason, once again, is that energy costs are too high. Let's consider again the filling of Period 4. At the beginning of Period 4 (the same point holds in other periods), penetration makes the 4*s* sublevel *more stable* than the 3*d*. Therefore, the first and second electrons added enter the 4*s*, which is the outer sublevel. But, the 3*d* is an *inner* sublevel, so as it begins to fill, its electrons are not well shielded from the increasing nuclear charge.

A *crossover in sublevel energy* results: the 3*d* becomes *more stable* than the 4*s* in the transition series (Figure 8.26). This crossover has a major effect on the formation of Period 4 transition metal ions: because the 3*d* electrons are held tightly and shield those in the outer sublevel, *the 4s electrons of a transition metal are lost* ***before*** *the 3d electrons.* Thus, 4*s* electrons are added before 3*d* electrons to form the *atom* and are lost before them to form the *ion,* the so-called "first-in, first-out" rule.

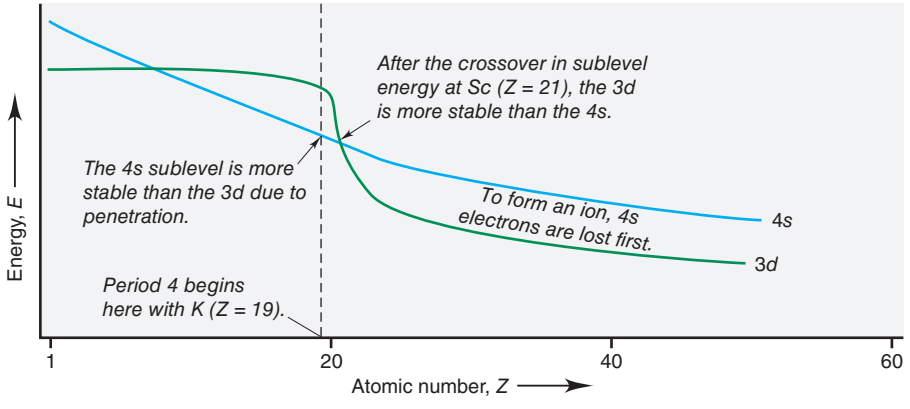

Figure 8.26 **The crossover of sublevel energies in Period 4.**

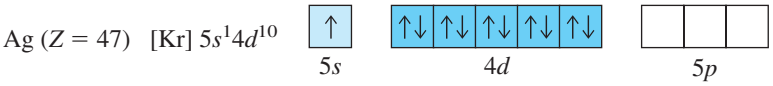
Ion Formation: A Summary of Electron Loss or Gain The various ways that cations form have one point in common—*outer electrons are removed first.* Here is a summary of the rules for formation of any main-group or transition metal ion:

- Main-group *s*-block metals lose all electrons with the highest *n* value.
- Main-group *p*-block metals lose *np* electrons before *ns* electrons.
- Transition (*d*-block) metals lose *ns* electrons before $(n - 1)d$ electrons.
- Nonmetals gain electrons in the *p* orbitals of highest *n* value.

Magnetic Properties of Transition Metal Ions We learn a great deal about an element's electron configuration from atomic spectra, and magnetic studies provide additional evidence.

Recall that electron spin generates a tiny magnetic field, which causes a beam of H atoms to split in an external magnetic field (see Figure 8.1). Only a beam of a species (atoms, ions, or molecules) with one or more *unpaired* electrons will split. A beam of silver atoms (Ag; $Z = 47$) was used in the original 1921 experiment:



Note the unpaired 5*s* electron. A beam of cadmium atoms (Cd; $Z = 48$) is not split because their 5*s* electrons are *paired* ([Kr] $5s^2 4d^{10}$).

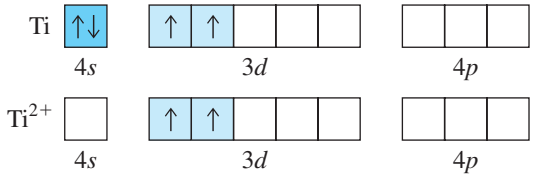
A species with unpaired electrons exhibits **paramagnetism:** it is attracted by an external field. A species with all of its electrons paired exhibits **diamagnetism:** it is not attracted (and is slightly repelled) by the field (Figure 8.27). Many transition metals and their compounds are paramagnetic because their atoms and ions have unpaired electrons.

Let's see three examples of how magnetic studies might provide evidence for a proposed electron configuration:

1. *The Ti^{2+} ion.* Spectral analysis of titanium metal yields the electron configuration [Ar] $4s^2 3d^2$, and experiment shows that the metal is paramagnetic, which indicates the presence of unpaired electrons. Spectral analysis shows that the Ti^{2+} ion is [Ar] $3d^2$, indicating loss of the 4*s* electrons. In support of the spectra, magnetic studies show that Ti^{2+} compounds are paramagnetic:

$$Ti\ ([Ar]\ 4s^2 3d^2) \longrightarrow Ti^{2+}\ ([Ar]\ 3d^2) + 2e^-$$

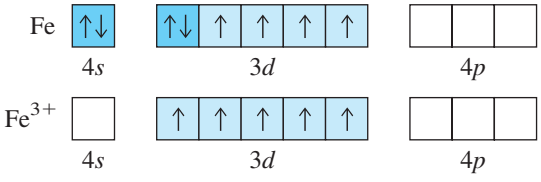
The partial orbital diagrams are



If Ti lost its 3*d* electrons to form Ti^{2+}, its compounds would be diamagnetic.

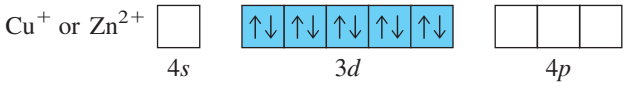
2. *The Fe^{3+} ion.* An increase in paramagnetism occurs when iron metal (Fe) becomes Fe^{3+} in compounds, which indicates an increase in the number of unpaired electrons. This fact is consistent with Fe losing its 4*s* pair and one electron of a 3*d* pair:

$$Fe\ ([Ar]\ 4s^2 3d^6) \longrightarrow Fe^{3+}\ ([Ar]\ 3d^5) + 3e^-$$



3. *The Cu^+ and Zn^{2+} ions.* Copper (Cu) metal is paramagnetic, but zinc (Zn) is diamagnetic. The Cu^+ and Zn^{2+} ions are diamagnetic, too. These observations are consistent with the ions being isoelectronic, which means 4*s* electrons were lost:

$$Cu\ ([Ar]\ 4s^1 3d^{10}) \longrightarrow Cu^+\ ([Ar]\ 3d^{10}) + e^-$$
$$Zn\ ([Ar]\ 4s^2 3d^{10}) \longrightarrow Zn^{2+}\ ([Ar]\ 3d^{10}) + 2e^-$$



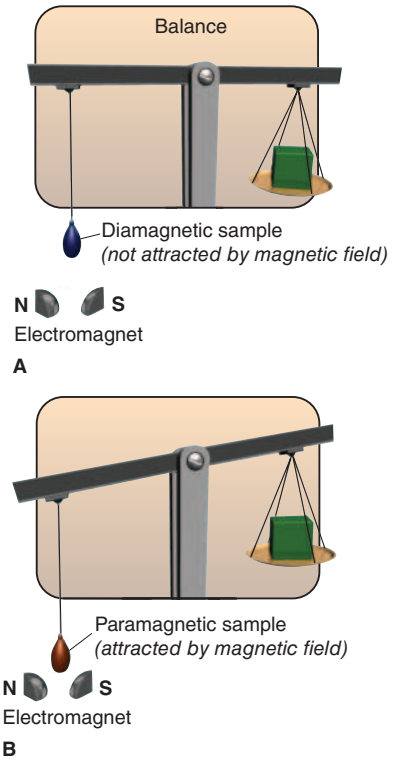


Figure 8.27 Measuring the magnetic behavior of a sample. The substance is weighed with the external magnetic field "off." **A,** If the substance is diamagnetic (has all *paired* electrons), its apparent mass is unaffected (or slightly reduced) with the field "on." **B,** If the substance is paramagnetic (has *unpaired* electrons), its apparent mass increases.

SAMPLE PROBLEM 8.7 **Writing Electron Configurations and Predicting Magnetic Behavior of Transition Metal Ions**

Problem Use condensed electron configurations to write an equation for the formation of each transition metal ion, and predict whether it is paramagnetic:
(a) Mn^{2+} ($Z = 25$) **(b)** Cr^{3+} ($Z = 24$) **(c)** Hg^{2+} ($Z = 80$)

Plan We first write the condensed electron configuration of the atom, recalling the irregularity for Cr. Then we remove electrons, beginning with *ns* electrons, to attain the ion charge. If unpaired electrons are present, the ion is paramagnetic.

Solution **(a)** $Mn\ ([Ar]\ 4s^2 3d^5) \longrightarrow Mn^{2+}\ ([Ar]\ 3d^5) + 2e^-$
There are five unpaired e^-, so Mn^{2+} is paramagnetic.

(b) $Cr\ ([Ar]\ 4s^1 3d^5) \longrightarrow Cr^{3+}\ ([Ar]\ 3d^3) + 3e^-$
There are three unpaired e^-, so Cr^{3+} is paramagnetic.

(c) $Hg\ ([Xe]\ 6s^2 4f^{14} 5d^{10}) \longrightarrow Hg^{2+}\ ([Xe]\ 4f^{14} 5d^{10}) + 2e^-$
The 4*f* and 5*d* sublevels are filled, so there are no unpaired e^-: Hg^{2+} is *not* paramagnetic.

Check We removed the *ns* electrons first, and the sum of the lost electrons and those in the electron configuration of the ion equals *Z*.

FOLLOW-UP PROBLEMS

8.7A Write the condensed electron configuration of each transition metal ion, and predict whether it is paramagnetic:
(a) V^{3+} ($Z = 23$) **(b)** Ni^{2+} ($Z = 28$) **(c)** La^{3+} ($Z = 57$)

8.7B Write the condensed electron configuration of each transition metal ion, and give the number of unpaired electrons:
(a) Zr^{2+} ($Z = 40$) **(b)** Os^{3+} ($Z = 76$) **(c)** Co^{2+} ($Z = 27$)

SOME SIMILAR PROBLEMS 8.82–8.84

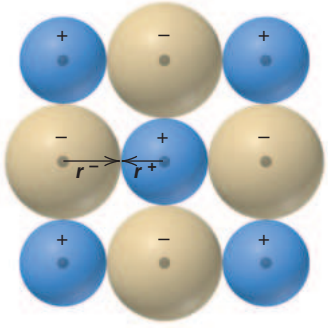

Figure 8.28 **Ionic radius.** Cation radius (r^+) and anion radius (r^-) together make up the distance between nuclei.

Ionic Size vs. Atomic Size The **ionic radius** is a measure of the size of an ion and is obtained from the distance between the nuclei of adjacent ions in a crystalline ionic compound (Figure 8.28). From the relation between effective nuclear charge (Z_{eff}) and atomic size, we can predict the size of an ion relative to its parent atom:

- *Cations are smaller than parent atoms.* When a cation forms, electrons are *removed from* the outer level. The resulting decrease in shielding and value of *nl* allows the nucleus to pull the remaining electrons closer.
- *Anions are larger than parent atoms.* When an anion forms, electrons are *added to* the outer level. The increases in shielding and electron repulsions means the electrons occupy more space.

Figure 8.29 shows the radii of some main-group ions and their parent atoms:

1. *Down a group, ionic size increases* because *n* increases.
2. *Across a period,* the pattern is complex. For instance, consider Period 3:
   - *Among cations,* the increase in Z_{eff} from left to right makes Na^+ larger than Mg^{2+}, which is larger than Al^{3+}.
   - *From last cation to first anion,* a great jump in size occurs: we are *adding* electrons rather than removing them, so repulsions increase sharply. For instance, P^{3-} has eight more electrons than Al^{3+}.
   - *Among anions,* the increase in Z_{eff} from left to right makes P^{3-} larger than S^{2-}, which is larger than Cl^-.
   - *Within an isoelectronic series,* these factors have striking results. Within the dashed outline in Figure 8.29, the ions are isoelectronic with neon. Period 2 anions are much larger than Period 3 cations because the same number of electrons are attracted by an increasing nuclear charge. The size pattern is

$3-$	$>$	$2-$	$>$	$1-$	$>$	$1+$	$>$	$2+$	$>$	$3+$
$7p^+$		$8p^+$		$9p^+$		$11p^+$		$12p^+$		$13p^+$
$10e^-$		$10e^-$		$10e^-$		$10e^-$		$10e^-$		$10e^-$

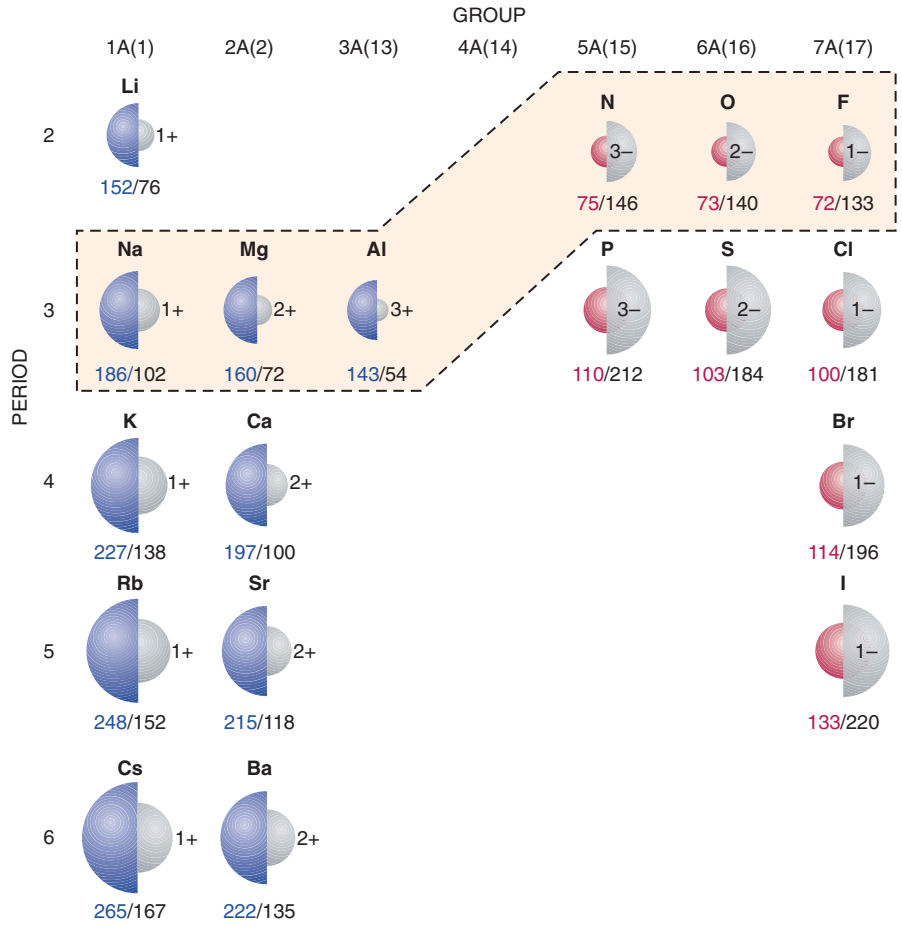

Figure 8.29 **Ionic vs. atomic radii.** Atomic radii *(color)* and ionic radii *(gray)* are given in picometers. Metal atoms *(blue)* form *smaller* positive ions, and nonmetal atoms *(red)* form *larger* negative ions. Ions in the dashed outline are *isoelectronic* with neon.

3. *Cation size decreases with charge*. When a metal forms more than one cation, *the greater the ionic charge, the smaller the ionic radius.* With the two ions of iron, for example, Fe^{3+} has one fewer electron, so shielding is reduced somewhat, and the same nucleus is attracting fewer electrons. As a result, Z_{eff} increases, so Fe^{3+} (65 pm) is smaller than Fe^{2+} (78 pm).

SAMPLE PROBLEM 8.8 Ranking Ions by Size

Problem Rank each set of ions in order of *decreasing* size, and explain your ranking:
(a) Ca^{2+}, Sr^{2+}, Mg^{2+} **(b)** K^+, S^{2-}, Cl^- **(c)** Au^+, Au^{3+}

Plan We find the position of each element in the periodic table and apply the ideas presented in the text.

Solution **(a)** Mg^{2+}, Ca^{2+}, and Sr^{2+} are all from Group 2A(2), so their sizes decrease up the group: $Sr^{2+} > Ca^{2+} > Mg^{2+}$.
(b) The ions K^+, S^{2-}, and Cl^- are isoelectronic. S^{2-} has a lower Z_{eff} than Cl^-, so it is larger. K^+ is a cation and has the highest Z_{eff}, so it is smallest: $S^{2-} > Cl^- > K^+$.
(c) Au^+ has a lower charge than Au^{3+}, so it is larger: $Au^+ > Au^{3+}$.

FOLLOW-UP PROBLEMS

8.8A Rank the ions in each set in order of *increasing* size:
(a) Cl^-, Br^-, F^- **(b)** Na^+, Mg^{2+}, F^- **(c)** Cr^{2+}, Cr^{3+}

8.8B Rank the ions in each set in order of *decreasing* size:
(a) V^{2+}, V^{3+} **(b)** Rb^+, K^+, Cs^+ **(c)** I^-, Ba^{2+}, Cs^+

SOME SIMILAR PROBLEMS 8.87 and 8.88

Summary of Section 8.4

- Metallic behavior correlates with large atomic size and low ionization energy. Thus, metallic behavior increases down a group and decreases from left to right across a period.
- Elements in Groups 1A(1) and 2A(2) are strong reducing agents; nonmetals in Groups 6A(16) and 7A(17) are strong oxidizing agents.
- Within the main groups, metal oxides are basic and nonmetal oxides acidic. Thus, oxides become more acidic across a period and more basic down a group.
- Many main-group elements form ions that are isoelectronic with the nearest noble gas. Removing (or adding) more electrons than needed to attain the noble gas configuration requires a prohibitive amount of energy.
- Metals in Groups 3A(13) to 5A(15) lose either their *np* electrons or both their *ns* and *np* electrons.
- Transition metals lose *ns* electrons before $(n - 1)d$ electrons and commonly form more than one ion.
- Many transition metals and their compounds are paramagnetic because their atoms (or ions) have unpaired electrons.
- Cations are smaller and anions larger than their parent atoms. Ionic radius increases down a group. Across a period, ionic radii generally decrease, but a large increase occurs from the last cation to the first anion.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The meaning of the periodic law and the arrangement of elements by atomic number (Introduction)
2. The reason for the spin quantum number and its two possible values (§8.1)
3. How the exclusion principle applies to orbital filling (§8.1)
4. The effects of nuclear charge, shielding, and penetration on the splitting of energy levels; the meaning of effective nuclear charge (§8.1)
5. How the arrangement of the periodic table is based on the order of sublevel energies (§8.2)
6. How sublevels are filled in main-group and transition elements; the importance of Hund's rule (§8.2)
7. How outer electron configuration within a group is related to chemical behavior (§8.2)
8. The distinction among inner, outer, and valence electrons (§8.2)
9. The meaning of atomic radius, ionization energy, and electron affinity (§8.3)
10. How *n* value and effective nuclear charge give rise to the periodic trends of atomic size and ionization energy (§8.3)
11. The importance of core electrons to the pattern of successive ionization energies (§8.3)
12. How atomic properties relate to the tendency to form ions (§8.3)
13. The general properties of metals and nonmetals (§8.4)
14. How vertical and horizontal trends in metallic behavior are related to ion formation and oxide acidity (§8.4)
15. How atomic size and IE relate to redox behavior (§8.4)
16. Why main-group ions are either isoelectronic with the nearest noble gas or have a pseudo–noble gas electron configuration (§8.4)
17. Why transition elements lose *ns* electrons first (§8.4)
18. The origin of paramagnetic and diamagnetic behavior (§8.4)
19. The relation between ionic and atomic size and the trends in ionic size (§8.4)

Master These Skills

1. Correlating orbital diagrams and the set of quantum numbers for any electron in an atom (SP 8.1)
2. Writing full and condensed electron configurations for an element (SP 8.2)
3. Using periodic trends to rank elements by atomic size and first ionization energy (SPs 8.3, 8.4)
4. Identifying an element from its successive ionization energies (SP 8.5)
5. Writing electron configurations of main-group and transition metal ions (SPs 8.6, 8.7)
6. Using periodic trends to rank ions by size (SP 8.8)

Key Terms

Page numbers appear in parentheses.

Introduction
periodic law (323)
electron configuration (323)

Section 8.1
spin quantum number (m_s) (324)
exclusion principle (325)
shielding (325)
effective nuclear charge (Z_{eff}) (325)
penetration (326)

Section 8.2
aufbau principle (327)
orbital diagram (327)
Hund's rule (328)
transition elements (332)
inner (core) electrons (334)
outer electrons (334)
valence electrons (334)
inner transition elements (335)
lanthanides (rare earths) (335)
actinides (335)

Section 8.3
atomic size (336)
metallic radius (336)
covalent radius (336)
ionization energy (IE) (339)
electron affinity (EA) (343)

Section 8.4
amphoteric (346)
isoelectronic (347)
pseudo–noble gas configuration (347)
paramagnetism (349)
diamagnetism (349)
ionic radius (350)

Key Equations and Relationships

Page numbers appear in parentheses.

8.1 Defining the energy order of sublevels in terms of the angular momentum quantum number (l value) (326):

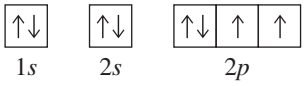
Order of sublevel energies: $s < p < d < f$

8.2 Meaning of the first ionization energy (339):

$$\text{Atom}(g) \longrightarrow \text{ion}^+(g) + e^- \qquad \Delta E = IE_1 > 0$$

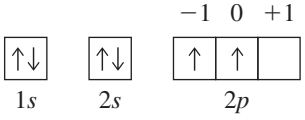
BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

8.1A The element has eight electrons, so $Z = 8$: oxygen.

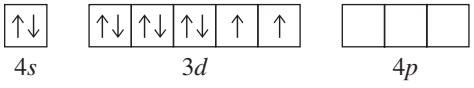


Sixth electron: $n = 2$, $l = 1$, $m_l = 0$, $+\frac{1}{2}$

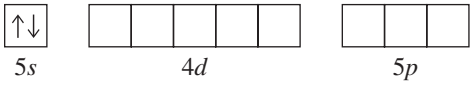
8.1B The element is carbon; $1s^2 2s^2 2p^2$.



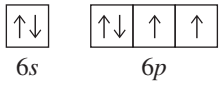
8.2A (a) For Ni, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^8$; [Ar] $4s^2 3d^8$



Ni has 18 inner electrons.
(b) For Sr, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2$; [Kr] $5s^2$



Sr has 36 inner electrons.
(c) For Po, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6 6s^2 4f^{14} 5d^{10} 6p^4$; [Xe] $6s^2 4f^{14} 5d^{10} 6p^4$



Po has 78 inner electrons.

8.2B (a) As; $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^3$; [Ar] $4s^2 3d^{10} 4p^3$; As has 28 inner electrons.
(b) Zr; $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^2$; [Kr] $5s^2 4d^2$; Zr has 36 inner electrons.
(c) I; $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^5$; [Kr] $5s^2 4d^{10} 5p^5$; I has 46 inner electrons.

8.3A (a) Cl < Br < Se; (b) Xe < I < Ba

8.3B (a) Cs > As > S; (b) K > P > F

8.4A (a) Sn < Sb < I; (b) Cs < Na < Mg

8.4B (a) O > As > Rb; (b) Cl > Si > Sn

8.5A Q is aluminum: $1s^2 2s^2 2p^6 3s^2 3p^1$

8.5B Rb: [Kr] $5s^1$; Sr: [Kr] $5s^2$; Y: [Kr] $5s^2 4d^1$
Highest IE_2: Rb; highest IE_3: Sr

8.6A (a) Ba ([Xe] $6s^2$) $\longrightarrow$ Ba^{2+} ([Xe]) + $2e^-$
(b) O ([He] $2s^2 2p^4$) + $2e^-$ $\longrightarrow$ O^{2-} ([He] $2s^2 2p^6$) (same as Ne)
(c) Pb ([Xe] $6s^2 4f^{14} 5d^{10} 6p^2$) $\longrightarrow$ Pb^{2+} ([Xe] $6s^2 4f^{14} 5d^{10}$) + $2e^-$
Pb ([Xe] $6s^2 4f^{14} 5d^{10} 6p^2$) $\longrightarrow$ Pb^{4+} ([Xe] $4f^{14} 5d^{10}$) + $4e^-$

8.6B (a) F ([He] $2s^2 2p^5$) + e^- $\longrightarrow$ F^- ([He] $2s^2 2p^6$) (same as Ne)
(b) Tl ([Xe] $6s^2 4f^{14} 5d^{10} 6p^1$) $\longrightarrow$ Tl^+ ([Xe] $6s^2 4f^{14} 5d^{10}$) + e^-
Tl ([Xe] $6s^2 4f^{14} 5d^{10} 6p^1$) $\longrightarrow$ Tl^{3+} ([Xe] $4f^{14} 5d^{10}$) + $3e^-$
(c) Mg ([Ne] $3s^2$) $\longrightarrow$ Mg^{2+} ([Ne]) + $2e^-$

8.7A (a) V^{3+}: [Ar] $3d^2$; paramagnetic
(b) Ni^{2+}: [Ar] $3d^8$; paramagnetic
(c) La^{3+}: [Xe]; not paramagnetic (diamagnetic)

8.7B (a) Zr^{2+}: [Kr] $4d^2$; 2 unpaired electrons
(b) Os^{3+}: [Xe] $4f^{14} 5d^5$; 5 unpaired electrons
(c) Co^{2+}: [Ar] $3d^7$; 3 unpaired electrons

8.8A (a) $F^- < Cl^- < Br^-$
(b) $Mg^{2+} < Na^+ < F^-$
(c) $Cr^{3+} < Cr^{2+}$

8.8B (a) $V^{2+} > V^{3+}$
(b) $Cs^+ > Rb^+ > K^+$
(c) $I^- > Cs^+ > Ba^{2+}$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. Comprehensive Problems are based on material from any section or previous chapter.

Introduction

Concept Review Questions

8.1 What would be your reaction to a claim that a new element had been discovered and it fit between tin (Sn) and antimony (Sb) in the periodic table?

8.2 Based on results of his study of atomic x-ray spectra, Moseley discovered a relationship that replaced atomic mass as the criterion for ordering the elements. By what criterion are the elements now ordered in the periodic table? Give an example of a sequence of element order that was confirmed by Moseley's findings.

Skill-Building Exercises (grouped in similar pairs)

8.3 Before Mendeleev published his periodic table, Döbereiner grouped elements with similar properties into "triads," in which the unknown properties of one member could be predicted by averaging known values of the properties of the others. To test this idea, predict the values of the following quantities:
(a) The atomic mass of K from the atomic masses of Na and Rb
(b) The melting point of Br_2 from the melting points of Cl_2 (−101.0°C) and I_2 (113.6°C) (actual value = −7.2°C)

8.4 To test Döbereiner's idea (Problem 8.3), predict:
(a) The boiling point of HBr from the boiling points of HCl (−84.9°C) and HI (−35.4°C) (actual value = −67.0°C)
(b) The boiling point of AsH_3 from the boiling points of PH_3 (−87.4°C) and SbH_3 (−17.1°C) (actual value = −55°C)

Characteristics of Many-Electron Atoms

Concept Review Questions

8.5 Summarize the rules for the allowable values of the four quantum numbers of an electron in an atom.

8.6 Which of the quantum numbers relate(s) to the electron only? Which relate(s) to the orbital?

8.7 State the exclusion principle. What does it imply about the number and spin of electrons in an atomic orbital?

8.8 What is the key distinction between sublevel energies in one-electron species, such as the H atom, and those in many-electron species, such as the C atom? What factors lead to this distinction? Would you expect the pattern of sublevel energies in Be^{3+} to be more like that in H or that in C? Explain.

8.9 Define *shielding* and *effective nuclear charge*. What is the connection between the two?

8.10 What is penetration? How is it related to shielding? Use the penetration effect to explain the difference in relative orbital energies of a 3*p* and a 3*d* electron in the same atom.

Skill-Building Exercises (grouped in similar pairs)

8.11 How many electrons in an atom can have each of the following quantum number or sublevel designations?
(a) $n = 2, l = 1$ (b) 3*d* (c) 4*s*

8.12 How many electrons in an atom can have each of the following quantum number or sublevel designations?
(a) $n = 2, l = 1, m_l = 0$ (b) 5*p* (c) $n = 4, l = 3$

8.13 How many electrons in an atom can have each of the following quantum number or sublevel designations?
(a) 4*p* (b) $n = 3, l = 1, m_l = +1$ (c) $n = 5, l = 3$

8.14 How many electrons in an atom can have each of the following quantum number or sublevel designations?
(a) 2*s* (b) $n = 3, l = 2$ (c) 6*d*

The Quantum-Mechanical Model and the Periodic Table

(Sample Problems 8.1 and 8.2)

Concept Review Questions

8.15 State the periodic law, and explain its relation to electron configuration. (Use Na and K in your explanation.)

8.16 State Hund's rule in your own words, and show its application in the orbital diagram of the nitrogen atom.

8.17 How does the aufbau principle, in connection with the periodic law, lead to the format of the periodic table?

8.18 For main-group elements, are outer electron configurations similar or different within a group? Within a period? Explain.

8.19 For which blocks of elements are outer electrons the same as valence electrons? For which are *d* electrons often included among the valence electrons?

8.20 What is the electron capacity of the *n*th energy level? What is the capacity of the fourth energy level?

Skill-Building Exercises (grouped in similar pairs)

8.21 Write a full set of quantum numbers for the following:
(a) The outermost electron in an Rb atom
(b) The electron gained when an S^- ion becomes an S^{2-} ion
(c) The electron lost when an Ag atom ionizes
(d) The electron gained when an F^- ion forms from an F atom

8.22 Write a full set of quantum numbers for the following:
(a) The outermost electron in an Li atom
(b) The electron gained when a Br atom becomes a Br^- ion
(c) The electron lost when a Cs atom ionizes
(d) The highest energy electron in the ground-state B atom

8.23 Write the full ground-state electron configuration for each:
(a) Rb (b) Ge (c) Ar

8.24 Write the full ground-state electron configuration for each:
(a) Br (b) Mg (c) Se

8.25 Write the full ground-state electron configuration for each:
(a) Cl (b) Si (c) Sr

8.26 Write the full ground-state electron configuration for each:
(a) S (b) Kr (c) Cs

8.27 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:
(a) Ti (b) Cl (c) V

8.28 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:
(a) Ba (b) Co (c) Ag

8.29 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:
(a) Mn (b) P (c) Fe

8.30 Draw a partial (valence-level) orbital diagram, and write the condensed ground-state electron configuration for each:
(a) Ga (b) Zn (c) Sc

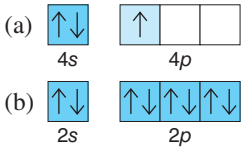
8.31 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:
(a) [He] $2s^2 2p^4$ (b) [Ne] $3s^2 3p^3$

8.32 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:
(a) [Kr] $5s^2 4d^{10}$ (b) [Ar] $4s^2 3d^8$

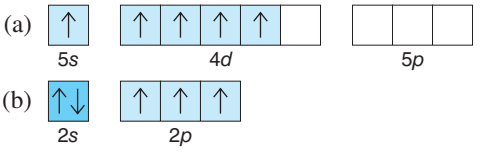
8.33 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:
(a) [Ne] $3s^2 3p^5$ (b) [Ar] $4s^2 3d^{10} 4p^3$

8.34 Draw the partial (valence-level) orbital diagram, and write the symbol, group number, and period number of the element:
(a) [Ar] $4s^2 3d^5$ (b) [Kr] $5s^2 4d^2$

8.35 From each partial (valence-level) orbital diagram, write the condensed electron configuration and group number:



8.36 From each partial (valence-level) orbital diagram, write the condensed electron configuration and group number:



8.37 How many inner, outer, and valence electrons are present in an atom of each of the following elements?
(a) O (b) Sn (c) Ca (d) Fe (e) Se

8.38 How many inner, outer, and valence electrons are present in an atom of each of the following elements?
(a) Br (b) Cs (c) Cr (d) Sr (e) F

8.39 Identify each element below, and give the symbols of the other elements in its group:
(a) [He] $2s^2 2p^1$ (b) [Ne] $3s^2 3p^4$ (c) [Xe] $6s^2 5d^1$

8.40 Identify each element below, and give the symbols of the other elements in its group:
(a) [Ar] $4s^2 3d^{10} 4p^4$ (b) [Xe] $6s^2 4f^{14} 5d^2$ (c) [Ar] $4s^2 3d^5$

8.41 Identify each element below, and give the symbols of the other elements in its group:
(a) [He] $2s^2 2p^2$ (b) [Ar] $4s^2 3d^3$ (c) [Ne] $3s^2 3p^3$

8.42 Identify each element below, and give the symbols of the other elements in its group:
(a) [Ar] $4s^2 3d^{10} 4p^2$ (b) [Ar] $4s^2 3d^7$ (c) [Kr] $5s^2 4d^5$

Problems in Context

8.43 After an atom in its ground state absorbs energy, it exists in an excited state. Spectral lines are produced when the atom returns to its ground state. The yellow-orange line in the sodium spectrum, for example, is produced by the emission of energy when excited sodium atoms return to their ground state. Write the electron configuration and the orbital diagram of the first excited state of sodium. (*Hint:* The outermost electron is excited.)

8.44 One reason spectroscopists study excited states is to gain information about the energies of orbitals that are unoccupied in an atom's ground state. Each of the following electron configurations represents an atom in an excited state. Identify the element, and write its condensed ground-state configuration:
(a) $1s^2 2s^2 2p^6 3s^1 3p^1$ (b) $1s^2 2s^2 2p^6 3s^2 3p^4 4s^1$
(c) $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^4 4p^1$ (d) $1s^2 2s^2 2p^5 3s^1$

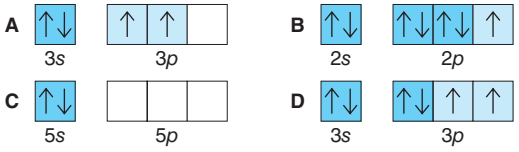
Trends in Three Atomic Properties

(Sample Problems 8.3 to 8.5)

Concept Review Questions

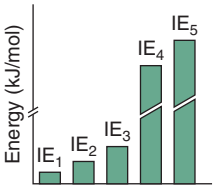
8.45 If the exact outer limit of an isolated atom cannot be measured, what criterion can we use to determine atomic radii? What is the difference between a covalent radius and a metallic radius?

8.46 Given the following partial (valence-level) electron configurations, (a) identify each element, (b) rank the four elements in order of increasing atomic size, and (c) rank them in order of increasing ionization energy:



8.47 In what region of the periodic table will you find elements with relatively high IEs? With relatively low IEs?

8.48 (a) Why do successive IEs of a given element always increase? (b) When the difference between successive IEs of a given element is exceptionally large (for example, between IE_1 and IE_2 of K), what do we learn about its electron configuration? (c) The bars represent the relative magnitudes of the first five ionization energies of an atom:



Identify the element and write its complete electron configuration, assuming it comes from (a) Period 2; (b) Period 3; (c) Period 4.

8.49 In a plot of IE_1 for the Period 3 elements (see Figure 8.15, p. 340), why do the values for elements in Groups 3A(13) and 6A(16) drop slightly below the generally increasing trend?

8.50 Which group in the periodic table has elements with high (endothermic) IE_1 and very negative (exothermic) first electron affinities (EA_1)? Give the charge on the ions these atoms form.

8.51 The EA_2 of an oxygen atom is positive, even though its EA_1 is negative. Why does this change of sign occur? Which other elements exhibit a positive EA_2? Explain.

8.52 How does *d*-electron shielding influence atomic size among the Period 4 transition elements?

Skill-Building Exercises (grouped in similar pairs)

8.53 Arrange each set in order of *increasing* atomic size:
(a) Rb, K, Cs (b) C, O, Be (c) Cl, K, S (d) Mg, K, Ca

8.54 Arrange each set in order of *decreasing* atomic size:
(a) Ge, Pb, Sn (b) Sn, Te, Sr (c) F, Ne, Na (d) Be, Mg, Na

8.55 Arrange each set of atoms in order of *increasing* IE_1:
(a) Sr, Ca, Ba (b) N, B, Ne (c) Br, Rb, Se (d) As, Sb, Sn

8.56 Arrange each set of atoms in order of *decreasing* IE_1:
(a) Na, Li, K (b) Be, F, C (c) Cl, Ar, Na (d) Cl, Br, Se

8.57 Write the full electron configuration of the Period 2 element with the following successive IEs (in kJ/mol):
$IE_1 = 801$ $IE_2 = 2427$ $IE_3 = 3659$
$IE_4 = 25{,}022$ $IE_5 = 32{,}822$

8.58 Write the full electron configuration of the Period 3 element with the following successive IEs (in kJ/mol):
$IE_1 = 738$ $IE_2 = 1450$ $IE_3 = 7732$
$IE_4 = 10{,}539$ $IE_5 = 13{,}628$

8.59 Which element in each of the following sets would you expect to have the *highest* IE_2?
(a) Na, Mg, Al (b) Na, K, Fe (c) Sc, Be, Mg

8.60 Which element in each of the following sets would you expect to have the *lowest* IE_3?
(a) Na, Mg, Al (b) K, Ca, Sc (c) Li, Al, B

Atomic Properties and Chemical Reactivity

(Sample Problems 8.6 to 8.8)

Concept Review Questions

8.61 List three ways in which metals and nonmetals differ.

8.62 Summarize the trend in metallic character as a function of position in the periodic table. Is it the same as the trend in atomic size? The trend in ionization energy?

8.63 Explain the relationship between atomic size and reducing strength in Group 1A(1). Explain the relationship between IE and oxidizing strength in Group 7A(17).

8.64 Summarize the acid-base behavior of the main-group metal and nonmetal oxides in water. How does oxide acidity in water change down a group and across a period?

8.65 What ions are possible for the two largest stable elements in Group 4A(14)? How does each arise?

8.66 What is a pseudo–noble gas configuration? Give an example of one ion from Group 3A(13) that has it.

8.67 How are measurements of paramagnetism used to support electron configurations derived spectroscopically? Use Cu(I) and Cu(II) chlorides as examples.

8.68 The charges of a set of isoelectronic ions vary from 3+ to 3−. Place the ions in order of increasing size.

Skill-Building Exercises (grouped in similar pairs)

8.69 Which element would you expect to be *more* metallic?
(a) Ca or Rb (b) Mg or Ra (c) Br or I

8.70 Which element would you expect to be *more* metallic?
(a) S or Cl (b) In or Al (c) As or Br

8.71 Which element would you expect to be *less* metallic?
(a) Sb or As (b) Si or P (c) Be or Na

8.72 Which element would you expect to be *less* metallic?
(a) Cs or Rn (b) Sn or Te (c) Se or Ge

8.73 Does the reaction of a main-group nonmetal oxide in water produce an acidic or a basic solution? Write a balanced equation for the reaction of a Group 6A(16) nonmetal oxide with water.

8.74 Does the reaction of a main-group metal oxide in water produce an acidic or a basic solution? Write a balanced equation for the reaction of a Group 2A(2) oxide with water.

8.75 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:
(a) Cl (b) Na (c) Ca

8.76 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:
(a) Rb (b) N (c) Br

8.77 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:
(a) Al (b) S (c) Sr

8.78 Write the charge and full ground-state electron configuration of the monatomic ion most likely to be formed by each:
(a) P (b) Mg (c) Se

8.79 How many unpaired electrons are present in a ground-state atom from each of the following groups?
(a) 2A(2) (b) 5A(15) (c) 8A(18) (d) 3A(13)

8.80 How many unpaired electrons are present in a ground-state atom from each of the following groups?
(a) 4A(14) (b) 7A(17) (c) 1A(1) (d) 6A(16)

8.81 Which of these are paramagnetic in their ground state?
(a) Ga (b) Si (c) Be (d) Te

8.82 Are compounds of these ground-state ions paramagnetic?
(a) Ti^{2+} (b) Zn^{2+} (c) Ca^{2+} (d) Sn^{2+}

8.83 Write the condensed ground-state electron configurations of these transition metal ions, and state which are paramagnetic:
(a) V^{3+} (b) Cd^{2+} (c) Co^{3+} (d) Ag^{+}

8.84 Write the condensed ground-state electron configurations of these transition metal ions, and state which are paramagnetic:
(a) Mo^{3+} (b) Au^{+} (c) Mn^{2+} (d) Hf^{2+}

8.85 Palladium (Pd; $Z = 46$) is diamagnetic. Draw partial orbital diagrams to show which of the following electron configurations is consistent with this fact:
(a) [Kr] $5s^2 4d^8$ (b) [Kr] $4d^{10}$ (c) [Kr] $5s^1 4d^9$

8.86 Niobium (Nb; $Z = 41$) has an anomalous ground-state electron configuration for a Group 5B(5) element: [Kr] $5s^1 4d^4$. What is the expected electron configuration for elements in this group? Draw partial orbital diagrams to show how paramagnetic measurements could support niobium's actual configuration.

8.87 Rank the ions in each set in order of *increasing* size, and explain your ranking:
(a) Li^+, K^+, Na^+ (b) Se^{2-}, Rb^+, Br^- (c) O^{2-}, F^-, N^{3-}

8.88 Rank the ions in each set in order of *decreasing* size, and explain your ranking:
(a) Se^{2-}, S^{2-}, O^{2-} (b) Te^{2-}, Cs^+, I^- (c) Sr^{2+}, Ba^{2+}, Cs^+

Comprehensive Problems

8.89 Name the element described in each of the following:
(a) Smallest atomic radius in Group 6A(16)
(b) Largest atomic radius in Period 6
(c) Smallest metal in Period 3
(d) Highest IE_1 in Group 4A(14)
(e) Lowest IE_1 in Period 5
(f) Most metallic in Group 5A(15)
(g) Group 3A(13) element that forms the most basic oxide
(h) Period 4 element with highest energy level filled
(i) Condensed ground-state electron configuration of [Ne] $3s^2 3p^2$
(j) Condensed ground-state electron configuration of [Kr] $5s^2 4d^6$
(k) Forms 2+ ion with electron configuration [Ar] $3d^3$
(l) Period 5 element that forms 3+ ion with pseudo–noble gas configuration
(m) Period 4 transition element that forms 3+ diamagnetic ion
(n) Period 4 transition element that forms 2+ ion with a half-filled *d* sublevel
(o) Heaviest lanthanide
(p) Period 3 element whose 2− ion is isoelectronic with Ar
(q) Alkaline earth metal whose cation is isoelectronic with Kr
(r) Group 5A(15) metalloid with the most acidic oxide

8.90 Use electron configurations to account for the stability of the lanthanide ions Ce^{4+} and Eu^{2+}.

8.91 When a nonmetal oxide reacts with water, it forms an oxoacid with the same oxidation number as the nonmetal. Give the name and formula of the oxide used to prepare each of these oxoacids: (a) hypochlorous acid; (b) chlorous acid; (c) chloric acid; (d) perchloric acid; (e) sulfuric acid; (f) sulfurous acid; (g) nitric acid; (h) nitrous acid; (i) carbonic acid; (j) phosphoric acid.

8.92 A fundamental relationship of electrostatics states that the energy required to separate opposite charges of magnitudes Q_1 and Q_2 that are a distance d apart is proportional to $\dfrac{Q_1 \times Q_2}{d}$. Use this relationship and any other factors to explain the following:
(a) The IE_2 of He ($Z = 2$) is *more* than twice the IE_1 of H ($Z = 1$).
(b) The IE_1 of He is *less* than twice the IE_1 of H.

8.93 The energy difference between the 5*d* and 6*s* sublevels in gold accounts for its color. Assuming this energy difference is about 2.7 eV (electron volt; 1 eV = 1.602×10^{-19} J), explain why gold has a warm yellow color.

8.94 Write the formula and name of the compound formed from the following ionic interactions: (a) The 2+ ion and the 1− ion are both isoelectronic with the atoms of a chemically unreactive Period 4 element. (b) The 2+ ion and the 2− ion are both isoelectronic with the Period 3 noble gas. (c) The 2+ ion is the smallest with a filled *d* sublevel; the anion forms from the smallest halogen. (d) The ions form from the largest and smallest ionizable atoms in Period 2.

8.95 The energy changes for many unusual reactions can be determined using Hess's law (Section 6.5).
(a) Calculate ΔE for the conversion of $F^-(g)$ into $F^+(g)$.
(b) Calculate ΔE for the conversion of $Na^+(g)$ into $Na^-(g)$.

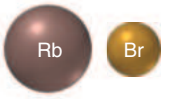
8.96 Discuss each conclusion from a study of redox reactions:
(a) The sulfide ion functions only as a reducing agent.
(b) The sulfate ion functions only as an oxidizing agent.
(c) Sulfur dioxide functions as an oxidizing or a reducing agent.

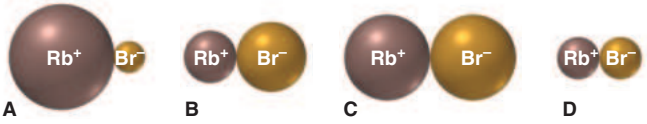
8.97 The hot glowing gases around the Sun, the *corona*, can reach millions of degrees Celsius, high enough to remove many electrons from gaseous atoms. Iron ions with charges as high as 14+ have been observed in the corona. Which ions from Fe^+ to Fe^{14+} are paramagnetic? Which would be most strongly attracted to a magnetic field?

8.98 There are some exceptions to the trends of first and successive ionization energies. For each of the following pairs, explain which ionization energy would be higher:
(a) IE_1 of Ga or IE_1 of Ge
(b) IE_2 of Ga or IE_2 of Ge
(c) IE_3 of Ga or IE_3 of Ge
(d) IE_4 of Ga or IE_4 of Ge

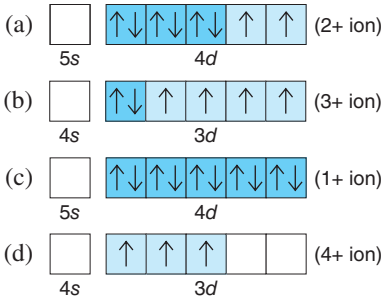
8.99 Use Figure 8.16, p. 340, to find: (a) the longest wavelength of electromagnetic (EM) radiation that can ionize an alkali metal atom; (b) the longest wavelength of EM radiation that can ionize an alkaline earth metal atom; (c) the elements, other than the alkali and alkaline earth metals, that could also be ionized by the radiation of part (b); (d) the region of the EM spectrum in which these photons are found.

8.100 Rubidium and bromine atoms are depicted at right. (a) What monatomic ions do they form? (b) What electronic feature characterizes this pair of ions, and which noble gas are they related to? (c) Which pair best represents the relative ionic sizes?





8.101 Partial (valence-level) electron configurations for four different ions are shown below:



Identify the elements from which the ions are derived, and write the formula of the oxide each ion forms.

8.102 Data from the planet Zog for some main-group elements are shown below (Zoggian units are linearly related to Earth units but are not shown). Radio signals from Zog reveal that balloonium is a monatomic gas with two positive nuclear charges. Use the data to deduce the names that Earthlings give to these elements:

Name	Atomic Radius	IE_1	EA_1
Balloonium	10	339	0
Inertium	24	297	+4.1
Allotropium	34	143	−28.6
Brinium	63	70.9	−7.6
Canium	47	101	−15.3
Fertilium	25	200	0
Liquidium	38	163	−46.4
Utilium	48	82.4	−6.1
Crimsonium	72	78.4	−2.9

Concepts and Skills to Review Before You Study This Chapter

- characteristics of ionic and covalent substances; Coulomb's law (Section 2.7)
- polar covalent bonds and the polarity of water (Section 4.1)
- Hess's law, ΔH°_{rxn}, and ΔH°_f (Sections 6.5 and 6.6)
- atomic and ionic electron configurations (Sections 8.2 and 8.4)
- trends in atomic properties and metallic behavior (Sections 8.3 and 8.4)

Why do substances behave as they do? That is, why is table salt *(photo),* or any other ionic substance, a hard, brittle, high-melting solid that conducts a current only when molten or dissolved in water? Why is candle wax (along with most covalent substances) low melting, soft, and nonconducting, even though diamond (and a few other exceptions) is high melting and extremely hard? And why is copper (and most other metals) shiny, malleable, and able to conduct a current whether molten or solid? The answers lie in the *type of bonding within the substance*. In Chapter 8, we examined the properties of individual atoms and ions. But the behavior of matter really depends on how those atoms and ions bond.

IN THIS CHAPTER . . . *We examine how atomic properties give rise to three models of chemical bonding—ionic, covalent, and metallic—and how each model explains the behavior of substances.*

- We see how metals and nonmetals combine via three types of bonding and learn how to depict atoms and ions with Lewis symbols.
- We detail the steps in the formation of an ionic solid and focus on the importance of lattice energy.
- Covalent bonding occurs in the vast majority of compounds, so we look at how a bond forms and discuss the relations among bond order, energy, and length.
- We explore the relationship between bond energy and the enthalpy change of a reaction, with a focus on fuels and foods.
- We examine periodic trends in electronegativity and learn its role in the range of bonding, from pure covalent to ionic, and in bond polarity.
- We consider a simple bonding model that explains the properties of metals.

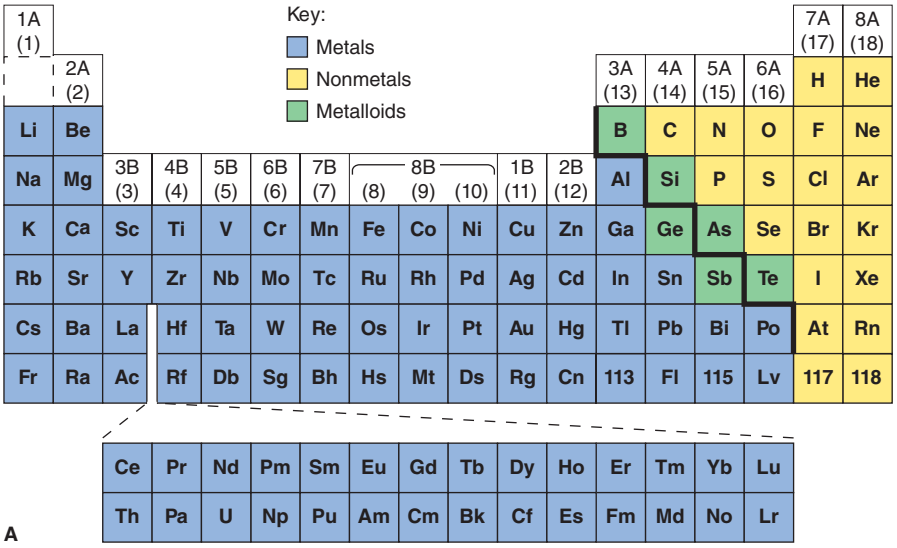
9.1 ATOMIC PROPERTIES AND CHEMICAL BONDS

Just as the electron configuration and the strength of nucleus-electron attractions determine the properties of an atom, the type and strength of chemical bonds determine the properties of a substance.

The Three Ways Elements Combine

Before we examine the types of chemical bonding, we should answer a fundamental question: why do atoms bond at all? In general, *bonding lowers the potential energy between positive and negative particles* (see Figure 1.3C, p. 9), whether they are oppositely charged ions or nuclei and electrons.

As you saw in Chapter 8, there is, in general, a gradation from more metallic elements to more nonmetallic elements across a period *and* up a group (Figure 9.1, *next page*). Three models of bonding result from the three ways atoms of these two types of elements can combine.



A

Figure 9.1 **A comparison of metals and nonmetals. A,** Location within the periodic table. **B,** Relative magnitudes of some atomic properties across a period.

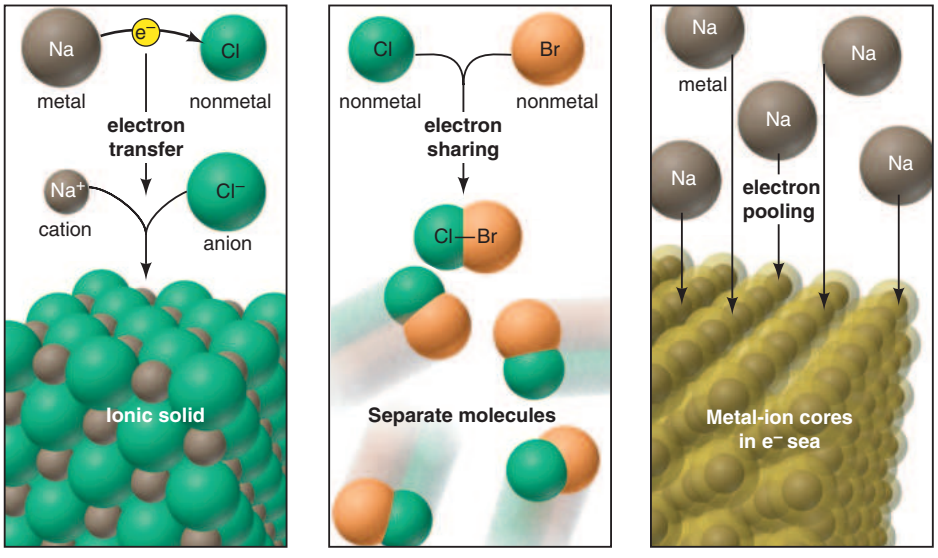
B

PROPERTY	METAL ATOM	NONMETAL ATOM
Atomic size	Larger	Smaller
Z_{eff}	Lower	Higher
IE	Lower	Higher
EA	Less negative	More negative

1. *Metal with nonmetal: electron transfer and ionic bonding* (Figure 9.2A). We observe *electron transfer* and **ionic bonding** between atoms with *large differences in their tendencies to lose or gain electrons*. Such differences occur between reactive metals [Groups 1A(1) and 2A(2)] and nonmetals [Group 7A(17) and the top of Group 6A(16)]. A metal atom (low IE) loses its one or two valence electrons, and a nonmetal atom (highly negative EA) gains the electron(s). As the transfer of electron(s) from metal atom to nonmetal atom occurs, each atom forms an ion with a noble gas electron configuration. The electrostatic attractions between these positive and negative ions draw them into a three-dimensional array to form an ionic solid. The chemical formula of an ionic compound is the *empirical formula* because it gives the cation-to-anion ratio.

2. *Nonmetal with nonmetal: electron sharing and covalent bonding* (Figure 9.2B). When two atoms *differ little, or not at all, in their tendencies to lose or gain electrons,* we observe *electron sharing* and **covalent bonding,** which occurs most commonly between nonmetals. Each nonmetal atom holds onto its own electrons tightly (high IE) and attracts other electrons as well (highly negative EA). The nucleus of each atom attracts the valence electrons of the other, which draws the atoms together. The shared electron pair is typically *localized* between the two atoms, linking them in a covalent bond of a particular length and strength. In most cases, separate molecules result when atoms bond covalently. Note that the chemical formula of a covalent compound is the *molecular formula* because it gives the actual numbers of atoms in each molecule.

Figure 9.2 **Three models of chemical bonding.**



A Ionic bonding B Covalent bonding C Metallic bonding

3. *Metal with metal: electron pooling and metallic bonding* (Figure 9.2C). A different way to share electrons occurs with metals. Their atoms are relatively large, and the few outer electrons are well shielded by filled inner levels (core electrons). Thus, they lose outer electrons easily (low IE) and do not gain them readily (slightly negative or positive EA). These properties lead metal atoms to share their valence electrons, but not by covalent bonding. In the simplest model of **metallic bonding,** the enormous number of atoms in a sample of a metal *pool* their valence electrons into a "sea" of electrons that "flows" between and around each metal-ion core (nucleus plus inner electrons), thereby attracting and holding them together. Unlike the localized electrons in covalent bonding, electrons in metallic bonding are *delocalized,* moving freely throughout the entire piece of metal.

In the world of real substances, there are exceptions to these idealized models, so you can't always predict bond type from positions of the elements in the periodic table. As just one example, when the metal beryllium [Group 2A(2)] combines with the nonmetal chlorine [Group 7A(17)], the bonding fits the covalent model better than the ionic model. Just as we see gradations in atomic behavior within a group or period, we see a gradation in bonding from one type to another between atoms from different groups and periods (Figure 9.3).

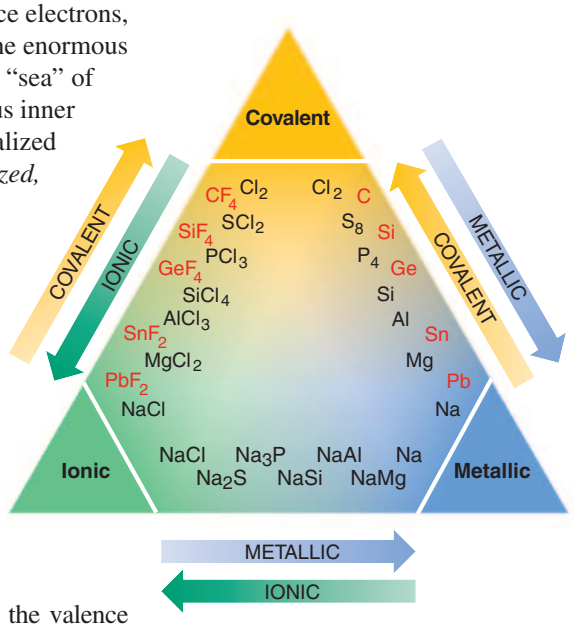


Figure 9.3 Gradations in bond type among Period 3 *(black type)* and Group 4A *(red type)* elements.

Lewis Symbols and the Octet Rule

Before examining each of the models, we consider a method for depicting the valence electrons of interacting atoms that predicts how they bond. In a **Lewis electron-dot symbol** (named for the American chemist G. N. Lewis), the element symbol represents the nucleus *and* inner electrons, and dots around the symbol represent the valence electrons (Figure 9.4). Note that the pattern of dots is the same for elements within a group.

Period	1A(1)	2A(2)	3A(13)	4A(14)	5A(15)	6A(16)	7A(17)	8A(18)
	ns^1	ns^2	ns^2np^1	ns^2np^2	ns^2np^3	ns^2np^4	ns^2np^5	ns^2np^6
2	Li	Be	B	C	N	O	F	Ne
3	Na	Mg	Al	Si	P	S	Cl	Ar

Figure 9.4 Lewis electron-dot symbols for elements in Periods 2 and 3.

We use these steps to write the Lewis symbol for any main-group element:

1. Note its A-group number (1A to 8A), which is the number of valence-electron dots.
2. Place one dot at a time on each of the four sides (top, right, bottom, left) of the element symbol.
3. Keep adding dots, pairing them, until all are used up.

The specific placement of dots is not important; that is, in addition to the one shown in Figure 9.4, the Lewis symbol for nitrogen can *also* be written as

·N: or ·N· or :N·

The Lewis symbol provides information about an element's bonding behavior:

- For a *metal,* the *total* number of dots is the number of electrons an atom loses to form a cation; for example, Mg loses 2 to form Mg^{2+}.
- For a *nonmetal,* the number of *unpaired* dots equals either the number of electrons an atom *gains* to form an anion (F gains 1 to form F^-) or the number it *shares* to form covalent bonds.

The Lewis symbol for carbon illustrates the last point. Rather than one pair of dots and two unpaired dots, as its electron configuration seems to call for ([He] $2s^2 2p^2$), carbon has four unpaired dots because it forms four bonds. Larger nonmetals can form as many bonds as the number of dots in their Lewis symbol (Chapter 10).

In his pioneering studies, Lewis generalized much of bonding behavior into the **octet rule:** *when atoms bond, they lose, gain, or share electrons to attain a filled outer level of eight electrons* (*or two,* for H and Li). The octet rule holds for nearly all of the compounds of Period 2 elements and a large number of others as well.

Summary of Section 9.1

- Nearly all naturally occurring substances consist of atoms or ions bonded to others. Chemical bonding allows atoms to lower their energy.
- Ionic bonding occurs when metal atoms transfer electrons to nonmetal atoms, and the resulting ions attract each other and form an ionic solid.
- Covalent bonding is most common between nonmetal atoms and usually results in individual molecules. Bonded atoms share one or more pairs of electrons that are localized between them.
- Metallic bonding occurs when many metal atoms pool their valence electrons into a delocalized electron "sea" that holds all the atoms in the sample together.
- The Lewis electron-dot symbol of a main-group atom shows valence electrons as dots surrounding the element symbol.
- The octet rule says that, when bonding, many atoms lose, gain, or share electrons to attain a filled outer level of eight (or two) electrons.

9.2 THE IONIC BONDING MODEL

The central idea of the ionic bonding model is the *transfer of electrons from metal atoms to nonmetal atoms to form ions that attract each other and form a solid compound.* In most cases, for the main groups, the ion that forms has a filled outer level of either two or eight electrons (octet rule), the number in the nearest noble gas.

The transfer of an electron from a lithium atom to a fluorine atom is depicted in three ways in Figure 9.5. In each, Li loses its single outer electron and is left with a filled $n = 1$ level (two e^-), while F gains a single electron to fill its $n = 2$ level (eight e^-). In this case, each atom is one electron away from the configuration of its nearest noble gas, so the number of electrons lost by each Li equals the number gained by each F. Therefore, equal numbers of Li^+ and F^- ions form, as the formula LiF indicates. That is, in ionic bonding, *the total number of electrons lost by the metal atom(s) equals the total number of electrons gained by the nonmetal atom(s).*

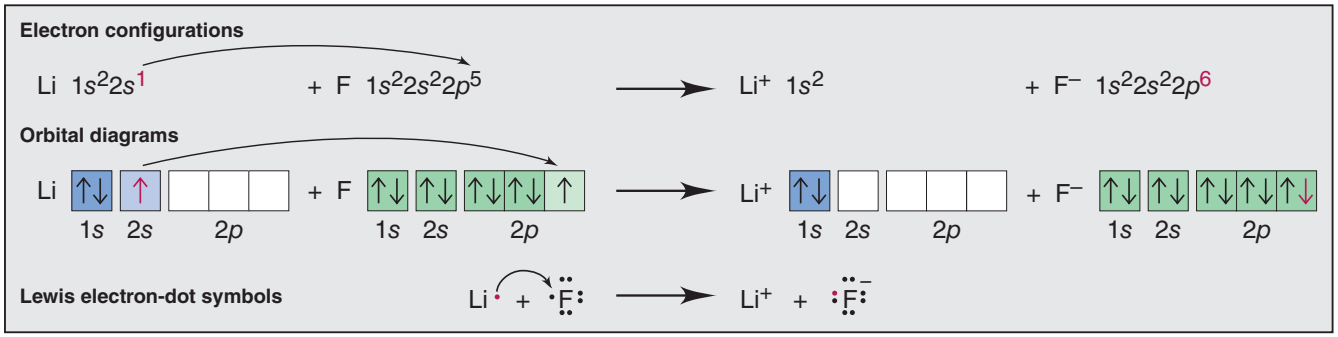

Figure 9.5 Three ways to depict electron transfer in the formation of Li^+ and F^-. The electron being transferred is shown in red.

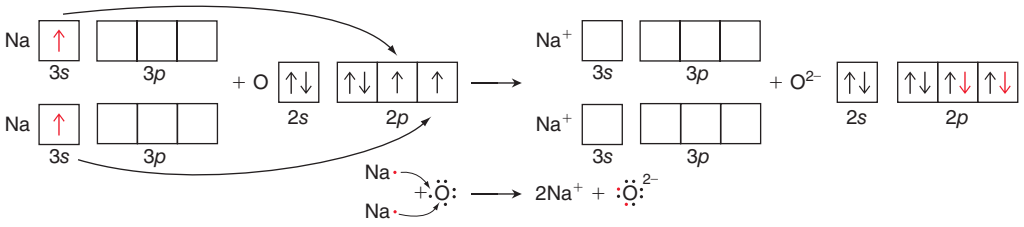
SAMPLE PROBLEM 9.1 Depicting Ion Formation

Problem Use partial orbital diagrams and Lewis symbols to depict the formation of Na^+ and O^{2-} ions from the atoms, and give the formula of the compound formed.

Plan First we draw the orbital diagrams and Lewis symbols for Na and O atoms. To attain filled outer levels, Na loses one electron and O gains two. To make the number of electrons lost equal the number gained, two Na atoms are needed for each O atom.

Solution



The formula is Na_2O.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

9.1A Use condensed electron configurations, partial orbital diagrams (*ns* and *np* only), and Lewis symbols to depict the formation of Mg^{2+} and Cl^- ions from the atoms, and give the formula of the compound formed.

9.1B Use condensed electron configurations, partial orbital diagrams (*ns* and *np* only), and Lewis symbols to depict the formation of Ca^{2+} and O^{2-} ions, and give the formula of the compound formed.

SOME SIMILAR PROBLEMS 9.20 and 9.21

Why Ionic Compounds Form: The Importance of Lattice Energy

You may be surprised to learn that energy is actually *absorbed* during electron transfer. So why does it occur? And, given this absorption of energy, why do ionic substances exist at all? As you'll see, the answer involves the enormous quantity of energy *released* after electron transfer, as the ions form a solid.

1. *The electron-transfer process.* Consider just the electron-transfer process for the formation of lithium fluoride, which involves a gaseous Li atom losing an electron, and a gaseous F atom gaining it:

- The first ionization energy (IE_1) of Li is the energy absorbed when 1 mol of gaseous Li atoms loses 1 mol of valence electrons:

$$Li(g) \longrightarrow Li^+(g) + e^- \qquad IE_1 = 520 \text{ kJ}$$

- The first electron affinity (EA_1) of F is the energy released when 1 mol of gaseous F atoms gains 1 mol of electrons:

$$F(g) + e^- \longrightarrow F^-(g) \qquad EA_1 = -328 \text{ kJ}$$

- Taking the sum shows that electron transfer *by itself* requires energy:

$$Li(g) + F(g) \longrightarrow Li^+(g) + F^-(g) \qquad IE_1 + EA_1 = 192 \text{ kJ}$$

2. *Other steps that absorb energy.* The total energy needed prior to ion formation is added to the sum of IE_1 and EA_1: metallic Li must be made into gaseous Li atoms (161 kJ/mol), and F_2 molecules must be broken into separate F atoms (79.5 kJ/mol).

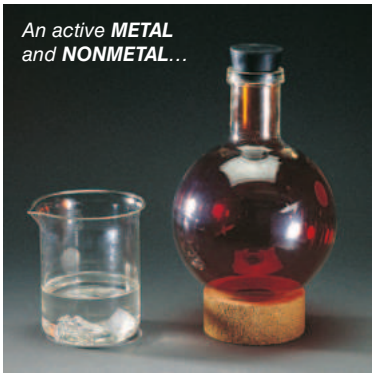
3. *Steps that release energy.* Despite these endothermic steps, the standard enthalpy of formation (ΔH_f°) of solid LiF is −617 kJ/mol; that is, 617 kJ is *released* when 1 mol of LiF(*s*) forms from its elements. Formation of LiF is typical of reactions between active metals and nonmetals: ionic solids form readily (Figure 9.6).

If the overall reaction releases energy, there must be some step that is exothermic enough to outweigh the endothermic steps. This step involves the *strong attraction between pairs of oppositely charged ions.* When 1 mol of $Li^+(g)$ and 1 mol of $F^-(g)$ form 1 mol of gaseous LiF molecules, a large quantity of heat is released:

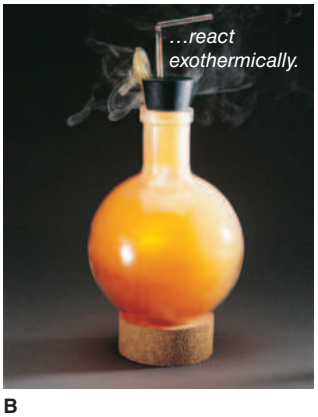
$$Li^+(g) + F^-(g) \longrightarrow LiF(g) \qquad \Delta H^\circ = -755 \text{ kJ}$$

But, as you know, under ordinary conditions, LiF does not exist as gaseous molecules: *even more energy is released when the separate gaseous ions coalesce into a crystalline solid* because each ion attracts *several* oppositely charged ions:

$$Li^+(g) + F^-(g) \longrightarrow LiF(s) \qquad \Delta H^\circ = -1050 \text{ kJ}$$



A



B

Figure 9.6 The exothermic formation of sodium bromide. A, Sodium (in beaker under mineral oil) and bromine. **B,** The reaction is rapid and vigorous.

The negative of this enthalpy change is 1050 kJ, the lattice energy of LiF. The **lattice energy ($\Delta H^\circ_{\text{lattice}}$)** is the enthalpy change that accompanies the reverse of the previous equation—1 mol of ionic solid separating into gaseous ions.

Determining Lattice Energy with a Born-Haber Cycle The magnitude of the lattice energy is a measure of the strength of the ionic interactions and influences macroscopic properties, such as melting point, hardness, and solubility. Despite playing this crucial role in the formation of ionic compounds, lattice energy is usually *not* measured directly. One way to determine it applies Hess's law (see Section 6.5) in a **Born-Haber cycle,** a series of steps from elements to ionic solid for which all the enthalpies* are known except the lattice energy.

Let's go through a Born-Haber cycle for the formation of lithium fluoride to calculate $\Delta H^\circ_{\text{lattice}}$. Figure 9.7 shows two possible paths, a direct combination reaction (ΔH°_f; *black arrow*) and a multistep path *(orange arrows)* in which one step is the unknown $\Delta H^\circ_{\text{lattice}}$. Hess's law tells us both paths involve the same overall enthalpy change:

$$\Delta H^\circ_f \text{ of LiF}(s) = \text{sum of } \Delta H^\circ \text{ values for multistep path}$$

Hess's law lets us choose *hypothetical* steps whose enthalpy changes we can measure, even though *they are **not** the actual steps that occur when lithium reacts with fluorine.* We identify each ΔH° by its step number in Figure 9.7:

*Strictly speaking, ionization energy (IE) and electron affinity (EA) are internal energy changes (ΔE), not enthalpy changes (ΔH), but in these steps, $\Delta H = \Delta E$ because $\Delta V = 0$ (Section 6.2).

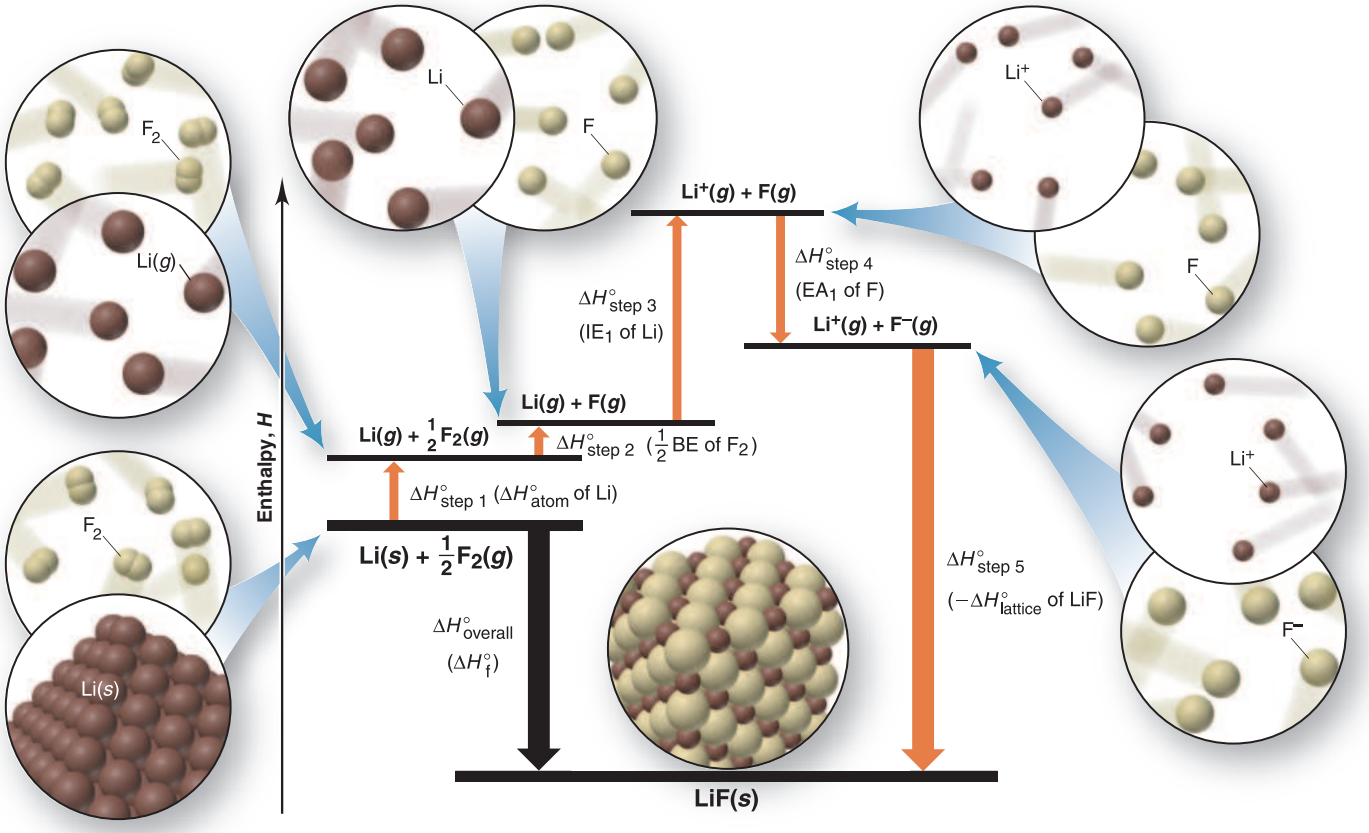


Figure 9.7 The Born-Haber cycle for lithium fluoride. The formation of LiF(*s*) from its elements can happen in one combination reaction *(black arrow)* or in five steps *(orange arrows)*. The unknown enthalpy change is $\Delta H^\circ_{\text{step 5}}$ ($-\Delta H^\circ_{\text{lattice}}$ of LiF).

Step 1. From solid Li to Li atoms. This step, called *atomization,* has the enthalpy change ΔH°_{atom}. It involves breaking metallic bonds, so it absorbs energy:

$$Li(s) \longrightarrow Li(g) \qquad \Delta H^\circ_{step\ 1} = \Delta H^\circ_{atom} = 161\ kJ$$

Step 2. From F_2 molecules to F atoms. This step involves breaking a covalent bond, so it absorbs energy; as we discuss later, this is the *bond energy* (BE) of F_2. Since we need 1 mol of F atoms to make 1 mol of LiF, we start with $\frac{1}{2}$ mol of F_2:

$$\tfrac{1}{2}F_2(g) \longrightarrow F(g) \qquad \Delta H^\circ_{step\ 2} = \tfrac{1}{2}(\text{BE of } F_2) = \tfrac{1}{2}(159\ kJ) = 79.5\ kJ$$

Step 3. From Li to Li^+. Removing the 2*s* electron from Li absorbs energy:

$$Li(g) \longrightarrow Li^+(g) + e^- \qquad \Delta H^\circ_{step\ 3} = IE_1 = 520\ kJ$$

Step 4. From F to F^-. Adding an electron to F releases energy:

$$F(g) + e^- \longrightarrow F^-(g) \qquad \Delta H^\circ_{step\ 4} = EA_1 = -328\ kJ$$

Step 5. From gaseous ions to ionic solid. Forming solid LiF from gaseous Li^+ and F^- releases a lot of energy. The enthalpy change for this step is unknown but is, by definition, the negative of the lattice energy:

$$Li^+(g) + F^-(g) \longrightarrow LiF(s) \qquad \Delta H^\circ_{step\ 5} = -\Delta H^\circ_{lattice} \text{ of LiF} = ?$$

The enthalpy change of the combination reaction *(black arrow)* is

$$Li(s) + \tfrac{1}{2}F_2(g) \longrightarrow LiF(s) \qquad \Delta H^\circ_{overall} = \Delta H^\circ_f = -617\ kJ$$

We set ΔH°_f equal to the sum of the ΔH° values for the steps and solve for $\Delta H^\circ_{lattice}$:

$$\Delta H^\circ_f = \Delta H^\circ_{step\ 1} + \Delta H^\circ_{step\ 2} + \Delta H^\circ_{step\ 3} + \Delta H^\circ_{step\ 4} + (-\Delta H^\circ_{lattice} \text{ of LiF})$$

Solving for $-\Delta H^\circ_{lattice}$ of LiF gives

$$\begin{aligned} -\Delta H^\circ_{lattice} \text{ of LiF} &= \Delta H^\circ_f - (\Delta H^\circ_{step\ 1} + \Delta H^\circ_{step\ 2} + \Delta H^\circ_{step\ 3} + \Delta H^\circ_{step\ 4}) \\ &= -617\ kJ - [161\ kJ + 79.5\ kJ + 520\ kJ + (-328\ kJ)] \\ &= -1050\ kJ \end{aligned}$$

And changing the sign gives,

$$\Delta H^\circ_{lattice} \text{ of LiF} = -(-1050\ kJ) = 1050\ kJ$$

Note that *the lattice energy is, by far, the largest component of the multistep process.* (Problems 9.30 and 9.31 are among several that focus on Born-Haber cycles.)

The Born-Haber cycle shows that the energy *required* for elements to form ions is *supplied* by the attraction among the ions in the solid. And the "take-home lesson" is that *ionic solids exist* ***only*** *because the lattice energy far exceeds the total energy needed to form the ions.*

Periodic Trends in Lattice Energy

The lattice energy results from electrostatic interactions among ions, so its magnitude depends on ionic size, ionic charge, and the arrangement of the ions in the solid. Therefore, we expect to see periodic trends in lattice energy.

Explaining the Trends with Coulomb's Law Recall from Chapter 2 that **Coulomb's law** states that the electrostatic energy between particles A and B is directly proportional to the product of their charges and inversely proportional to the distance between them:

$$\text{Electrostatic energy} \propto \frac{\text{charge A} \times \text{charge B}}{\text{distance}}$$

Lattice energy is directly proportional to electrostatic energy. In an ionic solid, cations and anions lie as close to each other as possible, so the distance between them is the sum of the ionic radii (see Figure 8.28, p. 350):

$$\text{Electrostatic energy} \propto \frac{\text{cation charge} \times \text{anion charge}}{\text{cation radius} + \text{anion radius}} \propto \Delta H^\circ_{lattice} \qquad \textbf{(9.1)}$$

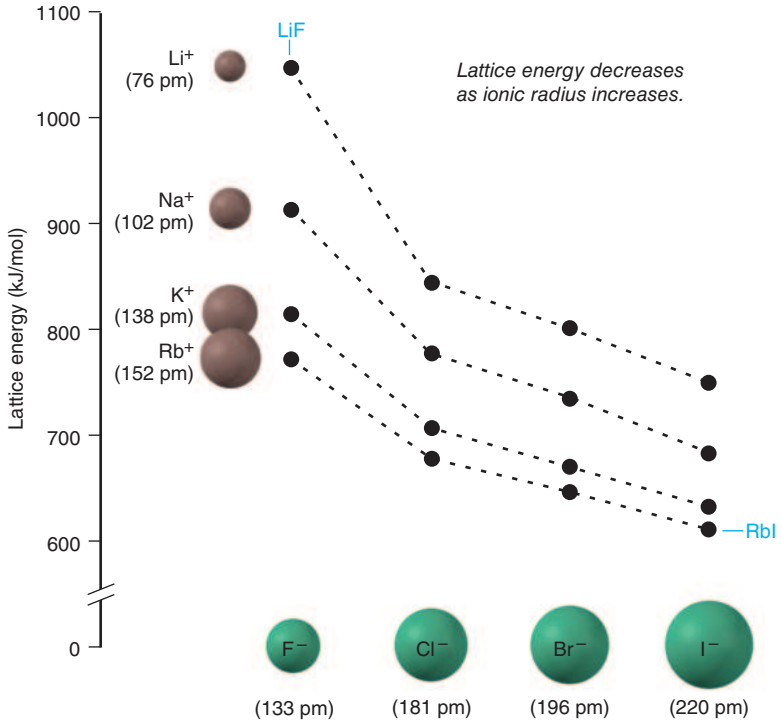

Figure 9.8 Trends in lattice energy. The lattice energies are shown for compounds formed from a given Group 1A(1) cation *(left side)* and one of the Group 7A(17) anions *(bottom)*. LiF (smallest ions) has the highest lattice energy, and RbI (largest ions) has the lowest.

This relationship helps us explain the effects of ionic size and charge on trends in lattice energy (also see Figure 2.12, p. 62):

1. *Effect of ionic size.* As we move down a group, ionic radii increase, so the electrostatic energy between cations and anions decreases; thus, lattice energies should decrease as well. Figure 9.8 shows that, for the alkali-metal halides, lattice energy decreases down the group whether we hold the cation constant (LiF to LiI) or the anion constant (LiF to RbF).

2. *Effect of ionic charge.* Across a period, ionic charge changes. For example, lithium fluoride and magnesium oxide have cations and anions of about equal radii (Li^+ = 76 pm and Mg^{2+} = 72 pm; F^- = 133 pm and O^{2-} = 140 pm). The major difference is between singly charged Li^+ and F^- ions and doubly charged Mg^{2+} and O^{2-} ions. The difference in the lattice energies of the two compounds is striking:

$$\Delta H^\circ_{\text{lattice}} \text{ of LiF} = 1050 \text{ kJ/mol} \quad \text{and} \quad \Delta H^\circ_{\text{lattice}} \text{ of MgO} = 3923 \text{ kJ/mol}$$

This nearly fourfold increase in $\Delta H^\circ_{\text{lattice}}$ reflects the fourfold increase in the product of the charges (1×1 vs. 2×2) in the numerator of Equation 9.1.

SAMPLE PROBLEM 9.2 Predicting Relative Lattice Energy from Ionic Properties

Problem Use ionic properties to explain which compound in each pair has the larger lattice energy: **(a)** RbI or NaBr; **(b)** KCl or CaS.

Plan To choose the compound with the larger lattice energy, we apply Coulomb's law and periodic trends in ionic radius and charge (see Figure 2.12, p. 62). We examine the ions in each compound: for ions of similar size, higher charge leads to a larger lattice energy; for ions with the same charge, smaller size leads to larger lattice energy because the ions can get closer together.

Solution **(a)** NaBr. All the ions have single charges, so charge is not a factor. Size increases down a group, so Rb^+ is larger than Na^+, and I^- is larger than Br^-. Therefore, NaBr has the larger lattice energy because it consists of smaller ions.

(b) CaS. Size decreases from left to right, so K^+ is slightly larger than Ca^{2+}, and S^{2-} is slightly larger than Cl^-. However, these small differences are not nearly as important as the charges: Ca^{2+} and S^{2-} have twice the charge of K^+ and Cl^-, so CaS has the larger lattice energy.

Check The actual lattice energies are **(a)** RbI = 598 kJ/mol and NaBr = 719 kJ/mol; **(b)** KCl = 676 kJ/mol and CaS = 3039 kJ/mol.

FOLLOW-UP PROBLEMS

9.2A Use ionic properties to explain which compound has the *larger* lattice energy: BaF_2 or SrF_2.

9.2B Use ionic properties to explain which compound has the *smaller* lattice energy: SrS or RbCl.

SOME SIMILAR PROBLEMS 9.26–9.29

Why Does MgO Exist? We might ask how ionic solids, like MgO, with doubly charged ions, could even form. After all, forming 1 mol of Mg^{2+} involves the sum of the first *and* second ionization energies:

$$Mg(g) \longrightarrow Mg^{2+}(g) + 2e^- \qquad \Delta H^\circ = IE_1 + IE_2 = 738\ kJ + 1450\ kJ = 2188\ kJ$$

And, while forming 1 mol of O^- ions is exothermic (first electron affinity, EA_1), adding a second mole of electrons (second electron affinity, EA_2) is endothermic because the electron is added to a negative ion. The overall formation of O^{2-} ions is endothermic:

$$\begin{array}{lll} O(g) + e^- \longrightarrow O^-(g) & \Delta H^\circ = EA_1 & = -141\ kJ \\ O^-(g) + e^- \longrightarrow O^{2-}(g) & \Delta H^\circ = EA_2 & = \ \ 878\ kJ \\ \hline O(g) + 2e^- \longrightarrow O^{2-}(g) & \Delta H^\circ = EA_1 + EA_2 = & \ \ 737\ kJ \end{array}$$

There are also the endothermic steps for converting Mg(*s*) to Mg(*g*) (148 kJ/mol) and breaking $\frac{1}{2}$ mol of O_2 molecules into O atoms (498 kJ/mol). Nevertheless, the 2+ and 2− ionic charges make the lattice energy so large ($\Delta H^\circ_{lattice} = 3923$ kJ/mol) that MgO forms readily whenever Mg burns in air ($\Delta H^\circ_f = -601$ kJ/mol; Figure 3.7, p. 109).

How the Model Explains the Properties of Ionic Compounds

The central role of any model is to explain the facts. With atomic-level views, we can see how the ionic bonding model accounts for the properties of ionic solids:

1. *Physical behavior.* As a typical ionic compound, a piece of rock salt (NaCl) is *hard* (does not dent), *rigid* (does not bend), and *brittle* (cracks without deforming). These properties arise from the strong attractive forces that hold the ions *in specific positions*. Moving them out of position requires overcoming these forces, so rock salt does not dent or bend. If enough force *is* applied, ions of like charge are brought next to each other, and repulsions between them crack the sample suddenly (Figure 9.9).

2. *Electrical conductivity.* Ionic compounds typically *do not* conduct electricity in the solid state but *do* conduct when melted or dissolved. According to the model, the solid consists of fixed ions, but when it melts or dissolves, the ions can move and carry a current (Figure 9.10, *next page*).

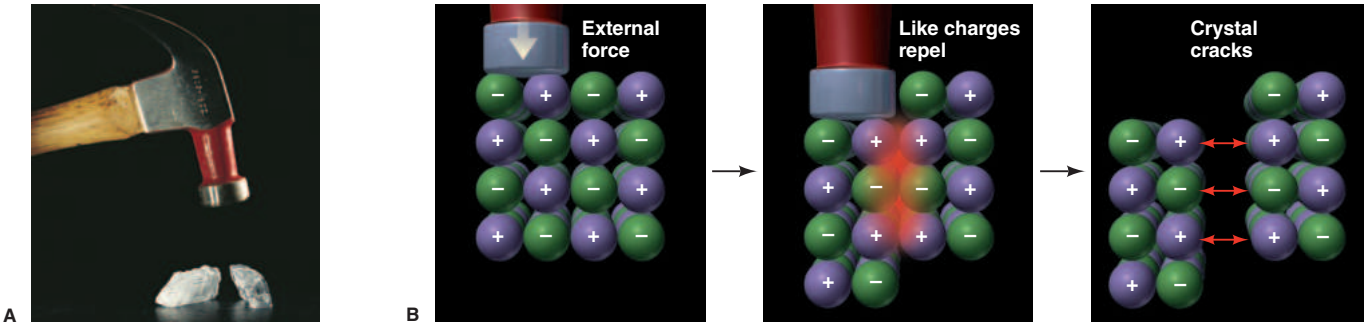

Figure 9.9 Why ionic compounds crack. **A,** Ionic compounds crack when struck with enough force. **B,** When a force moves like charges near each other, repulsions cause a crack.

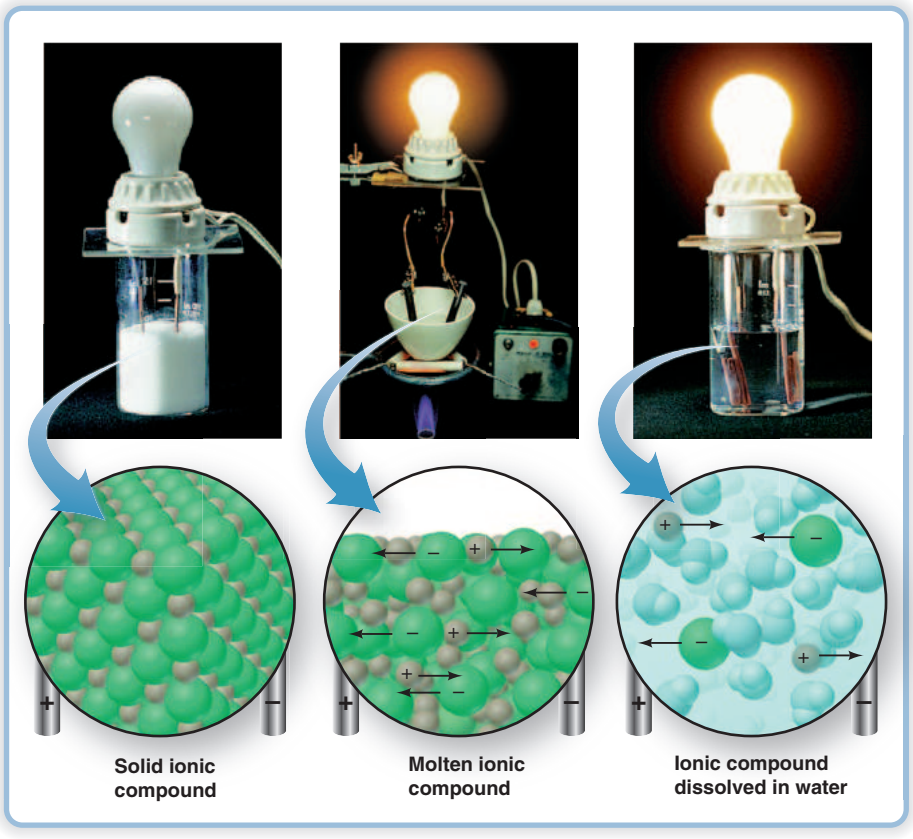

Figure 9.10 Electrical conductance and ion mobility.

Table 9.1 Melting and Boiling Points of Some Ionic Compounds

Compound	mp (°C)	bp (°C)
CsBr	636	1300
NaI	661	1304

LiF	845	1676
KF	858	1505
MgO	2852	3600

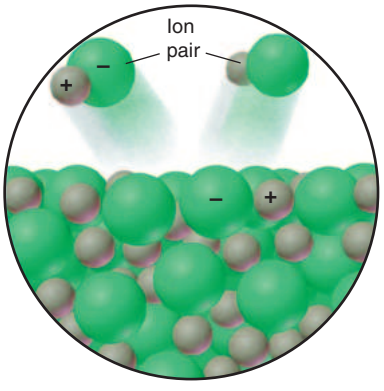

Figure 9.11 Ion pairs formed when an ionic compound vaporizes.

3. *Melting and boiling point*. Large amounts of energy are needed to free the ions from their positions and separate them. Thus, we expect ionic compounds to have high melting points and much higher boiling points (Table 9.1). In fact, the interionic attraction is so strong that a vaporized ionic compound consists of **ion pairs,** gaseous ionic molecules, rather than individual ions (Figure 9.11). In their normal state, as you know, *ionic compounds are solid arrays of ions, and no separate molecules exist.*

Summary of Section 9.2

- In ionic bonding, a metal transfers electrons to a nonmetal, and the resulting ions attract each other to form a solid.
- Main-group elements often attain a filled outer level (either eight electrons or two electrons) by forming ions that have the electron configuration of the nearest noble gas.
- Ion formation by itself *absorbs* energy, but more than that quantity of energy is *released* when the ions form a solid. The high lattice energy of an ionic solid, the energy required to separate the solid into gaseous ions, is the reason the compound forms.
- The lattice energy is determined by applying Hess's law in a Born-Haber cycle.
- Lattice energies increase with higher ionic charge and decrease with larger ionic radius (Coulomb's law).
- According to the ionic bonding model, the strong electrostatic attractions that keep ions in position explain why ionic solids are hard, conduct a current only when melted or dissolved, and have high melting and boiling points.
- Ion pairs form when an ionic compound vaporizes.

9.3 THE COVALENT BONDING MODEL

Look through the *Handbook of Chemistry and Physics,* and you'll find that the number of covalent compounds dwarfs the number of ionic compounds. Covalent substances range from diatomic hydrogen to biological and synthetic macromolecules with many thousands of atoms and even to some minerals that have covalent bonds throughout the sample. And covalent bonds occur in all polyatomic ions, too. Without doubt, *sharing electrons is the main way that atoms interact.*

The Formation of a Covalent Bond

Why does hydrogen gas consist of H_2 molecules and not separate H atoms? Figure 9.12 plots the potential energy of a system of two isolated H atoms versus the distance between their nuclei (see also Figure 2.14, p. 63). Let's start at the right end of the curve and move along it to the left, as the atoms get closer:

- *At point 1,* the atoms are far apart, and each acts as though the other were not present.
- *At point 2,* the distance between the atoms has decreased enough for each nucleus to start attracting the other atom's electron, which lowers the potential energy. As the atoms get closer, these attractions increase, but so do repulsions between the nuclei and between the electrons.
- *At point 3* (bottom of the energy "well"), the maximum attraction is achieved in the face of the increasing repulsion, and the system has its minimum energy.
- *At point 4,* if it were reached, the atoms would be too close, and the rise in potential energy from increasing repulsions would push them apart toward point 3 again.

Thus, a **covalent bond** arises from the balance between the nuclei attracting the electrons and electrons and nuclei repelling each other, as shown in the blow-up of the structure at point 3. (We'll return to Figure 9.12 shortly.)

Formation of a covalent bond always results in greater electron density ***between*** *the nuclei.* Figure 9.13 *(on the next page)* depicts this fact with an *electron density contour map* (A), and an *electron density relief map* (B).

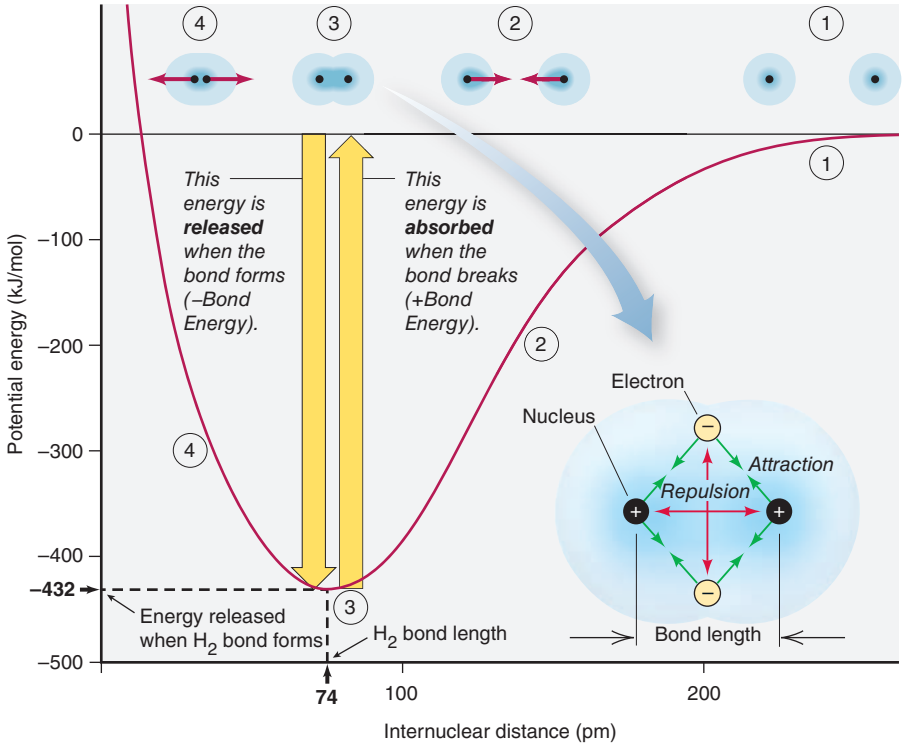

Figure 9.12 Covalent bond formation in H_2. The energy difference between points 1 and 3 is the H_2 *bond energy* (432 kJ/mol). The internuclear distance at point 3 is the H_2 *bond length* (74 pm).

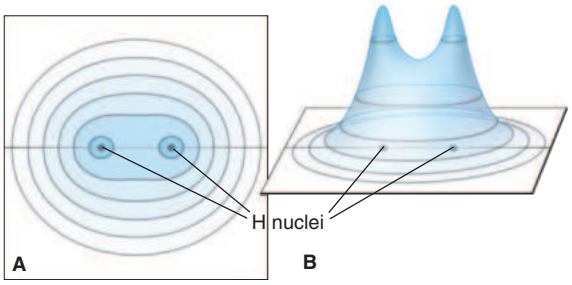

Figure 9.13 **Distribution of electron density in H_2.** **A,** Electron density *(blue shading)* is high around and between the nuclei. Electron density doubles with each concentric curve. **B,** The highest regions of electron density are shown as peaks.

Bonding Pairs and Lone Pairs

To achieve a full outer (valence) level of electrons, *each atom in a covalent bond "counts" the shared electrons as belonging entirely to itself.* Thus, the two shared electrons in H_2 simultaneously fill the outer level of *both* H atoms, as clarified by the blue circles added below. The **shared pair,** or **bonding pair,** is represented by a pair of dots or a line:

An outer-level electron pair that is *not* involved in bonding is called a **lone pair,** or **unshared pair.** The bonding pair in HF fills the outer level of the H atom *and,* together with three lone pairs, fills the outer level of the F atom as well:

In F_2 the bonding pair and three lone pairs fill the outer level of *each* F atom:

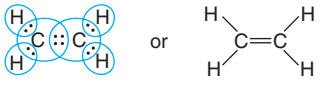
(This text generally shows bonding pairs as lines and lone pairs as dots.)

Properties of a Covalent Bond: Order, Energy, and Length

A covalent bond has three important properties that are closely related to one another and to the compound's reactivity—bond order, bond energy, and bond length.

1. *Bond order.* The **bond order** is the number of electron pairs being shared by a given pair of atoms:

- A **single bond,** as shown above in H_2, HF, or F_2, is the most common bond and consists of one bonding pair of electrons: *a single bond has a bond order of 1.*
- Many molecules (and ions) contain *multiple bonds,* in which more than one pair is shared between two atoms. Multiple bonds usually involve C, O, and/or N atoms. A **double bond** consists of two bonding electron pairs, four electrons shared between two atoms, so *the bond order is 2.* Ethylene (C_2H_4) contains a carbon-carbon double bond and four carbon-hydrogen single bonds:



Each carbon "counts" the four electrons in the double bond and the four in its two single bonds to hydrogens to attain an octet.

- A **triple bond** consists of three shared pairs: two atoms share six electrons, so *the bond order is 3.* The N_2 molecule has a triple bond, and each N atom also has a lone pair. Six shared and two unshared electrons give *each* N atom an octet:

2. *Bond energy.* The strength of a covalent bond depends on the magnitude of the attraction between the nuclei and shared electrons. The **bond energy (BE)** (also called *bond enthalpy* or *bond strength*) is the energy needed to overcome this attrac-

tion and is defined as *the standard enthalpy change for breaking the bond in 1 mol of gaseous molecules.* Bond breakage is an *endothermic* process, so *bond energy is always positive:*

$$A{-}B(g) \longrightarrow A(g) + B(g) \qquad \Delta H^\circ_{\text{bond breaking}} = BE_{A-B}\,(\text{always} > 0)$$

The bond energy is the difference in energy between separated and bonded atoms (the potential energy difference between points 1 and 3—the energy "well"—in Figure 9.12). *The same quantity of energy absorbed to break the bond is released when the bond forms.* Bond formation is an *exothermic* process, so *the sign of its enthalpy change is always negative:*

$$A(g) + B(g) \longrightarrow A{-}B(g) \qquad \Delta H^\circ_{\text{bond forming}} = -BE_{A-B}\,(\text{always} < 0)$$

Table 9.2 lists the energies of some common bonds. By definition,

- *Stronger bonds have a larger BE because they are lower in energy (have a deeper energy well).*
- *Weaker bonds have a smaller BE because they are higher in energy (have a shallower energy well).*

The energy of a given bond varies slightly from molecule to molecule and even within the same molecule, so each value is an *average* bond energy.

3. *Bond length.* A covalent bond has a **bond length,** the distance between the nuclei of two bonded atoms. In Figure 9.12, bond length is the distance between the nuclei at the point of minimum energy (bottom of the well), and Table 9.2 shows the lengths of some covalent bonds. Like bond energies, these values are *average* bond lengths for a bond in different substances. Bond length is related to the sum of the radii of the bonded atoms. In fact, most atomic radii are calculated from measured bond lengths (see Figure 8.12C, p. 336). Bond lengths for a series of similar bonds, as in the halogens, increase with atomic size (Figure 9.14).

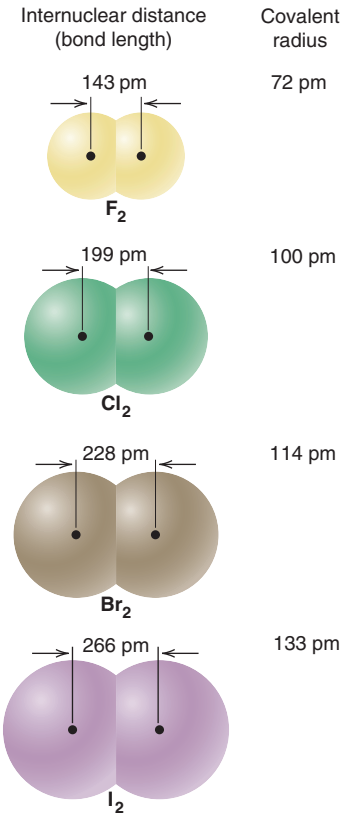


Figure 9.14 Bond length and covalent radius.

Bond	Bond Order	Average Bond Length (pm)	Average Bond Energy (kJ/mol)
C—O	1	143	358
C═O	2	123	745
C≡O	3	113	1070
C—C	1	154	347
C═C	2	134	614
C≡C	3	121	839
N—N	1	146	160
N═N	2	122	418
N≡N	3	110	945

The order, energy, and length of a covalent bond are interrelated. Two nuclei are more strongly attracted to two shared electron pairs than to one, so double-bonded atoms are drawn closer together *and* are more difficult to pull apart than single-bonded atoms: *for a given pair of atoms, a higher bond order results in a smaller bond length and a higher bond energy.* Thus, as Table 9.3 shows, for a given pair of atoms, *a shorter bond is a stronger bond.*

In some cases, we can see a relation among atomic size, bond length, and bond energy by varying one of the atoms in a single bond while holding the other constant:

- *Variation within a group.* The trend in carbon-halogen single bond lengths, C—I > C—Br > C—Cl, parallels the trend in atomic size, I > Br > Cl, and is opposite to the trend in bond energy, C—Cl > C—Br > C—I.
- *Variation within a period.* Looking again at single bonds involving carbon, the trend in bond lengths, C—N > C—O > C—F, is opposite to the trend in bond energy, C—F > C—O > C—N.

SAMPLE PROBLEM 9.3 Comparing Bond Length and Bond Strength

Problem Without referring to Table 9.2, rank the bonds in each set in order of *decreasing* bond length and *decreasing* bond strength:
(a) S—F, S—Br, S—Cl **(b)** C═O, C—O, C≡O

Plan **(a)** S is singly bonded to three different halogen atoms, so the bond order is the same. Bond length increases and bond strength decreases as the halogen's atomic radius increases. **(b)** The same two atoms are bonded, but the bond orders differ. In this case, bond strength increases and bond length decreases as bond order increases.

Solution **(a)** Atomic size increases down a group, so F < Cl < Br.

Bond length: S—Br > S—Cl > S—F

Bond strength: S—F > S—Cl > S—Br

(b) By ranking the bond orders, C≡O > C═O > C—O, we obtain

Bond length: C—O > C═O > C≡O

Bond strength: C≡O > C═O > C—O

Check From Table 9.2, we see that the rankings are correct.

Comment Remember that for bonds involving pairs of different atoms, as in part (a), *the relationship between length and strength holds* only *for single bonds* and not in every case, so apply it carefully.

FOLLOW-UP PROBLEMS

9.3A Rank the bonds in each set in order of *decreasing* bond length and *decreasing* bond strength: **(a)** C≡N, C═O, C≡C; **(b)** P—I, P—F, P—Br.

9.3B Rank the bonds in each set in order of *increasing* bond length and *increasing* bond strength: **(a)** Si—F, Si—C, Si—O; **(b)** N═N, N—N, N≡N.

SOME SIMILAR PROBLEMS 9.39 and 9.40

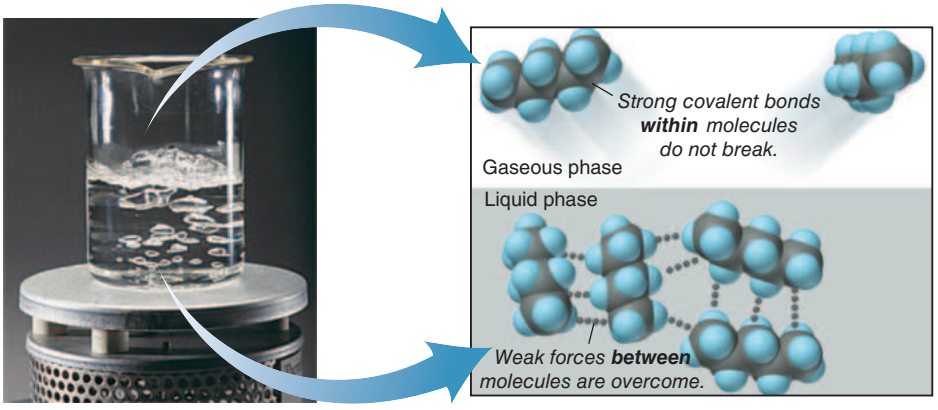

Figure 9.15 Strong forces within molecules and weak forces between them.

How the Model Explains the Properties of Covalent Substances

The covalent bonding model proposes that electron sharing between pairs of atoms leads to *strong, localized bonds*. Most, but not all, covalent substances consist of individual molecules. These *molecular* covalent substances have very different *physical* properties than *network* covalent solids because different types of forces give rise to them.

1. *Physical properties of molecular covalent substances.* At first glance, the model seems inconsistent with physical properties of covalent substances. Most are gases (such as methane and ammonia), liquids (such as benzene and water), or low-melting solids (such as sulfur and paraffin wax). If covalent bonds are so strong (~200 to 500 kJ/mol), why do covalent substances melt and boil at such low temperatures?

To answer this, we'll focus on two different forces: (1) *strong bonding forces* hold the atoms together *within* the molecule, and (2) *weak intermolecular forces* act *between* separate molecules in the sample. It is the weak forces *between* molecules that account for the physical properties of *molecular* covalent substances. For example, look what happens when pentane (C_5H_{12}) boils (Figure 9.15): weak forces *between* pentane molecules are overcome, not the strong C—C and C—H bonds *within* each pentane molecule.

2. *Physical properties of network covalent solids.* Some covalent substances do not consist of separate molecules. Rather, these *network covalent solids* are held together by covalent bonds *between atoms throughout the sample,* and their properties *do* reflect the strength of covalent bonds. Two examples are quartz and diamond (Figure 9.16). Quartz (SiO_2; *top*) has silicon-oxygen covalent bonds in three dimensions; no separate SiO_2 molecules exist. It is very hard and melts at 1550°C. Diamond *(bottom)* has covalent bonds connecting each carbon atom to four others. It is the hardest natural substance known and melts at around 3550°C. Thus, covalent bonds *are* strong, but most covalent substances consist of separate molecules with weak forces between them. (We discuss intermolecular forces in detail in Chapter 12.)

3. *Electrical conductivity*. An electric current is carried by either mobile electrons or mobile ions. Most covalent substances are poor electrical conductors, whether melted or dissolved, because their electrons are localized as either shared or unshared pairs, and no ions are present.

The Tools of the Laboratory essay describes a technique used widely for studying the types of bonds in covalent substances.

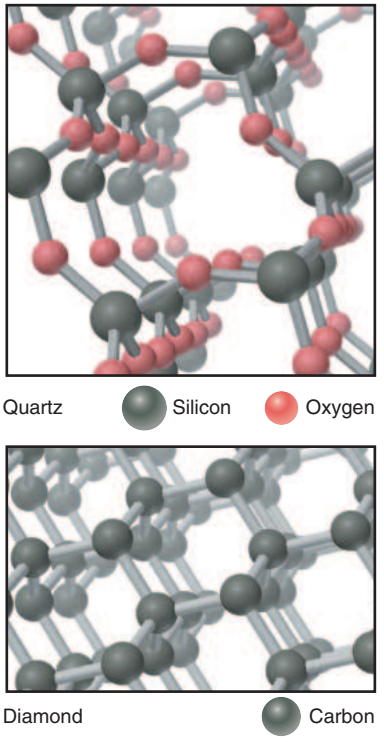

Figure 9.16 Covalent bonds of network covalent solids: quartz and diamond.

Infrared Spectroscopy

Infrared (IR) spectroscopy is an instrumental technique most often used to study covalently bonded molecules. The key components of an IR spectrometer are the same as those of other types of spectrometers (see Figure B7.3, p. 300). The source emits radiation of many wavelengths, but only those in the IR region are selected. The sample is typically a pure liquid or solid that absorbs varying amounts of different IR wavelengths. An IR spectrum consists of peaks that indicate these various absorptions.

Molecular Vibrations and IR Absorption

An IR spectrum indicates the types of bonds in a molecule based on their vibrations. All molecules undergo motion through space, rotation around several axes, and vibrations between bonded atoms. Consider a sample of ethane gas. The $H_3C—CH_3$ molecules zoom throughout the container, the whole molecule rotates, and its two CH_3 groups rotate about the C—C bond. But let's disregard motion through space and rotation and focus on the motion most important to IR spectroscopy: each pair of atoms is vibrating as though the bonds were springs. Figure B9.1 depicts the vibrations of diatomic and triatomic molecules; larger molecules vibrate in many more ways.

The energies of IR photons are in the range of these vibrational energies. *Each vibration has a frequency based on the type of motion, masses of the atoms, and strength of the bond.* The frequencies correspond to IR wavelengths between 2.5 and 25 μm. *The energy of these vibrations is quantized.* Just as an atom can absorb a photon whose energy equals the difference between *electron* energy levels, a molecule can absorb an IR photon whose energy equals the difference between *vibrational* energy levels.

IR Radiation and Global Warming

Carbon dioxide, O═C═O, is a linear molecule that bends and stretches symmetrically and asymmetrically when it absorbs IR radiation (Problem B9.2). Sunlight is absorbed by Earth's surface and re-emitted as heat, much of which is IR radiation. Atmospheric CO_2 absorbs this radiation and re-emits it, thus warming the atmosphere (see Chemical Connections, pp. 273–277).

Compound Identification

An IR spectrum can be used to identify a compound for three related reasons:

1. *Each kind of bond absorbs a specific range of wavelengths.* That is, a C—C bond absorbs a different range than does a C═C bond, a C—H bond, a C═O bond, and so forth.
2. *Different types of organic compounds have characteristic spectra.* The different groupings of atoms that define an alcohol, a carboxylic acid, an ether, and so forth (see Chapter 15) absorb differently.
3. *Each compound has a unique spectrum.* The IR spectrum acts like a fingerprint to identify the compound, because the quantity of each wavelength absorbed depends on the detailed molecular structure. For example, no other compound has the IR spectrum of acrylonitrile, a compound used to make plastics (Figure B9.2).

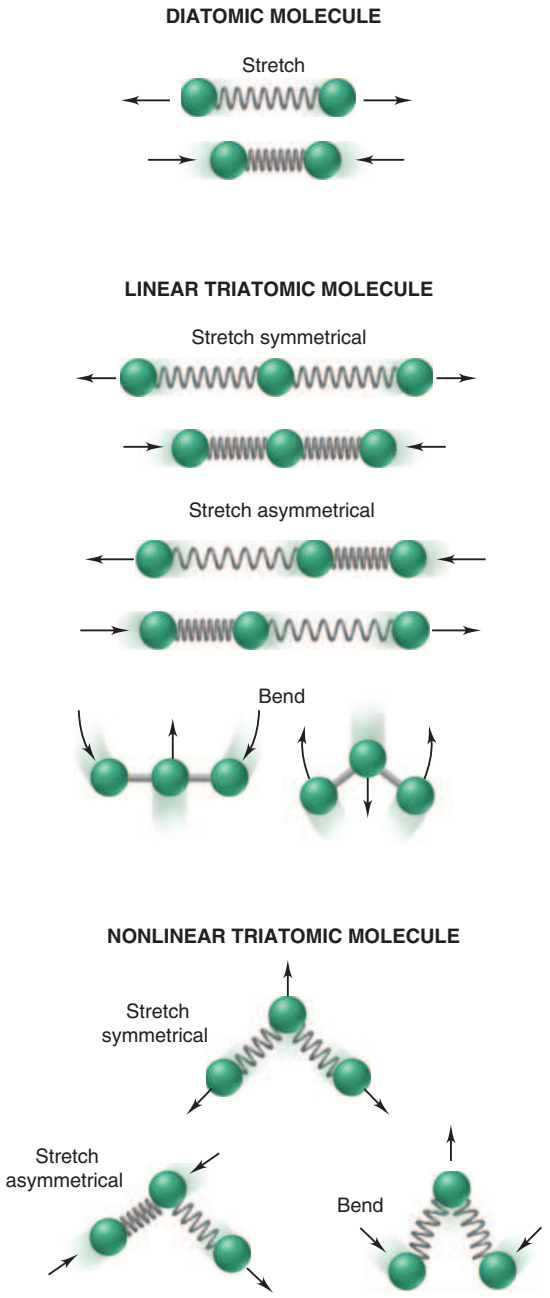

Figure B9.1 **Vibrational motions in general diatomic and triatomic molecules.**

Recall from Chapter 3 that constitutional (structural) isomers have the same molecular formula but different structures. We expect to see very different IR spectra for the isomers diethyl ether and 2-butanol because their molecular structures are so dissimilar (Figure B9.3). However, as shown in Figure B9.4, even the very similar 1,3-dimethylbenzene and 1,4-dimethylbenzene have different spectra.

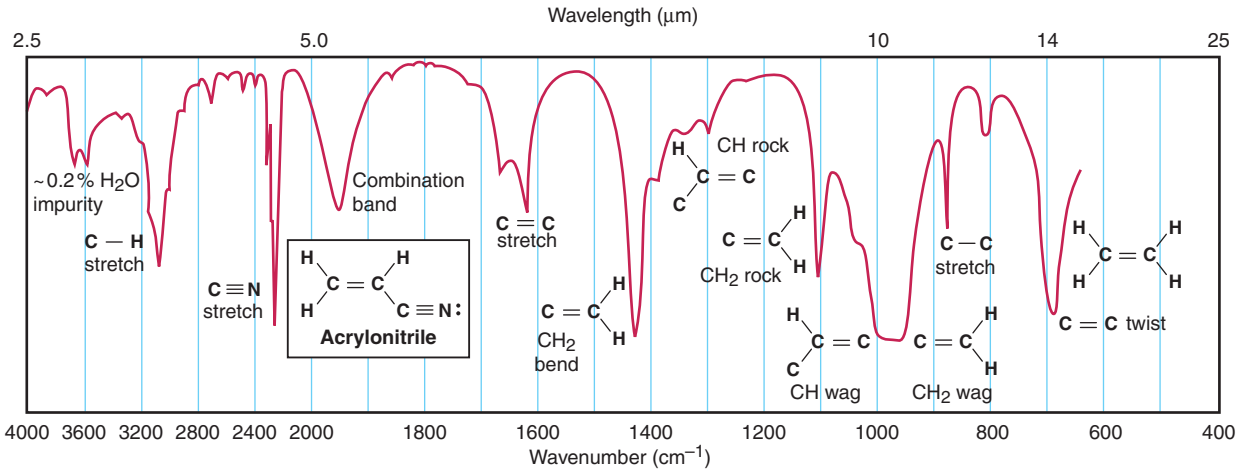

Figure B9.2 The infrared (IR) spectrum of acrylonitrile. In this typical IR spectrum, many absorption bands appear as downward-projecting "peaks" of differing depths and sharpness. Most correspond to a particular type of vibration (stretch, bend, rock, wag, or twist). Some broad peaks (e.g., "combination band") represent several overlapping vibrations. The bottom axis is given as wavenumber, the inverse of wavelength, and has units of cm^{-1}. (The scale expands to the right of 2000 cm^{-1}.)

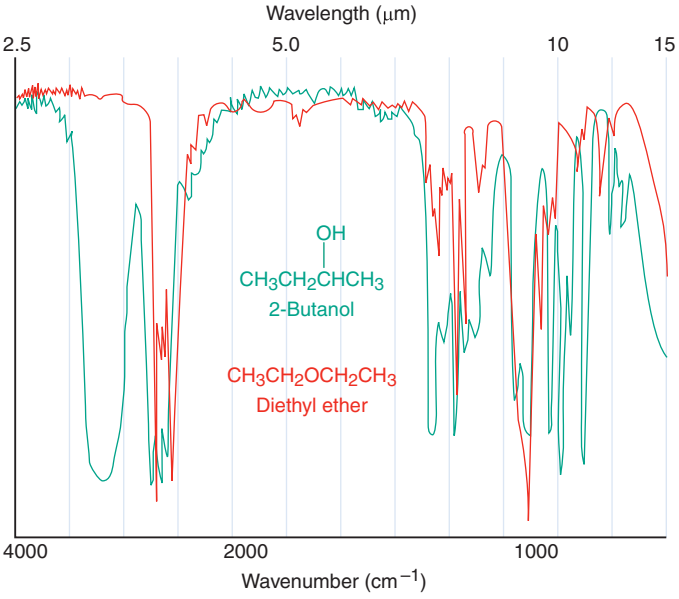

Figure B9.3 The infrared spectra of 2-butanol *(green)* and diethyl ether *(red)*.

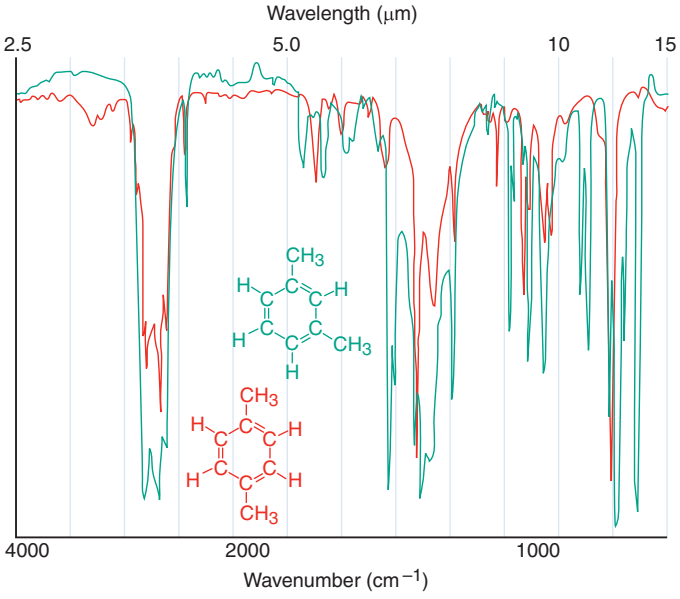

Figure B9.4 The infrared spectra of 1,3-dimethylbenzene *(green)* and 1,4-dimethylbenzene *(red)*.

Problems

B9.1 In Figure B9.2, the peak labeled "C═C stretch" occurs at a shorter wavelength (higher wavenumber) than that labeled "C—C stretch," as it does in the IR spectrum of any substance with those bonds. Explain the relative positions of these peaks. In what relative position along the wavelength scale of Figure B9.2 would you expect to find a peak for a C≡C stretch? Explain.

B9.2 The vibrations of a CO_2 molecule are symmetrical stretch, bend, and asymmetrical stretch (Figure B9.1), with frequencies of $4.02\times10^{13}\,s^{-1}$, $2.00\times10^{13}\,s^{-1}$, and $7.05\times10^{13}\,s^{-1}$, respectively.
(a) What wavelengths correspond to these vibrations?
(b) Calculate the energy (in J) of each vibration. Which uses the least energy?

Summary of Section 9.3

- A shared, localized pair of valence electrons holds the nuclei of two atoms together in a covalent bond, filling each atom's outer level.
- Bond order is the number of shared pairs between two atoms. Bond energy (strength) is the energy absorbed to separate the atoms; the same quantity of energy is released when the bond forms. Bond length is the distance between their nuclei.
- For a given pair of atoms, bond order is directly related to bond energy and inversely related to bond length.
- Molecular covalent substances are soft and low melting because of the weak forces *between* the molecules, not the strong bonding forces *within* them. Network covalent solids are hard and high melting because covalent bonds join all the atoms in the sample.
- Most covalent substances have low electrical conductivity because their electrons are localized and ions are absent.
- Atoms in a covalent bond vibrate, and the energies of these vibrations are studied with IR spectroscopy.

9.4 BOND ENERGY AND CHEMICAL CHANGE

The relative strengths of the bonds in reactants and products determine whether heat is released or absorbed in a chemical reaction. In Chapter 20, you'll see that the change in bond energy is one of two factors determining whether the reaction occurs at all. In this section, we'll discuss the origin of the enthalpy of reaction, use bond energies to calculate it, and look at the energy available from fuels and foods.

Changes in Bond Energy: Where Does ΔH°_{rxn} Come From?

In Chapter 6, we discussed the heat involved in a chemical change but never asked a central question: where does the enthalpy of reaction (ΔH°_{rxn}) come from? For example, when 1 mol of H_2 and 1 mol of F_2 react to form 2 mol of HF at 1 atm and 298 K,

$$H_2(g) + F_2(g) \longrightarrow 2HF(g) + 546\ kJ$$

where does the 546 kJ come from? We find the answer by looking closely at the energies of the molecules involved. A system's total internal energy is composed of its kinetic energy and potential energy. Let's see how these change during the formation of HF:

- *Kinetic energy*. The most important contributions to kinetic energy are the molecules' movements through space and their rotations and vibrations. However, since kinetic energy is proportional to temperature, which is constant at 298 K, it shows no net change.
- *Potential energy.* The most important contributions to potential energy are phase changes and changes in the attraction between vibrating atoms, between nucleus and electrons (and between electrons) in each atom, between protons and neutrons in each nucleus, and between nuclei and the shared electron pair in each bond. In this reaction, there are no phase changes, vibrational forces vary only slightly as the bonded atoms change, and forces within the atoms and nuclei don't change at all. The only major change in potential energy comes from changes in the attraction between the nuclei and the shared electron pair—the bond energies—of H_2, F_2, and HF.

Thus, our answer to "where does ΔH°_{rxn} come from?" is that it doesn't really "come from" anywhere: *the heat released or absorbed during a chemical change is due to differences between reactant bond energies and product bond energies*.

Using Bond Energies to Calculate ΔH°_{rxn}

Recall that Hess's law (Section 6.5) allows us to think of any reaction as a two-step process, whether or not it actually occurs that way:

1. *A certain quantity of heat is absorbed ($\Delta H^\circ > 0$) to break the reactant bonds and form separate atoms.*
2. *A different quantity of heat is then released ($\Delta H^\circ < 0$) when the atoms form product bonds.*

The sum (symbolized by Σ) of these enthalpy changes is the enthalpy of reaction, ΔH°_{rxn}:

$$\Delta H^\circ_{rxn} = \Sigma \Delta H^\circ_{\text{reactant bonds broken}} + \Sigma \Delta H^\circ_{\text{product bonds formed}} \qquad \textbf{(9.2)}$$

- In an exothermic reaction, the magnitude of $\Delta H^\circ_{\text{product bonds formed}}$ is *greater* than that of $\Delta H^\circ_{\text{reactant bonds broken}}$, so the sum, ΔH°_{rxn}, is *negative* (heat is released).
- In an endothermic reaction, the opposite situation is true: the magnitude of $\Delta H^\circ_{\text{product bonds formed}}$ is *smaller* than that of $\Delta H^\circ_{\text{reactant bonds broken}}$, so ΔH°_{rxn} is *positive* (heat is absorbed).

An equivalent form of Equation 9.2 uses bond energies:

$$\Delta H^\circ_{rxn} = \Sigma \text{BE}_{\text{reactant bonds broken}} - \Sigma \text{BE}_{\text{product bonds formed}}$$

(We need the minus sign because all bond energies are positive.)

In reality, only certain bonds break and form during a typical reaction, but with Hess's law, the following is a simpler method of calculating ΔH°_{rxn}:

1. Break **all** the reactant bonds to obtain individual atoms.
2. Use the atoms to form **all** the product bonds.
3. Add the bond energies, with appropriate signs, to obtain the enthalpy of reaction.

(This method assumes reactants and products do not change physical state; additional heat is involved when phase changes occur. We address this topic in Chapter 12.)

Let's use the method to calculate ΔH°_{rxn} for two reactions:

1. *Formation of HF.* When 1 mol of H—H bonds and 1 mol of F—F bonds absorb energy and break, the 2 mol of H atoms and 2 mol of F atoms form 2 mol of H—F bonds, which releases energy (Figure 9.17). We find the bond energy values in Table 9.2 (p. 371) and use a positive sign for bonds broken and a negative sign for bonds formed:

Bonds broken:

$$\begin{aligned} 1 \times \text{H—H} &= (1\text{ mol})(432\text{ kJ/mol}) = 432\text{ kJ} \\ 1 \times \text{F—F} &= (1\text{ mol})(159\text{ kJ/mol}) = 159\text{ kJ} \\ \hline \Sigma \Delta H^\circ_{\text{reactant bonds broken}} &= 591\text{ kJ} \end{aligned}$$

Bonds formed:

$$2 \times \text{H—F} = (2\text{ mol})(-565\text{ kJ/mol}) = \Sigma \Delta H^\circ_{\text{product bonds formed}} = -1130\text{ kJ}$$

Applying Equation 9.2 gives

$$\begin{aligned} \Delta H^\circ_{rxn} &= \Sigma \Delta H^\circ_{\text{reactant bonds broken}} + \Sigma \Delta H^\circ_{\text{product bonds formed}} \\ &= 591\text{ kJ} + (-1130\text{ kJ}) = -539\text{ kJ} \end{aligned}$$

The small discrepancy between this bond energy value (−539 kJ) and the value from tabulated ΔH° values (−546 kJ) is due to variations in experimental method.

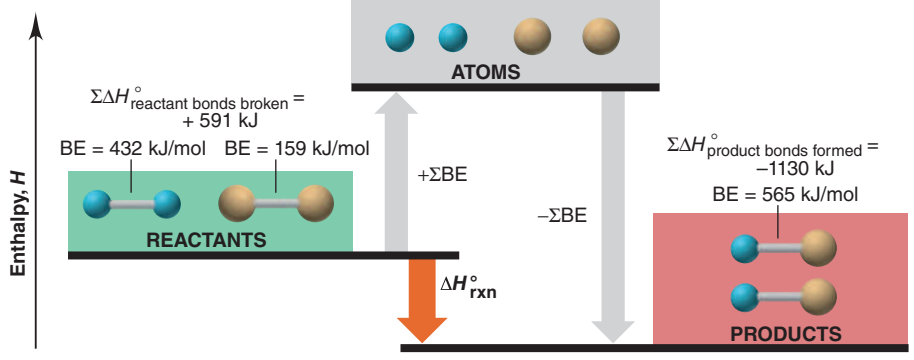

Figure 9.17 Using bond energies to calculate ΔH°_{rxn} for HF formation.

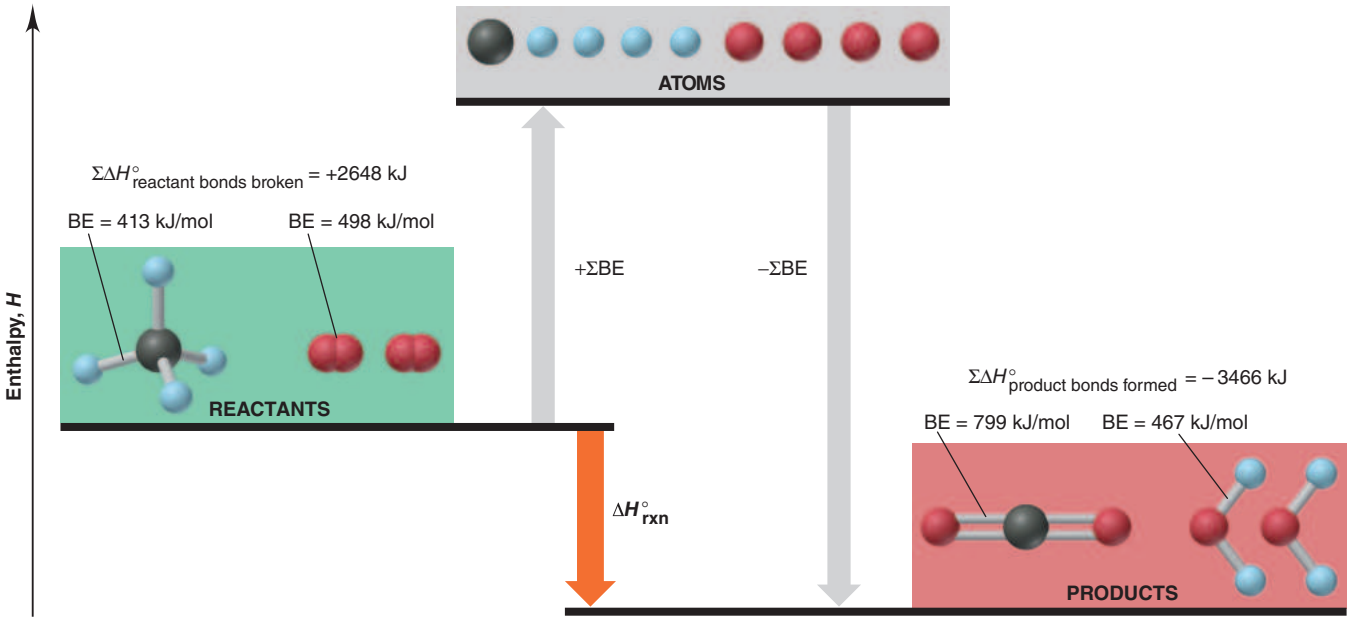

Figure 9.18 Using bond energies to calculate ΔH°_{rxn} for the combustion of methane.

2. *Combustion of CH_4.* In this more complicated reaction, all the bonds in CH_4 and O_2 break, and the atoms form all the bonds in CO_2 and H_2O (Figure 9.18). Once again, we use Table 9.2 and appropriate signs for bonds broken and bonds formed:

Bonds broken:

$$\begin{aligned} 4 \times \text{C—H} &= (4\text{ mol})(413\text{ kJ/mol}) = 1652\text{ kJ} \\ 2 \times \text{O}_2 &= (2\text{ mol})(498\text{ kJ/mol}) = 996\text{ kJ} \\ \hline \Sigma\Delta H^\circ_{\text{reactant bonds broken}} &= 2648\text{ kJ} \end{aligned}$$

Bonds formed:

$$\begin{aligned} 2 \times \text{C=O} &= (2\text{ mol})(-799\text{ kJ/mol}) = -1598\text{ kJ} \\ 4 \times \text{O—H} &= (4\text{ mol})(-467\text{ kJ/mol}) = -1868\text{ kJ} \\ \hline \Sigma\Delta H^\circ_{\text{product bonds formed}} &= -3466\text{ kJ} \end{aligned}$$

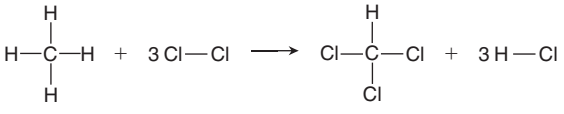
Applying Equation 9.2 gives

$$\begin{aligned} \Delta H^\circ_{rxn} &= \Sigma\Delta H^\circ_{\text{reactant bonds broken}} + \Sigma\Delta H^\circ_{\text{product bonds formed}} \\ &= 2648\text{ kJ} + (-3466\text{ kJ}) = -818\text{ kJ} \end{aligned}$$

In addition to variations in experimental method, there is a more basic reason for the discrepancy between the ΔH°_{rxn} obtained from bond energies (−818 kJ) and the value obtained by calorimetry (−802 kJ; Section 6.3). A bond energy is an *average* value for a given bond in many compounds. The value *in a particular substance* is usually close, but not equal, to the average. For example, the C—H bond energy of 413 kJ/mol is the average for C—H bonds in many molecules. In fact, 415 kJ is actually required to break 1 mol of C—H bonds in methane, or 1660 kJ for 4 mol of these bonds, which gives a ΔH°_{rxn} closer to the calorimetric value. Thus, it isn't surprising to find small discrepancies between ΔH°_{rxn} values obtained in different ways.

SAMPLE PROBLEM 9.4 Using Bond Energies to Calculate ΔH°_{rxn}

Problem Calculate ΔH°_{rxn} for the chlorination of methane to form chloroform:



Plan *All* the reactant bonds break, and *all* the product bonds form. We find the bond energies in Table 9.2 and substitute the two sums, with correct signs, into Equation 9.2.

Solution Finding the standard enthalpy changes for bonds broken and for bonds formed: For bonds broken, the bond energy values are positive:

$$\begin{aligned} 4 \times \text{C—H} &= (4\text{ mol})(413\text{ kJ/mol}) &&= 1652\text{ kJ} \\ 3 \times \text{Cl—Cl} &= (3\text{ mol})(243\text{ kJ/mol}) &&= 729\text{ kJ} \\ \hline \Sigma\Delta H^\circ_{\text{bonds broken}} &&&= 2381\text{ kJ} \end{aligned}$$

For bonds formed, the values are negative:

$$\begin{aligned} 3 \times \text{C—Cl} &= (3\text{ mol})(-339\text{ kJ/mol}) &&= -1017\text{ kJ} \\ 1 \times \text{C—H} &= (1\text{ mol})(-413\text{ kJ/mol}) &&= -413\text{ kJ} \\ 3 \times \text{H—Cl} &= (3\text{ mol})(-427\text{ kJ/mol}) &&= -1281\text{ kJ} \\ \hline \Sigma\Delta H^\circ_{\text{bonds formed}} &&&= -2711\text{ kJ} \end{aligned}$$

Calculating $\Delta H^\circ_{\text{rxn}}$:

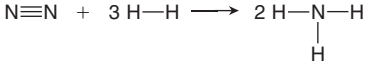
$$\Delta H^\circ_{\text{rxn}} = \Sigma\Delta H^\circ_{\text{bonds broken}} + \Sigma\Delta H^\circ_{\text{bonds formed}} = 2381\text{ kJ} + (-2711\text{ kJ}) = -330\text{ kJ}$$

Check The signs of the enthalpy changes are correct: $\Sigma\Delta H^\circ_{\text{bonds broken}} > 0$, and $\Sigma\Delta H^\circ_{\text{bonds formed}} < 0$. More energy is released than absorbed, so $\Delta H^\circ_{\text{rxn}}$ is negative:

$$\sim 2400\text{ kJ} + [\sim(-2700\text{ kJ})] = -300\text{ kJ}$$

FOLLOW-UP PROBLEMS

9.4A One of the most important industrial reactions is the formation of ammonia from its elements:



Use bond energies to calculate $\Delta H^\circ_{\text{rxn}}$.

9.4B Nitrosyl chloride is used in the manufacture of nylon. One way to prepare it is by the reaction of nitric oxide and chlorine:

Use bond energies to find $\Delta H^\circ_{\text{rxn}}$.

SOME SIMILAR PROBLEMS 9.47 and 9.48

Bond Strengths and the Heat Released from Fuels and Foods

A *fuel* is a material that reacts with atmospheric oxygen to release energy *and* is available at a reasonable cost. The most common fuels for machines are hydrocarbons and coal, and the most common ones for organisms are fats and carbohydrates. All of these fuels contain large organic molecules with many C—C and C—H bonds and fewer C—O and O—H bonds. According to our two-step approach for determining the enthalpy of reaction from bond energies, when the fuel reacts with O_2, all of the bonds break, and the C, H, and O atoms form C═O and O—H bonds in the products (CO_2 and H_2O). Because their combustion is exothermic, the total of the bond energies in the products is *greater* than the total in the reactants. *Weaker bonds (less stable, more reactive) are easier to break than stronger bonds (more stable, less reactive) because they are already higher in energy.* Therefore, the bonds in CO_2 and H_2O are stronger (lower energy, more stable) than those in gasoline (or cooking oil) and O_2 (weaker, higher energy, less stable).

Fuels with more weak bonds yield more energy than fuels with fewer weak bonds. When a hydrocarbon burns, C—C and C—H bonds break; when an alcohol burns, C—O and O—H bonds break as well. Table 9.2 (p. 371) shows that the sum for C—C and C—H bonds (760 kJ/mol) is less than the sum for C—O and O—H bonds (825 kJ/mol). Therefore, it takes more energy to break the bonds of a fuel with a lot of C—O and O—H bonds. Thus, in general, *a fuel with fewer bonds to O releases more energy* (Figure 9.19).

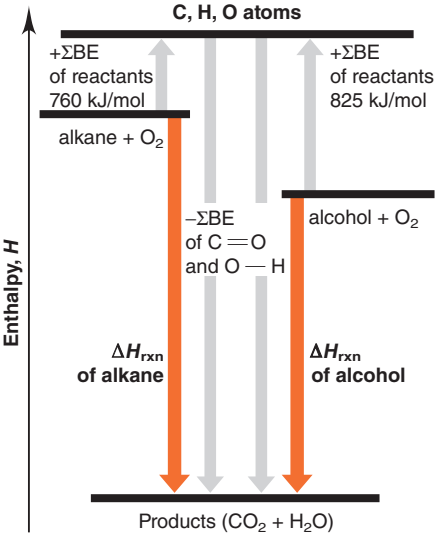


Figure 9.19 Relative bond strength and energy from fuels.

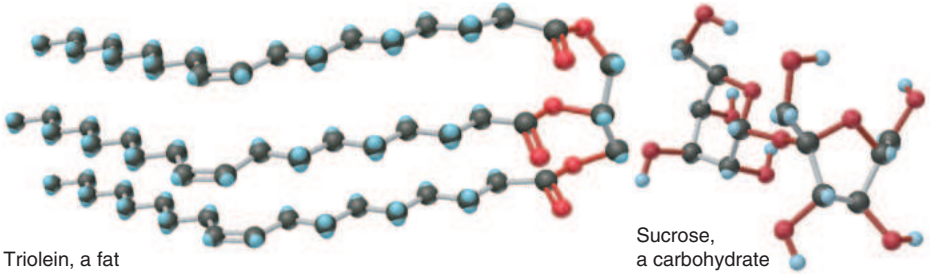
Table 9.4 Enthalpies of Reaction for Combustion of Some Foods

Substance	ΔH_{rxn} (kJ/g)
Fats	
Vegetable oil	−37.0
Margarine	−30.1
Butter	−30.0
Carbohydrates	
Table sugar (sucrose)	−16.2
Brown rice	−14.9
Maple syrup	−10.4

Both fats and carbohydrates serve as high-energy foods and consist of chains or rings of C atoms attached to H atoms, with some C—O, C═O, and O—H bonds *(shown in red below):*



Triolein, a fat

Sucrose, a carbohydrate

Carbohydrates have fewer chains of C atoms and bonds to H and more bonds to O. Fats "contain more Calories" per gram than carbohydrates because fats have fewer bonds to O (Table 9.4).

Summary of Section 9.4

- The only component of internal energy that changes significantly during a reaction is the bond energies of reactants and products, and this change appears as the enthalpy of reaction, ΔH°_{rxn}.
- A reaction involves breaking reactant bonds and forming product bonds. Applying Hess's law, we use tabulated bond energies to calculate ΔH°_{rxn}.
- Bonds in fuels are weaker (less stable, higher energy) than bonds in the combustion products. Fuels with more weak bonds release more energy than fuels with fewer.

9.5 BETWEEN THE EXTREMES: ELECTRONEGATIVITY AND BOND POLARITY

Scientific models are idealized descriptions of reality. The ionic and covalent bonding models portray compounds as formed by *either* complete electron transfer *or* complete electron sharing. But, in real substances, most atoms are joined by *polar covalent bonds*—between pure ionic and pure covalent (see Figure 9.20 and discussion on p. 382). In this section, we explore the "in-between" nature of these bonds and its importance for the properties of substances.

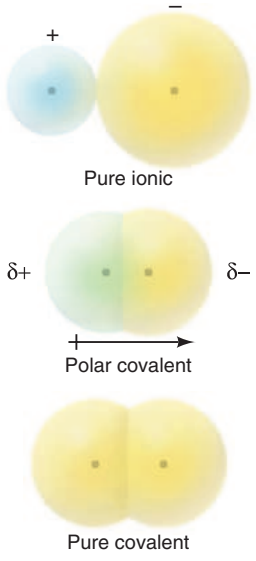


Figure 9.20 Bonding between the models. Pure ionic bonding *(top)* does not occur, and pure covalent bonding *(bottom)* is far less common than polar covalent bonding *(middle)*.

Electronegativity

Electronegativity (EN) is the relative ability of a bonded atom to attract shared electrons.* We might expect, for instance, the H—F bond energy to be the average of an H—H bond (432 kJ/mol) and an F—F bond (159 kJ/mol), or 296 kJ/mol. But, the actual HF bond energy is 565 kJ/mol, or 269 kJ/mol *higher!* To explain this difference, the American chemist Linus Pauling reasoned that, if F attracts the shared electron pair more strongly than H—that is, if F is more *electronegative* than H—the electrons will spend more time closer to F, and this unequal sharing makes the F end of the bond partially negative and the H end partially positive. The *electrostatic attraction* between these partial charges *increases* the energy required to break the bond. From studies with many compounds, Pauling derived a scale of *relative EN values* based on fluorine having the highest EN value, 4.0 (Figure 9.21).

Trends in Electronegativity In general, *electronegativity is inversely related to atomic size* because the nucleus of a smaller atom is closer to the shared pair than the nucleus of a larger atom, so it attracts the electrons more strongly (Figure 9.22):

- *Down a main group,* electronegativity (height of post) decreases as size (hemisphere on top of post) increases.
- *Across a period of main-group elements,* electronegativity increases.
- Nonmetals are *more* electronegative than metals.

*Electronegativity refers to a *bonded* atom attracting a shared pair; electron affinity refers to a gaseous atom gaining an electron to form an anion. Elements with a high EN also have a highly negative EA.

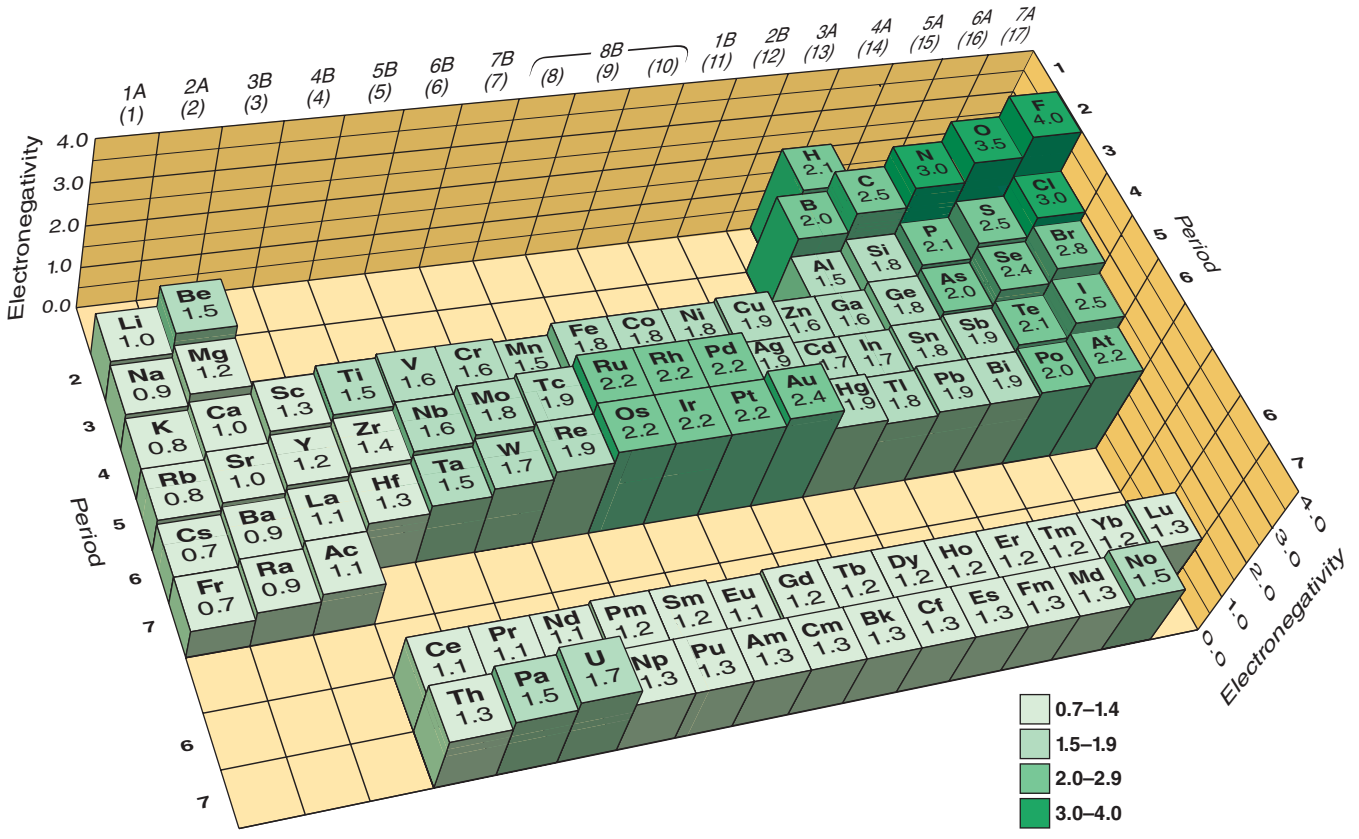

Figure 9.21 **The Pauling electronegativity (EN) scale.** The height of each post is proportional to the EN, which is shown on top. The key has several EN cutoffs. In the main groups, EN *increases* across and *decreases* down. The transition and inner transition elements show little change in EN. Here hydrogen is placed near elements with similar EN values.

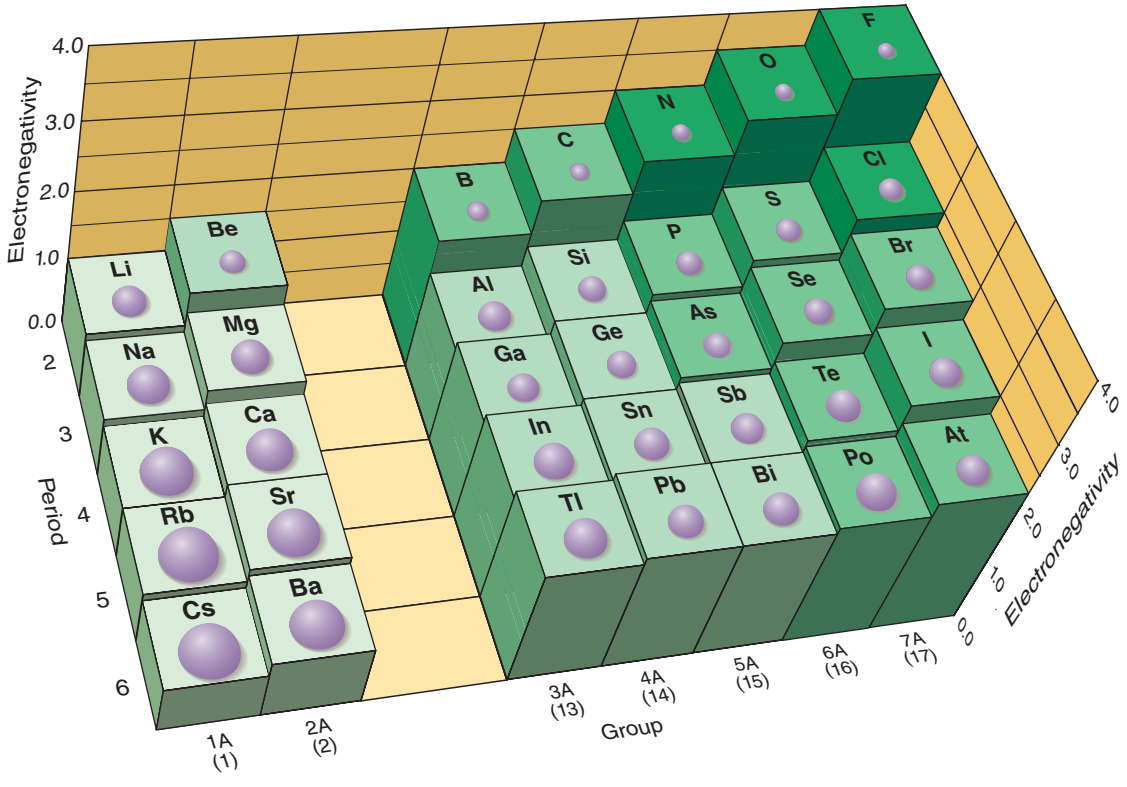

Figure 9.22 **Electronegativity and atomic size.**

The most electronegative element is fluorine, with oxygen a close second. Thus, except when it bonds with fluorine, oxygen always pulls bonding electrons toward itself. The least electronegative element (also referred to as the most *electropositive*) is francium, in the lower left corner of the periodic table, but it is radioactive and extremely rare, so for all practical purposes, cesium is the most electropositive.*

Electronegativity and Oxidation Number An important use of electronegativity is in determining an atom's oxidation number (O.N.; see Section 4.5):

1. The more electronegative atom in a bond is assigned *all* the *shared* electrons; the less electronegative atom is assigned *none.*
2. Each atom in a bond is assigned *all* of its *unshared* electrons.
3. The oxidation number is given by

$$\text{O.N.} = \text{no. of valence } e^- - (\text{no. of shared } e^- + \text{no. of unshared } e^-)$$

In HCl, for example, Cl is more electronegative than H. Cl has 7 valence electrons and is assigned 8 (2 shared + 6 unshared), so its O.N. is $7 - 8 = -1$. The H atom has 1 valence electron and is assigned none, so its O.N. is $1 - 0 = +1$.

Bond Polarity and Partial Ionic Character

Whenever atoms having different electronegativities form a bond, such as H (2.1) and F (4.0) in HF, the bonding pair is shared *unequally.* This unequal distribution of electron density results in a **polar covalent bond.** It is depicted by a polar arrow ($+\longrightarrow$) pointing toward the partially negative pole or by $\delta+$ and $\delta-$ symbols (see Figure 4.1):

In the H—H and F—F bonds, where the atoms are identical, the bonding pair is shared *equally,* and a **nonpolar covalent bond** results. In Figure 9.23, relief maps show the distribution of electron density in H_2, F_2, and HF.

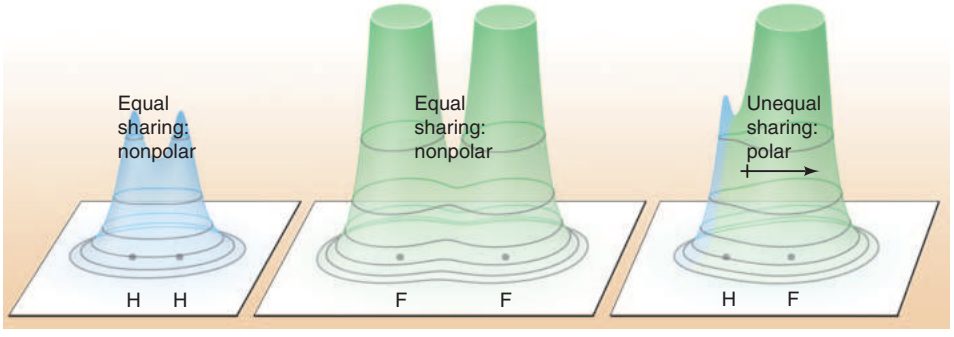

Figure 9.23 Electron density distributions shown as relief maps for H_2, F_2, and HF. In HF, the electron density shifts from H to F. (The electron density peak for F has been cut off to limit the figure height.)

The Importance of Electronegativity Difference (ΔEN) The **electronegativity difference (ΔEN),** the difference between the EN values of the bonded atoms, is directly related to a bond's polarity. It ranges from 0.0 in a diatomic element, such as H_2, O_2, or Cl_2, all the way up to 3.3, the difference between the most electronegative atom, F (4.0), and the most electropositive, Cs (0.7), in the ionic compound CsF.

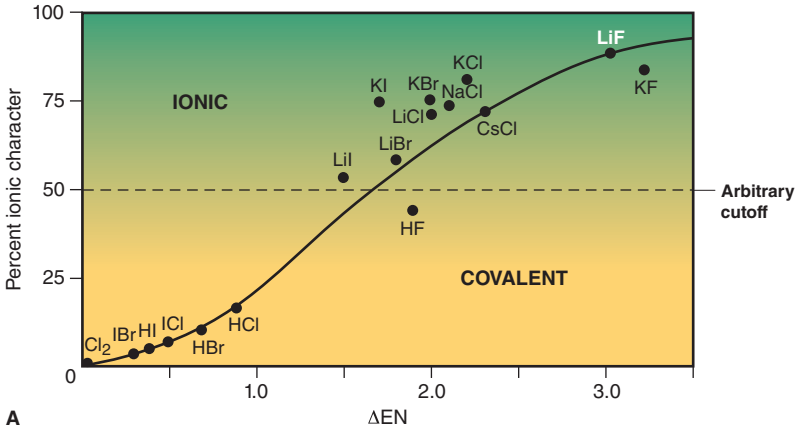
Another parameter closely related to ΔEN is the **partial ionic character** of a bond: *a greater ΔEN results in larger partial charges and higher partial ionic character.* Consider three Cl-containing gaseous molecules: ΔEN for LiCl(*g*) is $3.0 - 1.0 = 2.0$; for HCl(*g*), it is $3.0 - 2.1 = 0.9$; and for $Cl_2(g)$, it is $3.0 - 3.0 = 0.0$. Thus, the bond in LiCl has more ionic character than the one in HCl, which has more than the one in Cl_2.

*In 1934, the American physicist Robert S. Mulliken developed electronegativity values based on atomic properties: EN = (IE − EA)/2. By this approach as well, fluorine, with a high ionization energy (IE) and a large negative electron affinity (EA), has a high EN; and cesium, with a low IE and a small EA, has a low EN.

Here are two approaches that quantify ionic character. Both use arbitrary cutoffs, which is not really consistent with the actual gradation in bonding:

1. *ΔEN range.* This approach divides bonds into mostly ionic, polar covalent, mostly covalent, and nonpolar covalent based on a range of ΔEN values (Figure 9.24).

2. *Percent ionic character*. This approach is based on the behavior of a gaseous diatomic molecule in an electric field. A plot of *percent ionic character* vs. ΔEN for several molecules shows that, as expected, *percent ionic character generally increases with ΔEN* (Figure 9.25A). A value of 50% divides ionic from covalent bonds. Note that a substance like $Cl_2(g)$ has 0% ionic character, but none has 100% ionic character: *electron sharing occurs to some extent in every bond,* even between an ion pair of an alkali halide (Figure 9.25B).



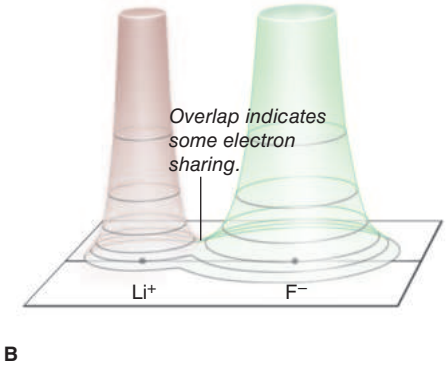


Figure 9.25 **Percent ionic character as a function of ΔEN. A,** ΔEN correlates with ionic character. **B,** Even in highly ionic LiF (ΔEN = 3.0), some electron sharing occurs between the ions in the gaseous ion pair.

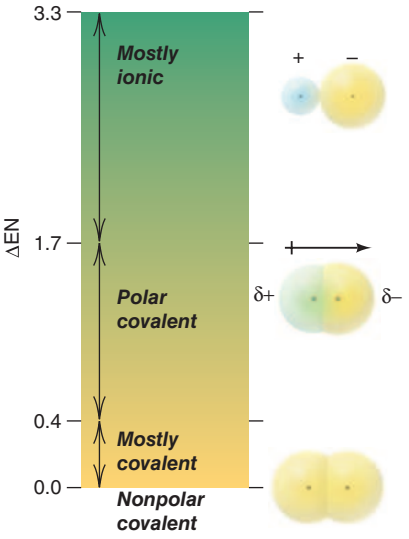

Figure 9.24 **ΔEN ranges for classifying the partial ionic character of bonds.**

SAMPLE PROBLEM 9.5 Determining Bond Polarity from EN Values

Problem **(a)** Use a polar arrow to indicate the polarity of each bond: N—H, F—N, I—Cl. **(b)** Rank the following bonds in order of *increasing* polarity and *decreasing* percent ionic character: H—N, H—O, H—C.

Plan **(a)** We use Figure 9.21 to find the EN values for the atoms and point the polar arrow toward the negative end. **(b)** To rank the bond polarity, we determine ΔEN: the higher the value, the greater the polarity. Percent ionic character is also directly related to ΔEN (and bond polarity); it decreases in the opposite order that polarity increases.

Solution **(a)** The EN of N = 3.0 and the EN of H = 2.1, so $\overset{\longleftarrow +}{\text{N—H}}$

The EN of F = 4.0 and the EN of N = 3.0, so $\overset{\longleftarrow +}{\text{F—N}}$

The EN of I = 2.5 and the EN of Cl = 3.0, so $\overset{+ \longrightarrow}{\text{I—Cl}}$

(b) The ΔEN values are 0.9 for H—N, 1.4 for H—O, and 0.4 for H—C.
The order of *increasing* bond polarity is H—C < H—N < H—O.
The order of *decreasing* percent ionic character is H—O > H—N > H—C.

Check In (b), we can check the order of bond polarity using periodic trends. Each bond involves H and a Period 2 atom. Since size decreases and EN increases across a period, the polarity is greatest for the bond to O (farthest to the right in Period 2).

Comment In Chapter 10, you'll see that the bond polarity contributes to the overall polarity of the molecule, which is a major factor determining behavior.

FOLLOW-UP PROBLEMS

9.5A Arrange each set of bonds in order of *increasing* polarity, and indicate bond polarity with δ+ and δ− symbols:
(a) Cl—F, Br—Cl, Cl—Cl **(b)** P—F, Si—F, S—F

9.5B Arrange each set of bonds in order of *decreasing* polarity, and indicate bond polarity with a polar arrow:
(a) Se—Cl, Se—F, Se—Br **(b)** S—B, F—B, Cl—B

SOME SIMILAR PROBLEMS 9.62 and 9.63

The Gradation in Bonding Across a Period

A metal and a nonmetal—elements from the left and right sides of the periodic table—have a relatively large ΔEN and typically form an ionic compound. Two nonmetals—both from the right side of the table—have a small ΔEN and form a covalent compound. When we combine chlorine with each of the Period 3 elements, starting with sodium, we observe a steady decrease in ΔEN and a gradation in bond type from ionic through polar covalent to nonpolar covalent.

Figure 9.26 shows an electron density relief map of a bond in each of the common Period 3 chlorides; note the steady increase in the height of electron density *between* the peaks—the bonding region—which indicates an *increase in electron sharing*. Figure 9.27 shows samples of common Period 3 chlorides—NaCl, $MgCl_2$, $AlCl_3$, $SiCl_4$, PCl_3, and SCl_2, as well as Cl_2—along with the change in ΔEN and two physical properties:

- NaCl. Sodium chloride is a white (colorless) crystalline solid with a ΔEN of 2.1, a high melting point, and high electrical conductivity when molten—ionic by any criterion. Nevertheless, just as for LiF (Figure 9.25B), a small but significant amount of electron sharing appears in the electron density relief map for NaCl.
- $MgCl_2$. With a ΔEN of 1.8, magnesium chloride is still ionic, but it has a lower melting point and lower conductivity, as well as slightly more electron sharing, than NaCl.
- $AlCl_3$. Rather than being a three-dimensional lattice of Al^{3+} and Cl^- ions, aluminum chloride, with a ΔEN value of 1.5, consists of layers of highly polar Al—Cl bonds. Weak forces between layers result in a much lower melting point, and the low conductivity implies few free ions. Electron density between the nuclei is even higher than in $MgCl_2$.
- $SiCl_4$, PCl_3, SCl_2, and Cl_2. The trend toward more covalent bonding continues through the remaining substances. Each occurs as separate molecules, which have no conductivity and such weak forces *between* them that melting points are below 0°C. In Cl_2, the bond is nonpolar (ΔEN = 0.0). The relief maps show the increasing electron density in the bonding region.

Thus, *as ΔEN decreases, the bond becomes more covalent,* and the character of the substance changes from ionic solid to covalent gas.

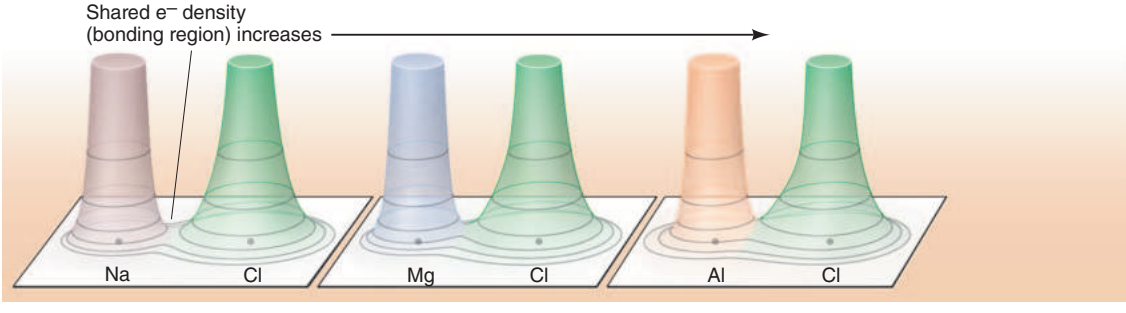

Figure 9.26 Electron density relief maps for bonds of the Period 3 chlorides. Note the steady increase in electron sharing from left to right (across pp. 384–385).

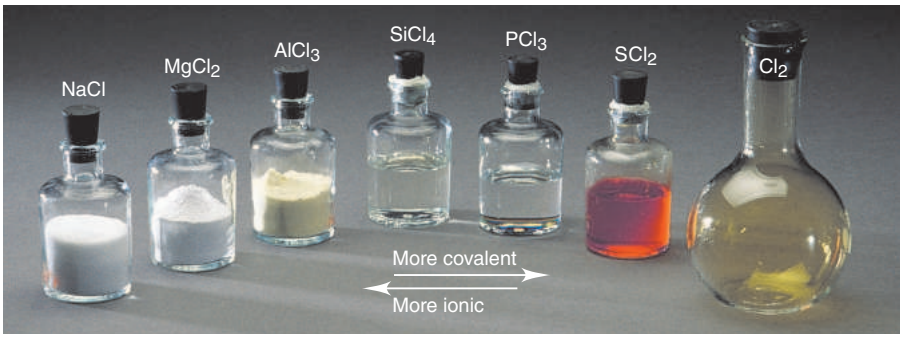

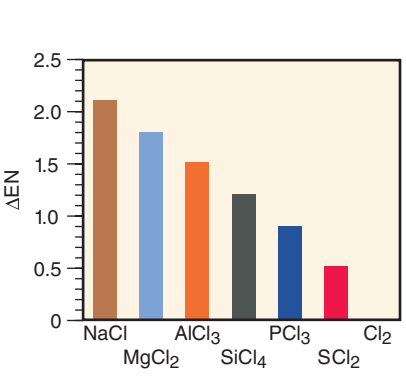

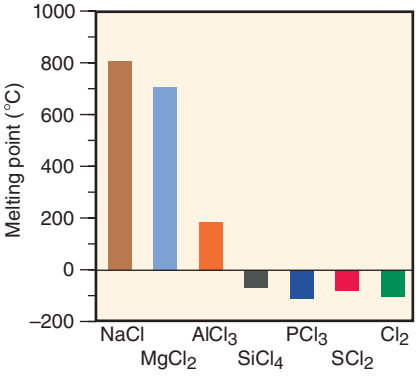

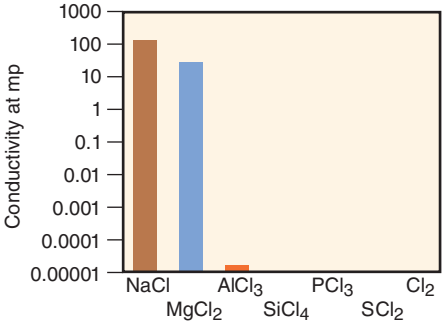

Figure 9.27 Properties of the Period 3 chlorides. As ΔEN decreases, melting point and electrical conductivity decrease because the bond type changes from ionic to polar covalent to nonpolar covalent.

Summary of Section 9.5

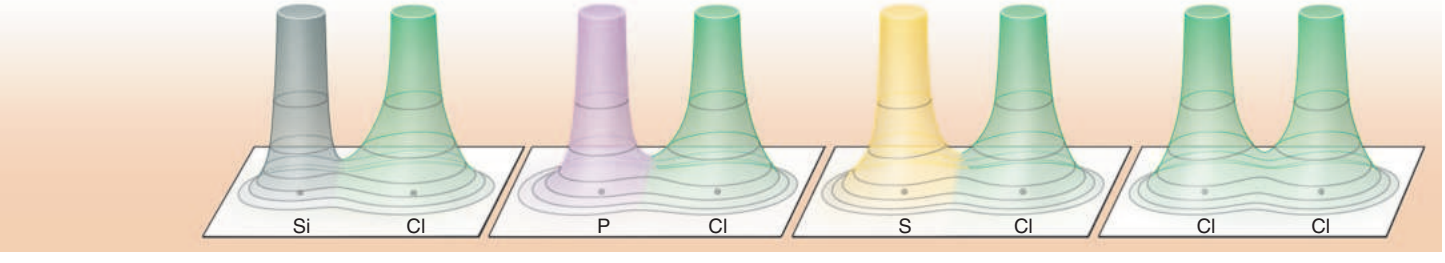
- Electronegativity is the ability of a bonded atom to attract shared electrons, which generates opposite partial charges at the ends of the bond and contributes to the bond energy.
- Electronegativity increases across a period and decreases down a group, the reverse of the trends in atomic size.
- The larger the ΔEN for two bonded atoms, the more polar the bond is and the greater its ionic character.
- For Period 3 chlorides, there is a gradation in bond type from ionic to polar covalent to nonpolar covalent.

9.6 AN INTRODUCTION TO METALLIC BONDING

In this section, you'll see how a simple, qualitative model for metallic bonding accounts for the properties of metals; a more detailed model is presented in Chapter 12.

The Electron-Sea Model

Metals can transfer electrons to nonmetals and form ionic solids, such as NaCl. And experiments with metals in the gas phase show that two metal atoms can even share their valence electrons to form gaseous, diatomic molecules, such as Na_2. But what holds the atoms together in a chunk of Na metal? The **electron-sea model** of



metallic bonding proposes that all the metal atoms in the sample contribute their valence electrons to form a delocalized electron "sea" throughout the piece, with the metal ions (nuclei and core electrons) lying in an orderly array (see Figure 9.2C). *All the atoms in the sample share the electrons,* and the piece is held together by the mutual attraction of the metal cations for the mobile valence electrons. Thus, bonding in metals is fundamentally different than the other two types:

- *In contrast to ionic bonding,* no anions are present, and the metal ions are not held in place as rigidly.
- *In contrast to covalent bonding,* no particular pair of metal atoms is bonded through a localized electron pair.
- *Instead of forming compounds,* two or more metals typically form **alloys,** solid mixtures of variable composition. Alloys appear in car and airplane bodies, bridges, coins, jewelry, dental fillings, and many other familiar objects.

How the Model Explains the Properties of Metals

The physical properties of metals vary over a wide range. Two features of the electron-sea model that account for these properties are (1) the *regularity,* but not rigidity, of the metal-ion array and (2) the *number* and *mobility* of the valence electrons.

1. *Melting and boiling points.* Nearly all metals are solids with moderate to high melting points and much higher boiling points (Table 9.5). These properties are related to the energy of the metallic bonding. Melting points are only moderately high because the cations can move without breaking the attraction to the surrounding electrons. Boiling points are very high because each cation and its valence electron(s) must break away from the others. Gallium provides a striking example: it can melt in your hand (mp 29.8°C) but doesn't boil until over 2400°C.

Periodic trends are consistent with the strength of the bonding:

- *Down a group,* melting points decrease because the larger metal ions have a weaker attraction to the electron sea.
- *Across a period,* melting points increase. Alkaline earth metals [Group 2A(2)] have higher melting points than alkali metals [Group 1A(1)] because their 2+ cations have stronger attractions to twice as many valence electrons (Figure 9.28).

Table 9.5 Melting and Boiling Points of Some Metals

Element	mp (°C)	bp (°C)
Lithium (Li)	180	1347
Tin (Sn)	232	2623
Aluminum (Al)	660	2467
Barium (Ba)	727	1850
Silver (Ag)	961	2155
Copper (Cu)	1083	2570
Uranium (U)	1130	3930

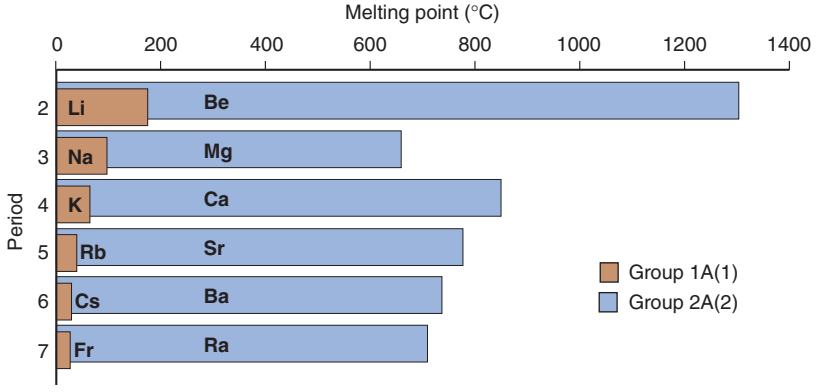


Figure 9.28 Melting points of Group 1A(1) and Group 2A(2) metals.

2. *Mechanical properties.* When a piece of metal is deformed by a hammer, the metal ions do not repel each other, but rather slide past each other through the electron sea and end up in new positions; thus metals dent and bend, as shown in Figure 9.29. Compare this behavior with the interionic repulsions that occur when an ionic solid is struck (see Figure 9.9, p. 367).

All the Group 1B(11) metals—copper, silver, and gold—are soft enough to be machined into sheets (malleable) and wires (ductile), but gold is in a class by itself.

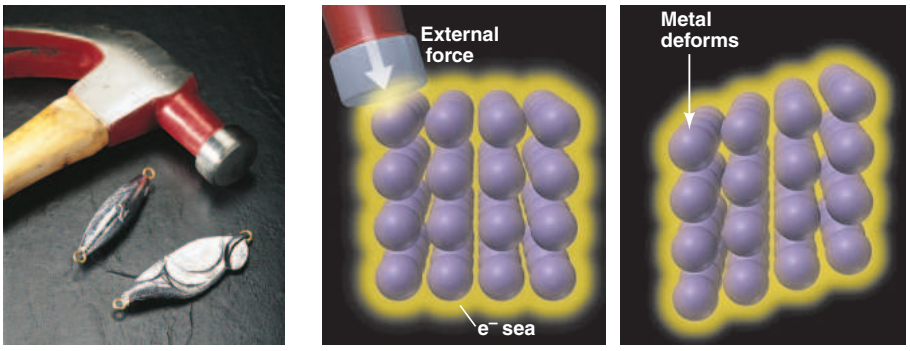

Figure 9.29 Why metals dent and bend rather than crack.

One gram of gold, about the size of a small ball-bearing, can be drawn into a wire 20 μm thick and 165 m long or hammered into a 1.0-m^2 sheet that is 230 atoms (about 70 nm) thick *(see photo)*!

How thin is gold leaf?

3. *Electrical conductivity.* Unlike ionic and covalent substances, metals are good conductors of electricity in both the solid and liquid states because of their mobile electrons. When a piece of metal wire is attached to a battery, electrons flow from the negative terminal into the wire, replacing the electrons that flow from the wire into the positive terminal. Foreign atoms disrupt the array of metal atoms and reduce conductivity. Copper used in electrical wiring is over 99.99% pure because traces of other atoms drastically restrict electron flow.

4. *Thermal conductivity*. Mobile electrons also make metals good conductors of heat. Place your hand on a piece of metal and a piece of wood that are both at room temperature. The metal feels colder because it conducts heat away from your hand much faster than the wood. The mobile, delocalized electrons in the metal disperse the heat from your hand more quickly than the localized electron pairs in the covalent bonds of wood.

Summary of Section 9.6

- According to the electron-sea model, the valence electrons of the metal atoms in a sample are highly delocalized and attract all the metal cations, holding them together.
- Metals have only moderately high melting points because the metal ions remain attracted to the electron sea even if their relative positions change.
- Boiling involves complete separation of individual cations with their valence electrons from all the others, so metals have very high boiling points.
- Metals can be deformed because the electron sea prevents repulsions among the cations.
- Metals conduct electricity and heat because their electrons are mobile.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How differences in atomic properties lead to differences in bond type; the basic distinctions among the three types of bonding (§9.1)
2. The essential features of ionic bonding: electron transfer to form ions, and their electrostatic attraction to form a solid (§9.2)
3. How lattice energy is ultimately responsible for the formation of ionic compounds (§9.2)
4. How ionic compound formation is conceptualized as occurring in hypothetical steps (a Born-Haber cycle) to calculate the lattice energy (§9.2)
5. How Coulomb's law explains the periodic trends in lattice energy (§9.2)

Learning Objectives (continued)

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

6. Why ionic compounds are brittle and high melting and conduct electricity only when molten or dissolved in water (§9.2)
7. How nonmetal atoms form a covalent bond (§9.3)
8. How bonding and lone electron pairs fill the outer (valence) level of each atom in a molecule (§9.3)
9. The interrelationships among bond order, bond length, and bond energy (§9.3)
10. How the distinction between bonding and nonbonding forces explains the properties of covalent molecules and network covalent solids (§9.3)
11. How changes in bond strength account for the enthalpy of reaction (§9.4)
12. How a reaction can be divided conceptually into bond-breaking and bond-forming steps (§9.4)
13. The periodic trends in electronegativity and the inverse relationship of EN values to atomic sizes (§9.5)
14. How bond polarity arises from differences in the electronegativities of bonded atoms; the direction of bond polarity (§9.5)
15. The change in partial ionic character with ΔEN and the change from ionic to polar covalent to nonpolar covalent bonding across a period (§9.5)
16. The role of delocalized electrons in metallic bonding (§9.6)
17. How the electron-sea model explains why metals bend, have very high boiling points, and conduct electricity in solid or molten form (§9.6)

Master These Skills

1. Using Lewis electron-dot symbols to depict main-group atoms (§9.1)
2. Depicting the formation of ions with electron configurations, orbital diagrams, and Lewis symbols, and writing the formula of the ionic compound (SP 9.1)
3. Calculating lattice energy from the enthalpies of the steps to ionic compound formation (§9.2)
4. Ranking lattice energies from ionic properties (SP 9.2)
5. Ranking similar covalent bonds according to their length and strength (SP 9.3)
6. Using bond energies to calculate ΔH°_{rxn} (SP 9.4)
7. Determining bond polarity from EN values (SP 9.5)

Key Equations and Relationships

Page numbers appear in parentheses.

9.1 Relating the energy of attraction to the lattice energy (365):

$$\text{Electrostatic energy} \propto \frac{\text{cation charge} \times \text{anion charge}}{\text{cation radius} + \text{anion radius}} \propto \Delta H^\circ_{lattice}$$

9.2 Calculating enthalpy of reaction from bond enthalpies or bond energies (377):

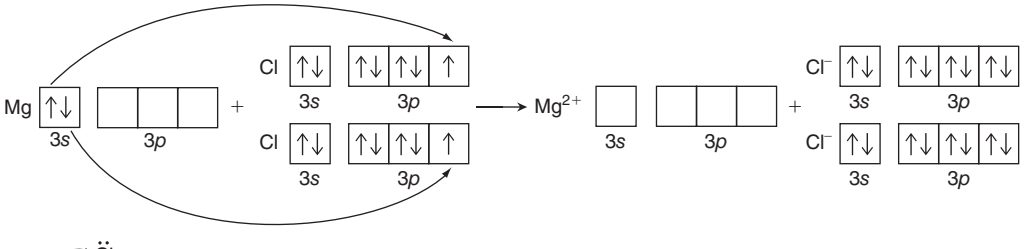
$$\Delta H^\circ_{rxn} = \Sigma \Delta H^\circ_{\text{reactant bonds broken}} + \Sigma \Delta H^\circ_{\text{product bonds formed}}$$

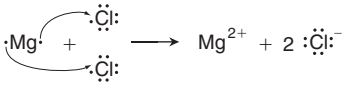
or

$$\Delta H^\circ_{rxn} = \Sigma BE_{\text{reactant bonds broken}} - \Sigma BE_{\text{product bonds formed}}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

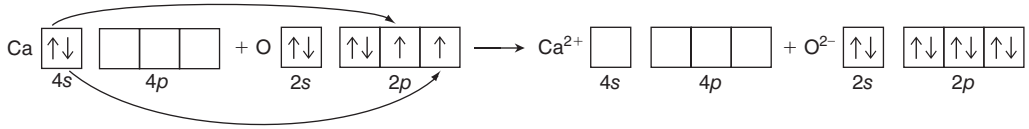
9.1A $Mg\ ([Ne]\ 3s^2) + 2Cl\ ([Ne]\ 3s^2 3p^5) \longrightarrow Mg^{2+}\ ([Ne]) + 2Cl^-\ ([Ne]\ 3s^2 3p^6)$





Formula: $MgCl_2$

9.1B $Ca\ ([Ar]\ 4s^2) + O\ ([Ne]\ 2s^2 2p^4) \longrightarrow Ca^{2+}\ ([Ar]) + O^{2-}\ ([Ne]\ 2s^2 2p^6)$



Formula: CaO

9.2A SrF_2. The only difference between these compounds is the size of the cation: the Sr^{2+} ion is smaller than the Ba^{2+} ion.

9.2B RbCl. The sizes of the cations and of the anions are nearly the same, but the charges of Rb^+ and Cl^- are half as much as the charges of Sr^{2+} and S^{2-}. In nearly every case, charge is more important than size.

9.3A (a) Bond length: C≡C > C≡N > C≡O
Bond strength: C≡O > C≡N > C≡C
(b) Bond length: P—I > P—Br > P—F
Bond strength: P—F > P—Br > P—I

9.3B (a) Bond length: Si—F < Si—O < Si—C
Bond strength: Si—C < Si—O < Si—F
(b) Bond length: N≡N < N=N < N—N
Bond strength: N—N < N=N < N≡N

9.4A $N{\equiv}N + 3\ H{-}H \longrightarrow 2\ H{-}\underset{\displaystyle H}{\overset{\displaystyle |}{N}}{-}H$

$\Sigma\Delta H^\circ_{\text{bonds broken}} = 1\ N{\equiv}N + 3\ H{-}H$
$= 945\ \text{kJ} + 1296\ \text{kJ} = 2241\ \text{kJ}$
$\Sigma\Delta H^\circ_{\text{bonds formed}} = 6\ N{-}H = -2346\ \text{kJ}$
$\Delta H^\circ_{\text{rxn}} = -105\ \text{kJ}$

9.4B $\Delta H^\circ_{\text{bonds broken}} = 2\ N{\equiv}O + 1\ Cl{-}Cl$
$= 1262\ \text{kJ} + 243\ \text{kJ} = 1505\ \text{kJ}$
$\Delta H^\circ_{\text{bonds formed}} = 2\ N{-}O + 2\ N{-}Cl$
$= 2(-201\ \text{kJ}) + 2(-200\ \text{kJ}) = -802\ \text{kJ}$
$\Delta H^\circ_{\text{rxn}} = 1505\ \text{kJ} + (-802\ \text{kJ}) = 703\ \text{kJ}$

9.5A (a) Cl—Cl < $\overset{\delta+}{\text{Br}}$—$\overset{\delta-}{\text{Cl}}$ < $\overset{\delta+}{\text{Cl}}$—$\overset{\delta-}{\text{F}}$
(b) $\overset{\delta+}{\text{S}}$—$\overset{\delta-}{\text{F}}$ < $\overset{\delta+}{\text{P}}$—$\overset{\delta-}{\text{F}}$ < $\overset{\delta+}{\text{Si}}$—$\overset{\delta-}{\text{F}}$

9.5B (a) $\overset{+\longrightarrow}{\text{Se}}$—F > $\overset{+\longrightarrow}{\text{Se}}$—Cl > $\overset{+\longrightarrow}{\text{Se}}$—Br
(b) $\overset{\longleftarrow}{\text{F}}$—$\overset{\longleftarrow}{\text{B}}$ > $\overset{\longleftarrow}{\text{Cl}}$—$\overset{\longleftarrow}{\text{B}}$ > $\overset{\longleftarrow}{\text{S}}$—$\overset{\longleftarrow}{\text{B}}$

PROBLEMS

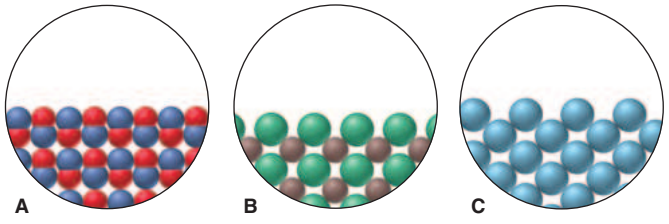
Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Atomic Properties and Chemical Bonds

Concept Review Questions

9.1 In general terms, how does each of the following atomic properties influence the metallic character of the main-group elements in a period?
(a) Ionization energy
(b) Atomic radius
(c) Number of outer electrons
(d) Effective nuclear charge

9.2 Three solids are represented below. What is the predominant type of intramolecular bonding in each?



9.3 What is the relationship between the tendency of a main-group element to form a monatomic ion and its position in the periodic table? In what part of the table are the main-group elements that typically form cations? Anions?

Skill-Building Exercises (grouped in similar pairs)

9.4 Which member of each pair is *more* metallic?
(a) Na or Cs (b) Mg or Rb (c) As or N

9.5 Which member of each pair is *less* metallic?
(a) I or O (b) Be or Ba (c) Se or Ge

9.6 State the type of bonding—ionic, covalent, or metallic—you would expect in each: (a) CsF(*s*); (b) $N_2(g)$; (c) Na(*s*).

9.7 State the type of bonding—ionic, covalent, or metallic—you would expect in each: (a) $ICl_3(g)$; (b) $N_2O(g)$; (c) LiCl(*s*).

9.8 State the type of bonding—ionic, covalent, or metallic—you would expect in each: (a) $O_3(g)$; (b) $MgCl_2(s)$; (c) $BrO_2(g)$.

9.9 State the type of bonding—ionic, covalent, or metallic—you would expect in each: (a) Cr(*s*); (b) $H_2S(g)$; (c) CaO(*s*).

9.10 Draw a Lewis electron-dot symbol for (a) Rb; (b) Si; (c) I.

9.11 Draw a Lewis electron-dot symbol for (a) Ba; (b) Kr; (c) Br.

9.12 Draw a Lewis electron-dot symbol for (a) Sr; (b) P; (c) S.

9.13 Draw a Lewis electron-dot symbol for (a) As; (b) Se; (c) Ga.

9.14 Give the group number and general electron configuration of an element with each electron-dot symbol: (a) ·Ẋ: (b) Ẋ·

9.15 Give the group number and general electron configuration of an element with each electron-dot symbol: (a) ·Ẋ: (b) ·Ẋ·

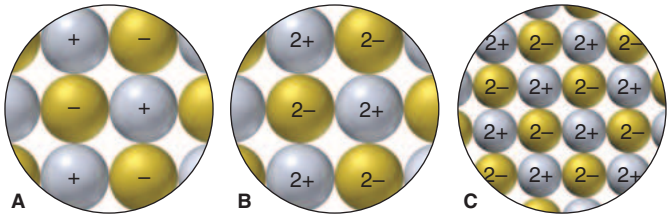
The Ionic Bonding Model

(Sample Problems 9.1 and 9.2)

Concept Review Questions

9.16 If energy is required to form monatomic ions from metals and nonmetals, why do ionic compounds exist?

9.17 (a) In general, how does the lattice energy of an ionic compound depend on the charges and sizes of the ions? (b) Ion arrangements of three general salts are represented below. Rank them in order of increasing lattice energy.



9.18 When gaseous Na^+ and Cl^- ions form gaseous NaCl ion pairs, 548 kJ/mol of energy is released. Why, then, does NaCl occur as a solid under ordinary conditions?

9.19 To form S^{2-} ions from gaseous sulfur atoms requires 214 kJ/mol, but these ions exist in solids such as K_2S. Explain.

Skill-Building Exercises (grouped in similar pairs)

9.20 Use condensed electron configurations and Lewis electron-dot symbols to depict the ions formed from each of the following atoms, and predict the formula of their compound:
(a) Ba and Cl (b) Sr and O (c) Al and F (d) Rb and O

9.21 Use condensed electron configurations and Lewis electron-dot symbols to depict the ions formed from each of the following atoms, and predict the formula of their compound:
(a) Cs and S (b) O and Ga (c) N and Mg (d) Br and Li

9.22 For each ionic compound formula, identify the main group to which X belongs: (a) XF_2; (b) MgX; (c) X_2SO_4.

9.23 For each ionic compound formula, identify the main group to which X belongs: (a) X_3PO_4; (b) $X_2(SO_4)_3$; (c) $X(NO_3)_2$.

9.24 For each ionic compound formula, identify the main group to which X belongs: (a) X_2O_3; (b) XCO_3; (c) Na_2X.

9.25 For each ionic compound formula, identify the main group to which X belongs: (a) CaX_2; (b) Al_2X_3; (c) XPO_4.

9.26 For each pair, choose the compound with the larger lattice energy, and explain your choice: (a) BaS or CsCl; (b) LiCl or CsCl.

9.27 For each pair, choose the compound with the larger lattice energy, and explain your choice: (a) CaO or CaS; (b) BaO or SrO.

9.28 For each pair, choose the compound with the smaller lattice energy, and explain your choice: (a) CaS or BaS; (b) NaF or MgO.

9.29 For each pair, choose the compound with the smaller lattice energy, and explain your choice: (a) NaF or NaCl; (b) K_2O or K_2S.

9.30 Use the following to calculate $\Delta H^\circ_{\text{lattice}}$ of NaCl:

$Na(s) \longrightarrow Na(g)$	$\Delta H^\circ = 109$ kJ
$Cl_2(g) \longrightarrow 2Cl(g)$	$\Delta H^\circ = 243$ kJ
$Na(g) \longrightarrow Na^+(g) + e^-$	$\Delta H^\circ = 496$ kJ
$Cl(g) + e^- \longrightarrow Cl^-(g)$	$\Delta H^\circ = -349$ kJ
$Na(s) + \frac{1}{2}Cl_2(g) \longrightarrow NaCl(s)$	$\Delta H^\circ = -411$ kJ

Compared with the lattice energy of LiF (1050 kJ/mol), is the magnitude of the value for NaCl what you expected? Explain.

9.31 Use the following to calculate $\Delta H^\circ_{\text{lattice}}$ of MgF_2:

$Mg(s) \longrightarrow Mg(g)$	$\Delta H^\circ = 148$ kJ
$F_2(g) \longrightarrow 2F(g)$	$\Delta H^\circ = 159$ kJ
$Mg(g) \longrightarrow Mg^+(g) + e^-$	$\Delta H^\circ = 738$ kJ
$Mg^+(g) \longrightarrow Mg^{2+}(g) + e^-$	$\Delta H^\circ = 1450$ kJ
$F(g) + e^- \longrightarrow F^-(g)$	$\Delta H^\circ = -328$ kJ
$Mg(s) + F_2(g) \longrightarrow MgF_2(s)$	$\Delta H^\circ = -1123$ kJ

Compared with the lattice energy of LiF (1050 kJ/mol) or the lattice energy you calculated for NaCl in Problem 9.30, does the relative magnitude of the value for MgF_2 surprise you? Explain.

Problems in Context

9.32 Aluminum oxide (Al_2O_3) is a widely used industrial abrasive (emery, corundum), for which the specific application depends on the hardness of the crystal. What does this hardness imply about the magnitude of the lattice energy? Would you have predicted from the chemical formula that Al_2O_3 is hard? Explain.

9.33 Born-Haber cycles were used to obtain the first reliable values for electron affinity by considering the EA value as the unknown and using a theoretically calculated value for the lattice energy. Use a Born-Haber cycle for KF and the following values to calculate a value for the electron affinity of fluorine:

$K(s) \longrightarrow K(g)$	$\Delta H^\circ = 90$ kJ
$K(g) \longrightarrow K^+(g) + e^-$	$\Delta H^\circ = 419$ kJ
$F_2(g) \longrightarrow 2F(g)$	$\Delta H^\circ = 159$ kJ
$K(s) + \frac{1}{2}F_2(g) \longrightarrow KF(s)$	$\Delta H^\circ = -569$ kJ
$K^+(g) + F^-(g) \longrightarrow KF(s)$	$\Delta H^\circ = -821$ kJ

The Covalent Bonding Model

(Sample Problem 9.3)

Concept Review Questions

9.34 Describe the interactions that occur between individual chlorine atoms as they approach each other and form Cl_2. What combination of forces gives rise to the energy holding the atoms together and to the final internuclear distance?

9.35 Define bond energy using the H—Cl bond as an example. When this bond breaks, is energy absorbed or released? Is the accompanying ΔH value positive or negative? How do the magnitude and sign of this ΔH value relate to the value that accompanies H—Cl bond formation?

9.36 For single bonds between similar types of atoms, how does the strength of the bond relate to the sizes of the atoms? Explain.

9.37 How does the energy of the bond between a given pair of atoms relate to the bond order? Why?

9.38 When liquid benzene (C_6H_6) boils, does the gas consist of molecules, ions, or separate atoms? Explain.

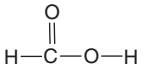
Skill-Building Exercises (grouped in similar pairs)

9.39 Using the periodic table only, arrange the members of each of the following sets in order of increasing bond *strength:*
(a) Br—Br, Cl—Cl, I—I (b) S—H, S—Br, S—Cl
(c) C═N, C—N, C≡N

9.40 Using the periodic table only, arrange the members of each of the following sets in order of increasing bond *length:*
(a) H—F, H—I, H—Cl (b) C—S, C═O, C—O
(c) N—H, N—S, N—O

Problem in Context

9.41 Formic acid (HCOOH; structural formula shown below) is secreted by certain species of ants when they bite.



Rank the relative strengths of (a) the C—O and C═O bonds and (b) the H—C and H—O bonds. Explain these rankings.

Bond Energy and Chemical Change
(Sample Problem 9.4)

Concept Review Questions

9.42 Write a solution Plan (without actual numbers, but including the bond energies you would use and how you would combine them algebraically) for calculating the total enthalpy change of the following reaction:

$$H_2(g) + O_2(g) \longrightarrow H_2O_2(g) \qquad (H—O—O—H)$$

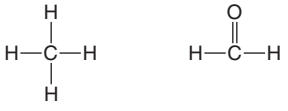
9.43 The text points out that, for similar types of substances, one with weaker bonds is usually more reactive than one with stronger bonds. Why is this generally true?

9.44 Why is there a discrepancy between a heat of reaction obtained from calorimetry and one obtained from bond energies?

Skill-Building Exercises (grouped in similar pairs)

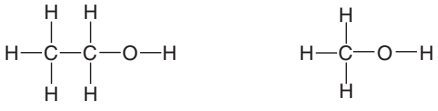
9.45 Which of the following gases would you expect to have the greater heat of reaction per mole for combustion? Why?

methane or formaldehyde

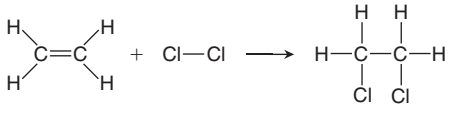


9.46 Which of the following gases would you expect to have the greater heat of reaction per mole for combustion? Why?

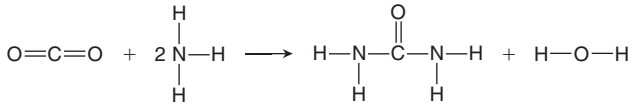
ethanol or methanol



9.47 Use bond energies to calculate the heat of reaction:

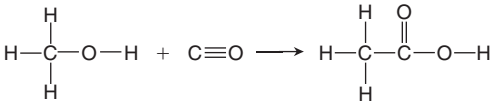


9.48 Use bond energies to calculate the heat of reaction:



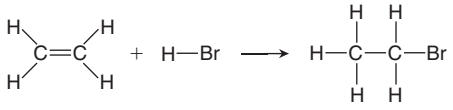
Problems in Context

9.49 An important industrial route to extremely pure acetic acid is the reaction of methanol with carbon monoxide:



Use bond energies to calculate the enthalpy of reaction.

9.50 Sports trainers treat sprains and soreness with ethyl bromide. It is manufactured by reacting ethylene with hydrogen bromide:



Use bond energies to find the enthalpy of reaction.

Between the Extremes: Electronegativity and Bond Polarity
(Sample Problem 9.5)

Concept Review Questions

9.51 Describe the vertical and horizontal trends in electronegativity (EN) among the main-group elements. According to Pauling's scale, what are the two most electronegative elements? The two least electronegative elements?

9.52 What is the general relationship between IE_1 and EN for the elements? Why?

9.53 Is the H—O bond in water nonpolar covalent, polar covalent, or ionic? Define each term, and explain your choice.

9.54 How does electronegativity differ from electron affinity?

9.55 How is the partial ionic character of a bond in a diatomic molecule related to ΔEN for the bonded atoms? Why?

Skill-Building Exercises (grouped in similar pairs)

9.56 Using the periodic table only, arrange the elements in each set in order of *increasing* EN: (a) S, O, Si; (b) Mg, P, As.

9.57 Using the periodic table only, arrange the elements in each set in order of *increasing* EN: (a) I, Br, N; (b) Ca, H, F.

9.58 Using the periodic table only, arrange the elements in each set in order of *decreasing* EN: (a) N, P, Si; (b) Ca, Ga, As.

9.59 Using the periodic table only, arrange the elements in each set in order of *decreasing* EN: (a) Br, Cl, P; (b) I, F, O.

9.60 Use Figure 9.21, p. 381, to indicate the polarity of each bond with a *polar arrow:* (a) N—B; (b) N—O; (c) C—S; (d) S—O; (e) N—H; (f) Cl—O.

9.61 Use Figure 9.21, p. 381, to indicate the polarity of each bond with *partial charges:* (a) Br—Cl; (b) F—Cl; (c) H—O; (d) Se—H; (e) As—H; (f) S—N.

9.62 Which is the more polar bond in each of the following pairs from Problem 9.60: (a) or (b); (c) or (d); (e) or (f)?

9.63 Which is the more polar bond in each of the following pairs from Problem 9.61: (a) or (b); (c) or (d); (e) or (f)?

9.64 Are the bonds in each of the following substances ionic, nonpolar covalent, or polar covalent? Arrange the substances with polar covalent bonds in order of increasing bond polarity:
(a) S_8 (b) RbCl (c) PF_3 (d) SCl_2 (e) F_2 (f) SF_2

9.65 Are the bonds in each of the following substances ionic, nonpolar covalent, or polar covalent? Arrange the substances with polar covalent bonds in order of increasing bond polarity:
(a) KCl (b) P_4 (c) BF_3 (d) SO_2 (e) Br_2 (f) NO_2

9.66 Rank the members of each set of compounds in order of *increasing* ionic character of their bonds. Use *polar arrows* to indicate the bond polarity of each:
(a) HBr, HCl, HI (b) H_2O, CH_4, HF (c) SCl_2, PCl_3, $SiCl_4$

9.67 Rank the members of each set of compounds in order of *decreasing* ionic character of their bonds. Use *partial charges* to indicate the bond polarity of each:
(a) PCl_3, PBr_3, PF_3 (b) BF_3, NF_3, CF_4 (c) SeF_4, TeF_4, BrF_3

Problem in Context

9.68 The energy of the C—C bond is 347 kJ/mol, and that of the Cl—Cl bond is 243 kJ/mol. Which of the following values might you expect for the C—Cl bond energy? Explain.
(a) 590 kJ/mol (sum of the values given)
(b) 104 kJ/mol (difference of the values given)
(c) 295 kJ/mol (average of the values given)
(d) 339 kJ/mol (greater than the average of the values given)

An Introduction to Metallic Bonding

Concept Review Questions

9.69 (a) List four physical characteristics of a solid metal.
(b) List two chemical characteristics of a metallic element.

9.70 Briefly account for the following relative values:
(a) The melting points of Na and K are 89°C and 63°C, respectively.
(b) The melting points of Li and Be are 180°C and 1287°C, respectively.
(c) Li boils more than 1100°C higher than it melts.

9.71 Magnesium metal is easily deformed by an applied force, whereas magnesium fluoride is shattered. Why do these two solids behave so differently?

Comprehensive Problems

9.72 Geologists have a rule of thumb: when molten rock cools and solidifies, crystals of compounds with the smallest lattice energies appear at the bottom of the mass. Suggest a reason for this.

9.73 Acetylene gas (ethyne; HC≡CH) burns in an oxyacetylene torch to produce carbon dioxide and water vapor. The heat of reaction for the combustion of acetylene is 1259 kJ/mol. (a) Calculate the C≡C bond energy, and compare your value with that in Table 9.2, p. 371. (b) When 500.0 g of acetylene burns, how many kilojoules of heat are given off? (c) How many grams of CO_2 form? (d) How many liters of O_2 at 298 K and 18.0 atm are consumed?

9.74 Use Lewis electron-dot symbols to represent the formation of (a) BrF_3 from bromine and fluorine atoms; (b) AlF_3 from aluminum and fluorine atoms.

9.75 Even though so much energy is required to form a metal cation with a 2+ charge, the alkaline earth metals form halides with general formula MX_2, rather than MX.
(a) Use the following data to calculate ΔH_f° of MgCl:

$$Mg(s) \longrightarrow Mg(g) \qquad \Delta H^\circ = 148 \text{ kJ}$$
$$Cl_2(g) \longrightarrow 2Cl(g) \qquad \Delta H^\circ = 243 \text{ kJ}$$
$$Mg(g) \longrightarrow Mg^+(g) + e^- \qquad \Delta H^\circ = 738 \text{ kJ}$$
$$Cl(g) + e^- \longrightarrow Cl^-(g) \qquad \Delta H^\circ = -349 \text{ kJ}$$
$$\Delta H^\circ_{\text{lattice}} \text{ of MgCl} = 783.5 \text{ kJ/mol}$$

(b) Is MgCl favored energetically relative to Mg and Cl_2? Explain.
(c) Use Hess's law to calculate ΔH° for the conversion of MgCl to $MgCl_2$ and Mg (ΔH_f° of $MgCl_2 = -641.6$ kJ/mol).
(d) Is MgCl favored energetically relative to $MgCl_2$? Explain.

9.76 Gases react explosively if the heat released when the reaction begins is sufficient to cause more reaction, which leads to a rapid expansion of the gases. Use bond energies to calculate ΔH° of each of the following reactions, and predict which occurs explosively:
(a) $H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$
(b) $H_2(g) + I_2(g) \longrightarrow 2HI(g)$
(c) $2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$

9.77 By using photons of specific wavelengths, chemists can dissociate gaseous HI to produce H atoms with certain speeds. When HI dissociates, the H atoms move away rapidly, whereas the heavier I atoms move more slowly. (a) What is the longest wavelength (in nm) that can dissociate a molecule of HI? (b) If a photon of 254 nm is used, what is the excess energy (in J) over that needed for dissociation? (c) If this excess energy is carried away by the H atom as kinetic energy, what is its speed (in m/s)?

9.78 In developing the concept of electronegativity, Pauling used the term *excess bond energy* for the difference between the actual bond energy of X—Y and the average bond energies of X—X and Y—Y (see text discussion for the case of HF). Based on the values in Figure 9.21, p. 381, which of the following substances contains bonds with no excess bond energy?
(a) PH_3 (b) CS_2 (c) BrCl (d) BH_3 (e) Se_8

9.79 Use condensed electron configurations to predict the relative hardnesses and melting points of rubidium ($Z = 37$), vanadium ($Z = 23$), and cadmium ($Z = 48$).

9.80 Without stratospheric ozone (O_3), harmful solar radiation would cause gene alterations. Ozone forms when the bond in O_2 breaks and each O atom reacts with another O_2 molecule. It is destroyed by reaction with Cl atoms formed when the C—Cl bond in synthetic chemicals breaks. Find the wavelengths of light that can break the C—Cl bond and the bond in O_2.

9.81 "Inert" xenon actually forms many compounds, especially with highly electronegative fluorine. The ΔH_f° values for xenon difluoride, tetrafluoride, and hexafluoride are −105, −284, and −402 kJ/mol, respectively. Find the average bond energy of the Xe—F bonds in each fluoride.

9.82 The HF bond length is 92 pm, 16% shorter than the sum of the covalent radii of H (37 pm) and F (72 pm). Suggest a reason for this difference. Similar data show that the difference becomes smaller down the group, from HF to HI. Explain.

9.83 There are two main types of covalent bond breakage. In homolytic breakage (as in Table 9.2, p. 371), each atom in the bond gets one of the shared electrons. In some cases, the electronegativity of adjacent atoms affects the bond energy. In heterolytic breakage, one atom gets both electrons and the other gets none; thus, a cation and an anion form.
(a) Why is the C—C bond in $H_3C—CF_3$ (423 kJ/mol) stronger than that in $H_3C—CH_3$ (376 kJ/mol)?
(b) Use bond energy and any other data to calculate the enthalpy of reaction for the heterolytic cleavage of O_2.

9.84 Find the longest wavelengths of light that can cleave the bonds in elemental nitrogen, oxygen, and fluorine.

9.85 The work function (ϕ) of a metal is the minimum energy needed to remove an electron from its surface. (a) Is it easier

to remove an electron from a gaseous silver atom or from the surface of solid silver ($\phi = 7.59\times10^{-19}$ J; IE = 731 kJ/mol)? (b) Explain the results in terms of the electron-sea model of metallic bonding.

9.86 Lattice energies can also be calculated for covalent solids using a Born-Haber cycle, and the network solid silicon dioxide has one of the highest $\Delta H^\circ_{\text{lattice}}$ values. Silicon dioxide is found in pure crystalline form as transparent rock quartz. Much harder than glass, this material was once prized for making lenses for optical devices and expensive spectacles. Use Appendix B and the following data to calculate $\Delta H^\circ_{\text{lattice}}$ of SiO_2:

$Si(g) \longrightarrow Si(g)$ $\quad \Delta H^\circ = 454$ kJ
$Si(g) \longrightarrow Si^{4+}(g) + 4e^-$ $\quad \Delta H^\circ = 9949$ kJ
$O_2(g) \longrightarrow 2O(g)$ $\quad \Delta H^\circ = 498$ kJ
$O(g) + 2e^- \longrightarrow O^{2-}(g)$ $\quad \Delta H^\circ = 737$ kJ

9.87 The average C—H bond energy in CH_4 is 415 kJ/mol. Use Table 9.2 (p. 371) and the following to calculate the average C—H bond energy in ethane (C_2H_6; C—C bond), in ethene (C_2H_4; C═C bond), and in ethyne (C_2H_2; C≡C bond):

$C_2H_6(g) + H_2(g) \longrightarrow 2CH_4(g)$ $\quad \Delta H^\circ_{\text{rxn}} = -65.07$ kJ/mol
$C_2H_4(g) + 2H_2(g) \longrightarrow 2CH_4(g)$ $\quad \Delta H^\circ_{\text{rxn}} = -202.21$ kJ/mol
$C_2H_2(g) + 3H_2(g) \longrightarrow 2CH_4(g)$ $\quad \Delta H^\circ_{\text{rxn}} = -376.74$ kJ/mol

9.88 Carbon-carbon bonds form the "backbone" of nearly every organic and biological molecule. The average bond energy of the C—C bond is 347 kJ/mol. Calculate the frequency and wavelength of the least energetic photon that can break an average C—C bond. In what region of the electromagnetic spectrum is this radiation?

9.89 In a future hydrogen-fuel economy, the cheapest source of H_2 will certainly be water. It takes 467 kJ to produce 1 mol of H atoms from water. What is the frequency, wavelength, and minimum energy of a photon that can free an H atom from water?

9.90 Dimethyl ether (CH_3OCH_3) and ethanol (CH_3CH_2OH) are constitutional isomers (see Table 3.4, p. 113). (a) Use Table 9.2 (p. 371) to calculate $\Delta H^\circ_{\text{rxn}}$ for the formation of each compound as a gas from methane and oxygen; water vapor also forms. (b) State which reaction is more exothermic. (c) Calculate $\Delta H^\circ_{\text{rxn}}$ for the conversion of ethanol to dimethyl ether.

9.91 Enthalpies of reaction calculated from bond energies and from enthalpies of formation are often, but not always, close to each other.

(a) Industrial ethanol (CH_3CH_2OH) is produced by a catalytic reaction of ethylene ($CH_2{=}CH_2$) with water at high pressures and temperatures. Calculate $\Delta H^\circ_{\text{rxn}}$ for this gas-phase hydration of ethylene to ethanol, using bond energies and then using enthalpies of formation.

(b) Ethylene glycol is produced by the catalytic oxidation of ethylene to ethylene oxide, which then reacts with water to form ethylene glycol:

The $\Delta H^\circ_{\text{rxn}}$ for this hydrolysis step, based on enthalpies of formation, is −97 kJ/mol. Calculate $\Delta H^\circ_{\text{rxn}}$ for the hydrolysis using bond energies.

(c) Why are the two values relatively close for the hydration in part (a) but not close for the hydrolysis in part (b)?

10 The Shapes of Molecules

10.1 Depicting Molecules and Ions with Lewis Structures
- Applying the Octet Rule
- Resonance
- Formal Charge
- Exceptions to the Octet Rule

10.2 Valence-Shell Electron-Pair Repulsion (VSEPR) Theory
- Electron-Group Arrangements and Molecular Shapes
- Molecular Shape with Two Electron Groups
- Molecular Shapes with Three Electron Groups
- Molecular Shapes with Four Electron Groups
- Molecular Shapes with Five Electron Groups
- Molecular Shapes with Six Electron Groups

- Molecular Shapes with More Than One Central Atom

10.3 Molecular Shape and Molecular Polarity
- Bond Polarity, Bond Angle, and Dipole Moment
- Molecular Polarity and Behavior

Concepts and Skills to Review Before You Study This Chapter

- electron configurations of main-group elements (Section 8.2)
- electron-dot symbols (Section 9.1)
- octet rule (Section 9.1)
- bond order, bond length, and bond energy (Sections 9.3 and 9.4)
- polar covalent bonds and bond polarity (Section 9.5)

In the everyday world, the shapes of interacting objects reflect their function—cup and saucer, hand and glove, lock and key. The same is true in the molecular world. Molecular shape plays a crucial role in the interactions of reactants, in the behavior of synthetic materials, and especially in the life-sustaining processes in cells. But, with all the symbols, lines, and dots you've been seeing in representations of molecules, it's easy to forget that every molecule has a characteristic minute architecture. Each atom, bonding pair, and lone pair of electrons has a specific position relative to the others, and the angles and distances between these constituents are determined by the attractive and repulsive forces governing all matter.

IN THIS CHAPTER . . . *We learn how to picture a molecule by writing a two-dimensional structure for it and converting it to a three-dimensional shape, and we examine some effects of molecular shape on physical and biochemical behavior.*

- We learn how to apply the octet rule to convert a molecular formula into a flat structural formula that shows atom attachments and electron-pair locations.
- We see how electron delocalization limits our ability to depict a molecule with a single structural formula and requires us to apply the concept of resonance.
- We introduce bond angle and apply a theory that converts two-dimensional formulas into three-dimensional shapes.
- We describe five basic classes of shapes that many molecules adopt and consider how multiple bonds and lone pairs affect them and how to combine smaller molecular portions into the shapes of more complex molecules.
- We discuss the relation among bond polarity, shape, and molecular polarity and the effect of polarity on behavior.
- We describe a few examples of the influence of shape on biological function.

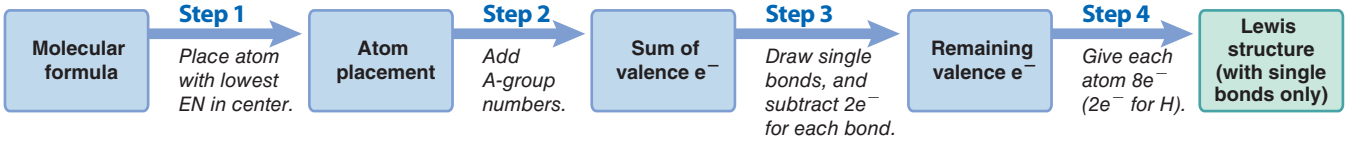
10.1 DEPICTING MOLECULES AND IONS WITH LEWIS STRUCTURES

The first step toward visualizing a molecule is to convert its molecular formula to its **Lewis structure** (or **Lewis formula***), which shows symbols for the atoms, the bonding electron pairs as lines, and the lone electron pairs that fill each atom's outer level (valence shell) as pairs of dots.

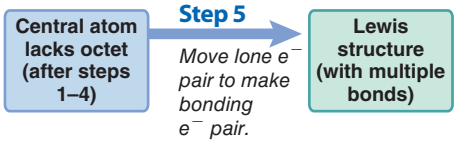
Applying the Octet Rule to Write Lewis Structures

To write a Lewis structure, we decide on the relative placement of the atoms in the molecule or polyatomic ion and then distribute the total number of valence electrons as bonding and lone pairs. In many, but not all, cases, the octet rule (Section 9.1) guides us in distributing the electrons. We begin with species that "obey" the octet rule, in which each atom fills its outer level with eight electrons (or two for hydrogen).

*A Lewis *structure* does ***not*** indicate the three-dimensional shape, so it may be more correct to call it a Lewis *formula*, but we follow convention and use the term *structure*.



A Species with single bonds only



B Species with multiple bonds

Figure 10.1 The steps in converting a molecular formula into a Lewis structure.

Molecules with Single Bonds Figure 10.1A lays out the four steps for writing Lewis structures for species with only single bonds. Let's use nitrogen trifluoride, NF_3, to introduce the steps:

Step 1. Place the atoms relative to each other. For compounds with the general molecular formula AB_n, place the atom with the *lower group number* in the center because it needs more electrons to attain an octet; usually, this is also the atom with the *lower electronegativity*. In NF_3, the N [Group 5A(15); EN = 3.0] has five electrons and so needs three, whereas each F [Group 7A(17); EN = 4.0] has seven and needs only one; thus, N goes in the center with the three F atoms around it:

If the atoms have the same group number, as in SO_3, place the atom with the *higher period number* (also lower EN) in the center. H can form only one bond, so it is *never* a central atom.

Step 2. Determine the total number of valence electrons.

- For molecules, add up the valence electrons of the atoms. (Recall that the number of valence electrons equals the A-group number.) In NF_3, N has five valence electrons, and each F has seven:

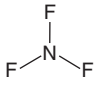
$$[1 \times N(5e^-)] + [3 \times F(7e^-)] = 5e^- + 21e^- = 26 \text{ valence } e^-$$

- For polyatomic ions, *add* one e^- for each negative charge, or *subtract* one e^- for each positive charge. For example, the CO_3^{2-} ion has 24 valence electrons:

$$[1 \times C(4e^-)] + [3 \times O(6e^-)] + [\text{charge } (2e^-)] = 24 \text{ valence } e^-$$

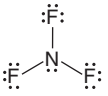
You don't need to keep track of which electrons come from which atoms, because only the total number of valence electrons is important.

Step 3. Draw a single bond from each surrounding atom to the central atom, and subtract $2e^-$ from the total for each bond to find the number of e^- remaining:



$$3 \text{ N—F bonds} \times 2e^- = 6e^- \quad \text{so} \quad 26e^- - 6e^- = 20e^- \text{ remaining}$$

Step 4. Distribute the remaining electrons in pairs so that each atom ends up with $8e^-$ (or $2e^-$ for H). First, place lone pairs on the *surrounding (more electronegative) atoms* to give each an octet. If any electrons remain, place them around the central atom. So, each F gets three pairs ($3 \times 6e^- = 18e^-$) and the N gets one pair ($2e^-$), for a total of $20e^-$. Then check that each atom has $8e^-$:

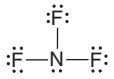


This is the Lewis structure for NF_3. It is a neutral species, so the total number of electrons (bonds plus lone pairs) equals the sum of the valence electrons:

$$6e^- \text{ in three bonds} + 20e^- \text{ in ten lone pairs} = 26 \text{ valence } e^-$$

If we were writing a Lewis structure for a polyatomic ion, we would also take the charge into account, as described in step 2, and put the structure in square brackets with the ion charge as a superscript outside the brackets.

Since Lewis structures do not indicate shape, an equally correct depiction of NF_3 is



or any other that retains the *same connections among the atoms*—a central N atom connected by single bonds to each of three surrounding F atoms.

Using these four steps, you can write a Lewis structure for any singly bonded species with a central C, N, or O atom, as well as for some species with central atoms from higher periods. In nearly all their compounds,

- Hydrogen atoms form one bond.
- Carbon atoms form four bonds.
- Nitrogen atoms form three bonds.
- Oxygen atoms form two bonds.
- Surrounding halogens form one bond; fluorine is *always* a surrounding atom.

Molecules with Multiple Bonds After completing step 4, we may find that a central atom still does not have an octet. In most of these cases, we add the following step (Figure 10.1B):

Step 5. If a central atom does not end up with an octet, form one or more multiple bonds. Change a lone pair on a surrounding atom into another bonding pair to the central atom, thus forming a double bond. This may be done again if necessary to form a triple bond, or another double bond.

Sample Problems 10.1 and 10.2 demonstrate the procedure for drawing Lewis structures for species with single bonds, while Sample Problem 10.3 shows the procedure for species with multiple bonds.

SAMPLE PROBLEM 10.1 Writing Lewis Structures for Species with One Central Atom

Problem Write a Lewis structure for **(a)** CCl_2F_2; **(b)** PCl_2^-.

Solution **(a)** *Step 1.* Place the atoms relative to each other. In CCl_2F_2, carbon has the lowest group number and EN, so it is the central atom *(see margin)*. The halogen atoms surround it, but their specific positions are not important.

Step 2. Determine the total number of valence electrons (from A-group numbers): C is in Group 4A; F and Cl are in Group 7A. Therefore, we have

$$[1 \times C(4e^-)] + [2 \times F(7e^-)] + [2 \times Cl(7e^-)] = 32 \text{ valence } e^-$$

Step 3. Draw single bonds to the central atom *(see margin)* and subtract $2e^-$ for each bond:

$$4 \text{ bonds} \times 2e^- = 8e^- \quad \text{so} \quad 32e^- - 8e^- = 24e^- \text{ remaining}$$

Step 4. Distribute the remaining electrons in pairs, beginning with the surrounding atoms, so that each atom has an octet. Each surrounding halogen gets three pairs *(see margin)*.

(b) *Step 1.* Place the atoms relative to each other. In PCl_2^-, phosphorus has the lower group number and EN, so it is the central atom *(see margin)*. The chlorine atoms surround it.

Step 2. Determine the total number of valence electrons (from A-group numbers and ion charge): P is in Group 5A and Cl is in Group 7A. Add $1e^-$ to the total number of valence electrons because of the $1-$ charge:

$$[1 \times P(5e^-)] + [2 \times Cl(7e^-)] + [\text{charge } (1e^-)] = 20 \text{ valence } e^-$$

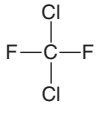
Step 3. Draw single bonds to the central atom *(see margin)* and subtract $2e^-$ for each bond:

$$2 \text{ bonds} \times 2e^- = 4e^- \quad \text{so} \quad 20e^- - 4e^- = 16e^- \text{ remaining}$$

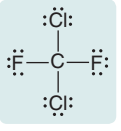
Step 4. Distribute the remaining electrons in pairs, beginning with surrounding atoms, so that each atom has an octet. Each surrounding chlorine atom gets three pairs, and the central phosphorus atom gets two pairs. Since this is an ion, place brackets around the Lewis structure and indicate the $1-$ charge as a superscript negative sign outside the brackets *(see margin)*.

(a) *Step 1:*

Step 3:



Step 4:



(b) *Step 1:*

Step 3:

Step 4:

Check Always check that each atom has an octet. Bonding electrons belong to each atom in the bond. In CCl_2F_2, the total number in bonds ($8e^-$) and lone pairs ($24e^-$) equals 32 valence e^-. As expected, C has four bonds and each of the surrounding halogens has one bond. In PCl_2^-, the total number of electrons in bonds ($4e^-$) and lone pairs ($16e^-$) equals 20 valence e^-.

FOLLOW-UP PROBLEMS

*Brief Solutions to **all** Follow-up Problems appear at the end of the chapter.*

10.1A Write a Lewis structure for **(a)** H_2S; **(b)** $AlCl_4^-$; **(c)** $SOCl_2$.

10.1B Write a Lewis structure for **(a)** OF_2; **(b)** CH_2Br_2; **(c)** IBr_2^+.

SOME SIMILAR PROBLEMS 10.5(a), 10.5(b), 10.6(a), 10.6(c), 10.7(a), and 10.8(c)

In molecules with two or more central atoms bonded to each other, it is usually clear which atoms are central and which surrounding.

SAMPLE PROBLEM 10.2 Writing Lewis Structures for Molecules with More Than One Central Atom

Problem Write the Lewis structure for methanol (molecular formula CH_4O), an important industrial alcohol that can be used as a gasoline alternative in cars.

Solution *Step 1.* Place the atoms relative to each other. The H atoms can have only one bond, so C and O must be central and adjacent to each other. C has four bonds and O has two, so we arrange the H atoms accordingly *(see margin).*

Step 2. Find the sum of valence electrons (C is in Group 4A, O is in Group 6A):

$$[1 \times C(4e^-)] + [1 \times O(6e^-)] + [4 \times H(1e^-)] = 14e^-$$

Step 3. Add single bonds *(see margin)* and subtract $2e^-$ for each bond:

$$5 \text{ bonds} \times 2e^- = 10e^- \qquad \text{so} \qquad 14e^- - 10e^- = 4e^- \text{ remaining}$$

Step 4. Add the remaining electrons in pairs to fill each valence level. C already has an octet, and each H shares $2e^-$ with the C; so the remaining $4e^-$ form two lone pairs on O to give the Lewis structure for methanol *(see margin).*

Check Each H atom has $2e^-$, and C and O each have $8e^-$. The total number of valence electrons is $14e^-$, which equals $10e^-$ in bonds plus $4e^-$ in two lone pairs. Each H has one bond, C has four, and O has two.

FOLLOW-UP PROBLEMS

10.2A Write a Lewis structure for **(a)** hydroxylamine (NH_3O); **(b)** dimethyl ether (C_2H_6O; no O—H bonds).

10.2B Write a Lewis structure for **(a)** hydrazine (N_2H_4); **(b)** methylamine (CH_3NH_2).

SOME SIMILAR PROBLEMS 10.8(a) and 10.8(b)

SAMPLE PROBLEM 10.3 Writing Lewis Structures for Molecules with Multiple Bonds

Problem Write Lewis structures for the following:

(a) Ethylene (C_2H_4), the most important reactant in the manufacture of polymers

(b) Nitrogen (N_2), the most abundant atmospheric gas

Solution **(a)** *Step 1.* Place the atoms relative to each other. In C_2H_4, the two C atoms must be bonded to each other since H atoms can have only one bond *(see margin, facing page).*

Step 2. Determine the total number of valence electrons (C is in Group 4A; H is in Group 1A):

$$[2 \times C(4e^-)] + [4 \times H(1e^-)] = 12 \text{ valence } e^-$$

Step 3. Add single bonds *(see margin, facing page)* and subtract $2e^-$ for each bond:

$$5 \text{ bonds} \times 2e^- = 10e^- \qquad \text{so} \qquad 12e^- - 10e^- = 2e^- \text{ remaining}$$

Step 4. Distribute the remaining valence electrons to attain octets *(see margin)*.
Step 5. Change a lone pair to a bonding pair. The right C has an octet, but the left C has only $6e^-$, so we change the lone pair on the right C to another bonding pair between the two C atoms *(see margin)*.
(b) *Step 1*. Place the atoms relative to each other *(see margin)*.
Step 2. Determine the total number of valence electrons (N is in Group 5A):

$$[2 \times N(5e^-)] = 10 \text{ valence } e^-$$

Step 3. Add single bonds *(see margin)* and subtract $2e^-$ for each bond:

$$1 \text{ bond} \times 2e^- = 2e^- \quad \text{so} \quad 10e^- - 2e^- = 8e^- \text{ remaining}$$

Step 4. Distribute the remaining valence electrons to attain octets *(see margin)*.
Step 5. Neither N ends up with an octet, so we change a lone pair to a bonding pair. In this case, moving one lone pair to make a double bond still does not give both N atoms an octet, so we also move another lone pair from the other N to make a triple bond *(see margin)*.

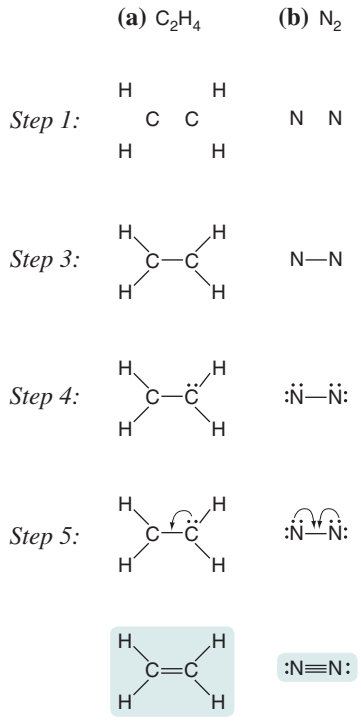
Check **(a)** Each C has four bonds and counts the $4e^-$ in the double bond as part of its own octet. The valence electron total is $12e^-$, all in six bonds. **(b)** Each N counts the $6e^-$ in the triple bond as part of its own octet. The valence electron total is $10e^-$, which equals the electrons in three bonds and two lone pairs.

FOLLOW-UP PROBLEMS

10.3A Write Lewis structures for **(a)** CO (the only common molecule in which C has three bonds); **(b)** HCN; **(c)** CO_2.

10.3B Write Lewis structures for **(a)** NO^+; **(b)** H_2CO; **(c)** N_2H_2.

SOME SIMILAR PROBLEMS 10.5(c), 10.6(b), 10.7(b), and 10.7(c)



Resonance: Delocalized Electron-Pair Bonding

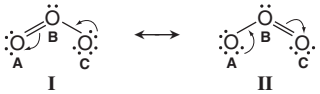
We often find that, for a molecule or polyatomic ion with *double bonds next to single bonds,* we can write more than one Lewis structure. Which, if any, is correct?

The Need for Resonance Structures To understand this issue, consider ozone (O_3), an air pollutant at ground level but an absorber of harmful ultraviolet (UV) radiation in the stratosphere. Two Lewis structures (with lettered O atoms for clarity) are

I II

In structure I, oxygen B has a double bond to oxygen A and a single bond to oxygen C. In structure II, the single and double bonds are reversed. You can rotate I to get II, so these are *not* different types of ozone molecules, but different Lewis structures for the *same* molecule.

In fact, *neither* Lewis structure depicts O_3 accurately, because the two oxygen-oxygen bonds in O_3 are actually identical in length and energy. The bonds in O_3 (bond length = 128 pm) have properties between an O—O bond (bond length = 148 pm) and an O=O bond (bond length = 121 pm), something like a "one-and-a-half" bond. The molecule is shown more correctly with two Lewis structures, called **resonance structures** (or **resonance forms**), and a two-headed resonance arrow (⟷) between them. Resonance structures *have the same relative placement of atoms but different locations of bonding and lone electron pairs.* You can convert one resonance form to another by moving lone pairs to bonding positions, and vice versa:

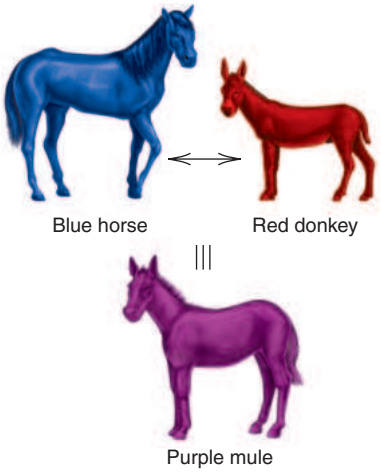


I II

Resonance structures are not real bonding depictions: O_3 does *not* change back and forth quickly from structure I to structure II. The actual molecule is a **resonance hybrid,** an average of the resonance structures.

A Purple Mule, Not a Blue Horse and a Red Donkey

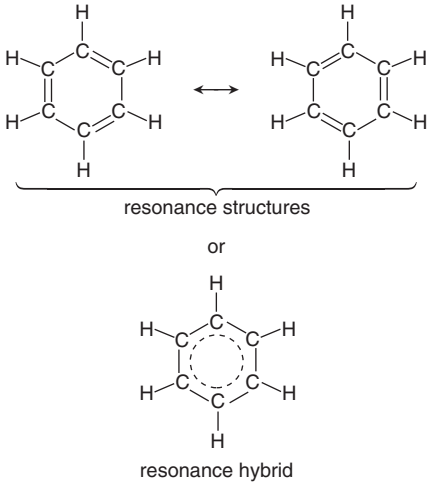
A mule is a genetic mix, a hybrid, of a horse and a donkey; it is not a horse one instant and a donkey the next. Similarly, the color purple is a mix of red and blue, not red one instant and blue the next. In the same sense, a resonance hybrid is one molecular species, not one resonance form this instant and another resonance form the next. The problem is that we cannot depict the actual species, the hybrid, accurately with a single Lewis structure.



Electron Delocalization Our need for more than one Lewis structure to depict O_3 is due to **electron-pair delocalization.** In a single, double, or triple bond, each electron pair is *localized* between the bonded atoms. In a resonance hybrid, two of the electron pairs (one bonding and one lone pair) are *delocalized:* their density is "spread" over a few adjacent atoms. (This delocalization involves just a few e^- pairs, so it is *much* less extensive than the electron delocalization in metals that we saw in Section 9.6.)

In O_3, the result is two identical bonds, each consisting of a single bond (the localized pair) and a *partial bond* (the contribution from one of the delocalized pairs). We draw the resonance hybrid with a curved dashed line to show the delocalized pairs:

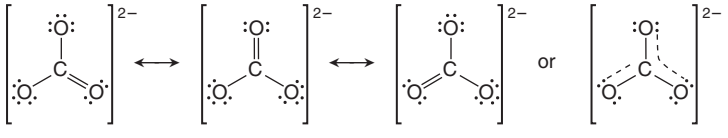
Resonance is very common. For example, benzene (C_6H_6, *shown below*) has two important resonance structures in which alternating single and double bonds have different positions. The actual molecule is an average of the two structures, with six carbon-carbon bonds of equal length and three electron pairs delocalized over all six C atoms. The delocalized pairs are often shown as a dashed circle (or simply a circle):



Fractional Bond Orders Partial bonding, as in resonance hybrids, often leads to fractional bond orders. For O_3, we have

$$\text{Bond order} = \frac{\text{3 shared electron pairs}}{\text{2 bonded-atom (O—O) pairs}} = 1\tfrac{1}{2}$$

The bond order in the benzene ring is 9 shared electron pairs/6 bonded-atom (C—C) pairs, or $1\frac{1}{2}$ also. For the carbonate ion, CO_3^{2-}, three resonance structures can be drawn:



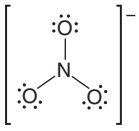
Each has 4 electron pairs shared among 3 bonded-atom (C—O) pairs, so the bond order is $\frac{4}{3}$, or $1\frac{1}{3}$.

SAMPLE PROBLEM 10.4 Writing Resonance Structures

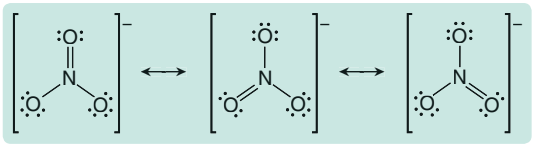
Problem Write resonance structures for the nitrate ion, NO_3^-, and find the bond order.

Plan We write a Lewis structure, remembering to add $1e^-$ to the total number of valence electrons because of the $1-$ ionic charge. Then we move lone and bonding pairs to write other resonance structures and connect them with resonance arrows. The bond order is the number of shared electron pairs divided by the number of atom pairs.

Solution After steps 1 to 4, we have



Step 5. Since N has only $6e^-$, we change a lone pair on one of the O atoms to a bonding pair to form a double bond, which gives each atom an octet. All the O atoms are equivalent, however, so we can move a lone pair from any one of the three and obtain three resonance structures:



The bond order is

$$\frac{\text{4 shared electron pairs}}{\text{3 bonded-atom (N—O) pairs}} = 1\tfrac{1}{3}$$

Check Each structure has the same relative placement of atoms, an octet around each atom, and $24e^-$ (the sum of the valence electrons and $1e^-$ from the ionic charge, distributed in four bonds and eight lone pairs).

Comment These three resonance structures contribute equally to the resonance hybrid because all of the surrounding atoms are identical. This is not always the case, as you'll see shortly.

FOLLOW-UP PROBLEMS

10.4A Write resonance structures for nitromethane, H_3CNO_2 (the H atoms are bonded to C, and the C atom is bonded to N, which is bonded to both O atoms).

10.4B Write resonance structures for the thiocyanate ion, SCN^- (C is the central atom).

SOME SIMILAR PROBLEMS 10.9–10.12

Formal Charge: Selecting the More Important Resonance Structure

If one resonance structure "looks" more like the resonance hybrid than the others, it "weights" the average in its favor. One way to select the more important resonance structure is by determining each atom's **formal charge,** the charge it would have *if the bonding electrons were shared equally*. We'll examine this concept and then see how formal charge compares with oxidation number.

Determining Formal Charge An atom's formal charge is its total number of valence electrons minus *all* of its unshared valence electrons and *half* of its shared valence electrons:

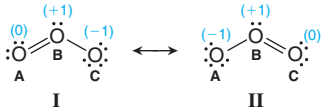
$$\text{Formal charge of atom} = \text{no. of valence } e^- - (\text{no. of unshared valence } e^- + \tfrac{1}{2}\,\text{no. of shared valence } e^-) \quad \textbf{(10.1)}$$

For example, in O_3, the formal charge of oxygen A in resonance form I is

$$6 \text{ valence } e^- - (4 \text{ unshared } e^- + \tfrac{1}{2} \text{ of } 4 \text{ shared } e^-) = 6 - 4 - 2 = 0$$

The formal charges of all the atoms in the two O_3 resonance structures are

$O_A\,[6 - 4 - \tfrac{1}{2}(4)] = 0$
$O_B\,[6 - 2 - \tfrac{1}{2}(6)] = +1$
$O_C\,[6 - 6 - \tfrac{1}{2}(2)] = -1$



I

II

$O_A\,[6 - 6 - \tfrac{1}{2}(2)] = -1$
$O_B\,[6 - 2 - \tfrac{1}{2}(6)] = +1$
$O_C\,[6 - 4 - \tfrac{1}{2}(4)] = 0$

Structures I and II have the same formal charges but on different O atoms, so they contribute equally to the resonance hybrid. *Formal charges must sum to the actual charge on the species:* zero for a molecule or the ionic charge for an ion.

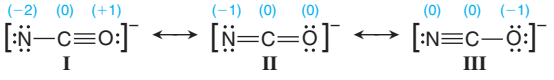
Note that, in I, instead of oxygen's usual two bonds, O_B has three bonds and O_C has one. Only when an atom has a zero formal charge does it have its usual number of bonds; the same holds for C in CO_3^{2-}, N in NO_3^-, and so forth.

Choosing the More Important Resonance Structure Three criteria help us choose the more important resonance structure:

- Smaller formal charges (positive *or* negative) are preferable to larger ones.
- The *same* nonzero formal charges on adjacent atoms are not preferred.
- A more negative formal charge should reside on a more electronegative atom.

As in the case of O_3, the resonance structures for CO_3^{2-}, NO_3^-, and benzene all have identical atoms surrounding the central atom(s) and, thus, have identical formal charges and are equally important contributors to the resonance hybrid. But, let's apply these criteria to the cyanate ion, NCO^-, which has two *different* atoms around the central one. Three resonance structures with formal charges are *(see margin)*

Formal charges:
Resonance structures:



Structure I is *not* an important contributor to the hybrid because it has a larger formal charge on N and a positive formal charge on the more electronegative O. Structures II and III have the same magnitude of charges, but III has a −1 charge on O, the more electronegative atom. Therefore, II and III are more important than I, and III is more important than II.

Formal Charge vs. Oxidation Number Formal charge (used to examine resonance structures) is *not* the same as oxidation number (used to monitor redox reactions):

- For a *formal charge,* bonding electrons are *shared equally* by the atoms (as if the bonding were *nonpolar covalent*), so each atom has half of them:

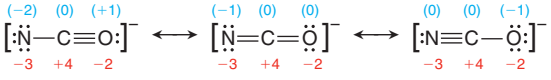
$$\text{Formal charge} = \text{valence } e^- - (\text{lone pair } e^- + \tfrac{1}{2}\,\text{bonding } e^-)$$

- For an *oxidation number,* bonding electrons are *transferred completely* to the more electronegative atom (as if the bonding were *pure ionic*):

$$\text{Oxidation number} = \text{valence } e^- - (\text{lone pair } e^- + \text{bonding } e^-)$$

Compare the two sets of numbers for the three cyanate ion resonance structures,

Formal charges:
Oxidation numbers:



Notice that the oxidation numbers *do not* change from one resonance structure to another (because the electronegativities *do not* change), but the formal charges *do* change (because the numbers of bonding and lone pairs *do* change). Neither an atom's formal charge nor its oxidation number represents an actual charge on the atom; both of these types of numbers serve simply to keep track of electrons.

Structure I:

$\text{N}\,[5 - 6 - \frac{1}{2}(2)] = -2$

$\text{C}\,[4 - 0 - \frac{1}{2}(8)] = 0$

$\text{O}\,[6 - 2 - \frac{1}{2}(6)] = +1$

Structure II:

$\text{N}\,[5 - 4 - \frac{1}{2}(4)] = -1$

$\text{C}\,[4 - 0 - \frac{1}{2}(8)] = 0$

$\text{O}\,[6 - 4 - \frac{1}{2}(4)] = 0$

Structure III:

$\text{N}\,[5 - 2 - \frac{1}{2}(6)] = 0$

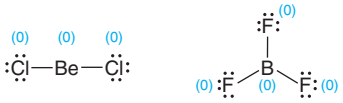
$\text{C}\,[4 - 0 - \frac{1}{2}(8)] = 0$

$\text{O}\,[6 - 6 - \frac{1}{2}(1)] = -1$

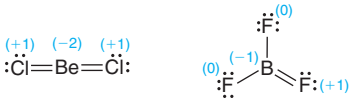
Lewis Structures for Exceptions to the Octet Rule

The octet rule applies to most molecules (and ions) with Period 2 central atoms, but not every one, and not to many with central atoms from Period 3 and higher. Three important exceptions occur in molecules with (1) electron-deficient atoms, (2) odd-electron atoms, and (3) atoms with expanded valence shells. In this discussion, you'll also see that formal charge has limitations for selecting the best resonance structure.

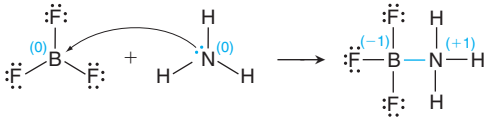
Molecules with Electron-Deficient Atoms Gaseous molecules containing either beryllium or boron as the central atom are often **electron deficient:** they have *fewer* than eight electrons around the central atom. The Lewis structures, with formal charges, of gaseous beryllium chloride* and boron trifluoride are



There are only four electrons around Be and six around B. Surrounding halogen atoms don't form multiple bonds to the central atoms to give them an octet, because the halogens are much more electronegative. Formal charges make the following structures unlikely:

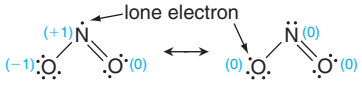


(Some data for BF_3 show a shorter than expected B—F bond. Shorter bonds indicate double-bond character, so the structure with the B═F bond may be a minor contributor to a resonance hybrid.) Electron-deficient atoms often attain an octet by forming additional bonds in reactions. When BF_3 reacts with ammonia, for instance, a compound forms in which boron attains an octet:†

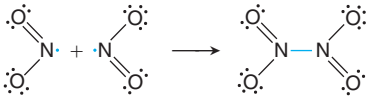


Molecules with Odd-Electron Atoms A few molecules contain a central atom with an odd number of valence electrons, so they cannot have all their electrons in pairs. Most have a central atom from an odd-numbered group, such as N [Group 5A(15)] or Cl [Group 7A(17)]. These are called **free radicals,** species that contain a lone (unpaired) electron, which makes them paramagnetic (Section 8.4) and extremely reactive. Free radicals are dangerous because they can bond to an H atom in a biomolecule and extract it, which forms a new free radical. This step repeats and can disrupt genes and membranes. Recent studies suggest that free radicals may be involved in cancer and even aging. Antioxidants like vitamin E interrupt free-radical proliferation.

Consider the free radical nitrogen dioxide, NO_2, a major contributor to urban smog that is formed when the NO in auto exhaust is oxidized. NO_2 has several resonance structures. Two differ in terms of which O atom is doubly bonded, as in the case of ozone. Two others have the lone electron residing on the N or on an O, so the resonance hybrid has the lone electron delocalized over these two atoms:



Let's see if formal charge considerations help us decide where the electron resides most of the time. The structure with it on the singly bonded O has zero formal charges *(right),* while the structure with it on N *(left)* has some nonzero charges. Thus, based on formal charges, the structure on the right is more important. But, chemical facts suggest otherwise. Free radicals often react with each other to pair their lone electrons. When two NO_2 molecules react, the lone electrons pair up to form the N—N bond in dinitrogen tetroxide (N_2O_4) and each N attains an octet:



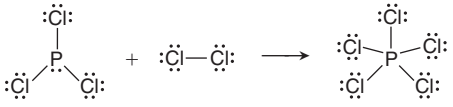
*Even though beryllium is in Group 2A(2), most Be compounds have considerable covalent bonding. For example, molten $BeCl_2$ does not conduct electricity, indicating a lack of ions.

†Reactions in which one species "donates" an electron pair to another to form a covalent bond are Lewis acid-base reactions, which we discuss fully in Chapter 18.

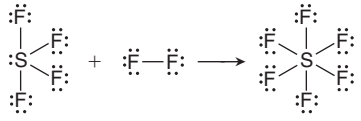
Thus, given the way NO_2 reacts, the lone electron may spend most of its time on N, making *that* resonance structure more important. Apparently, in this case, formal charge is not very useful for picking the most important resonance structure; we'll see other cases below.

Expanded Valence Shells Many molecules (and ions) have more than eight valence electrons around the central atom. *That atom expands its valence shell to form more bonds, which releases energy*. The central atom must be large and have empty orbitals that can hold the additional pairs. Therefore, **expanded valence shells** occur only with *nonmetals from Period 3 or higher because they have d orbitals available.* Such a central atom may be bonded to more than four atoms, or to four or fewer.

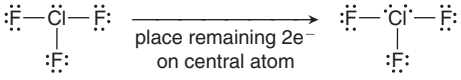
1. *Central atom bonded to more than four atoms.* Phosphorus pentachloride, PCl_5, is a fuming yellow-white solid used to manufacture lacquers and films. It forms when phosphorus trichloride, PCl_3, reacts with chlorine gas. The P in PCl_3 has an octet, but two more bonds to chlorine form and P expands its valence shell to 10 electrons in PCl_5. Note that when PCl_5 forms, *one* Cl—Cl bond breaks *(left side of the equation),* and two P—Cl bonds form *(right side),* for a net increase of one bond:



Sulfur hexafluoride, SF_6, is a dense, inert gas used as an electrical insulator. Analogously to PCl_5, it forms when sulfur tetrafluoride, SF_4, reacts with more F_2. The S in SF_4 already has an expanded valence shell of 10 electrons, but two more bonds to F expand the valence shell further to 12 electrons:



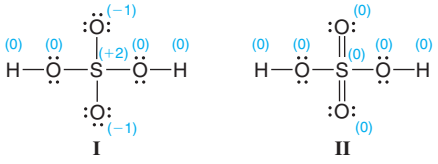
2. *Central atoms bonded to four or fewer atoms*. In some species, a central atom bonded to *four or fewer* atoms has an expanded valence shell. The S in SF_4 is one example; another is the Cl in chlorine trifluoride, ClF_3. There are 28 valence electrons in a ClF_3 molecule, 6 in the three single Cl—F bonds and 20 that complete the octets of the four atoms. The 2 remaining valence electrons are placed on the central Cl, giving it an expanded valence shell of 10 electrons:



In general, just as in ClF_3, any valence electrons remaining after completing the octets of all atoms in a species are given to the central atom.

For some species with central atoms bonded to four or fewer atoms, the concept of formal charge can be applied to draw Lewis structures with expanded valence shells. Some examples follow:

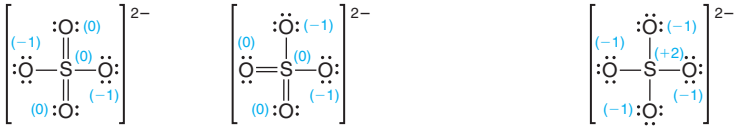
- *Sulfuric acid*. Two resonance structures of H_2SO_4, with formal charges, are



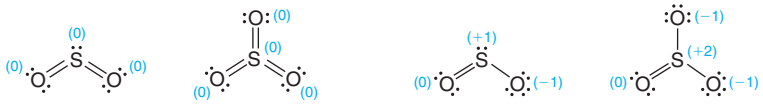
I II

Structure I obeys the octet rule, but it has several nonzero formal charges. In structure II, sulfur has 12 electrons (six bonds) around it, but all zero formal charges. Thus, based on the formal charge rules alone, II contributes more than I to the resonance hybrid. More important than whether rules are followed, structure II is consistent with observation. In gaseous H_2SO_4, the two sulfur-oxygen bonds *with* an H atom attached to the O are 157 pm long, whereas the two sulfur-oxygen bonds *without* an H attached to O are 142 pm long. This shorter bond indicates double-bond character, and other measurements indicate greater electron density in the bonds without the attached H.

- *Sulfate ion*. When sulfuric acid loses two H^+ ions, it forms the sulfate ion, SO_4^{2-}. Measurements indicate that all the bonds in SO_4^{2-} are 149 pm long, between the length of an S═O bond (~142 pm) and that of an S—O bond (~157 pm). Six of the seven resonance structures consistent with these data have an expanded valence shell and zero formal charges on some of the atoms. Two of the six *(left)* and the one that obeys the octet rule *(right)* are



- *Two sulfur oxides*. Measurements show that the sulfur-oxygen bonds in SO_2 and SO_3 are all approximately 142 pm long, indicating S═O bonds. Lewis structures consistent with these data have zero formal charges *(two at left)*, but others *(two at right)* obey the octet rule:



3. *Limitations of Lewis structures and formal charge*. Chemistry has been a central science for well over two centuries, yet controversies often arise over interpretation of data, even in established areas like bonding and structure. We've seen that a single Lewis structure often cannot accurately depict a molecule; in such cases, we need several resonance structures to do so.

Formal charge rules have limitations, too. They were not useful in choosing the correct location for the lone electron in NO_2. And, quantum-mechanical calculations indicate that resonance structures with expanded valence shells that have zero formal charges look *less* like the actual species than structures that follow the octet rule but have higher formal charges. Shorter bonds arise, these findings suggest, not from double-bond character, but because the higher formal charges draw the bonded atoms closer. Such considerations favor the octet-rule structures for H_2SO_4, SO_4^{2-}, SO_2, and SO_3. Thus, formal charge may be a useful tool for selecting the most important resonance structure, but it is far from perfect. Nevertheless, while keeping these contrary findings in mind, we will continue to draw structures based on formal charge rules because they provide a simple approach consistent with most experimental data.

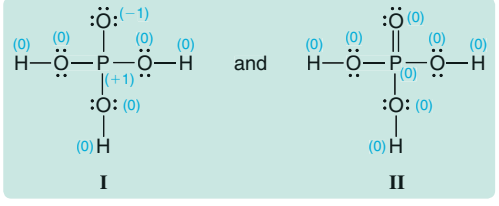
SAMPLE PROBLEM 10.5 Writing Lewis Structures for Octet-Rule Exceptions

Problem Write a Lewis structure and identify the octet-rule exception for **(a)** XeF_4; **(b)** H_3PO_4 (draw two resonance structures and select the more important); **(c)** $BFCl_2$.

Plan We write each Lewis structure and examine it for exceptions to the octet rule. **(a)** and **(b)** The central atoms are in Periods 5 and 3, respectively, so they can have more than an octet. **(c)** The central atom is B, which can have fewer than an octet of electrons.

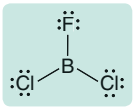
Solution **(a)** XeF_4 has a total of 36 valence electrons: 8 form the bonds and 24 complete the octets of the F atoms. The remaining 4 valence electrons are placed on the central atom, resulting in an *expanded valence shell:*

(b) H_3PO_4 has two resonance structures. The structures, with formal charges, are



Structure I obeys the octet rule but has nonzero formal charges. Structure II has an expanded valence shell with zero formal charges. According to formal charge rules, structure II is the more important structure.

(c) $BFCl_2$ is an *electron-deficient molecule;* B has only six electrons surrounding it:



Comment In (b), structure II is consistent with bond-length measurements, which show one shorter (152 pm) phosphorus-oxygen bond and three longer (157 pm) ones. Nevertheless, as for H_2SO_4, calculations show that structure I may be more important.

FOLLOW-UP PROBLEMS

10.5A Write a Lewis structure with minimal formal charges for **(a)** $POCl_3$; **(b)** ClO_2; **(c)** $SClF_5$.

10.5B Write a Lewis structure with minimal formal charges for **(a)** BeH_2; **(b)** I_3^-; **(c)** XeO_3.

SOME SIMILAR PROBLEMS 10.19–10.22

Summary of Section 10.1

- A stepwise process converts a molecular formula into a Lewis structure, a two-dimensional representation of a molecule (or ion) that shows the placement of atoms and the distribution of valence electrons among bonding and lone pairs.
- When two or more Lewis structures can be drawn for the same relative placement of atoms, the actual structure is a hybrid of those resonance structures.
- Formal charges can be useful for choosing the more important contributor to the hybrid, but experimental data always determine the choice.
- Molecules with an electron-deficient atom (central Be or B) or an odd-electron atom (free radicals) have less than an octet around the central atom but often attain an octet in reactions.
- In a molecule (or ion) with a central atom from Period 3 or higher, that atom can have more than eight valence electrons because it is larger and has empty *d* orbitals for expanding its valence shell.

10.2 VALENCE-SHELL ELECTRON-PAIR REPULSION (VSEPR) THEORY

Virtually every biochemical process hinges to a great extent on the shapes of interacting molecules. Every medicine you take, odor you smell, or flavor you taste depends on part or all of one molecule fitting together with another. Biologists have found that complex behaviors in many organisms, such as mating, defense, navigation, and feeding, often depend on one molecule's shape matching that of another. In this section, we discuss a model for predicting the shape of a molecule.

To obtain the molecular shape, chemists start with the Lewis structure and apply ***v*alence-*s*hell *e*lectron-*p*air *r*epulsion (VSEPR) theory.** Its basic principle is that, *to minimize repulsions, each group of valence electrons around a central atom is located as far as possible from the others.* A "group" of electrons is any number that occupies a localized region around an atom: single bond, double bond, triple bond,* lone pair, or even lone electron. Only electron groups around the *central* atom affect shape; electrons on atoms other than the central atom do not. The **molecular shape** is the three-dimensional arrangement of nuclei joined by the bonding groups.

*The two electron pairs in a double bond (or the three pairs in a triple bond) occupy separate orbitals, but they remain near each other and act as one electron group (see Chapter 11).

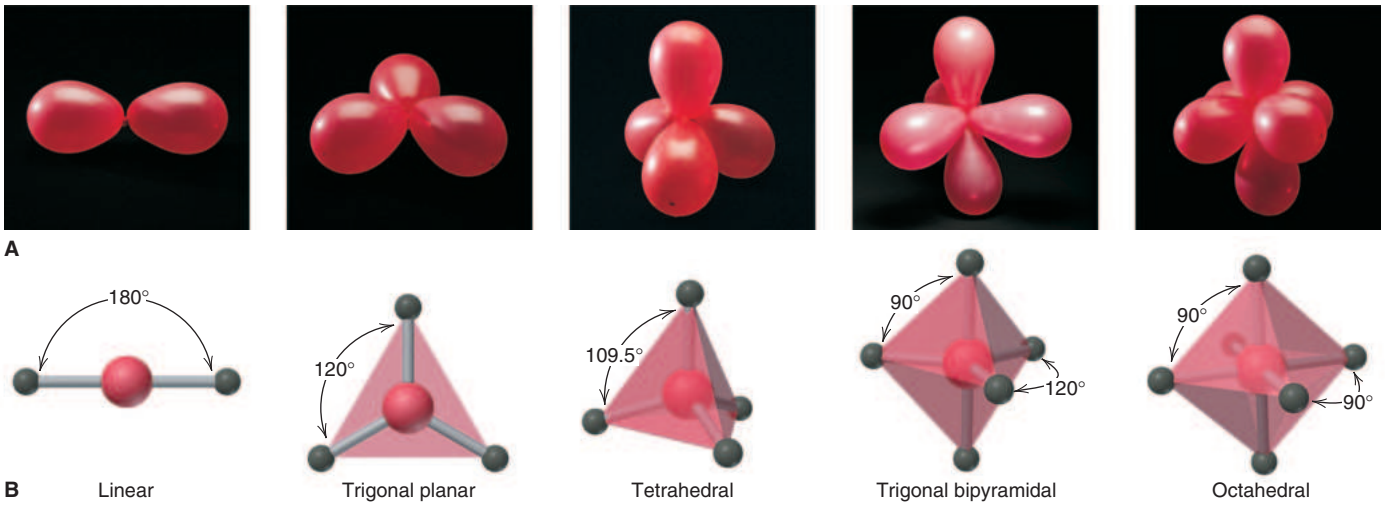


Figure 10.2 Electron-group repulsions and molecular shapes. A, Five geometric orientations arise when each balloon occupies as much space as possible. **B,** Mutually repelling bonding groups *(gray sticks)* attach a surrounding atom *(dark gray)* to the central atom *(red)*. The name is the electron-group arrangement.

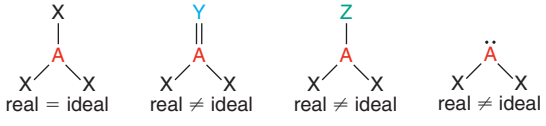
Electron-Group Arrangements and Molecular Shapes

When two, three, four, five, or six objects attached to a central point maximize the space between them, five geometric patterns result, which Figure 10.2A shows with balloons. If the objects are valence-electron groups, repulsions maximize the space each occupies around the central atom, and we obtain the five *electron-group arrangements* seen in the great majority of molecules and polyatomic ions.

Classifying Molecular Shapes *The electron-group arrangement* is defined by the bonding *and* nonbonding electron groups around the central atom, but the *molecular shape* is defined by the relative positions of the nuclei, which are connected by the bonding groups only. Figure 10.2B shows the molecular shapes that occur when *all* the surrounding electron groups are *bonding* groups. When some are *nonbonding* groups, different molecular shapes occur. Thus, *the same electron-group arrangement can give rise to different molecular shapes:* some with all bonding groups (as in Figure 10.2B) and others with bonding and nonbonding groups. To classify molecular shapes, we assign each a specific AX_mE_n designation, where m and n are integers, A is the central atom, X is a surrounding atom, and E is a nonbonding valence-electron group (usually a lone pair).

The Importance of Bond Angle The **bond angle** is the angle formed by the nuclei of two surrounding atoms with the nucleus of the central atom at the vertex. The angles shown for the shapes in Figure 10.2B are *ideal* bond angles determined by basic geometry alone. We observe them when all the bonding groups are the same and connected to the same type of atom. When this is not the case, the real bond angles deviate from the ideal angles:



The Molecular Shape with Two Electron Groups (Linear Arrangement)

Two electron groups attached to a central atom point in opposite directions. This **linear arrangement** of electron groups results in a molecule with a **linear shape** and a bond angle of 180°. Figure 10.3 shows the general form *(top)* and shape *(middle)* with VSEPR shape class (AX_2), and gives the formulas of some linear molecules.

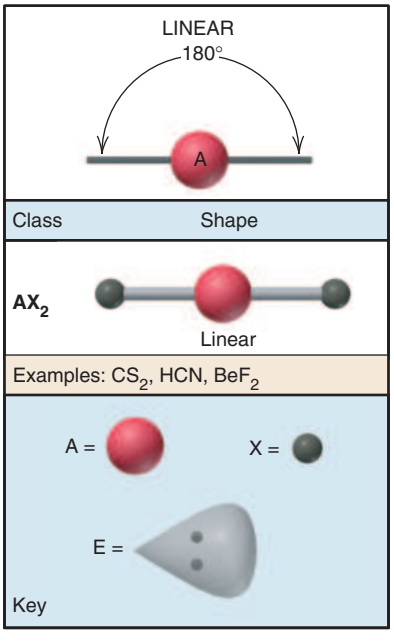


Figure 10.3 The single molecular shape of the linear electron-group arrangement. The key *(bottom)* for A, X, and E also refers to Figures 10.4, 10.5, 10.7, and 10.8.

Gaseous beryllium chloride ($BeCl_2$) is a linear molecule. Recall that gaseous Be compounds are electron deficient, with two electron pairs around the central Be:

In carbon dioxide, the central C atom forms two double bonds with the O atoms:

Each double bond acts as one electron group and is 180° away from the other. The lone pairs on the O atoms of CO_2 or on the Cl atoms of $BeCl_2$ are *not* involved in the molecular shape: only the two electron groups around the central C or Be atom affect the shape.

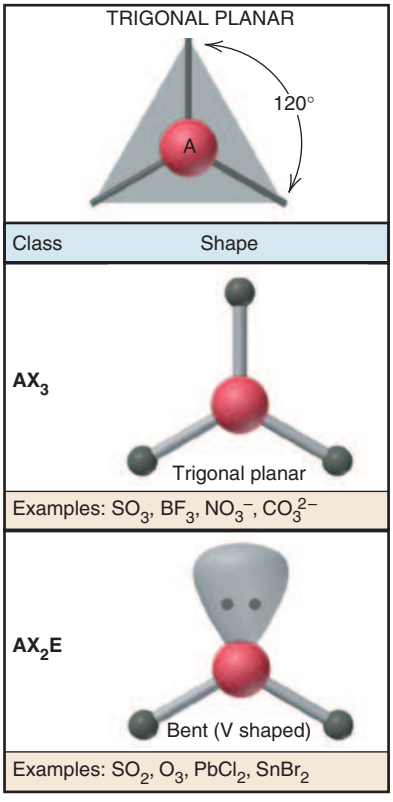

Figure 10.4 **The two molecular shapes of the trigonal planar electron-group arrangement.**

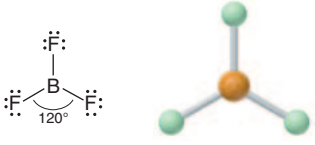
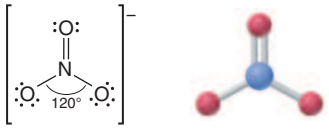
Molecular Shapes with Three Electron Groups (Trigonal Planar Arrangement)

Three electron groups around a central atom point to the corners of an equilateral triangle, which gives the **trigonal planar arrangement** and an ideal bond angle of 120° (Figure 10.4). This arrangement has two molecular shapes—one with all bonding groups and the other with one lone pair. It allows us to see *the effects of lone pairs and double bonds on bond angles.*

1. *All bonding groups: trigonal planar shape (AX_3).* Boron trifluoride (BF_3), another electron-deficient species, is an example of a trigonal planar molecule. It has six electrons around the central B atom in three single bonds to F atoms. The four nuclei lie in a plane, and each F—B—F angle is 120°:

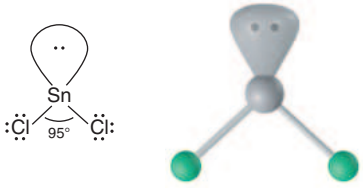


The nitrate ion (NO_3^-) is one of several polyatomic ions with the trigonal planar shape. One of three resonance structures of the nitrate ion (Sample Problem 10.4) is

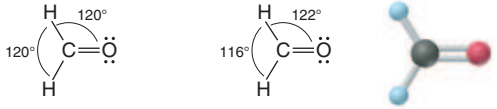


Any of the three resonance structures of NO_3^- can be used to determine its molecular shape. The resonance hybrid has three identical bonds of bond order $1\frac{1}{3}$, so the ideal bond angle is observed.

2. *One lone pair: bent or V shape (AX_2E).* Gaseous tin(II) chloride is a molecule with a **bent shape,** or **V shape,** with three electron groups in a trigonal plane and a lone pair at one of the triangle's corners. A lone pair often has a major effect on bond angle. Because it is held by only one nucleus, a lone pair is less confined than a bonding pair and so exerts stronger repulsions. In general, *a lone pair repels bonding pairs more than bonding pairs repel each other, so it decreases the angle between bonding pairs*. Note the 95° bond angle in $SnCl_2$, which is considerably less than the ideal 120°:



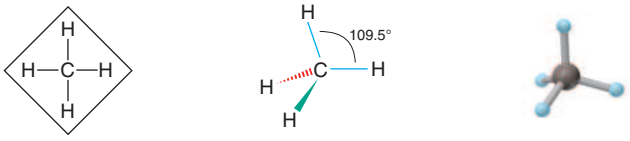
Effect of Double Bonds on Bond Angle When the surrounding atoms and electron groups are not identical, the bond angles are often affected. Consider formaldehyde (CH_2O), whose uses include the manufacture of countertops and the production of methanol. The three electron groups around the central C result in a trigonal planar shape. But there are two types of surrounding atoms (O and H) and two types of electron groups (single and double bonds):



The actual H—C—H bond angle is less than the ideal 120° because *the greater electron density of a double bond repels electrons in single bonds more than the single bonds repel each other.*

Molecular Shapes with Four Electron Groups (Tetrahedral Arrangement)

Shapes based on two or three electron groups lie in a plane, but four electron groups require three dimensions to maximize separation. Consider methane, whose Lewis structure *(below, left)* shows four bonds pointing to the corners of a square, which suggests 90° bond angles. But, *Lewis structures do* ***not*** *depict shape*. In three dimensions, the four electron groups lie at the corners of a *tetrahedron,* a polyhedron with four faces made of equilateral triangles, giving bond angles of 109.5° (Figure 10.5).



A *perspective drawing* for methane *(above, middle)* indicates depth by using solid and dashed wedges for bonds out of the plane of the page. The normal bond lines *(blue)* are in the plane of the page; the solid wedge *(green)* is the bond from the C atom in the plane of the page to the H above that plane; and the dashed wedge *(red)* is the bond from the C to the H below the plane of the page. The ball-and-stick model *(above, right)* shows the tetrahedral shape more clearly.

All molecules or ions with four electron groups around a central atom adopt the ***tetrahedral arrangement.*** There are three shapes with this arrangement:

1. *All bonding groups: tetrahedral shape (AX_4).* Methane has a tetrahedral shape, a very common geometry in organic molecules. In Sample Problem 10.1, we drew the Lewis structure for CCl_2F_2, without regard to relative placement of the four halogen atoms around the carbon atom. Because Lewis structures are flat, it may seem like you can write two different ones for CCl_2F_2, but they represent the same molecule, as a twist of the wrist reveals (Figure 10.6).

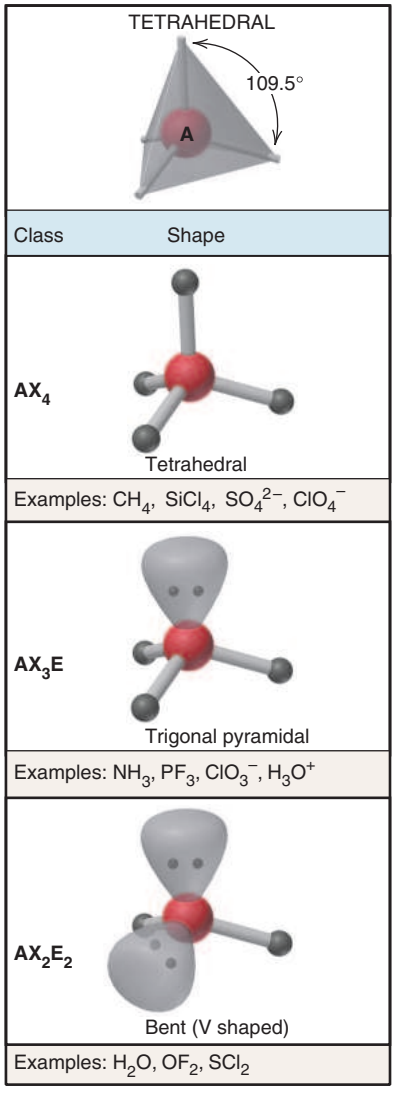


Figure 10.5 **The three molecular shapes of the tetrahedral electron-group arrangement.**

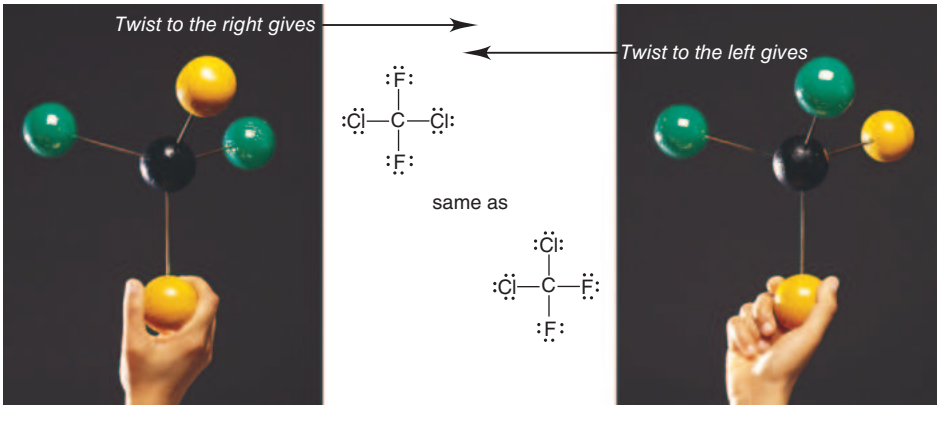

Figure 10.6 **Lewis structures do not indicate molecular shape.** In this model, Cl is green and F is yellow.

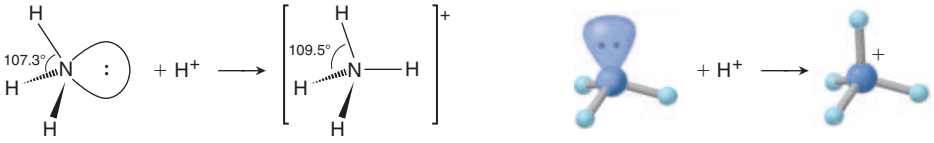
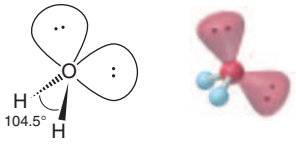
2. *One lone pair: trigonal pyramidal shape (AX_3E).* Ammonia (NH_3) is an example of a molecule with a **trigonal pyramidal shape,** a tetrahedron with one vertex "missing." Stronger repulsions by the lone pair make the H—N—H bond angle slightly less than the ideal 109.5°. The lone pair forces the N—H pairs closer to each other, and the bond angle is 107.3°. NF_3 (see p. 396) also has a trigonal pyramidal shape.

Picturing shapes is a great way to visualize a reaction. For instance, when ammonia reacts with an acid, the lone pair on N forms a bond to the H^+ and yields the ammonium ion (NH_4^+), one of many tetrahedral polyatomic ions. As the lone pair becomes a bonding pair, the H—N—H angle expands from 107.3° to 109.5°:



3. *Two lone pairs: bent or V shape (AX_2E_2).* Water is the most important V-shaped molecule with the tetrahedral arrangement. [Note that, in the trigonal planar arrangement, the V shape has two bonding groups and *one* lone pair (AX_2E), and its ideal bond angle is 120°, not 109.5°.] Repulsions from two lone pairs are greater than from one, and the H—O—H bond angle is 104.5°, less than the H—N—H angle in NH_3:



Thus, for similar molecules within a given electron-group arrangement, electron-electron repulsions cause deviations from ideal bond angles in the following order:

Lone pair–lone pair > lone pair–bonding pair > bonding pair–bonding pair **(10.2)**

Molecular Shapes with Five Electron Groups (Trigonal Bipyramidal Arrangement)

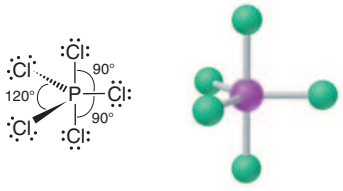
All molecules with five or six electron groups have a central atom from Period 3 or higher because only those atoms have *d* orbitals available to expand the valence shell.

Relative Positions of Electron Groups Five mutually repelling electron groups form the **trigonal bipyramidal arrangement,** in which two trigonal pyramids share a common base (Figure 10.7). This is the only case in which *there are two different positions for electron groups and two ideal bond angles.* Three **equatorial groups** lie in a trigonal plane that includes the central atom, and two **axial groups** lie above and below this plane. Therefore, a 120° bond angle separates equatorial groups, and a 90° angle separates axial from equatorial groups. Two factors come into play:

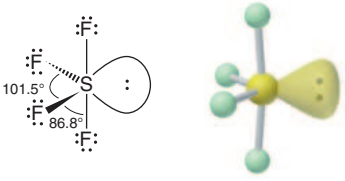
- The greater the bond angle, the weaker the repulsions, so *equatorial-equatorial (120°) repulsions are weaker than axial-equatorial (90°) repulsions.*
- The stronger repulsions from lone pairs means that, when possible, *lone pairs occupy equatorial positions*.

Shapes for the Trigonal Bipyramidal Arrangement The tendency for lone pairs to occupy equatorial positions, and thus minimize stronger axial-equatorial repulsions, governs three of the four shapes for this arrangement.

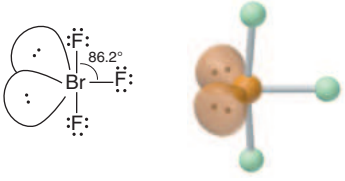
1. *All bonding groups: trigonal bipyramidal shape (AX_5).* Phosphorus pentachloride (PCl_5) has a trigonal bipyramidal shape. With five identical surrounding atoms, the bond angles are ideal:



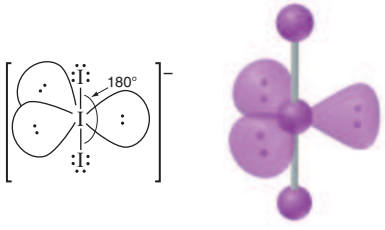
2. *One lone pair: seesaw shape (AX_4E).* Sulfur tetrafluoride (SF_4), a strong fluorinating agent, has the **seesaw shape;** in Figure 10.7, the "seesaw" is tipped on an end. This is the first example of *lone pairs occupying equatorial positions* to minimize repulsions. The lone pair repels all four bonding pairs, reducing the bond angles to 101.5° and 86.8°:



3. *Two lone pairs: T shape (AX_3E_2).* Bromine trifluoride (BrF_3), one of many compounds with fluorine bonded to a larger halogen, has a **T shape.** Since both lone pairs occupy equatorial positions, we see a greater decrease in the axial-equatorial bond angle, down to 86.2°:



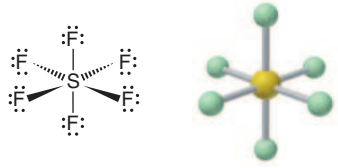
4. *Three lone pairs: linear shape (AX_2E_3).* The triiodide ion (I_3^-), which forms when I_2 dissolves in aqueous I^- solution, is linear. With three equatorial lone pairs and two axial bonding pairs, the three nuclei form a straight line and a 180° X—A—X bond angle:



Molecular Shapes with Six Electron Groups (Octahedral Arrangement)

Six electron groups form the **octahedral arrangement.** An *octahedron* is a polyhedron with eight equilateral triangles for faces and six identical vertices (Figure 10.8, *next page*). Each of the six groups points to a corner, which gives a 90° ideal bond angle.

1. *All bonding groups: octahedral shape (AX_6).* When seesaw-shaped SF_4 reacts with more F_2 (see p. 404), the central S atom expands its valence shell further to form octahedral sulfur hexafluoride (SF_6):



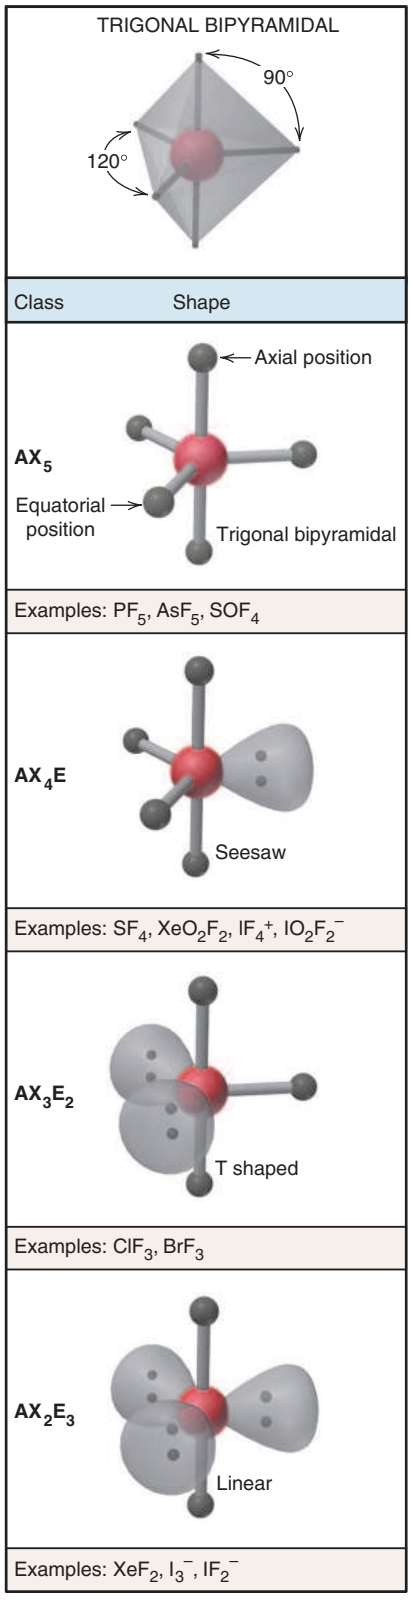


Figure 10.7 The four molecular shapes of the trigonal bipyramidal electron-group arrangement.

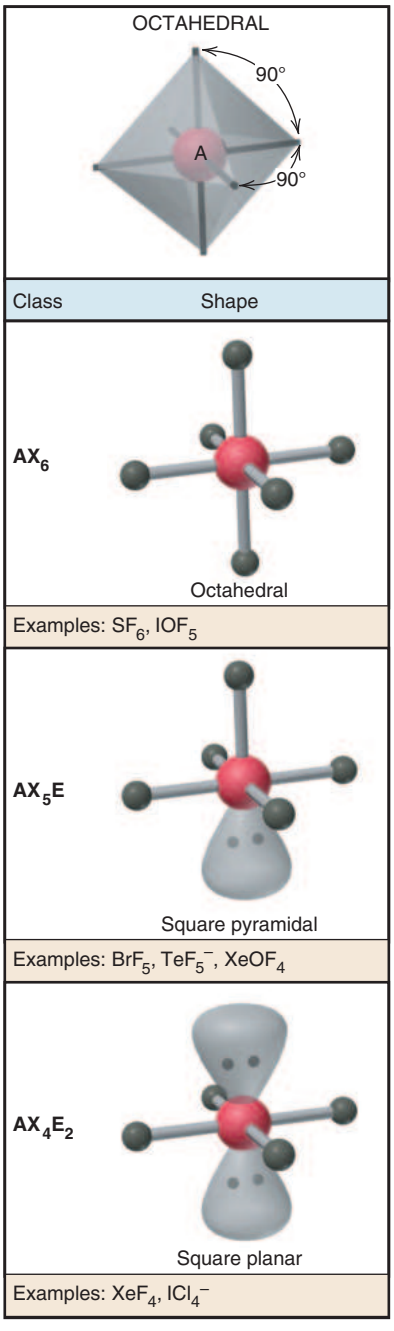

Figure 10.8 The three molecular shapes of the octahedral electron-group arrangement.

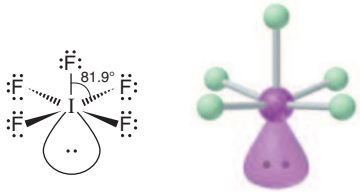
2. *One lone pair: square pyramidal shape (AX_5E).* Iodine pentafluoride (IF_5) has a **square pyramidal shape.** Note that it makes no difference where the one lone pair resides because all the bond angles are 90°. The lone pair reduces the bond angles to 81.9°:



3. *Two lone pairs: square planar shape (AX_4E_2).* Xenon tetrafluoride (XeF_4) has a **square planar shape.** To avoid stronger 90° lone pair–lone pair repulsions, two lone pairs lie *opposite* each other:

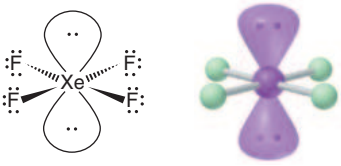


Figure 10.9 displays the shapes possible for elements in different periods, and Figure 10.10 summarizes the molecular shapes we've discussed.

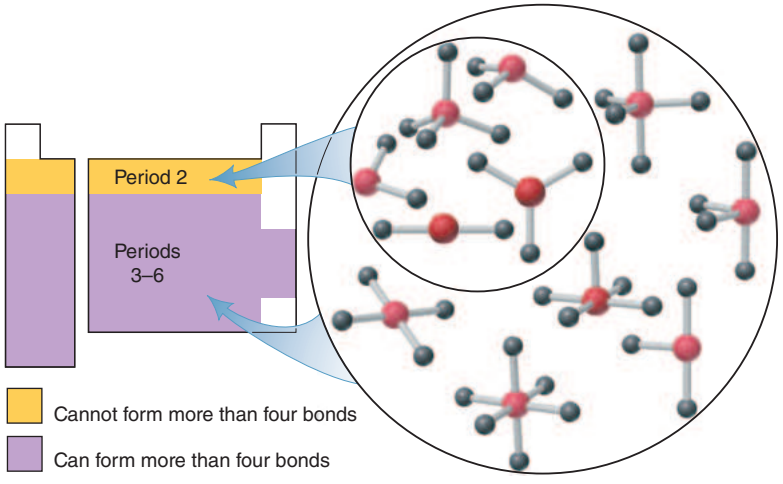

Figure 10.9 Molecular shapes for central atoms in Period 2 and in higher periods.

Using VSEPR Theory to Determine Molecular Shape

Let's apply a stepwise method for using VSEPR theory to determine a molecular shape from a molecular formula (Figure 10.11):

Step 1. Write the Lewis structure from the molecular formula (Figure 10.1, p. 396) to see the relative placement of atoms and the number of electron groups.

Step 2. Assign an electron-group arrangement by counting *all* electron groups (bonding plus nonbonding) around the central atom.

Step 3. Predict the ideal bond angle from the electron-group arrangement and *the effect of any deviation* caused by lone pairs or double bonds.

Step 4. Draw and name the molecular shape by counting bonding groups and nonbonding groups separately.

The next two sample problems apply these steps.

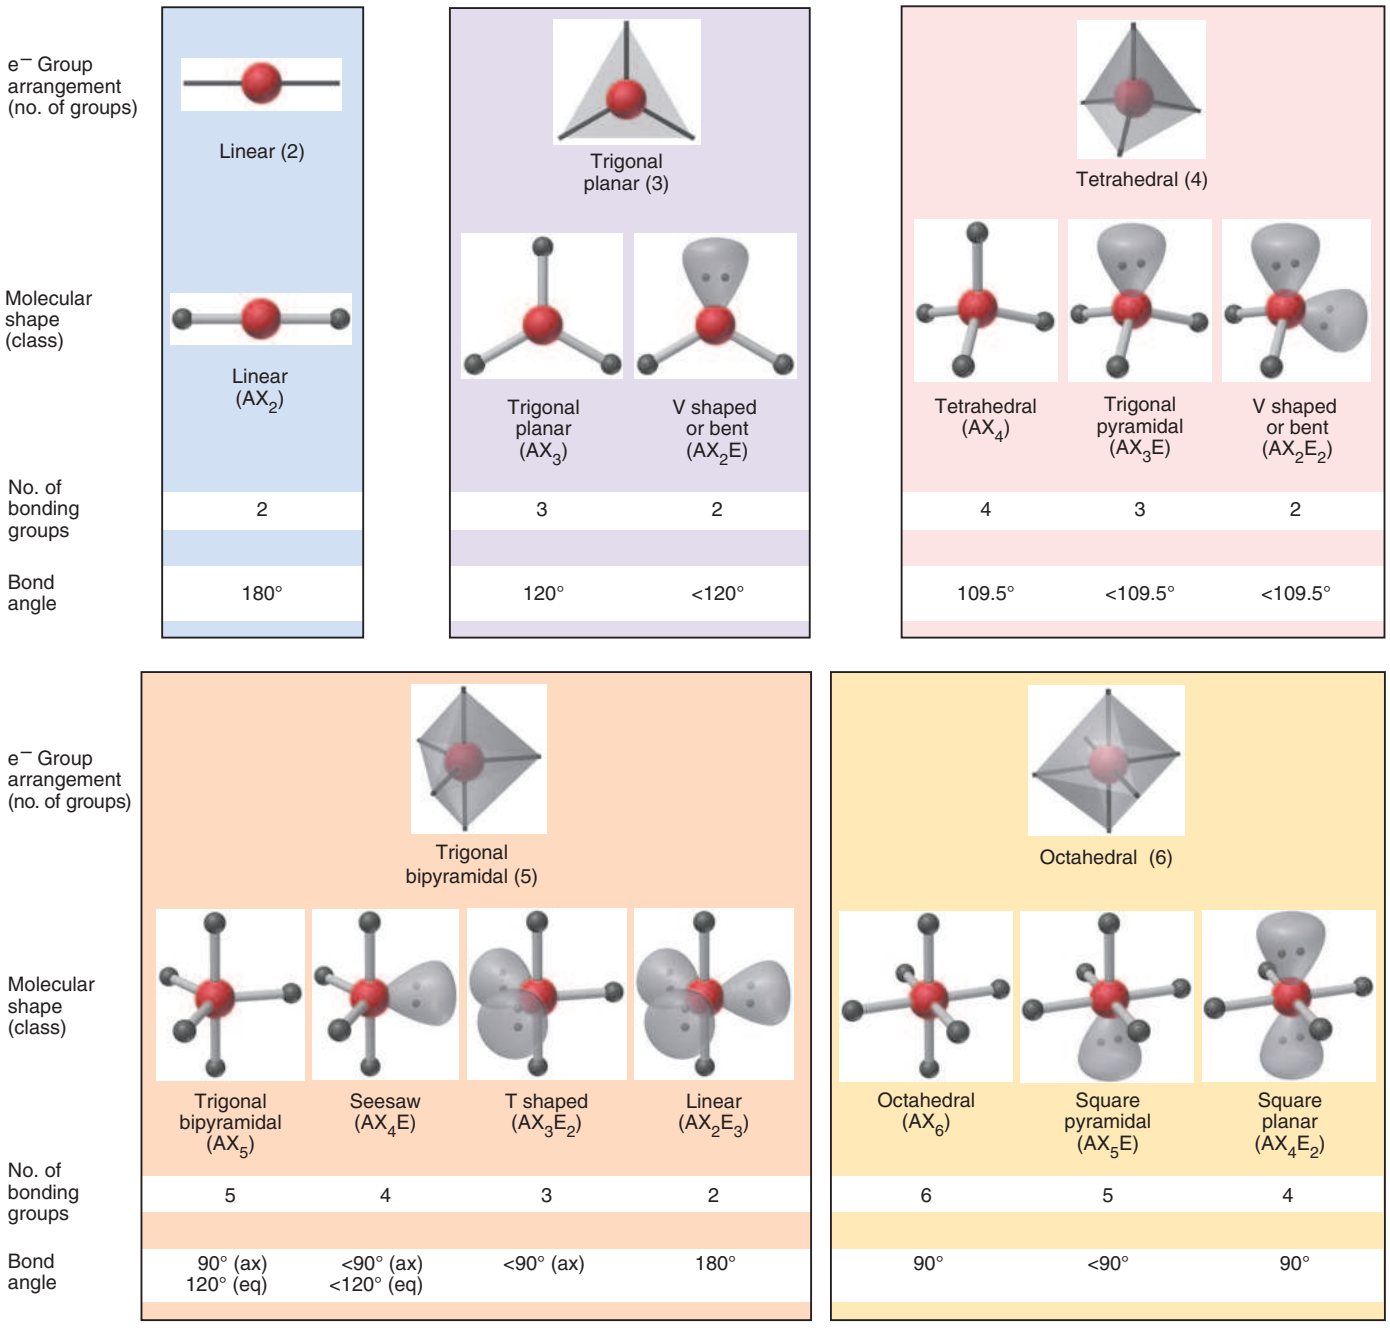

Figure 10.10 A summary of common molecular shapes with two to six electron groups.

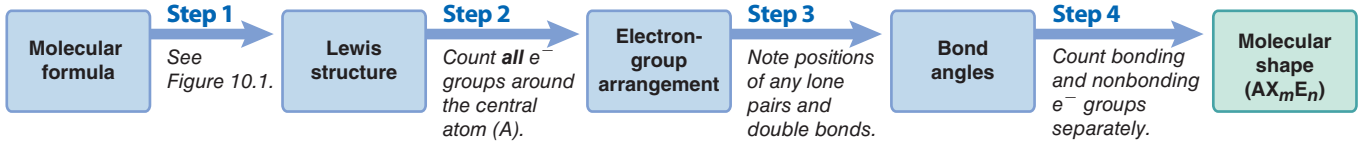

Figure 10.11 The four steps in converting a molecular formula to a molecular shape.

SAMPLE PROBLEM 10.6 Examining Shapes with Two, Three, or Four Electron Groups

Problem Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of **(a)** PF_3 and **(b)** $COCl_2$.

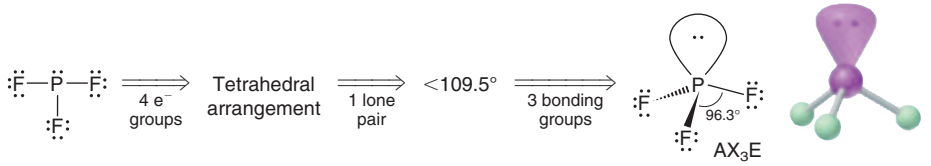
Solution **(a)** For PF_3.

Step 1. Write the Lewis structure from the formula *(see below, left).*

Step 2. Assign the electron-group arrangement: Three bonding groups and one lone pair give four electron groups around P and the *tetrahedral arrangement.*

Step 3. Predict the bond angle: The ideal bond angle is 109.5°. There is one lone pair, so the actual bond angle will be less than 109.5°.

Step 4. Draw and name the molecular shape: With one lone pair, PF_3 has a trigonal pyramidal shape (AX_3E):



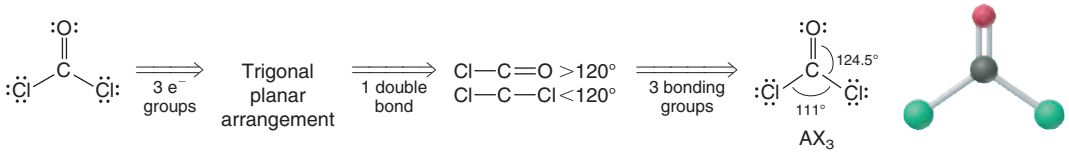
(b) For $COCl_2$.

Step 1. Write the Lewis structure from the formula *(see below, left).*

Step 2. Assign the electron-group arrangement: Two single bonds and one double bond give three electron groups around C and the *trigonal planar arrangement.*

Step 3. Predict the bond angles: The ideal bond angle is 120°, but the double bond between C and O will compress the Cl—C—Cl angle to less than 120°.

Step 4. Draw and name the molecular shape: With three electron groups and no lone pairs, $COCl_2$ has a trigonal planar shape (AX_3):



Check We compare the answers with the general information in Figure 10.10.

Comment Be sure the Lewis structure is correct because it determines the other steps.

FOLLOW-UP PROBLEMS

10.6A Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of **(a)** CS_2; **(b)** $PbCl_2$; **(c)** CBr_4; **(d)** SF_2.

10.6B Name the electron-group arrangements, draw and name the molecular shapes, and predict the bond angles (relative to the ideal angles) of **(a)** BrO_2^-; **(b)** AsH_3; **(c)** N_3^-; **(d)** SeO_3.

SOME SIMILAR PROBLEMS 10.34–10.37

SAMPLE PROBLEM 10.7 Examining Shapes with Five or Six Electron Groups

Problem Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of **(a)** SbF_5 and **(b)** BrF_5.

Plan We proceed as in Sample Problem 10.6, being sure to minimize the number of axial-equatorial repulsions.

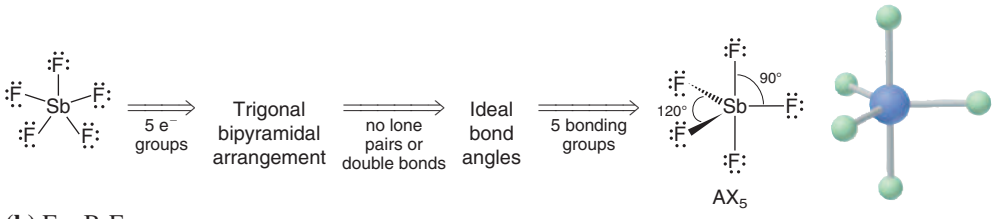
Solution **(a)** For SbF_5.

Step 1. Lewis structure *(see facing page, left).*

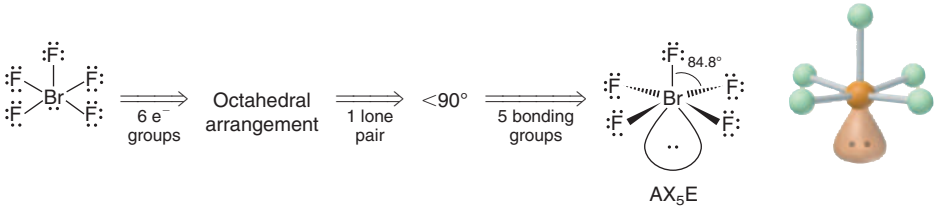
Step 2. Electron-group arrangement: With five electron groups, this is the *trigonal bipyramidal* arrangement.

Step 3. Bond angles: All the groups and surrounding atoms are identical, so the bond angles are ideal: 120° between equatorial groups and 90° between axial and equatorial groups.

Step 4. Molecular shape: Five electron groups and no lone pairs give the trigonal bipyramidal shape (AX_5):



(b) For BrF_5.
Step 1. Lewis structure *(see below, left).*
Step 2. Electron-group arrangement: Six electron groups give the *octahedral* arrangement.
Step 3. Bond angles: The lone pair will make all bond angles less than the ideal 90°.
Step 4. Molecular shape: With one lone pair, BrF_5 has the square pyramidal shape (AX_5E):



Check We compare our answers with Figure 10.10.

Comment We will also see the linear, tetrahedral, square planar, and octahedral shapes in an important group of substances, called *coordination compounds,* in Chapter 23.

FOLLOW-UP PROBLEMS

10.7A Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of **(a)** ICl_2^-; **(b)** ClF_3; **(c)** SOF_4.

10.7B Draw the molecular shapes and predict the bond angles (relative to the ideal angles) of **(a)** BrF_4^-; **(b)** ClF_4^+; **(c)** PCl_6^-.

SOME SIMILAR PROBLEMS 10.40 and 10.41

Molecular Shapes with More Than One Central Atom

The shapes of molecules with more than one central atom are composites of the shapes around each of the atoms. Here are two examples:

1. Ethane (CH_3CH_3; molecular formula C_2H_6) is a component of natural gas. With four bonding groups and no lone pairs around the two central carbons, ethane is shaped like two overlapping tetrahedra (Figure 10.12A).
2. Ethanol (CH_3CH_2OH; molecular formula C_2H_6O), the intoxicating substance in beer, wine, and whiskey, has three central atoms (Figure 10.12B). The CH_3— group is tetrahedrally shaped, and the —CH_2— group has four bonding groups around its central C atom, so it is also tetrahedrally shaped. The O atom has two bonding groups and two lone pairs around it, so the —OH group has a V shape (AX_2E_2).

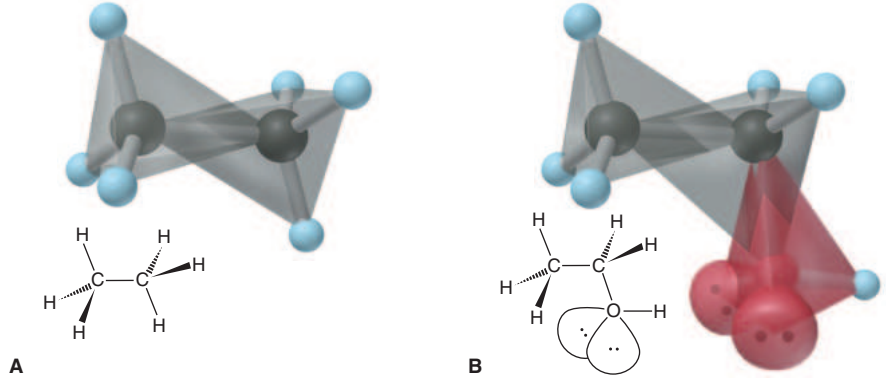


Figure 10.12 **The tetrahedral shapes around the central atoms and the overall shapes of ethane (A) and ethanol (B).**

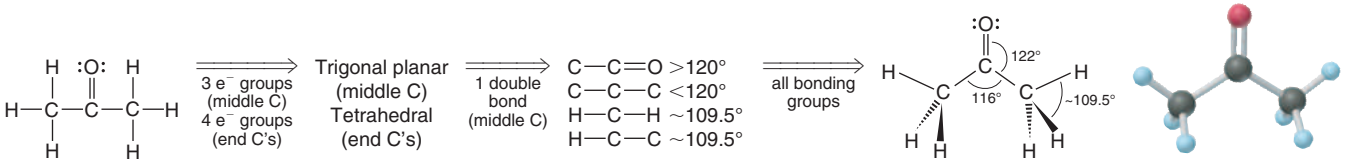
SAMPLE PROBLEM 10.8 Predicting Molecular Shapes with More Than One Central Atom

Problem Determine the shape around each central atom in acetone, $(CH_3)_2CO$.

Plan There are three central C atoms, two of which are in CH_3— groups. We determine the shape around one central atom at a time.

Solution *Step 1.* Lewis structure *(see below, left).*
Step 2. Electron-group arrangement: Each CH_3— group has four electron groups around its central C, so its electron-group arrangement is *tetrahedral*. The third C atom has three electron groups around it, so it has the *trigonal planar arrangement.*
Step 3. Bond angles: The H—C—H angle in CH_3— should be near the ideal 109.5°. The C═O double bond will compress the C—C—C angle to less than the ideal 120°.
Step 4. Shapes around central atoms: With four electron groups and no lone pairs, the shape around C in each CH_3— is tetrahedral (AX_4). With three electron groups and no lone pairs, the shape around the middle C is trigonal planar (AX_3):



FOLLOW-UP PROBLEMS

10.8A Determine the shape around each central atom and predict any deviations from ideal bond angles in the following: **(a)** H_2SO_4; **(b)** propyne (C_3H_4; there is one C≡C bond); **(c)** S_2F_2.

10.8B Determine the shape around each central atom and predict any deviations from ideal bond angles in the following: **(a)** CH_3NH_2; **(b)** C_2Cl_4; **(c)** Cl_2O_7 $(O_3ClOClO_3)$.

SOME SIMILAR PROBLEMS 10.42–10.45

Summary of Section 10.2

- VSEPR theory proposes that each electron group (single bond, multiple bond, lone pair, or lone electron) around a central atom remains as far from the others as possible.
- Five electron-group arrangements are possible when two, three, four, five, or six electron groups surround a central atom. Each arrangement is associated with one or more molecular shapes, depending on the numbers of bonding and lone pairs.
- Ideal bond angles are based on the regular geometric arrangements. Deviations from them occur when surrounding atoms and/or electron groups are not identical.
- Lone pairs and double bonds exert stronger repulsions than single bonds.
- Shapes of larger molecules are composites of the shapes around each central atom.

10.3 MOLECULAR SHAPE AND MOLECULAR POLARITY

Knowing the shape of its molecules is key to understanding the physical and chemical behavior of a substance. One of the most far-reaching effects of molecular shape is molecular polarity, which can influence melting and boiling points, solubility, reactivity, and even biological function.

Recall from Chapter 9 that a covalent bond is *polar* when the atoms have different electronegativities and, thus, share the electrons unequally. In diatomic molecules, such as HF, the only bond is polar, so the molecule is polar. In larger molecules, *both shape and bond polarity determine* **molecular polarity,** an uneven distribution of charge

over the whole molecule or large portion of it. Polar molecules become oriented in an electric field with their partially charged ends pointing toward the oppositely charged plates (Figure 10.13). **Dipole moment (μ)** is a measure of molecular polarity, given in the unit *debye* (D)* derived from SI units of charge (coulomb, C) and length (m): $1\ D = 3.34\times10^{-30}\ C\cdot m$.

Bond Polarity, Bond Angle, and Dipole Moment

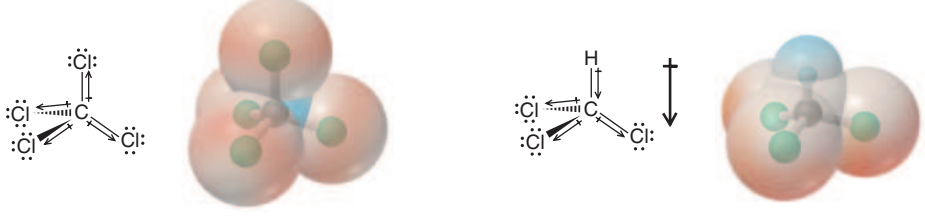
The presence of polar bonds does not *always* result in a polar molecule; we must also consider shape and the atoms surrounding the central atom. Here are three cases:

1. *CO_2: polar bonds, nonpolar molecule*. In carbon dioxide, the electronegativity difference between C (EN = 2.5) and O (EN = 3.5) makes each C═O bond polar, with electron density pulled from C toward O. But CO_2 is linear, so the bonds point 180° from each other. Since the two bonds have polarities that are equal in magnitude but opposite in direction, their polarities cancel, resulting in *no net dipole moment* for the molecule (μ = 0 D), just as two numbers of equal magnitude but opposite sign (for example, +1 and −1) add to 0. The electron density model shows regions of high negative charge *(red)* distributed equally on either side of the central region of high positive charge *(blue)*:

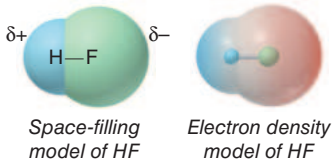
2. *H_2O: polar bonds, polar molecule*. Water also has two polar bonds, but it *is* polar (μ = 1.85 D). In each O—H bond, electron density is pulled from H (EN = 2.1) toward O (EN = 3.5). Bond polarities do *not* cancel because the molecule is V shaped (see also Figure 4.1, p. 140). The bond polarities are partially reinforced, making the O end partially negative and the other end (the region between the H atoms) partially positive:

(The molecular polarity of water has some amazing effects, from determining the composition of the oceans to supporting life itself, as you'll see in Chapter 12.)

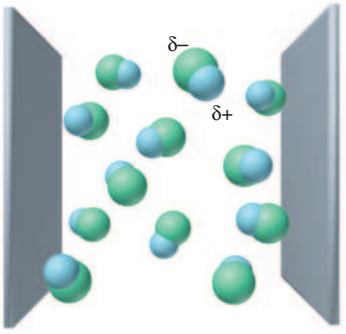
3. *Same shapes, different polarities*. When different molecules have the same shape, the identities of the surrounding atoms affect polarity. Carbon tetrachloride (CCl_4) and chloroform ($CHCl_3$) are tetrahedral molecules with very different polarities. In CCl_4, all the surrounding atoms are Cl atoms. Each C—Cl bond is equally polar (ΔEN = 0.5), but the molecule is nonpolar (μ = 0 D) because the bond polarities cancel each other. In $CHCl_3$, an H replaces one Cl. The polarity of the H—C bond differs in magnitude (ΔEN = 0.4) and direction from that of the three C—Cl bonds; thus, it disrupts the balance and gives chloroform a significant dipole moment (μ = 1.01 D):



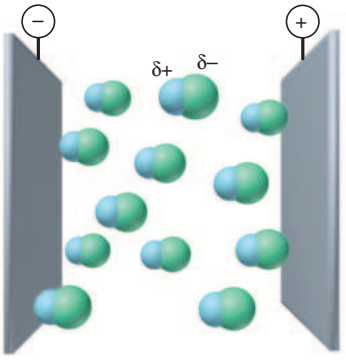
*The unit is named for the Dutch-American scientist Peter Debye (1884–1966) who won the Nobel Prize in chemistry in 1936 for contributions to the fields of molecular structure and solution behavior.



Space-filling model of HF *Electron density model of HF*



Electric field off: *HF molecules are oriented randomly.*



Electric field on: *HF molecules are oriented with their partially charged ends toward the oppositely charged plates.*

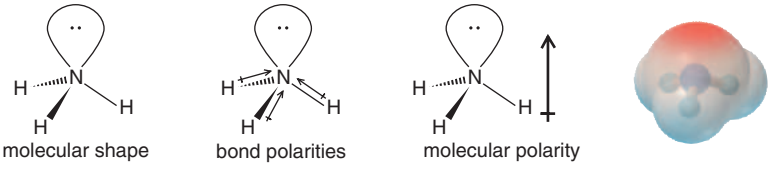
Figure 10.13 **The orientation of polar molecules in an electric field.**

SAMPLE PROBLEM 10.9 Predicting the Polarity of Molecules

Problem For each of the following, use the molecular shape and EN values and trends (Figure 9.21, p. 381) to predict the direction of bond and molecular polarity, if present: **(a)** ammonia, NH_3; **(b)** boron trifluoride, BF_3; **(c)** carbonyl sulfide, COS (atom sequence SCO).

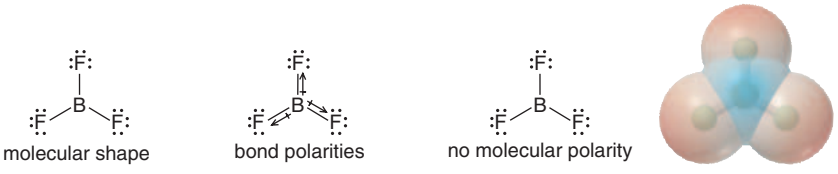
Plan We draw and name the molecular shape and point a polar arrow toward the atom with higher EN in each bond. If the bond polarities balance one another, the molecule is nonpolar; if they reinforce each other, we show the direction of the molecular polarity.

Solution **(a)** For NH_3. The molecular shape is trigonal pyramidal. N (EN = 3.0) is more electronegative than H (EN = 2.1), so the bond polarities point toward N and partially reinforce each other; thus the molecular polarity points toward N:



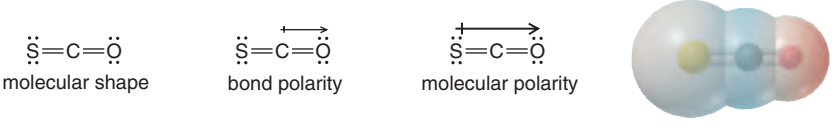
Therefore, ammonia is polar.

(b) For BF_3. The molecular shape is trigonal planar. F (EN = 4.0) is farther to the right in Period 2 than B (EN = 2.0), so it is more electronegative; thus, each bond polarity points toward F. However, the bond angle is 120°, so the three bond polarities balance each other, and BF_3 has no molecular polarity:



Therefore, boron trifluoride is nonpolar.

(c) For COS. The molecular shape is linear. With C and S having the same EN, the C═S bond is nonpolar, but the C═O bond is quite polar (ΔEN = 1.0), so there is a net molecular polarity toward the O:



Therefore, carbonyl sulfide is polar.

Check The electron density models confirm our conclusions. Note that, in (b), the negative *(red)* regions surround the central B *(blue)* symmetrically.

FOLLOW-UP PROBLEMS

10.9A Show the bond polarities and molecular polarity, if any, for each of the following: **(a)** dichloromethane (CH_2Cl_2); **(b)** iodine oxide pentafluoride (IOF_5); **(c)** iodine pentafluoride (IF_5).

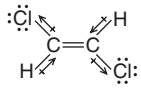
10.9B Show the bond polarities and molecular polarity, if any, for each of the following: **(a)** xenon tetrafluoride (XeF_4); **(b)** chlorine trifluoride (ClF_3); **(c)** sulfur monoxide tetrafluoride (SOF_4).

SOME SIMILAR PROBLEMS 10.55–10.58

The Effect of Molecular Polarity on Behavior

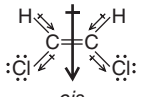
Earlier we mentioned that molecular polarity influences physical behavior. Let's see how a molecular property like dipole moment affects a macroscopic property like boiling point.

Consider the two dichloroethylenes shown below. They have the *same* molecular formula ($C_2H_2Cl_2$) but *different* physical and chemical properties; that is, they are isomers (Section 3.2). Both molecules are planar, with a trigonal planar shape around each C atom. The *trans* isomer is nonpolar ($\mu = 0$ D) because the polar C—Cl bonds balance each other. The *cis* isomer is polar ($\mu = 1.90$ D) because the bond polarities partially reinforce each other, with the molecular polarity pointing between the Cl atoms.



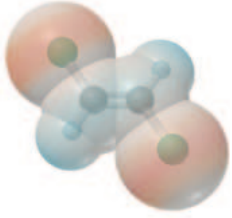
trans

$\mu = 0$ D
Boiling point = 47.5°C



cis

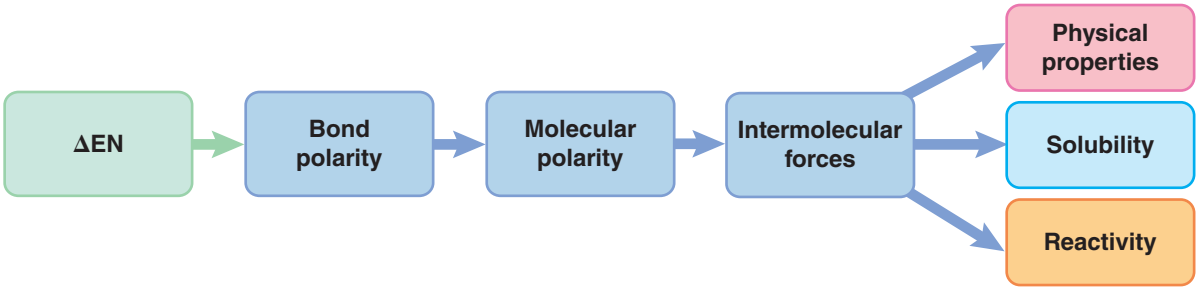
$\mu = 1.90$ D
Boiling point = 60.3°C



A liquid boils when it forms bubbles against the atmospheric pressure. To enter the bubble, molecules in the liquid must overcome the weak attractive forces *between* them. Because of their polarity, the *cis* molecules attract each other more strongly than the *trans* molecules do. Since more energy is needed to overcome the stronger attractions, we expect the *cis* isomer to have a higher boiling point: *cis*-1,2-dichloroethylene boils 13°C higher than *trans*-1,2-dichloroethylene.

Figure 10.14 shows the chain of influences of atomic properties on the behavior of substances. We extend these relationships in Chapter 12, and the upcoming Chemical Connections essay discusses some biological effects of molecular shape and polarity.

Figure 10.14 The influence of atomic properties on macroscopic behavior.



Summary of Section 10.3

- Bond polarity and molecular shape determine molecular polarity, which is measured as a dipole moment.
- A molecule with polar bonds is not necessarily a polar molecule. When bond polarities cancel each other, the molecule is nonpolar; when they reinforce each other, the molecule is polar.
- Molecular shape and polarity can affect physical properties, such as boiling point, and they play a central role in biological function.

Molecular Shape, Biological Receptors, and the Sense of Smell

A biological cell can be thought of as a membrane-bound sack filled with an aqueous fluid containing many molecules of various shapes. Many complex processes begin when a molecular "key" fits into a molecular "lock" with a complementary shape. Typically, the key is a small molecule circulating in cellular or other bodily fluid, and the lock, the *biological receptor,* is a large molecule often embedded in a membrane. The *receptor site* is a small region of the receptor with a shape that matches the molecular key. Thousands of molecules per second collide with the receptor site, but when one with the correct shape does, the receptor "grabs" it through intermolecular attractions, and the biological response begins.

Molecular Shape and the Sense of Smell

Molecular shapes fitting together is crucial to the sense of smell (olfaction). To have an odor, a substance must be a gas or a volatile liquid or solid and must be at least slightly soluble in the aqueous film of the nasal passages. And the odorous molecule, or a portion of it, must fit into one of the receptor sites on nerve endings in this area. When this happens, nerve impulses travel to the brain, which interprets them as a specific odor.

Over half a century ago, a new theory proposed that molecular shape (and sometimes polarity), but *not* composition, determines odor. It stated that any molecule producing one of seven primary odors—camphor-like, musky, floral, minty, ethereal, pungent, and putrid—matches a receptor site of a particular shape. Figure B10.1 shows three of the seven sites holding a molecule with that odor.

Several predictions of the theory proved to be correct:

- If different substances fit a given receptor, they have the same odor. The four molecules in Figure B10.2 fit the camphor-like receptor and smell like moth repellent.
- If different parts of a molecule fit different receptors, it has a mixed odor. Portions of benzaldehyde fit the camphor-like, floral, and minty receptors, and it smells like almonds; other molecules with this odor fit the same three receptors.

But, other predictions were not confirmed. For example, an odor predicted from the shape was often not the odor smelled. The reason is that molecules may not have the same shape in solution at the receptor as they have in the gas phase.

Evidence from the 1990s suggests that the original model is far too simple. The 2004 Nobel Prize in medicine or physiology was given to Richard Axel and Linda B. Buck for showing that olfaction involves about 1000 different receptors and molecules fitting various combinations of them produce the over 10,000 odors humans smell.

Thus, although the process is much more complex than originally thought, the central idea that odor depends on molecular shape is valid and is being actively researched in the food, cosmetics, and insecticide industries.

Biological Significance of Molecular Shape

Countless other examples show that no chemical property is more crucial to living systems than molecular shape. Here are just a few of the many biochemical processes controlled by one molecule fitting into a receptor site on another:

- Enzymes are proteins that bind cellular reactants and speed their reaction. An early step in energy metabolism involves glucose binding to the "active" site of the enzyme hexokinase (Figure B10.3).
- Nerve impulses are transmitted when small molecules released from one nerve fit into receptors on the next. Mind-altering drugs act by chemically mimicking the molecular fit at such nerve receptors in the brain.
- One type of immune response is triggered when a molecule on a bacterial surface binds to the receptors on "killer" cells in the bloodstream.
- Hormones regulate processes by fitting into and activating specific receptors on target tissues and organs.
- Genes function when certain nucleic acid molecules fit into specific regions of others.

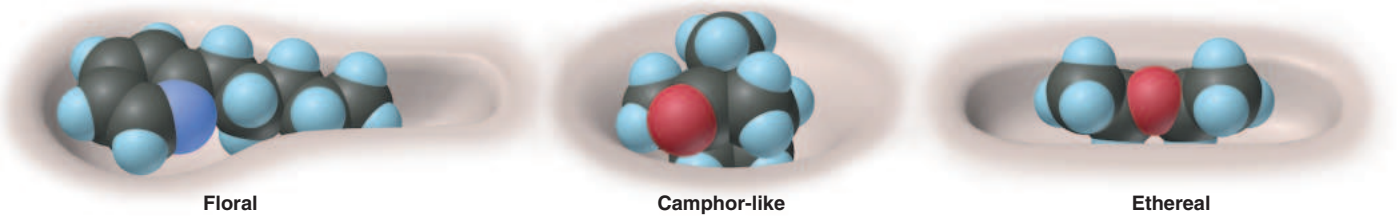


Figure B10.1 Shapes of some olfactory receptor sites.

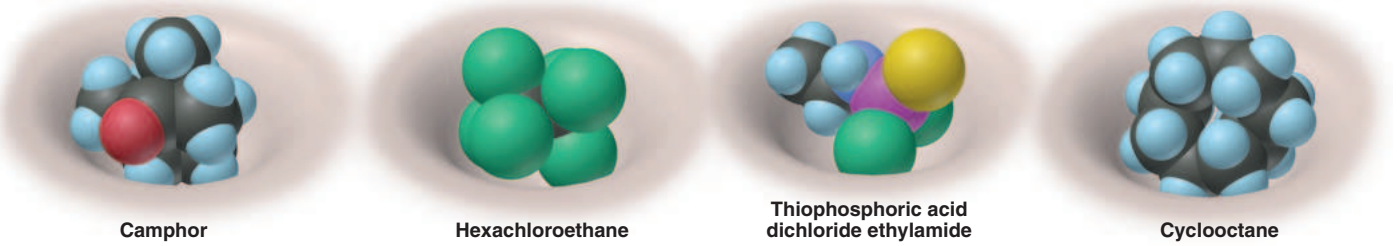

Figure B10.2 Different molecules with the same odor.

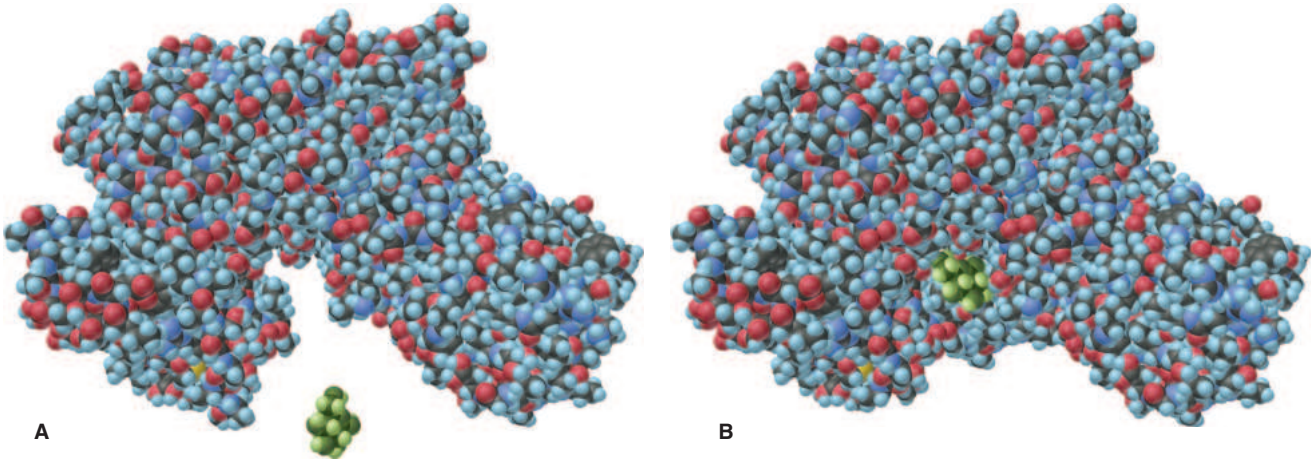

Figure B10.3 Molecular shape and enzyme action. A, A small sugar molecule *(bottom)* is shown near a specific region of an enzyme molecule. **B,** When the sugar lands in that region, the reaction begins.

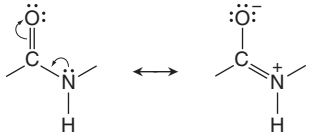
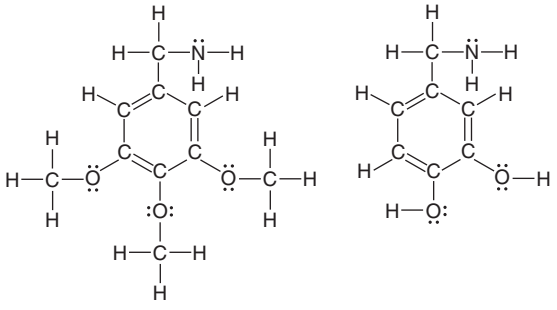
Problems

B10.1 As you'll learn in Chapter 11, groups joined by a single bond rotate freely around the bond, but those joined by double bonds don't. Peptide bonds make up a major portion of protein chains. Determine the molecular shape around the central C and N atoms in the two resonance forms of the peptide bond:



B10.2 Lewis structures of mescaline, a hallucinogenic compound in peyote cactus, and dopamine, a neurotransmitter in the mammalian brain, are shown below. Suggest a reason for mescaline's ability to disrupt nerve impulses.



mescaline dopamine

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How Lewis structures depict the atoms, bonding pairs, and lone electron pairs in a molecule or polyatomic ion (§10.1)
2. How resonance and electron delocalization explain bond properties in many compounds with double bonds adjacent to single bonds (§10.1)
3. The meaning of formal charge and how it is used to select the most important resonance structure; the difference between formal charge and oxidation number (§10.1)
4. The octet rule and its three major exceptions—molecules with a central atom that has an electron deficiency, an odd number of electrons, or an expanded valence shell (§10.1)
5. How electron-group repulsions lead to molecular shapes (§10.2)
6. The five electron-group arrangements and their associated molecular shapes (§10.2)
7. Why double bonds and lone pairs cause deviations from ideal bond angles (§10.2)
8. How bond polarities and molecular shape combine to give a molecule polarity (§10.3)

Learning Objectives (continued)

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Master These Skills

1. Using a stepwise method for writing a Lewis structure from a molecular formula (SPs 10.1–10.3, 10.5)
2. Writing resonance structures for molecules and ions (SP 10.4)
3. Calculating the formal charge of any atom in a molecule or ion (SP 10.5)
4. Predicting molecular shapes from Lewis structures (SPs 10.6–10.8)
5. Using molecular shape and electronegativity values to predict the polarity of a molecule (SP 10.9)

Key Terms

Page numbers appear in parentheses.

Section 10.1
Lewis structure (Lewis formula) (395)
resonance structure (resonance form) (399)
resonance hybrid (399)
electron-pair delocalization (400)
formal charge (401)
electron deficient (403)
free radical (403)

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Depicting Molecules and Ions with Lewis Structures

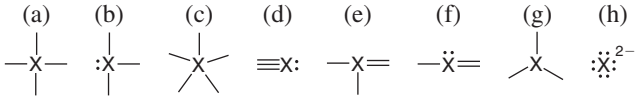
(Sample Problems 10.1 to 10.5)

Concept Review Questions

10.1 Which of these atoms *cannot* serve as a central atom in a Lewis structure: (a) O; (b) He; (c) F; (d) H; (e) P? Explain.

10.2 When is a resonance hybrid needed to adequately depict the bonding in a molecule? Using NO_2 as an example, explain how a resonance hybrid is consistent with the actual bond length, bond strength, and bond order.

10.3 In which of these bonding patterns does X obey the octet rule?



10.4 What is required for an atom to expand its valence shell? Which of the following atoms can expand its valence shell: F, S, H, Al, Se, Cl?

Skill-Building Exercises (grouped in similar pairs)

10.5 Draw a Lewis structure for (a) SiF_4; (b) $SeCl_2$; (c) COF_2 (C is central).

10.6 Draw a Lewis structure for (a) PH_4^+; (b) C_2F_4; (c) SbH_3.

10.7 Draw a Lewis structure for (a) PF_3; (b) H_2CO_3 (both H atoms are attached to O atoms); (c) CS_2.

10.8 Draw a Lewis structure for (a) CH_4S; (b) S_2Cl_2; (c) $CHCl_3$.

10.9 Draw Lewis structures of all the important resonance forms of (a) NO_2^+; (b) NO_2F (N is central).

10.10 Draw Lewis structures of all the important resonance forms of (a) HNO_3 ($HONO_2$); (b) $HAsO_4^{2-}$ ($HOAsO_3^{2-}$).

10.11 Draw Lewis structures of all the important resonance forms of (a) N_3^-; (b) NO_2^-.

10.12 Draw Lewis structures of all the important resonance forms of (a) HCO_2^- (H is attached to C); (b) $HBrO_4$ ($HOBrO_3$).

10.13 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) IF_5; (b) AlH_4^-.

10.14 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) OCS; (b) NO.

10.15 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) CN^-; (b) ClO^-.

10.16 Draw the Lewis structure with lowest formal charges, and determine the charge of each atom in (a) BF_4^-; (b) ClNO.

10.17 Draw a Lewis structure for a resonance form of each ion with the lowest possible formal charges, show the charges, and give oxidation numbers of the atoms: (a) BrO_3^-; (b) SO_3^{2-}.

10.18 Draw a Lewis structure for a resonance form of each ion with the lowest possible formal charges, show the charges, and give oxidation numbers of the atoms: (a) AsO_4^{3-}; (b) ClO_2^-.

10.19 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) BH_3 (b) AsF_4^- (c) $SeCl_4$

10.20 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) PF_6^- (b) ClO_3 (c) H_3PO_3 (one P—H bond)

10.21 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) BrF_3 (b) ICl_2^- (c) BeF_2

10.22 These species do not obey the octet rule. Draw a Lewis structure for each, and state the type of octet-rule exception:
(a) O_3^- (b) XeF_2 (c) SbF_4^-

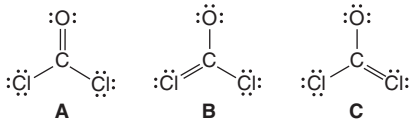
Problems in Context

10.23 Molten beryllium chloride reacts with chloride ion from molten NaCl to form the $BeCl_4^{2-}$ ion, in which the Be atom attains an octet. Show the net ionic reaction with Lewis structures.

10.24 Despite many attempts, the perbromate ion (BrO_4^-) was not prepared in the laboratory until about 1970. (In fact, articles were published explaining theoretically why it could never be prepared!) Draw a Lewis structure for BrO_4^- in which all atoms have lowest formal charges.

10.25 Cryolite (Na_3AlF_6) is an indispensable component in the electrochemical production of aluminum. Draw a Lewis structure for the AlF_6^{3-} ion.

10.26 Phosgene is a colorless, highly toxic gas that was employed against troops in World War I and is used today as a key reactant in organic syntheses. From the following resonance structures, select the one with the lowest formal charges:



Valence-Shell Electron-Pair Repulsion (VSEPR) Theory

(Sample Problems 10.6 to 10.8)

Concept Review Questions

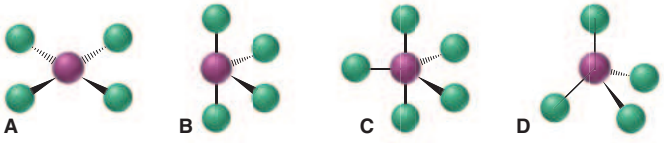
10.27 If you know the formula of a molecule or ion, what is the first step in predicting its shape?

10.28 In what situation is the name of the molecular shape the same as the name of the electron-group arrangement?

10.29 Which of the following numbers of electron groups can give rise to a bent (V-shaped) molecule: two, three, four, five, six? Draw an example for each case, showing the shape classification (AX_mE_n) and the ideal bond angle.

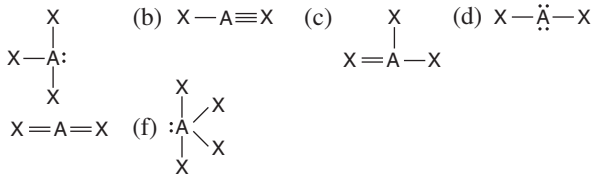
10.30 Name all the molecular shapes that have a tetrahedral electron-group arrangement.

10.31 Consider the following molecular shapes. (a) Which has the most electron pairs (both shared and unshared) around the central atom? (b) Which has the most unshared pairs around the central atom? (c) Do any have only shared pairs around the central atom?



10.32 Use wedge-bond perspective drawings (if necessary) to sketch the atom positions in a general molecule of formula (not shape class) AX_n that has each of the following shapes:
(a) V shaped (b) trigonal planar (c) trigonal bipyramidal
(d) T shaped (e) trigonal pyramidal (f) square pyramidal

10.33 What would you expect to be the electron-group arrangement around atom A in each of the following cases? For each arrangement, give the ideal bond angle and the direction of any expected deviation:



Skill-Building Exercises (grouped in similar pairs)

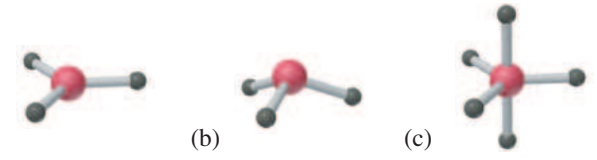
10.34 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:
(a) O_3 (b) H_3O^+ (c) NF_3

10.35 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:
(a) SO_4^{2-} (b) NO_2^- (c) PH_3

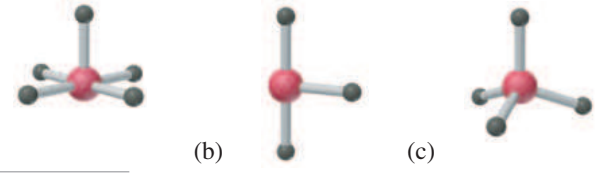
10.36 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:
(a) CO_3^{2-} (b) SO_2 (c) CF_4

10.37 Determine the electron-group arrangement, molecular shape, and ideal bond angle(s) for each of the following:
(a) SO_3 (b) N_2O (N is central) (c) CH_2Cl_2

10.38 Name the shape and give the AX_mE_n classification and ideal bond angle(s) for each of the following general molecules:



10.39 Name the shape and give the AX_mE_n classification and ideal bond angle(s) for each of the following general molecules:



10.40 Determine the shape, ideal bond angle(s), and the direction of any deviation from those angles for each of the following:
(a) ClO_2^- (b) PF_5 (c) SeF_4 (d) KrF_2

10.41 Determine the shape, ideal bond angle(s), and the direction of any deviation from those angles for each of the following:
(a) ClO_3^- (b) IF_4^- (c) $SeOF_2$ (d) TeF_5^-

10.42 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:
(a) CH_3OH (b) N_2O_4 (O_2NNO_2)

10.43 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:
(a) H_3PO_4 (no H—P bond) (b) $CH_3—O—CH_2CH_3$

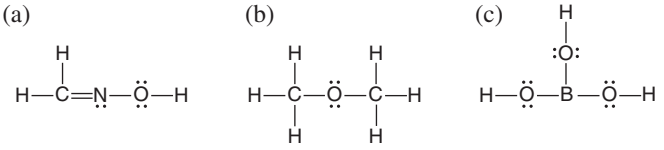
10.44 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:
(a) CH_3COOH (b) H_2O_2

10.45 Determine the shape around each central atom in each molecule, and explain any deviation from ideal bond angles:
(a) H_2SO_3 (no H—S bond) (b) N_2O_3 ($ONNO_2$)

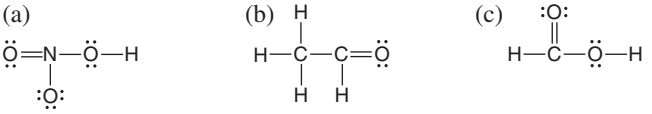
10.46 Arrange the following AF_n species in order of *increasing* F—A—F bond angles: BF_3, BeF_2, CF_4, NF_3, OF_2.

10.47 Arrange the following ACl_n species in order of *decreasing* Cl—A—Cl bond angles: SCl_2, OCl_2, PCl_3, $SiCl_4$, $SiCl_6^{2-}$.

10.48 State an ideal value for each of the bond angles in each molecule, and note where you expect deviations:



10.49 State an ideal value for each of the bond angles in each molecule, and note where you expect deviations:



Problems in Context

10.50 Because both tin and carbon are members of Group 4A(14), they form structurally similar compounds. But tin exhibits a greater variety of structures because it forms several ionic species. Predict the shapes and ideal bond angles, including any deviations:
(a) $Sn(CH_3)_2$ (b) $SnCl_3^-$ (c) $Sn(CH_3)_4$
(d) SnF_5^- (e) SnF_6^{2-}

10.51 In the gas phase, phosphorus pentachloride exists as separate molecules. In the solid phase, however, the compound is composed of alternating PCl_4^+ and PCl_6^- ions. What change(s) in molecular shape occur(s) as PCl_5 solidifies? How does the Cl—P—Cl angle change?

Molecular Shape and Molecular Polarity

(Sample Problem 10.9)

Concept Review Questions

10.52 For molecules of general formula AX_n (where $n > 2$), how do you determine if a molecule is polar?

10.53 How can a molecule with polar covalent bonds not be polar? Give an example.

10.54 Explain in general why the shape of a biomolecule is important to its function.

Skill-Building Exercises (grouped in similar pairs)

10.55 Consider the molecules SCl_2, F_2, CS_2, CF_4, and BrCl.
(a) Which has bonds that are the most polar?
(b) Which molecules have a dipole moment?

10.56 Consider the molecules BF_3, PF_3, BrF_3, SF_4, and SF_6.
(a) Which has bonds that are the most polar?
(b) Which molecules have a dipole moment?

10.57 Which molecule in each pair has the greater dipole moment? Give the reason for your choice.
(a) SO_2 or SO_3 (b) ICl or IF
(c) SiF_4 or SF_4 (d) H_2O or H_2S

10.58 Which molecule in each pair has the greater dipole moment? Give the reason for your choice.
(a) ClO_2 or SO_2 (b) HBr or HCl
(c) $BeCl_2$ or SCl_2 (d) AsF_3 or AsF_5

Problems in Context

10.59 There are three different dichloroethylenes (molecular formula $C_2H_2Cl_2$), which we can designate X, Y, and Z. Compound X has no dipole moment, but compound Z does. Compounds X and Z each combine with hydrogen to give the same product:

$$C_2H_2Cl_2\,(\text{X or Z}) + H_2 \longrightarrow ClCH_2{-}CH_2Cl$$

What are the structures of X, Y, and Z? Would you expect compound Y to have a dipole moment?

10.60 Dinitrogen difluoride, N_2F_2, is the only stable, simple inorganic molecule with an N═N bond. It occurs in *cis* and *trans* forms.
(a) Draw the molecular shapes of the two forms of N_2F_2.
(b) Predict the direction of the polarity, if any, of each form.

Comprehensive Problems

10.61 In addition to ammonia, nitrogen forms three other hydrides: hydrazine (N_2H_4), diazene (N_2H_2), and tetrazene (N_4H_4).
(a) Use Lewis structures to compare the strength, length, and order of the nitrogen-nitrogen bonds in hydrazine, diazene, and N_2.
(b) Tetrazene (atom sequence H_2NNNNH_2) decomposes above 0°C to hydrazine and nitrogen gas. Draw a Lewis structure for tetrazene, and calculate ΔH°_{rxn} for this decomposition.

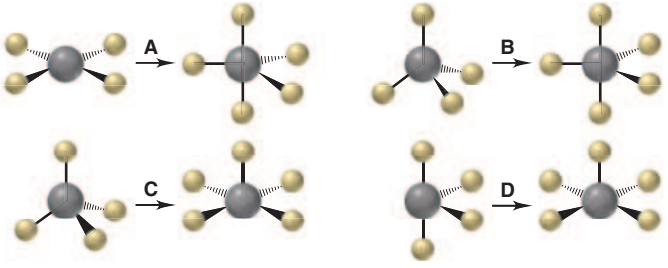
10.62 Draw a Lewis structure for each species: (a) PF_5; (b) CCl_4; (c) H_3O^+; (d) ICl_3; (e) BeH_2; (f) PH_2^-; (g) $GeBr_4$; (h) CH_3^-; (i) BCl_3; (j) BrF_4^+; (k) XeO_3; (l) TeF_4.

10.63 Give the molecular shape of each species in Problem 10.62.

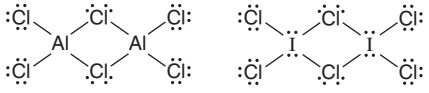
10.64 Consider the following reaction of silicon tetrafluoride:

$$SiF_4 + F^- \longrightarrow SiF_5^-$$

(a) Which depiction below best illustrates the change in molecular shape around Si? (b) Give the name and AX_mE_n designation of each shape in the depiction chosen in part (a).



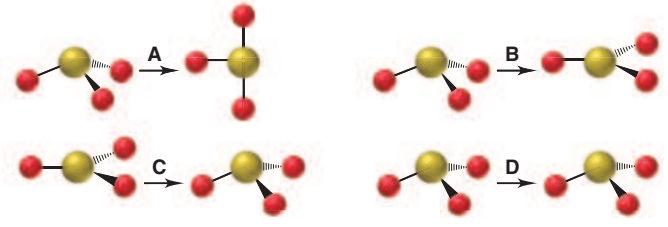
10.65 Both aluminum and iodine form chlorides, Al_2Cl_6 and I_2Cl_6, with "bridging" Cl atoms. The Lewis structures are



(a) What is the formal charge on each atom? (b) Which of these molecules has a planar shape? Explain.

10.66 The VSEPR model was developed before any xenon compounds had been prepared. Thus, these compounds provided an excellent test of the model's predictive power. What would you have predicted for the shapes of XeF_2, XeF_4, and XeF_6?

10.67 When SO_3 gains two electrons, SO_3^{2-} forms. (a) Which depiction best illustrates the change in molecular shape around S? (b) Does molecular polarity change during this reaction?



10.68 The actual bond angle in NO_2 is 134.3°, and in NO_2^- it is 115.4°, although the ideal bond angle is 120° for both. Explain.

10.69 "Inert" xenon actually forms several compounds, especially with the highly electronegative elements oxygen and fluorine. The simple fluorides XeF_2, XeF_4, and XeF_6 are all formed by direct reaction of the elements. As you might expect from the size of the xenon atom, the Xe—F bond is not a strong one. Calculate the Xe—F bond energy in XeF_6, given that the enthalpy of formation is −402 kJ/mol.

10.70 Propylene oxide is used to make many products, including plastics such as polyurethane. One method for synthesizing it involves oxidizing propene with hydrogen peroxide:

$$CH_3{-}CH{=}CH_2 + H_2O_2 \longrightarrow CH_3{-}\underset{\diagdown\,O\,\diagup}{CH}{-}CH_2 + H_2O$$

(a) What is the molecular shape and ideal bond angle around each carbon atom in propylene oxide?
(b) Predict any deviation from the ideal for the actual C—C—C bond angles (assume the three atoms in the ring form an equilateral triangle).

10.71 Chloral, $Cl_3C{-}CH{=}O$, reacts with water to form the sedative and hypnotic agent chloral hydrate, $Cl_3C{-}CH(OH)_2$. Draw Lewis structures for these substances, and describe the change in molecular shape, if any, that occurs around each of the carbon atoms during the reaction.

10.72 Like several other bonds, carbon-oxygen bonds have lengths and strengths that depend on the bond order. Draw Lewis structures for the following species, and arrange them in order of increasing carbon-oxygen bond length and then by increasing carbon-oxygen bond strength: (a) CO; (b) CO_3^{2-}; (c) H_2CO; (d) CH_4O; (e) HCO_3^- (H attached to O).

10.73 In the 1980s, there was an international agreement to destroy all stockpiles of mustard gas, $ClCH_2CH_2SCH_2CH_2Cl$. When this substance contacts the moisture in eyes, nasal passages, and skin, the —OH groups of water replace the Cl atoms and create high local concentrations of hydrochloric acid, which cause severe blistering and tissue destruction. Write a balanced equation for this reaction, and calculate ΔH°_{rxn}.

10.74 The four bonds of carbon tetrachloride (CCl_4) are polar, but the molecule is nonpolar because the bond polarity is canceled by the symmetric tetrahedral shape. When other atoms substitute for some of the Cl atoms, the symmetry is broken and the molecule becomes polar. Use Figure 9.21 (p. 381) to rank the following molecules from the least polar to the most polar: CH_2Br_2, CF_2Cl_2, CH_2F_2, CH_2Cl_2, CBr_4, CF_2Br_2.

10.75 Ethanol (CH_3CH_2OH) is being used as a gasoline additive or alternative in many parts of the world.
(a) Use bond energies to find ΔH°_{rxn} for the combustion of gaseous ethanol. (Assume H_2O forms as a gas.)
(b) In its standard state at 25°C, ethanol is a liquid. Its vaporization requires 40.5 kJ/mol. Correct the value from part (a) to find the enthalpy of reaction for the combustion of liquid ethanol.
(c) How does the value from part (b) compare with the value you calculate from standard enthalpies of formation (Appendix B)?
(d) "Greener" methods produce ethanol from corn and other plant material, but the main industrial method involves hydrating ethylene from petroleum. Use Lewis structures and bond energies to calculate ΔH°_{rxn} for the formation of gaseous ethanol from ethylene gas with water vapor.

10.76 In the following compounds, the C atoms form a single ring. Draw a Lewis structure for each compound, identify cases

for which resonance exists, and determine the carbon-carbon bond order(s): (a) C_3H_4; (b) C_3H_6; (c) C_4H_6; (d) C_4H_4; (e) C_6H_6.

10.77 An experiment requires 50.0 mL of 0.040 *M* NaOH for the titration of 1.00 mmol of acid. Mass analysis of the acid shows 2.24% hydrogen, 26.7% carbon, and 71.1% oxygen. Draw the Lewis structure of the acid.

10.78 A gaseous compound has a composition by mass of 24.8% carbon, 2.08% hydrogen, and 73.1% chlorine. At STP, the gas has a density of 4.3 g/L. Draw a Lewis structure that fits these facts. Would another structure be equally satisfactory? Explain.

10.79 Perchlorates are powerful oxidizing agents used in fireworks, flares, and the booster rockets of space shuttles. Lewis structures for the perchlorate ion (ClO_4^-) can be drawn with all single bonds or with one, two, or three double bonds. Draw each of these possible resonance forms, use formal charges to determine the most important, and calculate its average bond order.

10.80 Methane burns in oxygen to form carbon dioxide and water vapor. Hydrogen sulfide burns in oxygen to form sulfur dioxide and water vapor. Use bond energies (Table 9.2, p. 371) to determine the enthalpy of each reaction per mole of O_2 (assume Lewis structures with zero formal charges; BE of S═O is 552 kJ/mol).

10.81 Use Lewis structures to determine which *two* of the following are unstable: (a) SF_2; (b) SF_3; (c) SF_4; (d) SF_5; (e) SF_6.

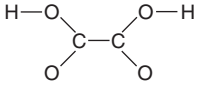
10.82 A major short-lived, neutral species in flames is OH.
(a) What is unusual about the electronic structure of OH?
(b) Use the standard enthalpy of formation of OH(*g*) (39.0 kJ/mol) and bond energies to calculate the O—H bond energy in OH(*g*).
(c) From the average value for the O—H bond energy in Table 9.2 (p. 371) and your value for the O—H bond energy in OH(*g*), find the energy needed to break the first O—H bond in water.

10.83 Pure HN_3 (atom sequence HNNN) is explosive. In aqueous solution, it is a weak acid that yields the azide ion, N_3^-. Draw resonance structures to explain why the nitrogen-nitrogen bond lengths are equal in N_3^- but unequal in HN_3.

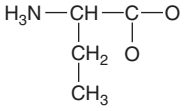
10.84 Except for nitrogen, the elements of Group 5A(15) all form pentafluorides, and most form pentachlorides. The chlorine atoms of PCl_5 can be replaced with fluorine atoms one at a time to give, successively, PCl_4F, PCl_3F_2, … , PF_5. (a) Given the sizes of F and Cl, would you expect the first two F substitutions to be at axial or equatorial positions? Explain. (b) Which of the five fluorine-containing molecules have no dipole moment?

10.85 Dinitrogen monoxide (N_2O) supports combustion in a manner similar to oxygen, with the nitrogen atoms forming N_2. Draw three resonance structures for N_2O (one N is central), and use formal charges to decide the relative importance of each. What correlation can you suggest between the most important structure and the observation that N_2O supports combustion?

10.86 Oxalic acid ($H_2C_2O_4$) is found in toxic concentrations in rhubarb leaves. The acid forms two ions, $HC_2O_4^-$ and $C_2O_4^{2-}$, by the sequential loss of H^+ ions. Draw Lewis structures for the three species, and comment on the relative lengths and strengths of their carbon-oxygen bonds. The connections among the atoms are shown below with single bonds only.



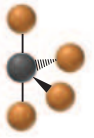
10.87 The Murchison meteorite that landed in Australia in 1969 contained 92 different amino acids, including 21 found in Earth organisms. A skeleton structure (single bonds only) of one of these extraterrestrial amino acids is shown below.



Draw a Lewis structure, and identify any atoms having a nonzero formal charge.

10.88 Hydrazine (N_2H_4) is used as a rocket fuel because it reacts very exothermically with oxygen to form nitrogen gas and water vapor. The heat released and the increase in number of moles of gas provide thrust. Calculate the enthalpy of reaction.

10.89 A student isolates a product with the molecular shape shown at right (F is orange). (a) If the species is a neutral compound, can the black sphere represent selenium (Se)? (b) If the species is an anion, can the black sphere represent N? (c) If the black sphere represents Br, what is the charge of the species?



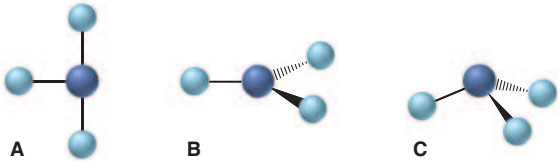
10.90 When gaseous sulfur trioxide is dissolved in concentrated sulfuric acid, disulfuric acid forms:

$$SO_3(g) + H_2SO_4(l) \longrightarrow H_2S_2O_7(l)$$

Use bond energies (Table 9.2, p. 371) to determine ΔH°_{rxn}. (The S atoms in $H_2S_2O_7$ are bonded through an O atom. Assume Lewis structures with zero formal charges; BE of S═O is 552 kJ/mol.)

10.91 A molecule of formula AY_3 is found experimentally to be polar. Which molecular shapes are possible and which are impossible for AY_3?

10.92 Consider the following molecular shapes:



(a) Match each shape with one of the following species: XeF_3^+, $SbBr_3$, $GaCl_3$.
(b) Which, if any, is polar?
(c) Which has the most valence electrons around the central atom?

10.93 Hydrogen cyanide can be catalytically reduced with hydrogen to form methylamine. Use Lewis structures and bond energies to determine ΔH°_{rxn} for

$$HCN(g) + 2H_2(g) \longrightarrow CH_3NH_2(g)$$

10.94 Ethylene, C_2H_4, and tetrafluoroethylene, C_2F_4, are used to make the polymers polyethylene and polytetrafluoroethylene (Teflon), respectively.
(a) Draw the Lewis structures for C_2H_4 and C_2F_4, and give the ideal H—C—H and F—C—F bond angles.
(b) The actual H—C—H and F—C—F bond angles are 117.4° and 112.4°, respectively. Explain these deviations.

10.95 Using bond lengths in Table 9.2 (p. 371) and assuming ideal geometry, calculate each of the following distances:
(a) Between H atoms in C_2H_2
(b) Between F atoms in SF_6 (two answers)
(c) Between equatorial F atoms in PF_5

10.96 Phosphorus pentachloride, a key industrial compound with annual world production of about 2×10^7 kg, is used to make other compounds. It reacts with sulfur dioxide to produce phosphorus oxychloride ($POCl_3$) and thionyl chloride ($SOCl_2$). Draw a Lewis structure and name the molecular shape of each of these products.

Concepts and Skills to Review Before You Study This Chapter

- atomic orbital shapes (Section 7.4)
- exclusion principle (Section 8.1)
- Hund's rule (Section 8.2)
- Lewis structures (Section 10.1)
- resonance in covalent bonding (Section 10.1)
- molecular shapes (Section 10.2)
- molecular polarity (Section 10.3)

All scientific models have limitations because they are simplifications of reality. The VSEPR theory, covered in Chapter 10, accounts for molecular shapes, but it doesn't explain how they arise from atomic orbitals. After all, the orbitals described in Chapter 7 aren't oriented toward the corners of, say, a trigonal bipyramid, like the one at left for phosphorus in PF_5. Moreover, knowing the shape doesn't help us explain the magnetic and spectral properties of molecules; only an understanding of their orbitals and energy levels can.

The two theories presented in this chapter focus on different questions and complement each other. Don't be concerned if we need several models to explain a complex phenomenon like bonding. In every science, one model may account for some aspect of a topic better than another, and several are employed to explain a wider range of phenomena.

IN THIS CHAPTER . . . *We introduce two theories of bonding in molecules based on the interactions of the orbitals of their atoms.*

- We discuss valence bond (VB) theory, which rationalizes molecular shapes through interactions of atomic orbitals during bonding to form hybrid orbitals.
- We apply VB theory to sigma and pi bonds, the two types of covalent bonds.
- We see why parts of molecules don't rotate freely around multiple bonds, which has major effects on reactivity, physical properties, and biological behavior.
- We discuss molecular orbital (MO) theory, which explains molecular energy levels and properties through formation of orbitals that spread over the whole molecule.
- We apply MO theory to understand key properties of some diatomic and simple polyatomic molecules.

11.1 VALENCE BOND (VB) THEORY AND ORBITAL HYBRIDIZATION

What *is* a covalent bond, and what characteristic gives it strength? And how can we explain *molecular* shapes based on the interactions of *atomic* orbitals? One very useful approach for answering these questions is based on quantum mechanics (Chapter 7) and called **valence bond (VB) theory.**

The Central Themes of VB Theory

The basic principle of VB theory is that *a covalent bond forms when orbitals of two atoms overlap and a pair of electrons occupy the overlap region.* In the terminology of quantum mechanics, overlap of the two orbitals means their wave functions are *in phase* (constructive interference; see Figure 7.5, p. 291), so the amplitude between the nuclei increases. The central themes of VB theory derive from this principle:

1. *Opposing spins of the electron pair.* As the exclusion principle (Section 8.1) requires, the space formed by the overlapping orbitals *has a maximum capacity for two electrons that have opposite (paired) spins.* In the simplest case, a molecule of H_2 forms when the 1*s* orbitals of two H atoms overlap, and the electrons, with their spins paired, spend more time in the overlap region (up and down arrows in Figure 11.1).

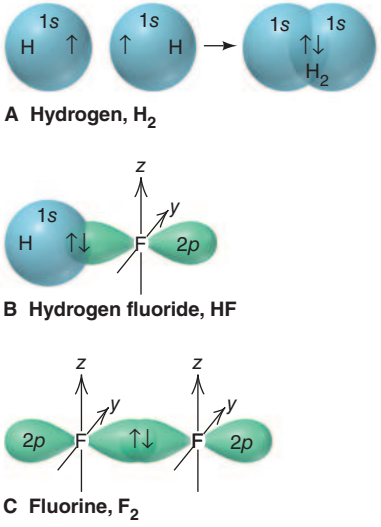

Figure 11.1 Orbital overlap and spin pairing in three diatomic molecules. (In **B** and **C,** the $2p_x$ orbital is shown bonding; the other two 2*p* orbitals of F are omitted for clarity.)

2. *Maximum overlap of bonding orbitals.* Bond strength depends on the attraction between nuclei and shared electrons, so *the greater the orbital overlap, the closer the nuclei are to the electrons, and the stronger the bond.* Extent of overlap depends on orbital shape and direction. An *s* orbital is spherical, but *p* and *d* orbitals have specified directions. Thus, a *p* or *d* orbital involved in a bond is oriented so as to *maximize overlap*. In HF, for example, the 1*s* orbital of H overlaps a half-filled 2*p* orbital of F *along its long axis* (Figure 11.1B). In F_2, the two half-filled 2*p* orbitals interact end to end, that is, *along their long axes* (Figure 11.1C).

3. *Hybridization of atomic orbitals.* To account for the bonding in diatomic molecules like HF and F_2, we picture direct overlap of *s* and/or *p* orbitals of isolated atoms. But how can we account for the shape of a molecule like methane from the shapes and orientations of C and H atomic orbitals? A C atom ([He] $2s^2 2p^2$) has two valence electrons in the spherical 2*s* orbital and one each in two of the three mutually perpendicular 2*p* orbitals. If the half-filled *p* orbitals overlap the 1*s* orbitals of two H atoms, *two* C—H bonds would form with a 90° H—C—H bond angle. But methane has the formula CH_4, not CH_2, and its bond angles are 109.5°.

To explain such facts, Linus Pauling proposed that, during bonding, *the valence orbitals in the isolated atoms become* ***new*** *orbitals in the molecule.* Quantum-mechanical calculations show that if we mathematically "mix" certain combinations of orbitals, we form new ones whose spatial orientations *do* match the observed molecular shapes. The process of orbital mixing is called **hybridization,** and the new atomic orbitals are called **hybrid orbitals.**

4. *Features of hybrid orbitals.* Here are some central points about the hybrid orbitals that form during bonding:

- The *number* of hybrid orbitals formed *equals* the number of atomic orbitals mixed.
- The *type* of hybrid orbitals formed *varies* with the types of atomic orbitals mixed.
- The *shape* and *orientation* of a hybrid orbital *maximize* its overlap with the orbital of the other atom in the bond.

It is useful to think of hybridization as a process in which atomic orbitals mix, hybrid orbitals form, they overlap other orbitals, and electrons enter the overlap region with opposing spins, thus forming stable bonds. In truth, hybridization is a mathematical concept that helps us explain the molecular shapes we observe.

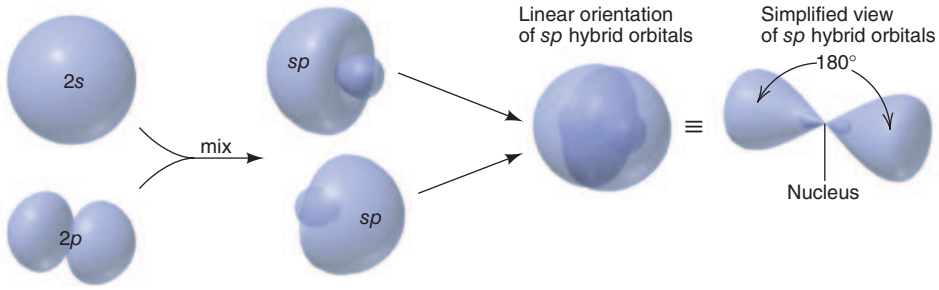
Types of Hybrid Orbitals

We postulate the type of hybrid orbitals in a molecule *after* we observe its shape. Note that the orientations of the five types of hybrid orbitals we discuss next correspond to the five electron-group arrangements in VSEPR theory.

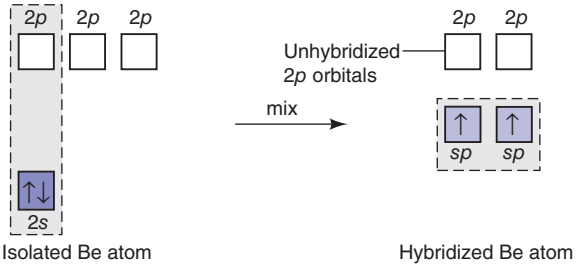
***sp* Hybridization** When two electron groups surround the central atom, we observe a linear shape.

1. *Orbitals mixed and orbitals formed.* VB theory explains this linear orientation by proposing that two *nonequivalent* orbitals of a central atom, one *s* and one *p*, mix and form two *equivalent* ***sp*** **hybrid orbitals** that are oriented 180° apart (Figure 11.2A). The shape of these hybrid orbitals, with one large and one small lobe, differs markedly from the shapes of the atomic orbitals that were mixed. The orbital orientations increase electron density *in the bonding direction* and minimize repulsions between the electrons that occupy the orbitals.

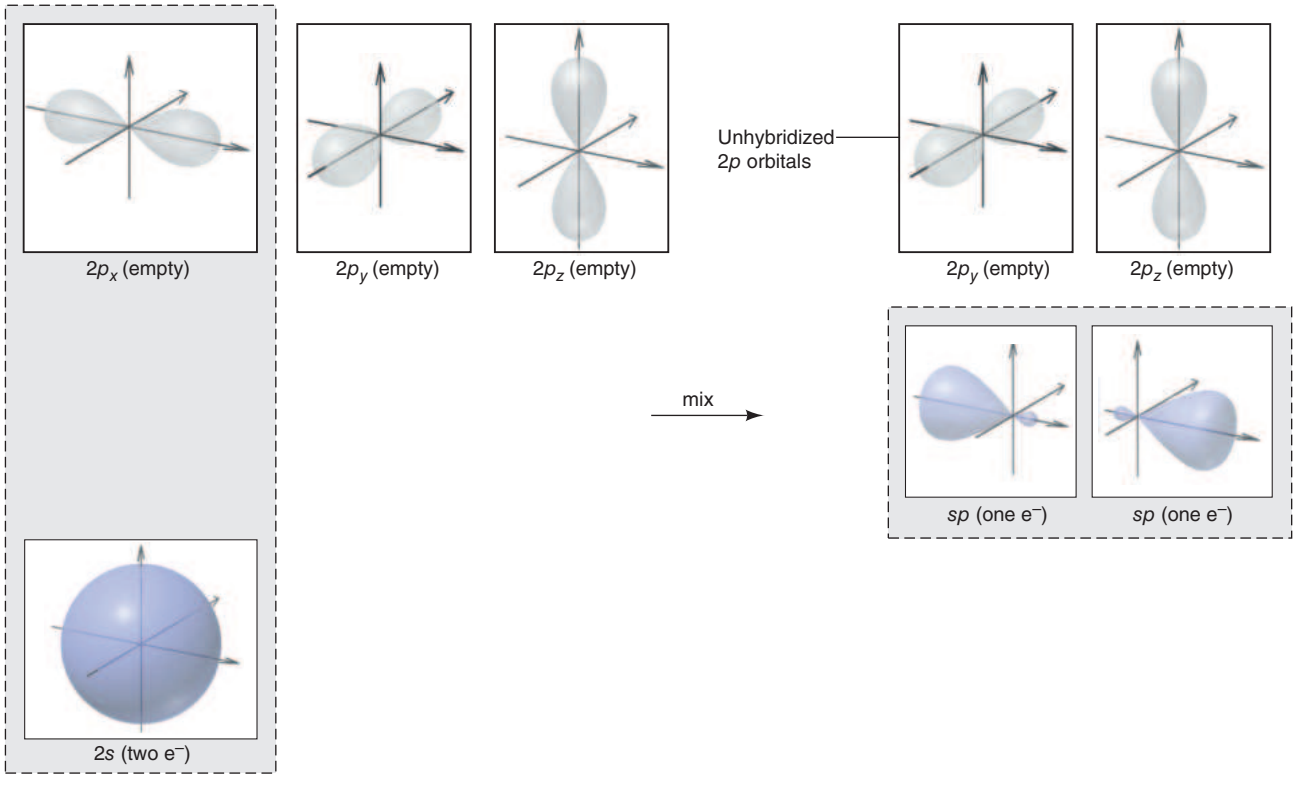
2. *Overlap of orbitals from central and surrounding atoms: $BeCl_2$.* In beryllium chloride, the Be atom is *sp* hybridized. Figure 11.2B depicts the hybridization of Be in an orbital box diagram, and Figure 11.2C shows an orbital box diagram with shaded contours instead of arrows. Bond formation with Cl is shown in Figure 11.2D. The filled 2*s* and one of the three empty 2*p* orbitals of Be mix and form two half-filled *sp* orbitals. Two empty unhybridized 2*p* orbitals of Be lie perpendicular to each other and to the *sp* hybrids. The hybrid orbitals overlap the half-filled 3*p* orbital in each of two Cl atoms. The four electrons—two from Be and one from each Cl—appear as



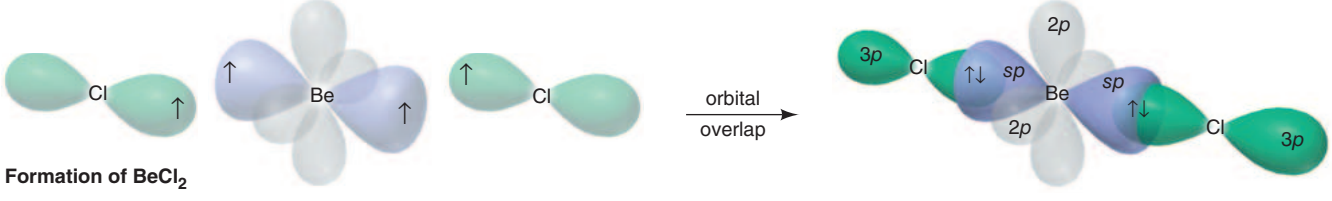
A Formation of *sp* hybrid orbitals



B Hybridization shown through orbital box diagram



C Hybridization shown through box diagram with orbital contours



D Formation of $BeCl_2$

Figure 11.2 Formation and orientation of *sp* hybrid orbitals and the bonding in $BeCl_2$. A, One 2*s* and one 2*p* atomic orbital mix to form two *sp* hybrid orbitals. (The simplified hybrid orbitals at far right are used elsewhere, often even without the small lobe.) **B,** The orbital box diagram for hybridization of Be, drawn vertically. (Full, partial, or no shading indicate orbital occupancy.) **C,** The orbital box diagram with orbital contours. **D,** Overlap of Be and Cl orbitals to form $BeCl_2$. (Simplified hybrid orbitals are shown for Be; only the 3*p* orbital of Cl that is involved in bonding is shown.)

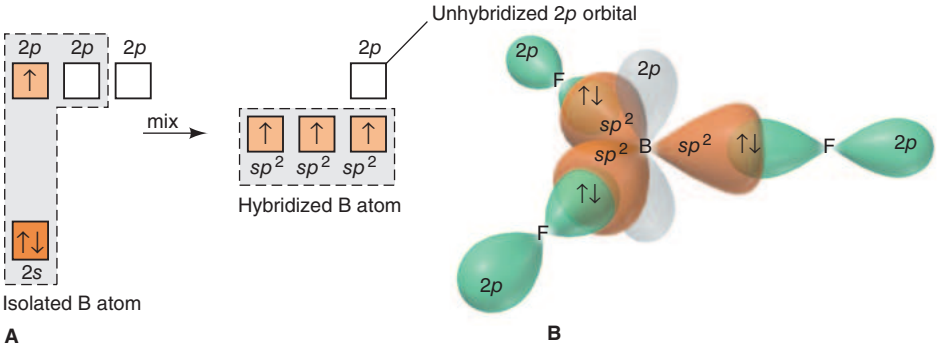


Figure 11.3 **The sp^2 hybrid orbitals in BF_3.** **A,** The orbital box diagram shows the formation of three sp^2 hybrid orbitals. One $2p$ orbital is unhybridized and empty. **B,** Contour depiction of BF_3.

pairs with opposite spins in the two overlap regions. (The $3p$ and sp hybrid orbitals that are partially colored on the left become fully colored on the right, after the bonds form and each orbital is filled with two electrons.)

sp^2 Hybridization We use this type of hybridization to explain the two shapes possible for the trigonal planar electron-group arrangement.

1. *Orbitals mixed and orbitals formed.* Mixing one s and two p orbitals gives three **sp^2 hybrid orbitals** that point to the corners of an equilateral triangle, their axes 120° apart. (In hybrid-orbital notations, unlike in electron configurations, superscripts indicate the number of *atomic orbitals* of a given type, *not* the number of *electrons* in the orbital: thus, one s and two p orbitals give s^1p^2, or sp^2.) The third $2p$ orbital remains unhybridized.

2. *Overlap of orbitals from central and surrounding atoms: BF_3.* The central B atom in BF_3 is sp^2 hybridized, with the three sp^2 orbitals in a trigonal plane and the third $2p$ orbital unhybridized and perpendicular to this plane (Figure 11.3). Each half-filled sp^2 orbital overlaps the half-filled $2p$ orbital of an F atom, and the six valence electrons—three from B and one from each of the three F atoms—form three bonding pairs.

3. *Placement of lone pairs.* To account for other molecular shapes within a given electron-group arrangement, one or more hybrid orbitals contains a lone pair. In ozone (O_3), for example, the shape is bent because the central O is sp^2 hybridized and a lone pair fills one of the three sp^2 orbitals.

sp^3 Hybridization Let's return to the question posed earlier about the shape of methane. The type of hybridization that accounts for methane's shape applies to any species with a tetrahedral electron-group arrangement.

1. *Orbitals mixed and orbitals formed.* Mixing one s and three p orbitals gives four **sp^3 hybrid orbitals** that point to the corners of a tetrahedron.

2. *Overlap of orbitals from central and surrounding atoms: CH_4.* The C atom in methane is sp^3 hybridized. Its four valence electrons half-fill the four sp^3 hybrids, which overlap the half-filled $1s$ orbitals of four H atoms to form four C—H bonds (Figure 11.4).

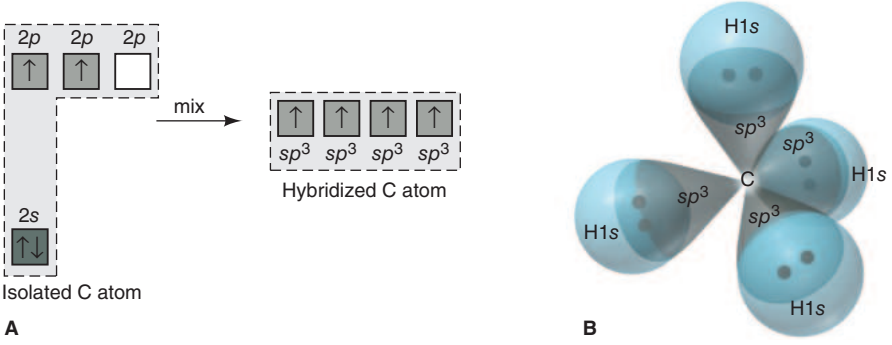

Figure 11.4 **The sp^3 hybrid orbitals in CH_4.** **A,** The orbital box diagram shows formation of four sp^3 hybrids. **B,** Contour depiction of CH_4, with electron pairs shown as dots.

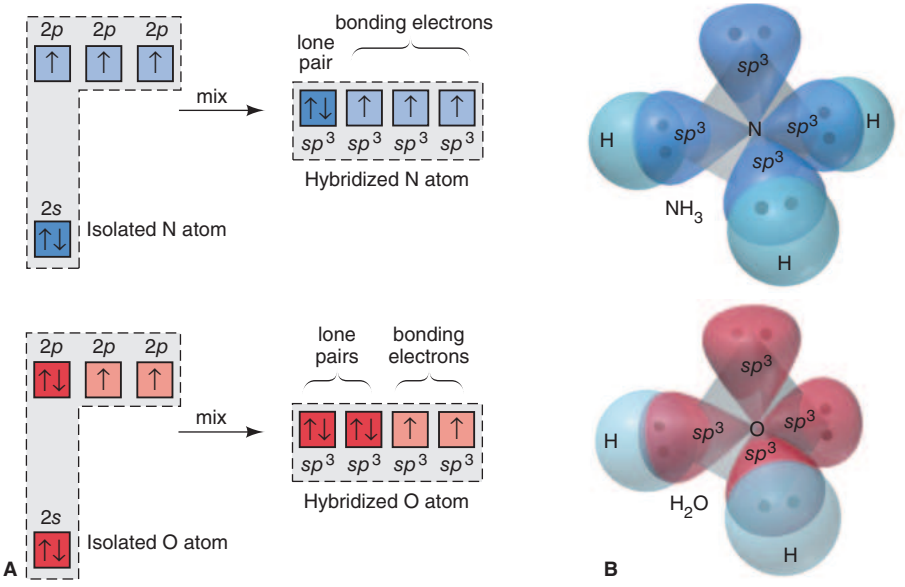

Figure 11.5 **The sp^3 hybrid orbitals in NH_3 and H_2O. A,** The orbital box diagrams show sp^3 hybridization, with lone pairs filling one (NH_3) or two (H_2O) hybrid orbitals. **B,** Contour depictions.

3. *Placement of lone pairs*. The trigonal pyramidal shape of NH_3 arises because a lone pair fills any one of the four sp^3 orbitals of N, and the bent shape of H_2O arises because lone pairs fill any two of the sp^3 orbitals of O (Figure 11.5).

sp^3d Hybridization Molecules with shapes due to the trigonal bipyramidal electron-group arrangement must have central atoms from Period 3 or higher, because *d* orbitals, as well as *s* and *p* orbitals, are mixed to form the hybrid orbitals.

1. *Orbitals mixed and orbitals formed*. Mixing one 3*s*, the three 3*p*, and one of the five 3*d* orbitals gives five ***sp^3d* hybrid orbitals,** which point to the corners of a trigonal bipyramid.

2. *Overlap of orbitals from central and surrounding atoms: PCl_5*. The P atom in PCl_5 is sp^3d hybridized. Each hybrid orbital overlaps a 3*p* orbital of a Cl atom, and ten valence electrons—five from P and one from each of the five Cl atoms—form five P—Cl bonds (Figure 11.6).

3. *Placement of lone pairs*. Seesaw, T-shaped, and linear molecules have lone pairs in one, two, or three of the central atom's sp^3d orbitals, respectively.

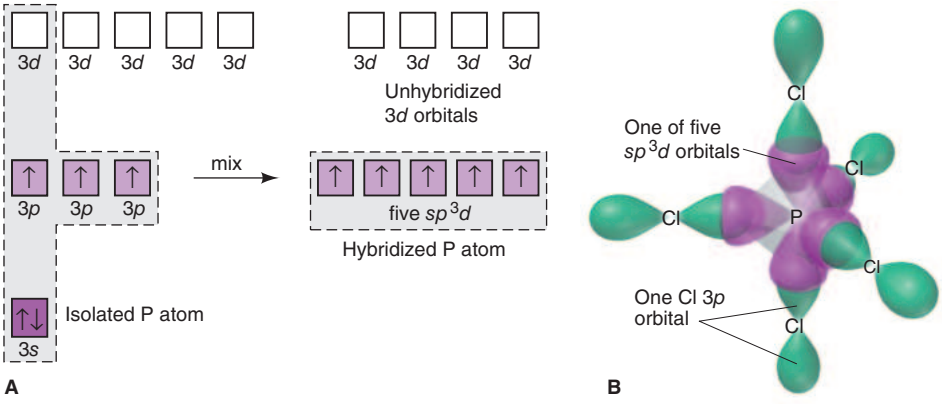

Figure 11.6 **The sp^3d hybrid orbitals in PCl_5. A,** The orbital box diagram shows the formation of five half-filled sp^3d orbitals. Four 3*d* orbitals are unhybridized and empty. **B,** Contour depiction of PCl_5. (For clarity, the unhybridized 3*d* orbitals of P, the other two 3*p* orbitals of Cl, and the five bonding P—Cl pairs are not shown.)

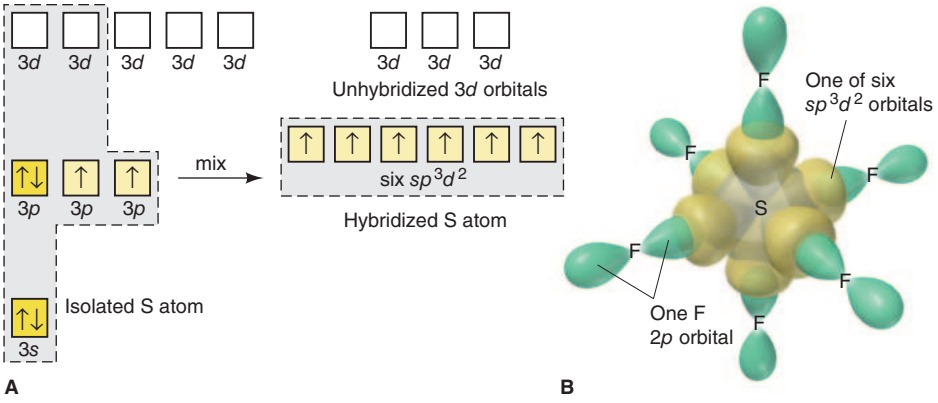

Figure 11.7 **The sp^3d^2 hybrid orbitals in SF_6. A,** The orbital box diagram shows formation of six half-filled sp^3d^2 orbitals; three 3*d* orbitals remain unhybridized and empty. **B,** Contour depiction of SF_6.

sp^3d^2 Hybridization The VB model proposes that molecules with shapes having the octahedral electron-group arrangement use two *d* orbitals to form hybrids.

1. *Orbitals mixed and orbitals formed.* Mixing one 3*s*, the three 3*p*, and two 3*d* orbitals gives six **sp^3d^2 hybrid orbitals,** which point to the corners of an octahedron.

2. *Overlap of orbitals from central and surrounding atoms: SF_6.* The S atom in SF_6 is sp^3d^2 hybridized. Each half-filled hybrid orbital overlaps a half-filled 2*p* orbital of an F atom, and 12 valence electrons—six from S and one from each of the six F atoms—form six S—F bonds (Figure 11.7).

3. *Placement of lone pairs.* Square pyramidal and square planar molecules have lone pairs in one and two of the central atom's sp^3d^2 orbitals, respectively.

Table 11.1 summarizes the numbers and types of atomic orbitals that mix to form the five types of hybrid orbitals. Once again, note the similarities between hybrid-orbital orientations and the shapes predicted by VSEPR theory. Figure 11.8 shows three conceptual steps from a molecular formula to the hybrid orbitals in the molecule, and Sample Problem 11.1 focuses on the last step of that process.

Table 11.1 Composition and Orientation of Hybrid Orbitals

	Linear	Trigonal Planar	Tetrahedral	Trigonal Bipyramidal	Octahedral
Atomic orbitals mixed	one *s* one *p*	one *s* two *p*	one *s* three *p*	one *s* three *p* one *d*	one *s* three *p* two *d*
Hybrid orbitals formed	two *p*	three sp^2	four sp^3	five sp^3d	six sp^3d^2
Unhybridized orbitals remaining	two *p*	one *p*	none	four *d*	three *d*
Orientation

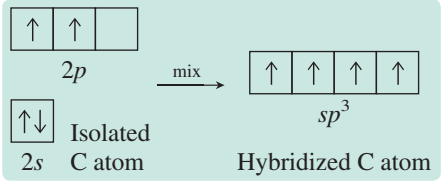
SAMPLE PROBLEM 11.1 Postulating Hybrid Orbitals in a Molecule

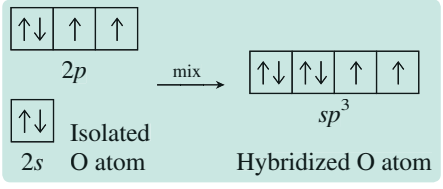
Problem Use partial orbital diagrams to describe how mixing the atomic orbitals of the central atom(s) leads to the hybrid orbitals in each of the following:
(a) Methanol, CH_3OH **(b)** Sulfur tetrafluoride, SF_4

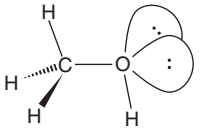
Plan Prior to the Solution steps below, we have used the molecular formula to draw the Lewis structure and determined the electron-group arrangement of each central atom. Then, starting from there, we use Table 11.1 to postulate the type of hybrid orbitals. We write the partial orbital diagram for each central atom before and after the orbitals are hybridized.

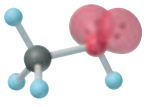
Solution **(a)** For CH_3OH. The electron-group arrangement is tetrahedral around both the C and the O atom, so each of them mixed one $2s$ and three $2p$ to become sp^3 hybridized. The C atom has four half-filled sp^3 orbitals:



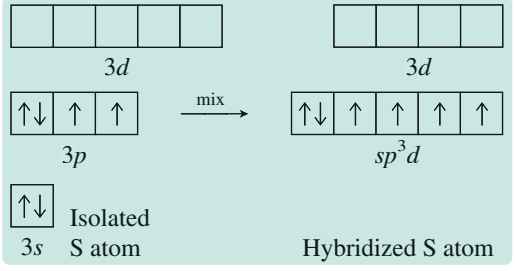
The O atom has two half-filled sp^3 orbitals and two filled with lone pairs:

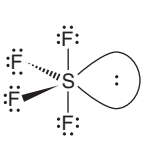


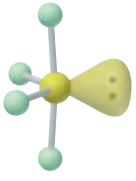




(b) For SF_4. The electron-group arrangement is trigonal bipyramidal, so the central S atom is sp^3d hybridized, which means one $3s$, three $3p$, and one $3d$ orbital were mixed. One hybrid orbital is filled with a lone pair, and four are half-filled. Four unhybridized $3d$ orbitals remain empty:







FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

11.1A Use partial orbital diagrams to show how the atomic orbitals of the central atom mix to form hybrid orbitals in **(a)** beryllium fluoride, BeF_2; **(b)** silicon tetrachloride, $SiCl_4$; **(c)** xenon tetrafluoride, XeF_4.

11.1B Use partial orbital diagrams to show how the atomic orbitals of the central atom mix to form hybrid orbitals in **(a)** nitrogen dioxide, NO_2; **(b)** phosphorus trichloride, PCl_3; **(c)** bromine pentafluoride, BrF_5.

SOME SIMILAR PROBLEMS 11.15–11.18

Limitations to the Concept of Hybridization We rely on the VSEPR and VB theories to explain an observed molecular shape. In some cases, however, the theories may not be consistent with other findings.

1. *Hybridization does not apply: large nonmetal hydrides.* Consider the Lewis structure and bond angle of H_2S:

Based on VSEPR theory, we would predict that, as in H_2O, the four electron groups around H_2S point to the corners of a tetrahedron, and the two lone pairs compress the H—S—H bond angle below the ideal 109.5°. Based on VB theory, we would propose that the 3*s* and 3*p* orbitals of the S atom mix and form four sp^3 hybrids, two of which are filled with lone pairs, while the other two overlap 1*s* orbitals of two H atoms and are filled with bonding pairs.

But observation does *not* support these arguments. The bond angle of 92° is close to the 90° angle between *unhybridized p* orbitals. Similar angles occur in the hydrides of other large nonmetals of Groups 5A(15) and 6A(16). Why apply a theory if the facts don't warrant it? Real factors—bond length, atomic size, and electrostatic repulsions—influence shape. Larger atoms form longer bonds to H, which decreases repulsions; thus, overlap of *unhybridized* orbitals adequately explains these shapes.

2. *d-Orbital hybridization is less important: shapes with expanded valence shells.* Quantum-mechanical calculations show that *d* orbitals have such high energies that they do not hybridize effectively with the *much* more stable *s* and *p* orbitals of a given *n* value. Thus, for example, some have proposed that SF_6 is most stable when the bonding orbitals of the central S use a combination of *sp* hybrid orbitals and unhybridized 3*p* orbitals instead of sp^3d^2 hybrid orbitals. Others prefer explanations that involve molecular orbitals or even ionic structures. These topics are beyond the scope of this text, and while they are being actively debated, we will continue to use the traditional, though limited, approach of including *d*-orbital hybridization for molecules with expanded valence shells.

Summary of Section 11.1

- VB theory explains that a covalent bond forms when two atomic orbitals overlap and two electrons with paired (opposite) spins occupy the overlap region.
- To explain molecular shape, the theory proposes that, during bonding, atomic orbitals mix to form hybrid orbitals with a different shape and direction. This process gives rise to greater overlap and, thus, stronger bonds.
- Based on the observed molecular shape (and the related electron-group arrangement), we postulate the type of hybrid orbital that accounts for the shape. In many cases, especially molecules with larger central atoms, the concept of hybridization has major limitations.

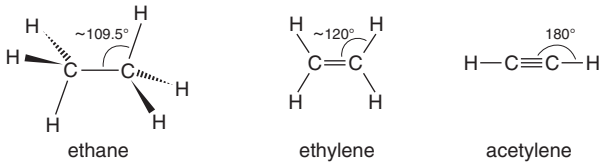
11.2 MODES OF ORBITAL OVERLAP AND THE TYPES OF COVALENT BONDS

Orbitals can overlap by two *modes*—end to end or side to side—which gives rise to two types of covalent bonds—*sigma* and *pi*. We'll use VB theory to describe the two types here; as you'll see, they are described by molecular orbital theory as well.

Orbital Overlap in Single and Multiple Bonds

Ethane (C_2H_6), ethylene (C_2H_4), and acetylene (C_2H_2) have different shapes. Ethane is tetrahedral at both carbons with bond angles near the ideal 109.5°. Ethylene is trigonal

planar at both carbons with bond angles near the ideal 120°. Acetylene is linear with bond angles of 180°:



In these molecules, two modes of orbital overlap result in two types of bonds.

End-to-End Overlap and Sigma (σ) Bonding Both C atoms of ethane are sp^3 hybridized (Figure 11.9). The C—C bond arises from overlap of the end of one sp^3 orbital with the end of the other. *End-to-end* overlap forms a **sigma (σ) bond,** which has its *highest electron density along the bond axis* and is shaped like an ellipse rotated about its long axis (like a football). *All single bonds are σ bonds,* including the six C—H bonds in ethane.

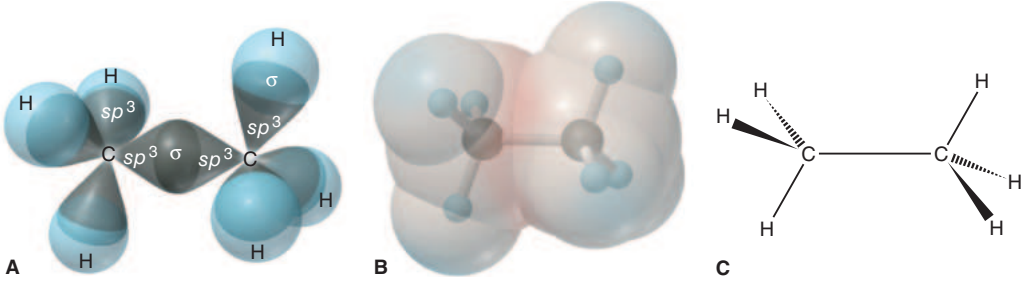


Figure 11.9 The σ bonds in ethane (C_2H_6). A, Depiction using atomic contours. **B,** An electron density model shows very slightly positive *(blue)* and negative *(red)* regions. **C,** Wedge-bond perspective drawing.

Side-to-Side Overlap and Pi (π) Bonding For this type of bonding, we'll examine ethylene and acetylene:

1. *In ethylene,* each C atom is sp^2 hybridized. The four valence electrons of C half-fill the three sp^2 orbitals *and* the unhybridized 2*p* orbital, which lies perpendicular to the sp^2 plane (Figure 11.10). Two sp^2 orbitals of each C form C—H σ bonds. The third sp^2 orbital forms a σ bond with the other C. With the σ-bonded C atoms near each other, their half-filled 2*p* orbitals overlap *side to side,* forming a **pi (π) bond.** It has *two regions (lobes) of electron density,* one above and one below the σ-bond axis. *The two electrons in one π bond occupy both lobes. A double bond consists of one σ bond and one π bond,* which increases electron density between the nuclei (Figure 11.10D). The two electron pairs act as one electron group because each pair occupies a different orbital, which reduces repulsions.

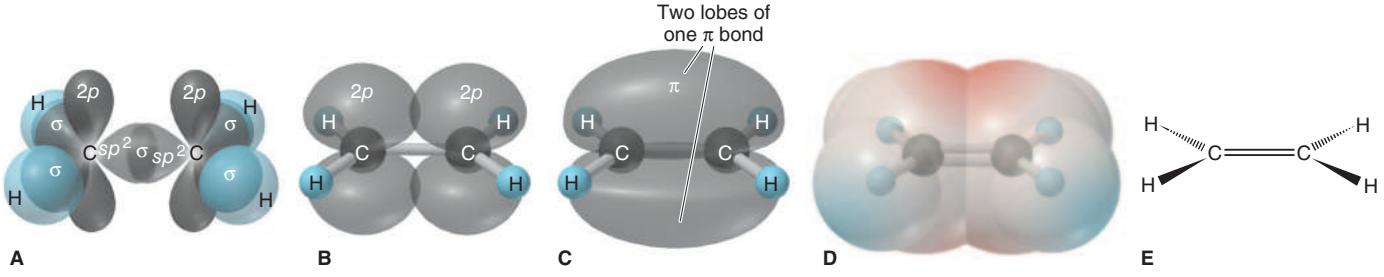

Figure 11.10 The σ and π bonds in ethylene (C_2H_4). A, The C—C σ bond and the four C—H σ bonds are shown with the unhybridized 2*p* orbitals. **B,** An accurate depiction of the 2*p* orbitals shows the side-to-side overlap; σ bonds are shown in ball-and-stick form. **C,** Two overlapping regions comprise *one* π bond, which is occupied by two electrons. **D,** With four electrons (one σ bond and one π bond) between the C atoms, electron density *(red)* is higher there. **E,** Wedge-bond perspective drawing.

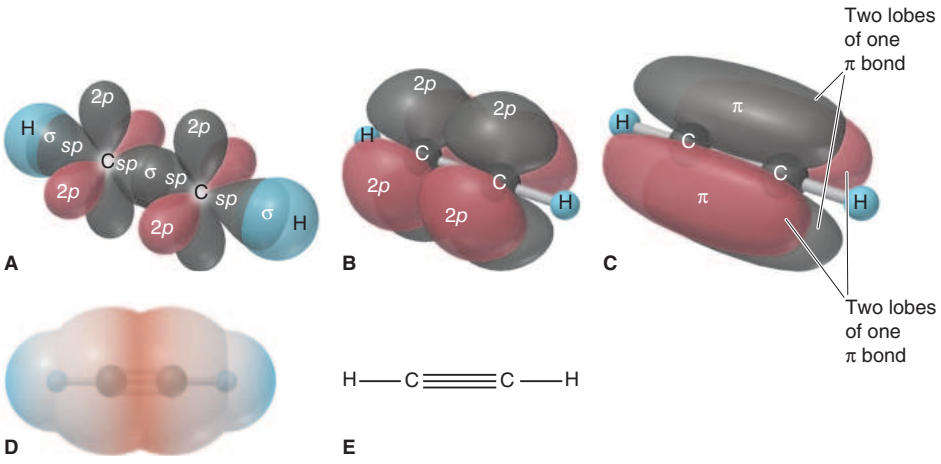

Figure 11.11 **The σ bonds and π bonds in acetylene (C_2H_2).** **A,** A contour depiction shows the C—C σ bond, the two C—H σ bonds, and two unhybridized 2*p* orbitals (one pair is in *red* for clarity). **B,** The 2*p* orbitals (accurate form) overlap side to side; σ bonds are shown by a ball-and-stick model. **C,** Overlapping regions of two π bonds, one black and the other red. **D,** The molecule has cylindrical symmetry. Six electrons (one σ bond and two π bonds) create even higher electron density *(red)* between the C atoms. **E,** Bond-line drawing.

2. *In acetylene,* each C atom is *sp* hybridized, and its four valence electrons half-fill the two *sp* hybrids *and* the two unhybridized 2*p* orbitals (Figure 11.11). Each C forms a C—H σ bond with one *sp* orbital and a C—C σ bond with the other. Side-to-side overlap of one pair of 2*p* orbitals gives one π bond, with electron density above and below the σ bond. Side-to-side overlap of the other pair of 2*p* orbitals gives another π bond, 90° away from the first, with electron density in front and back of the σ bond. The result is a *cylindrically symmetrical* H—C≡C—H molecule. Note the greater electron density between the C atoms created by the six bonding electrons. Any triple bond *consists of one* σ *and two* π *bonds*.

Mode of Overlap, Bond Strength, and Bond Order Because orbitals overlap less side to side than they do end to end, a π bond is weaker than a σ bond; thus, for carbon-carbon bonds, a double bond is less than twice as strong as a single bond (Table 9.2, p. 371). Figure 11.12 shows electron density relief maps of the three types of carbon-carbon bonds; note the increasing electron density between the nuclei from single to double to triple bond.

Lone-pair repulsions, bond polarities, and other factors affect overlap between other pairs of atoms. Nevertheless, as a rough approximation, in terms of bond order (BO), a double bond (BO = 2) is about twice as strong as a single bond (BO = 1), and a triple bond (BO = 3) is about three times as strong.

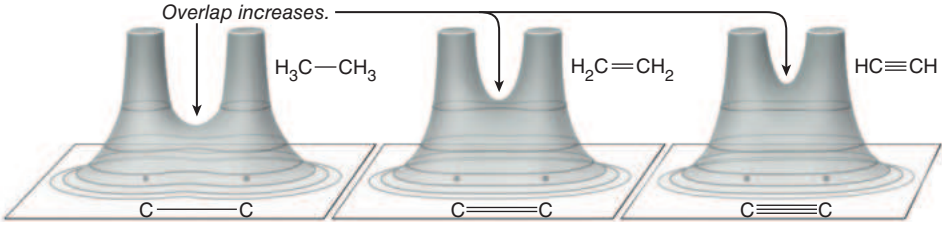

Figure 11.12 **Electron density and bond order in ethane, ethylene, and acetylene.**

SAMPLE PROBLEM 11.2 Describing the Types of Bonds in Molecules

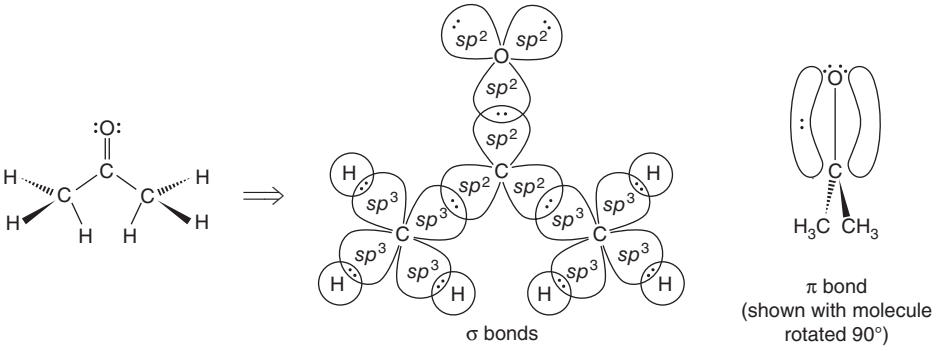
Problem Describe the types of bonds and orbitals in acetone, $(CH_3)_2CO$.

Plan We use the shape around each central atom to postulate the hybrid orbitals involved and use unhybridized orbitals to form the C═O bond.

Solution The shapes are tetrahedral around each C of the two CH_3 (methyl) groups and trigonal planar around the middle C (see Sample Problem 10.8, p. 416). Thus, the middle C has three sp^2 orbitals and one unhybridized *p* orbital. Each of the two methyl

C atoms has four sp^3 orbitals. Three of these form σ bonds with the 1*s* orbitals of H atoms; the fourth forms a σ bond with an sp^2 orbital of the middle C. Thus, two of the three sp^2 orbitals of the middle C form σ bonds to the other two C atoms.

The O atom is also sp^2 hybridized and has an unhybridized *p* orbital that can form a π bond. Two of the O atom's sp^2 orbitals hold lone pairs, and the third forms a σ bond with the third sp^2 orbital of the middle C atom. The unhybridized, half-filled 2*p* orbitals of C and O form a π bond. The σ and π bonds constitute the C═O bond:



Comment Why would the O atom in acetone be hybridized? After all, it could use two perpendicular *p* orbitals for the σ and π bonds with C and leave the other *p* and the *s* orbital to hold the two lone pairs. But, having each lone pair in an sp^2 orbital oriented away from the C═O bond lowers electron-electron repulsions.

FOLLOW-UP PROBLEMS

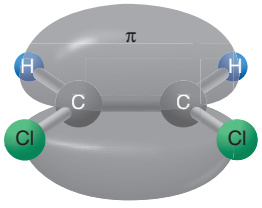
11.2B Describe the types of bonds and orbitals in **(a)** carbon monoxide, CO; **(b)** urea, H_2NCNH_2 (O).

SOME SIMILAR PROBLEMS 11.21–11.24

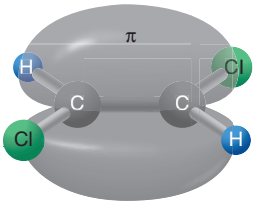
Orbital Overlap and Rotation Within a Molecule

The type of overlap—end to end or side to side—affects rotation around the bond:

- *Sigma bond.* A σ *bond allows free rotation* because the extent of overlap is not affected. If you could hold one CH_3 group of ethane, the other CH_3 could spin without affecting the overlap of the C—C σ bond (see Figure 11.9).
- *Pi bond.* A π *bond restricts rotation* because *p* orbitals must be parallel to each other to overlap most effectively. Holding one CH_2 group in ethylene and trying to spin the other decreases the side-to-side overlap and breaks the π bond. For this reason, distinct *cis* and *trans* structures exist for compounds such as 1,2-dichloroethylene (Section 10.3). As Figure 11.13 shows, the π bond allows two *different* arrangements of atoms around the C atoms, which has a major effect on molecular polarity (see p. 419). Rotation around a triple bond is not meaningful: each triple-bonded C atom is bonded to one other group in a linear arrangement, so there can be no difference in the relative positions of attached groups.



cis-1,2-Dichloroethylene



trans-1,2-Dichloroethylene

Figure 11.13 Restricted rotation around a π bond. *Cis*- and *trans*-1,2-dichloroethylene are different molecules because the π bond restricts rotation.

Summary of Section 11.2

- End-to-end overlap of atomic orbitals forms a σ bond, which allows free rotation of the bonded parts of the molecule.
- A multiple bond consists of a σ bond and either one π bond (double bond) or two π bonds (triple bond). Multiple bonds have greater electron density between the nuclei than single bonds do and, thus, higher bond energies.
- Side-to-side overlap of a π bond restricts rotation.

11.3 MOLECULAR ORBITAL (MO) THEORY AND ELECTRON DELOCALIZATION

Scientists choose the model that best answers their question: VSEPR theory for one about molecular shape, or VB theory for one about orbital overlap. But neither adequately explains magnetic and spectral properties, and both understate the importance of electron delocalization. To deal with these phenomena, which involve molecular energy levels, chemists choose **molecular orbital (MO) theory.** The MO model is a quantum-mechanical treatment for molecules similar to the one for atoms (Chapter 8): just as an atom has atomic orbitals (AOs) of given energies and shapes that are occupied by the atom's electrons, a molecule has **molecular orbitals (MOs)** of given energies and shapes that are occupied by the molecule's electrons.

There is a key distinction between VB and MO theories:

- VB theory pictures a molecule as a group of atoms bonded through overlapping of valence-shell atomic and/or hybrid orbitals occupied by *localized* electrons.
- MO theory pictures a molecule as a collection of nuclei with orbitals that extend over the whole molecule and are occupied by *delocalized* electrons.

Despite its usefulness, MO theory has the drawback that MOs are more difficult to visualize than the shapes of VSEPR theory or the hybrid AOs of VB theory.

The Central Themes of MO Theory

Several key ideas of MO theory appear in its description of H_2 and other simple species: how MOs form, what their energies and shapes are, and how they fill with electrons.

Formation of Molecular Orbitals Just as we need approximations to solve the Schrödinger equation for any atom with more than one electron, we need an approximation to determine the MOs of even the simplest molecule, H_2. The approximation is to mathematically *combine* (add or subtract) AOs (atomic wave functions) of nearby atoms to form MOs (molecular wave functions). Thus, when two H nuclei lie near each other, their AOs overlap and combine in two ways:

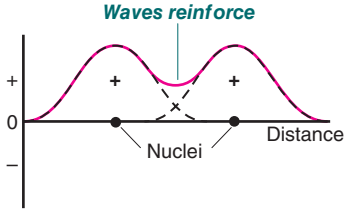
- *Adding the wave functions together.* This combination forms a **bonding MO,** which has *a region of high electron density between the nuclei.* Additive overlap is analogous to light waves reinforcing each other, which makes the amplitude higher and the light brighter. For electron waves, the overlap *increases* the probability that the electrons are between the nuclei (Figure 11.14A).
- *Subtracting the wave functions from each other.* This combination forms an **antibonding MO,** which has *a node, a region of zero electron density, between the nuclei* (Figure 11.14B). Subtractive overlap is analogous to light waves canceling each other, causing the light to disappear. With electron waves, subtractive overlap means the probability that the electrons lie between the nuclei *decreases* to zero.

The two possible combinations for hydrogen atoms H_A and H_B are

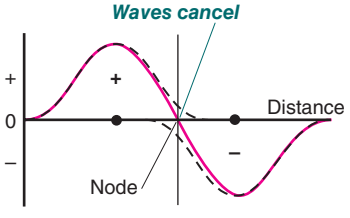
$$\text{AO of } H_A + \text{AO of } H_B = \text{bonding MO of } H_2 \text{ (more } e^- \text{ density between nuclei)}$$

$$\text{AO of } H_A - \text{AO of } H_B = \text{antibonding MO of } H_2 \text{ (less } e^- \text{ density between nuclei)}$$

Notice that *the number of AOs combined always equals the number of MOs formed:* two H atomic orbitals combine to form two H_2 molecular orbitals.



A Amplitudes of wave functions added



B Amplitudes of wave functions subtracted

Figure 11.14 An analogy between light waves and atomic wave functions.

Shape and Energy of H_2 Molecular Orbitals Bonding and antibonding MOs have different shapes and energies. Figure 11.15 shows these orbitals for H_2:

- *Bonding MO.* A bonding MO is *lower in energy* than the AOs that form it. Because it is spread mostly *between* the nuclei, nuclear repulsions decrease while nucleus-electron attractions increase. Moreover, two electrons in this MO can delocalize their charges over a larger volume than in nearby, separate AOs, which lowers electron repulsions. Because of these electrostatic effects, when electrons occupy this orbital, the H_2 molecule is *more stable* than the separate H atoms.

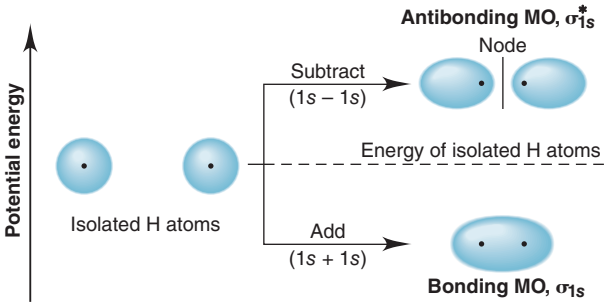


Figure 11.15 Contours and energies of H_2 bonding and antibonding MOs.

- *Antibonding MO.* An antibonding MO is *higher in energy* than the AOs that form it. With most of the electron density *outside* the internuclear region and *a node between the nuclei,* nuclear repulsions increase. Therefore, when electrons occupy this orbital, the H_2 molecule is *less stable* than the separate H atoms.

Both the bonding and antibonding MOs of H_2 are **sigma (σ) MOs** because they are cylindrically symmetrical about an imaginary line between the nuclei. The bonding MO is denoted by σ_{1s}; that is, a σ MO derived from 1*s* AOs. Antibonding orbitals are denoted with a superscript star: the antibonding MO derived from 1*s* AOs is σ^*_{1s} (spoken "sigma, one ess, star").

For AOs to interact enough to form MOs, they must be similar in *energy* and *orientation.* The 1*s* orbitals of two H atoms have identical energy and orientation, so they interact strongly. We'll revisit this requirement for molecules composed of many-electron atoms.

Electrons in Molecular Orbitals Several aspects of MO theory—filling of MOs, energy-level diagrams, electron configuration, and bond order—relate to earlier ideas:

1. *Filling MOs with electrons.* Electrons enter MOs just as they do AOs:
- MOs are filled in order of increasing energy (aufbau principle).
- An MO can hold a maximum of two electrons with opposite spins (exclusion principle).
- Orbitals of equal energy are half-filled, with spins parallel, before any of them are filled (Hund's rule).

2. *MO energy-level diagrams.* A **molecular orbital (MO) diagram** shows the relative energy and number of electrons for each MO, as well as for the AOs from which they are formed. In the MO diagram for H_2 (Figure 11.16), two electrons, one from the AO of each H, fill the H_2 bonding MO, while the antibonding MO remains empty.

3. *Electron configuration.* Just as we write an electron configuration for an atom, we can write one for a molecule. The symbol of each occupied MO is written in parentheses, with the number of electrons in it as a superscript outside: the electron configuration of H_2 is $(\sigma_{1s})^2$.

4. *Bond order.* In a Lewis structure, bond order is the number of electron pairs per atom-to-atom linkage. The **MO bond order** is the number of electrons in bonding MOs minus the number in antibonding MOs, multiplied by $\frac{1}{2}$:

$$\text{Bond order} = \tfrac{1}{2}[(\text{no. of } e^- \text{ in bonding MO}) - (\text{no. of } e^- \text{ in antibonding MO})] \qquad (11.1)$$

Here are three key points about MO bond order:
- Bond order > 0: the molecule is more stable than the separate atoms, so it *will* form. For H_2, the bond order is $\frac{1}{2}(2 - 0) = 1$.
- Bond order $= 0$: the molecule is as stable as the separate atoms, so it will *not* form (occurs when equal numbers of electrons occupy bonding and antibonding MOs).
- In general, the *higher* the bond order, the *stronger* the bond is.

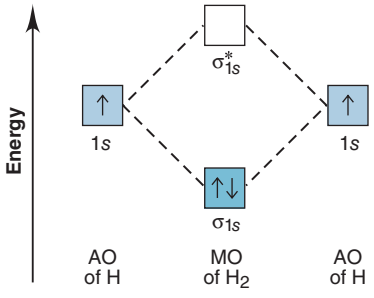

Figure 11.16 MO diagram for H_2. The vertical placement of the boxes indicates relative energies. Orbital occupancy is shown with arrows and color (dark = full, pale = half-filled, none = empty).

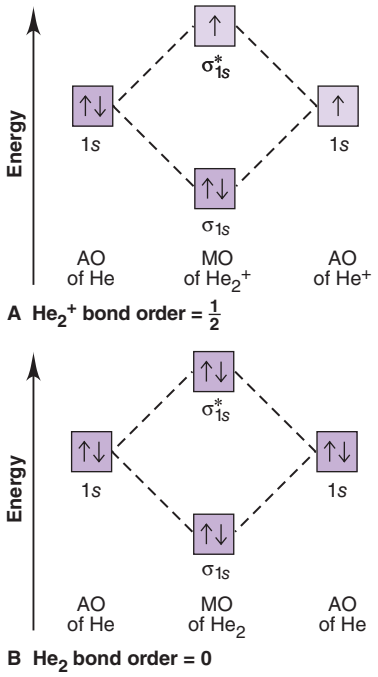

Figure 11.17 MO diagrams for He_2^+ and He_2.

Do He_2^+ and He_2 Exist? One of the early triumphs of MO theory was its ability to *predict* the existence of He_2^+, the helium molecule-ion, which consists of two He nuclei and three electrons. Let's use MO diagrams to see why He_2^+ exists but He_2 doesn't:

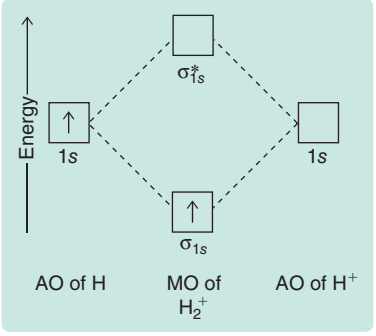
- In He_2^+, the 1*s* AOs form MOs (Figure 11.17A). The three electrons are distributed as a pair in the σ_{1s} MO and a lone electron in the σ^*_{1s} MO. The bond order is $\frac{1}{2}(2-1)=\frac{1}{2}$. Thus, He_2^+ has a relatively weak bond, but it should exist. Indeed, this species has been observed frequently when He atoms collide with He^+ ions. Its electron configuration is $(\sigma_{1s})^2(\sigma^*_{1s})^1$.
- In He_2, with four electrons in the σ_{1s} and σ^*_{1s} MOs, both the bonding and antibonding orbitals are filled (Figure 11.17B). Stabilization from the electron pair in the bonding MO is canceled by destabilization from the electron pair in the antibonding MO. With a zero bond order $[\frac{1}{2}(2-2)=0]$, we predict, and experiment has so far confirmed, that a covalent He_2 molecule does not exist.

SAMPLE PROBLEM 11.3 **Predicting Stability of Species Using MO Diagrams**

Problem Use an MO diagram to find the bond order and predict whether H_2^+ exists. If it exists, write its electron configuration.

Plan Since the 1*s* AOs form the MOs, the MO diagram is similar to the one for H_2. We find the number of electrons and distribute them one at a time to the MOs in order of increasing energy. We obtain the bond order with Equation 11.1 and write the electron configuration as described in the text.

Solution H_2 has two e^-, so H_2^+ has only one, which enters the bonding MO *(see diagram in margin)*. The bond order is $\frac{1}{2}(1-0)=\frac{1}{2}$, so we predict that H_2^+ exists. The electron configuration is $(\sigma_{1s})^1$.



Check The number of electrons in the MOs equals the number of electrons in the AOs.

Comment This species has been detected spectroscopically in the material around stars.

FOLLOW-UP PROBLEMS

11.3A Use an MO diagram to find the bond order and predict whether two H^- ions could form H_2^{2-}. If this species exists, write its electron configuration.

11.3B Use an MO diagram to find the bond order and predict whether two He^+ ions could form He_2^{2+}. If this species exists, write its electron configuration.

A SIMILAR PROBLEM 11.55

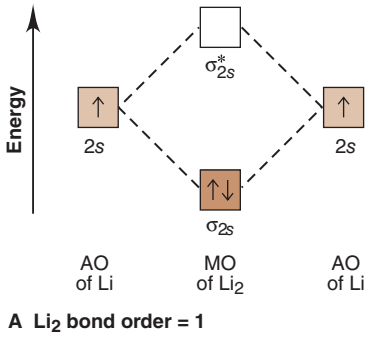
Homonuclear Diatomic Molecules of Period 2 Elements

Homonuclear diatomic molecules are composed of two identical atoms. In addition to H_2 from Period 1, you're familiar with N_2, O_2, and F_2 from Period 2 as the elemental forms under standard conditions. Others in Period 2—Li_2, Be_2, B_2, C_2, and Ne_2—are observed, if at all, at high temperatures. We'll divide them into molecules from the *s* block, Groups 1A(1) and 2A(2), and the *p* block, Groups 3A(13) through 8A(18).

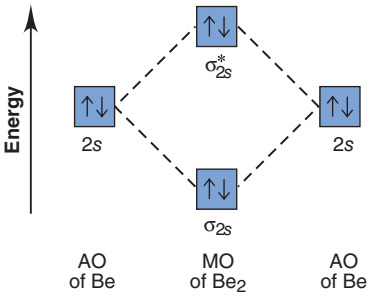
Bonding in the *s*-Block Homonuclear Diatomic Molecules Both Li and Be occur as metals under normal conditions, but MO theory can examine their stability as diatomic gases, dilithium (Li_2) and diberyllium (Be_2).

These atoms have electrons in inner (1*s*) and outer (2*s*) AOs, but we ignore the inner ones because, in general, *only outer (valence) AOs interact enough to form MOs.* Like those formed from 1*s* AOs, these 2*s* AOs form σ MOs, cylindrically symmetrical around the internuclear axis.

- In Li_2, the two valence electrons fill the bonding (σ_{2s}) MO, with opposing spins, leaving the antibonding (σ^*_{2s}) MO empty (Figure 11.18A). The bond order is $\frac{1}{2}(2 - 0) = 1$. In fact, Li_2 *has* been observed; the electron configuration is $(\sigma_{2s})^2$.
- In Be_2, the four valence electrons fill the σ_{2s} and σ^*_{2s} MOs (Figure 11.18B), giving an orbital occupancy similar to that in He_2. The bond order is $\frac{1}{2}(2 - 2) = 0$, and the ground state of Be_2 has never been observed.



A Li_2 bond order = 1



B Be_2 bond order = 0

Figure 11.18 Bonding in *s*-block homonuclear diatomic molecules. Only outer (valence) AOs interact enough to form MOs.

Shape and Energy of MOs from Atomic *p*-Orbital Combinations In boron, atomic $2p$ orbitals are occupied. Recall that p orbitals can overlap by two modes, which correspond to two ways their wave functions combine (Figure 11.19):

- End-to-end combination gives a pair of σ MOs, the σ_{2p} and σ^*_{2p}.
- Side-to-side combination gives a pair of **pi (π) MOs,** π_{2p} and π^*_{2p}.

Despite the different shapes, MOs derived from p orbitals are like those from s orbitals. Bonding MOs have most of the electron density *between* the nuclei, and antibonding MOs have most *outside* the internuclear region, with a node between the nuclei.

The order of energy levels for MOs, whether bonding or antibonding, is based on the order of AO energy levels *and* on the mode of the p-orbital overlap:

- MOs formed from $2s$ orbitals are *lower in energy* than MOs formed from $2p$ orbitals because $2s$ AOs are lower in energy than $2p$ AOs.
- Bonding MOs are *lower in energy* than antibonding MOs: σ_{2p} is lower in energy than σ^*_{2p} and π_{2p} is lower than π^*_{2p}.
- Atomic p orbitals overlap more extensively end to end than side to side. Thus, the σ_{2p} MO is usually lower in energy than the π_{2p} MO. We also find that the destabilizing effect of the σ^*_{2p} MO is greater than that of the π^*_{2p} MO.

Thus, the energy order for MOs derived from $2p$ orbitals is typically

$$\sigma_{2p} < \pi_{2p} < \pi^*_{2p} < \sigma^*_{2p}$$

Each atom has three mutually perpendicular $2p$ orbitals. When the six p orbitals in two atoms combine, the two that interact end to end form one σ and one σ* MO, and the two pairs of orbitals that interact side to side form two π MOs and two π* MOs. Placing these orientations within the energy order gives the *expected* MO diagram for the p-block Period 2 homonuclear diatomic molecules (Figure 11.20A, *next page*).

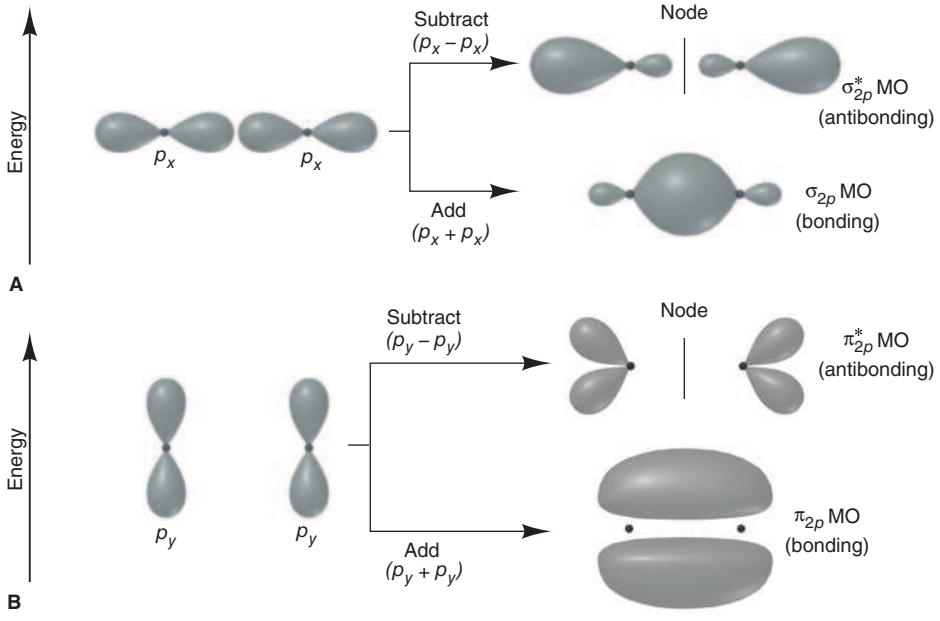


Figure 11.19 Shapes and energies of σ and π MOs from combinations of 2*p* atomic orbitals. A, The p orbitals lying along the internuclear axis (designated p_x) overlap end to end and form σ_{2p} and σ^*_{2p} MOs. **B,** The p orbitals perpendicular to the internuclear axis overlap side to side and form two π MOs. (The p_y interactions, shown here, are the same as for the p_z orbitals, giving a total of four π MOs.)

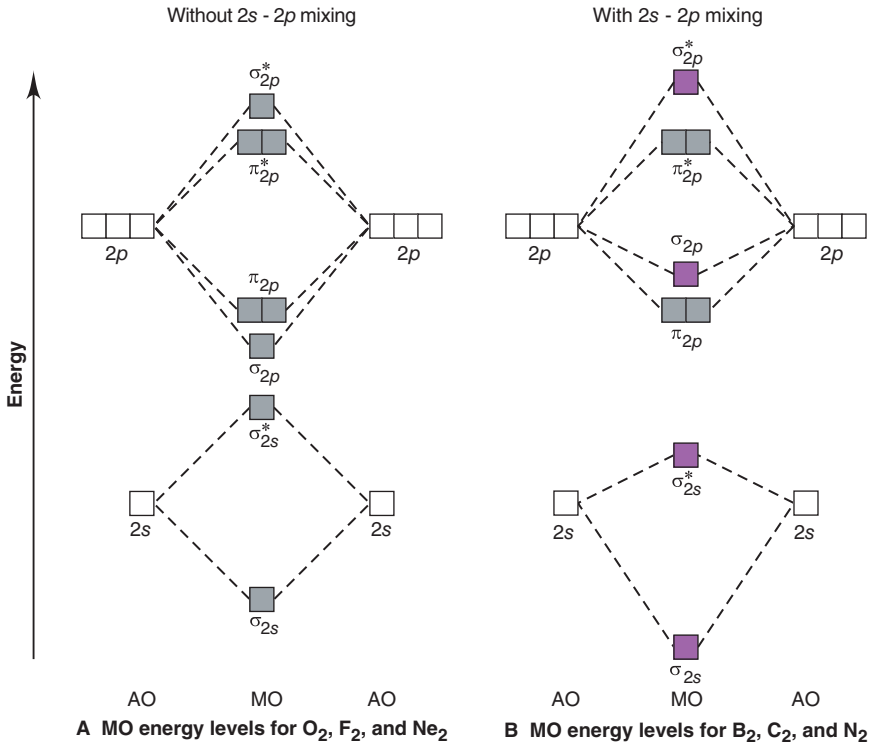

Figure 11.20 Relative MO energy levels for Period 2 homonuclear diatomic molecules. (For clarity, the MOs affected by mixing are shown in *purple*.)

Recall that only AOs of similar energy interact enough to form MOs. This fact leads to two energy orders:

1. ***Without*** *s and p orbital mixing: O_2, F_2, and Ne_2.* The order in Figure 11.20A assumes that *s* and *p* AOs are so different in energy that they do not interact; we say the orbitals do not *mix*. Lying at the right of Period 2, O, F, and Ne are relatively small. Thus, as electrons start to pair up in the half-filled 2*p* orbitals, strong repulsions raise the energy of the 2*p* orbitals high enough above the 2*s* orbitals to prevent orbital mixing.

2. ***With*** *s and p orbital mixing: B_2, C_2, and N_2.* B, C, and N atoms are relatively large, with 2*p* AOs only half-filled, so repulsions are weaker. As a result, orbital energies are close enough for some mixing to occur between the 2*s* of one atom and the end-on 2*p* of the other. The effect is to *lower* the energy of the σ_{2s} and σ^*_{2s} MOs and *raise* the energy of the σ_{2p} and σ^*_{2p} MOs; the π MOs are not affected. The MO diagram for B_2, C_2, and N_2 reflects this mixing (Figure 11.20B). The only qualitative difference from the MO diagram for O_2, F_2, and Ne_2 is the *reverse in energy order* of the σ_{2p} and π_{2p} MOs.

Bonding in the *p*-Block Homonuclear Diatomic Molecules Figure 11.21 shows the MOs, electron occupancy, and some properties of B_2 through Ne_2. Note that

1. *Higher* bond order correlates with *greater* bond energy and *shorter* bond length.

2. Orbital occupancy correlates with magnetic properties. Recall from Chapter 8 that if a substance has unpaired electrons, it is *paramagnetic,* and if all electrons are paired, the substance is *diamagnetic;* the same distinction applies to molecules. Let's examine the MO occupancy and some properties of these molecules:

- *B_2.* The B_2 molecule has six outer electrons: four fill the σ_{2s} and σ^*_{2s} MOs. The remaining two electrons occupy the two π_{2p} MOs, one in each orbital, in keeping with Hund's rule. With four electrons in bonding MOs and two in antibonding MOs, the bond order of B_2 is $\frac{1}{2}(4 - 2) = 1$. As expected from the two lone electrons, B_2 is paramagnetic.
- *C_2.* Two additional electrons in C_2 fill the two π_{2p} MOs. With two more bonding electrons than B_2, the bond order of C_2 is 2 and the bond is stronger and shorter. But with all the electrons paired, C_2 is diamagnetic.

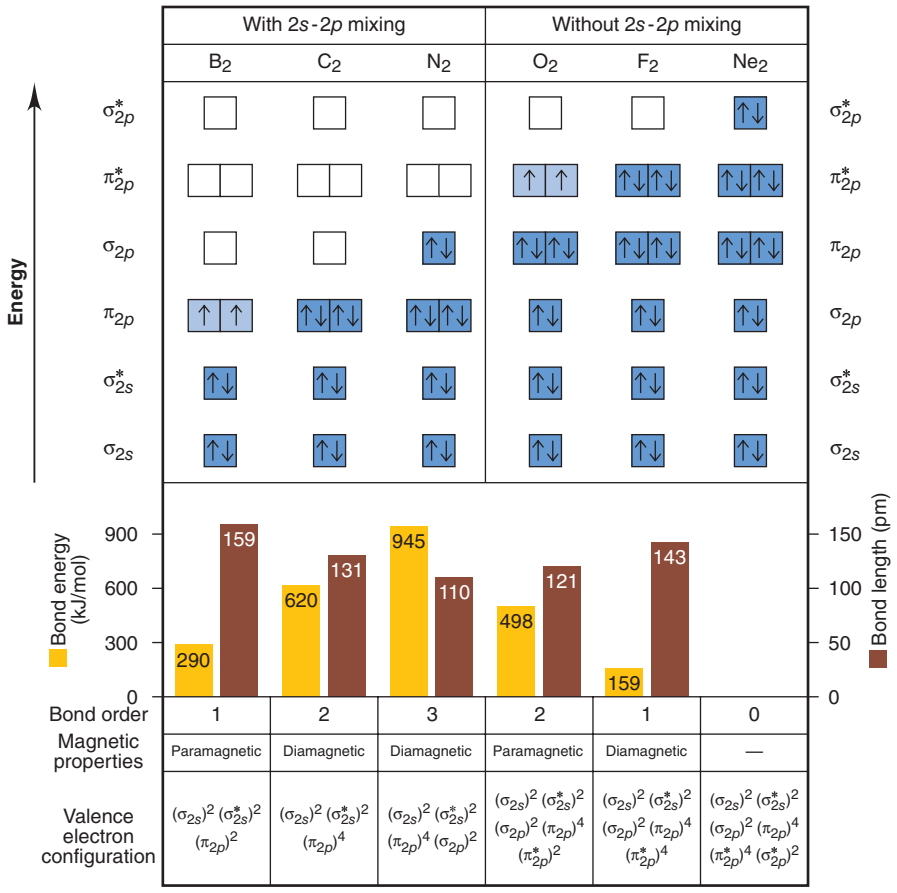

Figure 11.21 **MO occupancy and some properties of B_2 through Ne_2.** Energy order and occupancy of MOs are above a bar graph showing bond energy and length, bond orders, magnetic properties, and outer (valence) electron configurations.

- *N_2*. Two more electrons in N_2 fill the σ_{2p} MO, so the molecule is also diamagnetic. The bond order of 3 is consistent with the triple bond in the Lewis structure and with a stronger, shorter bond.
- *O_2*. With this molecule, we see the power of MO theory over VB theory and others based on electrons in localized orbitals. It is impossible to write one Lewis structure consistent with the fact that O_2 is double bonded and paramagnetic. We can write one with a double bond and paired electrons, and another with a single bond and two unpaired electrons:

MO theory resolves this paradox beautifully: with eight electrons in bonding MOs and four in antibonding MOs, the bond order is $\frac{1}{2}(8 - 4) = 2$, and it is paramagnetic because *one* electron occupies each of *two* π^*_{2p} MOs and these two electrons have unpaired (parallel) spins. A thin stream of liquid O_2 will remain suspended between the poles of a powerful magnet (Figure 11.22). As expected, the bond is weaker and longer than the one in N_2.
- *F_2*. Two more electrons in F_2 fill the π^*_{2p} orbitals, so it is diamagnetic. The bond has an order of 1 and is weaker and longer than the one in O_2. Note that this bond is shorter than the single bond in B_2 but only about half as strong. We might have expected it to be stronger because F is smaller than B. But 18 electrons in the smaller volume of F_2 cause greater repulsions than the 10 electrons in B_2, making the F_2 bond weaker.
- *Ne_2*. The final member of the Period 2 series doesn't exist for the same reason He_2 doesn't: all the MOs are filled, which gives a bond order of zero.

Figure 11.22 **The paramagnetic properties of O_2.**

SAMPLE PROBLEM 11.4 Using MO Theory to Explain Bond Properties

Problem Explain the following data with diagrams showing the occupancy of MOs:

	N_2	N_2^+	O_2	O_2^+
Bond energy (kJ/mol)	945	841	498	623
Bond length (pm)	110	112	121	112

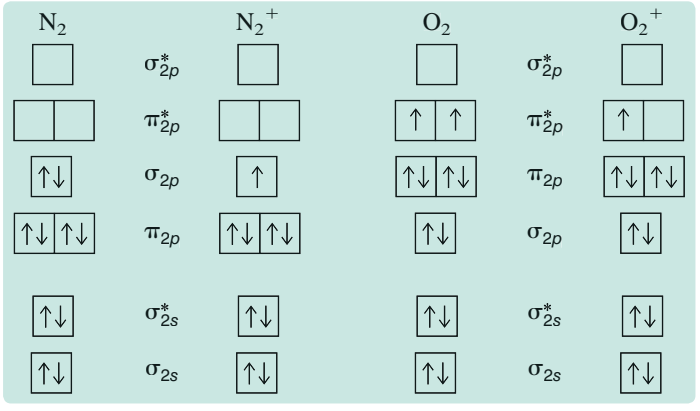
Plan The data show that removing an electron from each parent molecule has opposite effects: N_2^+ has a weaker, longer bond than N_2, but O_2^+ has a stronger, shorter bond than O_2. We determine the valence electrons in each species, draw the sequence of MO energy levels (showing orbital mixing in N_2 but not in O_2), and fill them with electrons. To explain the data, we calculate bond orders, which relate directly to bond energy and inversely to bond length.

Solution Determining the valence electrons:

N has 5 valence e^-, so N_2 has 10 and N_2^+ has 9

O has 6 valence e^-, so O_2 has 12 and O_2^+ has 11

Drawing and filling the MO diagrams:



Calculating bond orders:

$\frac{1}{2}(8-2)=3$ $\frac{1}{2}(7-2)=2.5$ $\frac{1}{2}(8-4)=2$ $\frac{1}{2}(8-3)=2.5$

Explaining the data:

1. When N_2 becomes N_2^+, a *bonding* electron is removed, so the bond order decreases. Thus, N_2^+ has a weaker, longer bond than N_2.
2. When O_2 becomes O_2^+, an *antibonding* electron is removed, so the bond order increases. Thus, O_2^+ has a stronger, shorter bond than O_2.

Check The answers make sense in terms of bond order, bond energy, and bond length. Check that the total number of bonding and antibonding electrons equals the total number of valence electrons for each species.

FOLLOW-UP PROBLEMS

11.4A Determine the bond orders for these other dinitrogen species: N_2^{2+}, N_2^-, and N_2^{2-}. List the species in order of decreasing bond energy and in order of decreasing bond length.

11.4B Determine the bond orders for the following species: F_2^{2-}, F_2^-, F_2, F_2^+, F_2^{2+}. List the species that exist in order of increasing bond energy and in order of increasing bond length.

SOME SIMILAR PROBLEMS 11.36 and 11.37

Two Heteronuclear Diatomic Molecules: HF and NO

Heteronuclear diatomic molecules have asymmetric MO diagrams because the AOs of the *different* atoms have unequal energies. Atoms with greater effective nuclear charge (Z_{eff}) pull their electrons closer, so they have more stable (lower energy) AOs (Section 8.1) and higher EN values (Section 9.5). Let's examine the bonding in HF and NO.

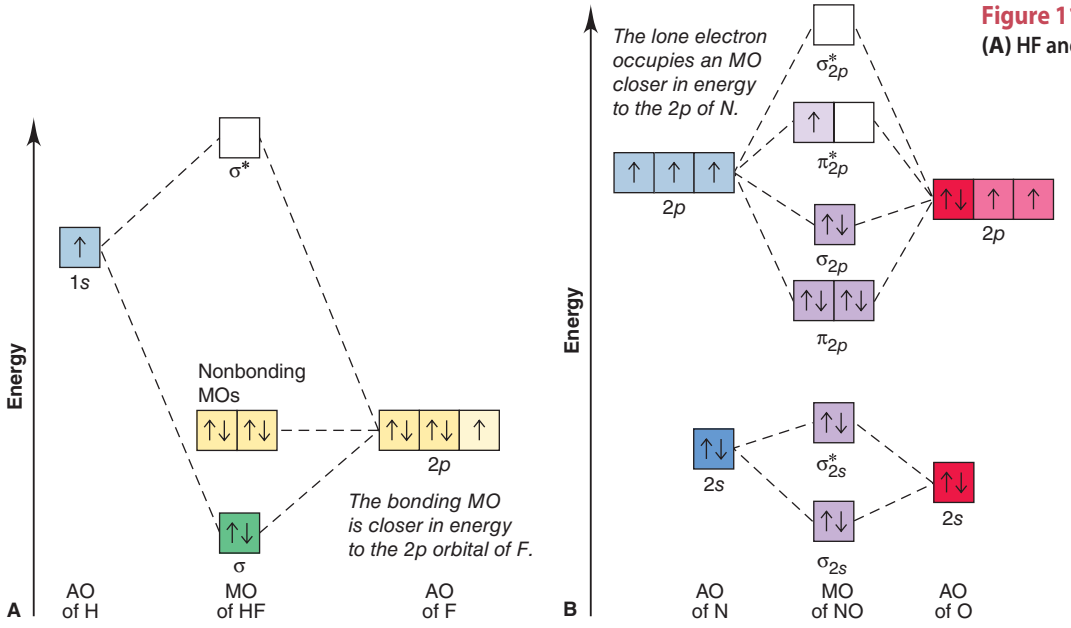


Figure 11.23 The MO diagrams for **(A)** HF and **(B)** NO.

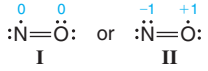
Bonding in HF To form the MOs in HF, we decide which AOs will combine. The high Z_{eff} of F holds its electrons so tightly that the 1*s*, 2*s*, and 2*p* orbitals of F have lower energy than the 1*s* of H. The half-filled F 2*p* orbital interacts with the H 1*s* through end-on overlap, which forms σ and σ* MOs. The two filled 2*p* orbitals of F are called **nonbonding MOs.** Because they are not involved in bonding, they have the same energy as the isolated AOs (Figure 11.23A).

The bonding MO is closer in energy to the AOs of F, so the F 2*p* orbital contributes more to the HF bond than the H 1*s* does. In polar covalent molecules, *bonding MOs are closer in energy to the AOs of the more electronegative atom.* In effect, fluorine's greater electronegativity lowers the energy of the bonding MO and draws the bonding electrons closer.

Bonding in NO Nitrogen monoxide (nitric oxide) is highly reactive because of its lone electron. Two possible Lewis structures for NO, with formal charges (Section 10.1), are



Both structures show a double bond, but the *measured* bond energy suggests a bond order *higher* than 2. Moreover, it is not clear where the lone electron resides, although the lower formal charges for structure I suggest that it is on the N.

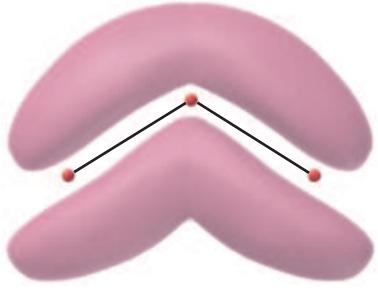
The MO diagram is asymmetric, with the AOs of the more electronegative O lower in energy (Figure 11.23B). When the 11 valence electrons fill the MOs of NO, the lone electron occupies one of the π^*_{2p} orbitals. Eight bonding and three antibonding electrons give a bond order of $\frac{1}{2}(8 - 3) = 2.5$, more in keeping with the data than either Lewis structure. Bonding electrons lie in MOs closer in energy to the AOs of the O atom. The 2*p* orbitals of N contribute more to the orbital that holds the lone electron, so it spends more time closer to N. (This diagram shows the energy order *with* 2*s*–2*p* mixing, as in Figure 11.20, but the result is the same as the order without mixing.)

Two Polyatomic Molecules: Benzene and Ozone

The orbital shapes and MO diagrams for polyatomic molecules are too complex for a detailed treatment here. But we'll briefly discuss how the model eliminates the need for resonance forms and helps explain the effects of the absorption of energy.

Recall that we cannot draw one Lewis structure for either benzene or ozone, so we draw separate forms of a resonance hybrid. The VB model also uses resonance

Benzene, C_6H_6



Ozone, O_3

Figure 11.24 The lowest energy π-bonding MOs in benzene and ozone.

because it relies on *localized* bonds. In contrast, MO theory pictures a structure of delocalized σ and π MOs. Figure 11.24 shows the lowest energy π-bonding MOs in benzene and ozone. The extended areas of electron density allow delocalization of one π-bonding electron pair over the entire molecule, thus eliminating the need for separate resonance forms:

- *In benzene*, the upper and lower hexagonal lobes of this MO lie above and below the σ plane of the six C nuclei.
- *In ozone*, the two lobes of this MO extend over and under the three O nuclei.

The full MO diagrams for these molecules help us rationalize how bonding electrons in O_3 become excited and occupy empty antibonding orbitals when the molecule absorbs UV radiation in the stratosphere, and why the UV spectrum of benzene has its characteristic absorption bands.

Summary of Section 11.3

- Molecular orbital (MO) theory treats a molecule as a collection of nuclei with MOs delocalized over the entire structure.
- Atomic orbitals of comparable energy can be added or subtracted to obtain bonding or antibonding MOs, respectively.
- Bonding MOs, whether σ or π, have most of the electron density between the nuclei and are lower in energy than the AOs that combine to form them; most of the electron density in antibonding MOs does not lie between the nuclei, so these MOs are higher in energy.
- MOs are filled in order of their energy with paired electrons having opposite spins.
- MO diagrams show energy levels and orbital occupancy. Diagrams for the Period 2 homonuclear diatomic molecules explain bond energy, bond length, and magnetic behavior.
- In heteronuclear diatomic molecules, the more electronegative atom contributes more to the bonding MOs.
- MO theory eliminates the need for resonance forms to depict larger molecules.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The main ideas of valence bond theory—orbital overlap, opposing electron spins, and hybridization—as a means of rationalizing molecular shapes (§11.1)
2. How orbitals mix to form hybrid orbitals with different spatial orientations (§11.1)
3. The distinction between end-to-end and side-to-side overlap and the origin of sigma (σ) and pi (π) bonds in simple molecules (§11.2)
4. How these two modes of orbital overlap lead to single, double, and triple bonds (§11.2)
5. Why π bonding restricts rotation around double bonds (§11.2)
6. The distinction between the localized bonding of VB theory and the delocalized bonding of MO theory (§11.3)
7. How addition or subtraction of AOs forms bonding or antibonding MOs (§11.3)
8. The shapes of MOs formed from combinations of two *s* orbitals and combinations of two *p* orbitals (§11.3)
9. How MO bond order predicts the stability of molecular species (§11.3)
10. How MO theory explains the bonding and magnetic properties of homonuclear and heteronuclear diatomic molecules of Period 2 elements (§11.3)

Master These Skills

1. Using molecular shape to postulate the hybrid orbitals used by a central atom (SP 11.1)
2. Describing the types of orbitals and bonds in a molecule (SP 11.2)
3. Drawing MO diagrams, writing electron configurations, and calculating bond orders of molecular species (SP 11.3)
4. Explaining bond and magnetic properties with MO theory (SP 11.4)

Key Terms

Page numbers appear in parentheses.

Section 11.1
valence bond (VB) theory (429)
hybridization (430)
hybrid orbital (430)
sp hybrid orbital (430)
sp^2 hybrid orbital (432)
sp^3 hybrid orbital (432)
sp^3d hybrid orbital (433)
sp^3d^2 hybrid orbital (434)

Section 11.2
sigma (σ) bond (437)
pi (π) bond (437)

Section 11.3
molecular orbital (MO) theory (440)
molecular orbital (MO) (440)
bonding MO (440)
antibonding MO (440)
sigma (σ) MO (441)
molecular orbital (MO) diagram (441)
MO bond order (441)
homonuclear diatomic molecule (442)
pi (π) MO (443)
nonbonding MO (447)

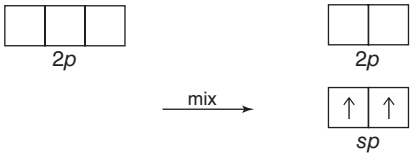
Key Equations and Relationships

Page numbers appear in parentheses.

11.1 Calculating the MO bond order (441): Bond order $= \frac{1}{2}[(\text{no. of } e^- \text{ in bonding MO}) - (\text{no. of } e^- \text{ in antibonding MO})]$

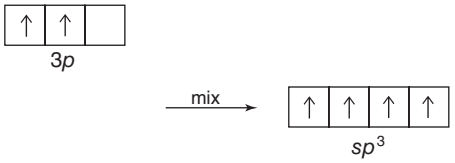
BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

11.1A (a) Shape is linear, so Be is *sp* hybridized:



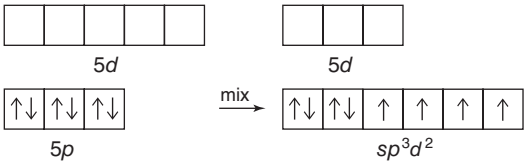
Isolated Be atom Hybridized Be atom

(b) Shape is tetrahedral, so Si is sp^3 hybridized:



Isolated Si atom Hybridized Si atom

(c) Shape is square planar, so Xe is sp^3d^2 hybridized:



Isolated Xe atom Hybridized Xe atom

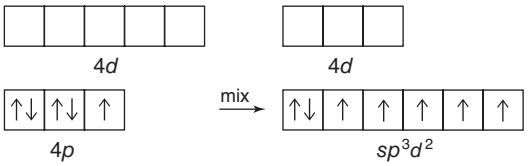
11.1B (a) Shape is trigonal planar, so N is sp^2 hybridized:

Isolated N atom Hybridized N atom

(b) Shape is trigonal pyramidal, so P is sp^3 hybridized:

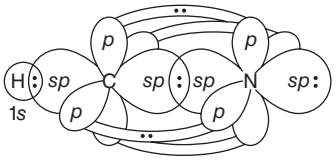
Isolated P atom Hybridized P atom

(c) Shape is square pyramidal, so Br is sp^3d^2 hybridized:



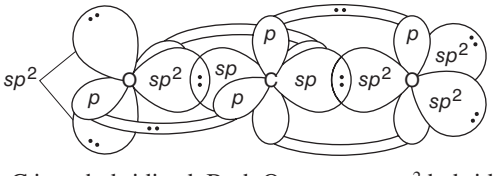
Isolated Br atom Hybridized Br atom

11.2A (a) H—C≡N:



HCN is linear, so C is *sp* hybridized. N is also *sp* hybridized. One *sp* of C overlaps the 1*s* of H to form a σ bond. The other *sp* of C overlaps one *sp* of N to form a σ bond. The other *sp* of N holds a lone pair. Two unhybridized *p* orbitals of N and two of C overlap to form two π bonds.

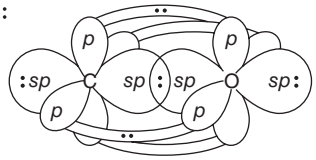
(b) Ö=C=Ö



CO_2 is linear, so C is *sp* hybridized. Both O atoms are sp^2 hybridized. Each *sp* of C overlaps one sp^2 of an O to form a σ bond, which gives a total of two σ bonds. Each of the two unhybridized *p* orbitals of C forms a π bond with the unhybridized *p* of one of the two O atoms. Two sp^2 of each O hold lone pairs.

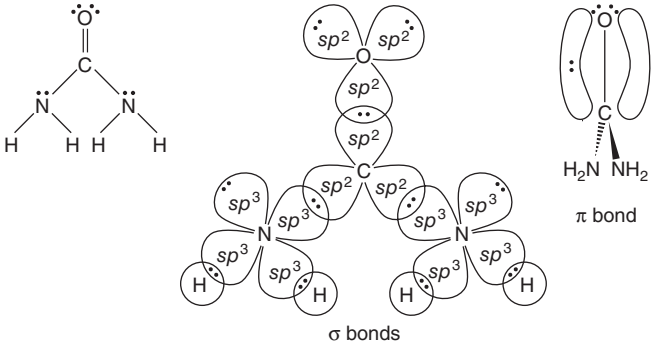
BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

11.2B (a) :C≡O:



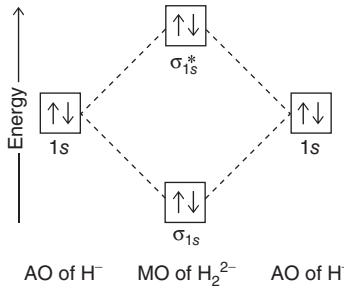
Both C and O are *sp* hybridized. One *sp* of C overlaps one *sp* of O to form one σ bond. The other *sp* of C and that of O hold lone pairs. Two unhybridized *p* orbitals of C and two of O overlap to form two π bonds.

(b)



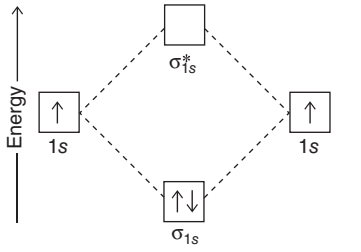
The C and O are sp^2 hybridized, and each N is sp^3 hybridized. The sp^3 orbitals of each N form three σ bonds, two with the 1*s* of two H atoms and one with an sp^2 of the C. A lone pair fills the fourth sp^3 of each N. The third sp^2 of the C forms a σ bond to one sp^2 of the O, and lone pairs fill the other sp^2 orbitals of the O. Unhybridized *p* orbitals on C and O form a π bond.

11.3A



Does not exist: bond order $= \frac{1}{2}(2 - 2) = 0$.

11.3B



Does exist: bond order $= \frac{1}{2}(2 - 0) = 1$; $(\sigma_{1s})^2$

11.4A Bond order: $N_2^{2+} = 2$; $N_2^{-} = 2.5$; $N_2^{2-} = 2$
Bond energy: $N_2^{-} > N_2^{2+} = N_2^{2-}$
Bond length: $N_2^{2+} = N_2^{2-} > N_2^{-}$

11.4B Bond order: $F_2^{2-} = 0$; $F_2^{-} = 0.5$; $F_2 = 1$; $F_2^{+} = 1.5$
$F_2^{2+} = 2$
Bond energy: F_2^{2-} does not exist; $F_2^{-} < F_2 < F_2^{+} < F_2^{2+}$
Bond length: $F_2^{2+} < F_2^{+} < F_2 < F_2^{-}$; F_2^{2-} does not exist

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Valence Bond (VB) Theory and Orbital Hybridization

(Sample Problem 11.1)

Concept Review Questions

11.1 What type of central-atom orbital hybridization corresponds to each electron-group arrangement: (a) trigonal planar; (b) octahedral; (c) linear; (d) tetrahedral; (e) trigonal bipyramidal?

11.2 What is the orbital hybridization of a central atom that has one lone pair and bonds to: (a) two other atoms; (b) three other atoms; (c) four other atoms; (d) five other atoms?

11.3 How do carbon and silicon differ with regard to the *types* of orbitals available for hybridization? Explain.

11.4 How many hybrid orbitals form when four atomic orbitals of a central atom mix? Explain.

Skill-Building Exercises (grouped in similar pairs)

11.5 Give the number and type of hybrid orbital that forms when each set of atomic orbitals mixes:
(a) two *d*, one *s*, and three *p* (b) three *p* and one *s*

11.6 Give the number and type of hybrid orbital that forms when each set of atomic orbitals mixes:
(a) one *p* and one *s* (b) three *p*, one *d*, and one *s*

11.7 What is the hybridization of nitrogen in each of the following: (a) NO; (b) NO_2; (c) NO_2^-?

11.8 What is the hybridization of carbon in each of the following: (a) CO_3^{2-}; (b) $C_2O_4^{2-}$; (c) NCO^-?

11.9 What is the hybridization of chlorine in each of the following: (a) ClO_2; (b) ClO_3^-; (c) ClO_4^-?

11.10 What is the hybridization of bromine in each of the following: (a) BrF_3; (b) BrO_2^-; (c) BrF_5?

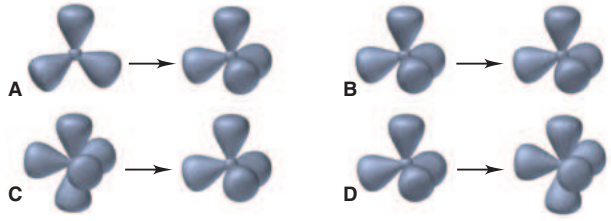
11.11 Which types of atomic orbitals of the central atom mix to form hybrid orbitals in (a) $SiClH_3$; (b) CS_2; (c) SCl_3F; (d) NF_3?

11.12 Which types of atomic orbitals of the central atom mix to form hybrid orbitals in (a) Cl_2O; (b) $BrCl_3$; (c) PF_5; (d) SO_3^{2-}?

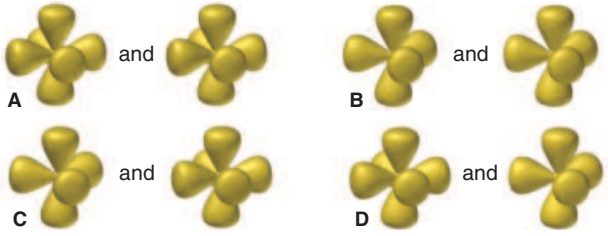
11.13 Phosphine (PH_3) reacts with borane (BH_3) as follows:

$$PH_3 + BH_3 \longrightarrow H_3P{-}BH_3$$

(a) Which of the illustrations below depicts the change, if any, in the orbital hybridization of P during this reaction? (b) Which depicts the change, if any, in the orbital hybridization of B?



11.14 The illustrations below depict differences in orbital hybridization of some tellurium (Te) fluorides. (a) Which depicts the difference, if any, between TeF_6 *(left)* and TeF_5^- *(right)*? (b) Which depicts the difference, if any, between TeF_4 *(left)* and TeF_6 *(right)*?



11.15 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) $GeCl_4$; (b) BCl_3; (c) CH_3^+.

11.16 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) BF_4^-; (b) PO_4^{3-}; (c) SO_3.

11.17 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) $SeCl_2$; (b) H_3O^+; (c) IF_4^-.

11.18 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to hybrid orbitals in (a) $AsCl_3$; (b) $SnCl_2$; (c) PF_6^-.

Problems in Context

11.19 Methyl isocyanate, $CH_3{-}\ddot{N}{=}C{=}\ddot{O}:$, is an intermediate in the manufacture of many pesticides. In 1984 a leak from a manufacturing plant resulted in the death of more than 2000 people in Bhopal, India. What are the hybridizations of the N atom and the two C atoms in methyl isocyanate? Sketch the molecular shape.

Modes of Orbital Overlap and the Types of Covalent Bonds

(Sample Problem 11.2)

Concept Review Questions

11.20 Are these statements true or false? Correct any false ones.
(a) Two σ bonds comprise a double bond.
(b) A triple bond consists of one π bond and two σ bonds.
(c) Bonds formed from atomic *s* orbitals are always σ bonds.
(d) A π bond restricts rotation about the σ-bond axis.
(e) A π bond consists of two pairs of electrons.
(f) End-to-end overlap results in a bond with electron density above and below the bond axis.

Skill-Building Exercises (grouped in similar pairs)

11.21 Describe the hybrid orbitals used by the central atom and the type(s) of bonds formed in (a) NO_3^-; (b) CS_2; (c) CH_2O.

11.22 Describe the hybrid orbitals used by the central atom and the type(s) of bonds formed in (a) O_3; (b) I_3^-; (c) $COCl_2$ (C is central).

11.23 Describe the hybrid orbitals used by the central atom(s) and the type(s) of bonds formed in (a) FNO; (b) C_2F_4; (c) $(CN)_2$.

11.24 Describe the hybrid orbitals used by the central atom(s) and the type(s) of bonds formed in (a) BrF_3; (b) $CH_3C{\equiv}CH$; (c) SO_2.

Problem in Context

11.25 2-Butene ($CH_3CH{=}CHCH_3$) is a starting material in the manufacture of lubricating oils and many other compounds. Draw two different structures for 2-butene, indicating the σ and π bonds in each.

Molecular Orbital (MO) Theory and Electron Delocalization

(Sample Problems 11.3 and 11.4)

Concept Review Questions

11.26 Two *p* orbitals from one atom and two *p* orbitals from another atom are combined to form molecular orbitals for the joined atoms. How many MOs will result from this combination? Explain.

11.27 Certain atomic orbitals on two atoms were combined to form the following MOs. Name the atomic orbitals used and the MOs formed, and explain which MO has higher energy:

11.28 How do the bonding and antibonding MOs formed from a given pair of AOs compare to each other with respect to (a) energy; (b) presence of nodes; (c) internuclear electron density?

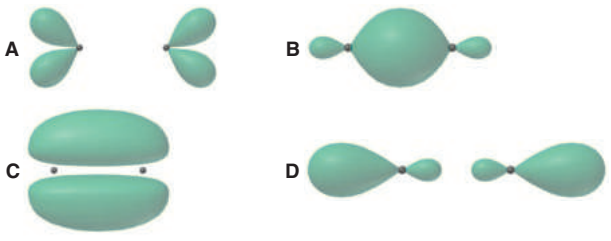
11.29 Antibonding MOs always have at least one node. Can a bonding MO have a node? If so, draw an example.

Skill-Building Exercises (grouped in similar pairs)

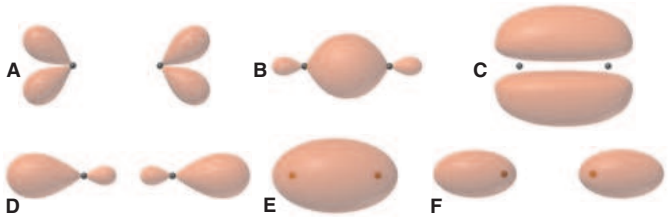
11.30 How many electrons does it take to fill (a) a σ bonding MO; (b) a π antibonding MO; (c) the MOs formed from combination of the 1*s* orbitals of two atoms?

11.31 How many electrons does it take to fill (a) the MOs formed from combination of the 2*p* orbitals of two atoms; (b) a σ^*_{2p} MO; (c) the MOs formed from combination of the 2*s* orbitals of two atoms?

11.32 The molecular orbitals depicted below are derived from 2*p* atomic orbitals in F_2^+. (a) Give the orbital designations. (b) Which is occupied by at least one electron in F_2^+? (c) Which is occupied by only one electron in F_2^+?



11.33 The molecular orbitals depicted below are derived from $n = 2$ atomic orbitals. (a) Give the orbital designations. (b) Which is highest in energy? (c) Lowest in energy? (d) Rank the MOs in order of increasing energy for B_2.



11.34 Use an MO diagram and the bond order you obtain from it to answer: (a) Is Be_2^+ stable? (b) Is Be_2^+ diamagnetic? (c) What is the outer (valence) electron configuration of Be_2^+?

11.35 Use an MO diagram and the bond order you obtain from it to answer: (a) Is O_2^- stable? (b) Is O_2^- paramagnetic? (c) What is the outer (valence) electron configuration of O_2^-?

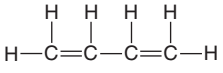
11.36 Use MO diagrams to place C_2^-, C_2, and C_2^+ in order of (a) increasing bond energy; (b) increasing bond length.

11.37 Use MO diagrams to place B_2^+, B_2, and B_2^- in order of (a) decreasing bond energy; (b) decreasing bond length.

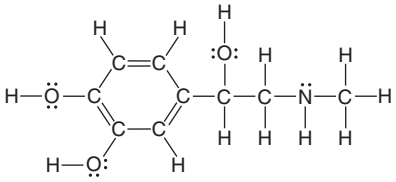
Comprehensive Problems

11.38 Predict the shape, state the hybridization of the central atom, and give the ideal bond angle(s) and any expected deviations for:
(a) BrO_3^- (b) $AsCl_4^-$ (c) SeO_4^{2-} (d) BiF_5^{2-}
(e) SbF_4^+ (f) AlF_6^{3-} (g) IF_4^+

11.39 Butadiene *(right)* is a colorless gas used to make synthetic rubber and many other compounds. (a) How many σ bonds and π bonds does the molecule have? (b) Are *cis-trans* arrangements about the double bonds possible? Explain.



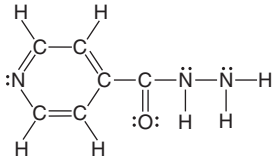
11.40 Epinephrine (or adrenaline; *below*) is a naturally occurring hormone that is also manufactured commercially for use as a heart stimulant, a nasal decongestant, and a glaucoma treatment.



(a) What is the hybridization of each C, O, and N atom? (b) How many σ bonds does the molecule have? (c) How many π electrons are delocalized in the ring?

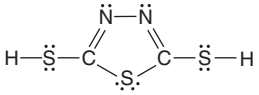
11.41 Use partial orbital diagrams to show how the atomic orbitals of the central atom lead to the hybrid orbitals in:
(a) IF_2^- (b) ICl_3 (c) $XeOF_4$ (d) BHF_2

11.42 Isoniazid *(below)* is an antibacterial agent that is very useful against many common strains of tuberculosis.



(a) How many σ bonds are in the molecule? (b) What is the hybridization of each C and N atom?

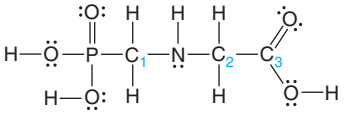
11.43 Hydrazine, N_2H_4, and carbon disulfide, CS_2, form a cyclic molecule *(below)*. (a) Draw Lewis structures for N_2H_4 and CS_2. (b) How do electron-group arrangement, molecular shape, and hybridization of N change when N_2H_4 reacts to form the product? (c) How do electron-group arrangement, molecular shape, and hybridization of C change when CS_2 reacts to form the product?



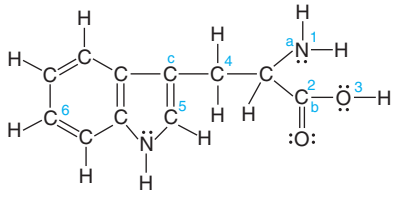
11.44 In each of the following equations, what hybridization change, if any, occurs for the underlined atom?
(a) $\underline{B}F_3 + NaF \longrightarrow Na^+BF_4^-$
(b) $\underline{P}Cl_3 + Cl_2 \longrightarrow PCl_5$
(c) $H\underline{C}{\equiv}CH + H_2 \longrightarrow H_2C{=}CH_2$
(d) $\underline{Si}F_4 + 2F^- \longrightarrow SiF_6^{2-}$
(e) $\underline{S}O_2 + \frac{1}{2}O_2 \longrightarrow SO_3$

11.45 The ionosphere lies about 100 km above Earth's surface. This layer consists mostly of NO, O_2, and N_2, and photoionization creates NO^+, O_2^+, and N_2^+. (a) Use MO theory to compare the bond orders of the molecules and ions. (b) Does the magnetic behavior of each species change when its ion forms?

11.46 Glyphosate *(below)* is a common herbicide that is relatively harmless to animals but deadly to most plants. Describe the shape around and the hybridization of the P, N, and three numbered C atoms.



11.47 Tryptophan is one of the amino acids found in proteins:



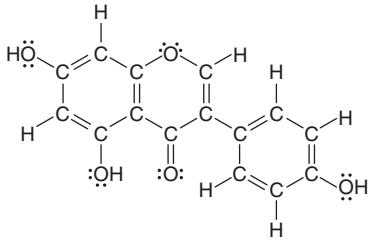
(a) What is the hybridization of each of the numbered C, N, and O atoms? (b) How many σ bonds are present in tryptophan? (c) Predict the bond angles at points a, b, and c.

11.48 Some species with two oxygen atoms only are the oxygen molecule, O_2, the peroxide ion, O_2^{2-}, the superoxide ion, O_2^-, and the dioxygenyl ion, O_2^+. Draw an MO diagram for each, rank them in order of increasing bond length, and find the number of unpaired electrons in each.

11.49 Molecular nitrogen, carbon monoxide, and cyanide ion are isoelectronic. (a) Draw an MO diagram for each. (b) CO and CN^- are toxic. What property may explain why N_2 isn't?

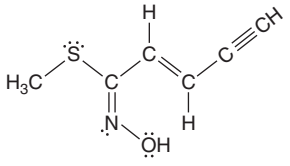
11.50 There is concern in health-related government agencies that the American diet contains too much meat, and numerous recommendations have been made urging people to consume more fruit and vegetables. One of the richest sources of vegetable protein is soy, available in many forms. Among these is soybean curd, or

tofu, which is a staple of many Asian diets. Chemists have isolated an anticancer agent called *genistein* from tofu, which may explain the much lower incidence of cancer among people in the Far East. A valid Lewis structure for genistein is



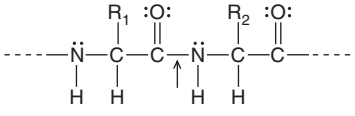
(a) Is the hybridization of each C in the right-hand ring the same? Explain. (b) Is the hybridization of the O atom in the center ring the same as that of the O atoms in the OH groups? Explain. (c) How many carbon-oxygen σ bonds are there? How many carbon-oxygen π bonds? (d) Do all the lone pairs on oxygens occupy the same type of hybrid orbital? Explain.

11.51 An organic chemist synthesizes the molecule below:



(a) Which of the orientations of hybrid orbitals shown below are present in the molecule? (b) Are there any present that are not shown below? If so, what are they? (c) How many of each type of hybrid orbital are present?

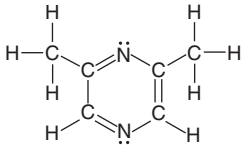
11.52 Simple proteins consist of amino acids linked together in a long chain; a small portion of such a chain is



Experiment shows that rotation about the C—N bond (indicated by the arrow) is somewhat restricted. Explain with resonance structures, and show the types of bonding involved.

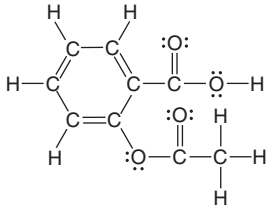
11.53 Sulfur forms oxides, oxoanions, and halides. What is the hybridization of the central S in SO_2, SO_3, SO_3^{2-}, SCl_4, SCl_6, and S_2Cl_2 (atom sequence Cl—S—S—Cl)?

11.54 The compound 2,6-dimethylpyrazine *(below)* gives chocolate its odor and is used in flavorings. (a) Which atomic orbitals mix to form the hybrid orbitals of N? (b) In what type of hybrid orbital do the lone pairs of N reside? (c) Is C in CH_3 hybridized the same as any C in the ring? Explain.

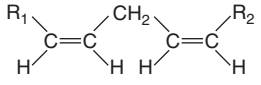


11.55 Use an MO diagram to find the bond order and predict whether H_2^- exists.

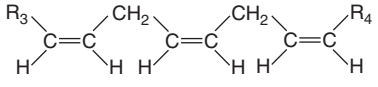
11.56 Acetylsalicylic acid (aspirin), the most widely used medicine in the world, has the Lewis structure shown below. (a) What is the hybridization of each C and each O atom? (b) How many localized π bonds are present? (c) How many C atoms have a trigonal planar shape around them? A tetrahedral shape?



11.57 Linoleic acid is an essential fatty acid found in many vegetable oils, such as soy, peanut, and cottonseed. A key structural feature of the molecule is the *cis* orientation around its two double bonds, where R_1 and R_2 represent two different groups that form the rest of the molecule.



(a) How many different compounds are possible, changing only the *cis-trans* arrangements around these two double bonds?
(b) How many are possible for a similar compound with three double bonds?



12 Intermolecular Forces: Liquids, Solids, and Phase Changes

12.1 An Overview of Physical States and Phase Changes

12.2 Quantitative Aspects of Phase Changes
- Heat Involved in Phase Changes
- Equilibrium Nature of Phase Changes
- Phase Diagrams

12.3 Types of Intermolecular Forces
- How Close Can Molecules Approach Each Other?
- Ion-Dipole Forces
- Dipole-Dipole Forces
- The Hydrogen Bond
- Polarizability and Induced Dipole Forces
- Dispersion (London) Forces

12.4 Properties of the Liquid State
- Surface Tension
- Capillarity
- Viscosity

12.5 The Uniqueness of Water
- Solvent Properties
- Thermal Properties
- Surface Properties
- Unusual Density of Solid Water

12.6 The Solid State: Structure, Properties, and Bonding
- Structural Features
- Crystalline Solids
- Amorphous Solids
- Bonding in Solids: Molecular Orbital Band Theory

12.7 Advanced Materials
- Electronic Materials
- Liquid Crystals
- Ceramic Materials
- Polymeric Materials
- Nanotechnology

Concepts and Skills to Review Before You Study This Chapter

- properties of gases, liquids, and solids (Section 5.1)
- kinetic-molecular theory of gases (Section 5.5)
- kinetic and potential energy (Section 6.1)
- enthalpy change, heat capacity, and Hess's law (Sections 6.2, 6.3, and 6.5)
- diffraction of light (Section 7.1)
- Coulomb's law (Section 9.2)
- chemical bonding models (Chapter 9)
- molecular polarity (Section 10.3)
- molecular orbital treatment of diatomic molecules (Section 11.3)

All the matter in and around you occurs in one or more of the three physical states—gas, liquid, or solid. Under different conditions, many substances can occur in any of the states. We're all familiar with the states of water *(photo):* we inhale and exhale gaseous water; drink, excrete, and wash with liquid water; and shovel, slide on, or cool our drinks with solid water. And, given the right conditions, other solids (gold jewelry, glass), liquids (gasoline, antifreeze), and gases (air, CO_2 bubbles) can exist in one or both of the other states.

The three states were introduced in Chapter 1, and their properties were compared when we examined gases in Chapter 5. You saw there that the particles in gases are, on average, very far apart. Now, we examine liquids and solids, which are called *condensed states* because *their particles are very close together.*

IN THIS CHAPTER . . . *We explore the interplay of forces that give rise to the three states of matter and their changes, with special attention to liquids and solids.*

- We use kinetic-molecular theory to see how relative magnitudes of potential and kinetic energy account for the behavior of gases, liquids, and solids and how temperature is related to phase changes.
- We calculate the heat associated with warming or cooling a phase and with a phase change.
- We highlight the effects of temperature and pressure on phases and their changes with phase diagrams.
- We describe the types and relative strengths of the intermolecular forces that give rise to the phases and phase changes of pure substances.
- We see how intermolecular forces operate in the properties of liquids.
- As a special case, we trace the unique and vital physical properties of water to the electron configurations of its atoms.
- We discuss the properties of solids, emphasizing the relationship between type of bonding and predominant intermolecular force, and we examine crystal structures and two of the methods used to study them.
- We introduce key features of several kinds of advanced materials—semiconductors, liquid crystals, ceramics, polymers, and nanostructures.

12.1 AN OVERVIEW OF PHYSICAL STATES AND PHASE CHANGES

Each physical state is called a **phase,** a physically distinct, homogeneous part of a system. The water in a closed container constitutes one phase; the water vapor above the liquid is a second phase; add some ice, and there are three.

In this section, you'll see that interactions between the potential energy and the kinetic energy of the particles give rise to the properties of each phase:

- The *potential energy* in the form of **intermolecular forces** (or, more generally, *interparticle forces*) tends to draw the molecules together. According to Coulomb's law, the electrostatic potential energy depends on the charges of the particles and the distances between them (Section 9.2). We'll examine the various types of intermolecular forces in Section 12.3.

- The *kinetic energy* associated with the random motion of the molecules tends to disperse them. It is related to their average speed and is proportional to the absolute temperature (Section 5.5).

These interactions also explain **phase changes**—liquid to solid, solid to gas, and so forth, or even one solid form to another.

A Kinetic-Molecular View of the Three States Imagine yourself among the particles in any of the three states of water. Look closely and you'll discover two types of electrostatic forces at work:

1. *Intra*molecular (bonding) forces exist *within* each molecule. The *chemical* behavior of the three states is identical because all of them consist of the same bent, polar H—O—H molecules, each held together by identical covalent bonding forces.
2. *Inter*molecular (nonbonding) forces exist *between* the molecules. The *physical* behavior of the states is different because the strengths of these forces differ from state to state.

Whether a substance occurs as a gas, liquid, or solid depends on the interplay of the potential and kinetic energy:

- *In a gas,* the potential energy (energy of attraction) is small relative to the kinetic energy (energy of motion); thus, on average, the particles are far apart. This large distance has several macroscopic consequences: a gas fills its container, is highly compressible, and flows easily through another gas (Table 12.1).
- *In a liquid,* attractions are stronger because the particles are touching, but they have enough kinetic energy to move randomly around each other. Thus, a liquid conforms to the shape of its container but has a surface, it resists an applied force and thus compresses very slightly, and it flows, but *much* more slowly than gases.
- *In a solid,* the attractions dominate the motion so much that the particles are fixed in position relative to one another, just jiggling in place. Thus, a solid has its own shape, compresses even less than liquids, and does not flow significantly.

Table 12.1 A Macroscopic Comparison of Gases, Liquids, and Solids

State	Shape and Volume	Compressibility	Ability to Flow
Gas	Conforms to shape and volume of container	High	High
Liquid	Conforms to shape of container; volume limited by surface	Very low	Moderate
Solid	Maintains its own shape and volume	Almost none	Almost none

Relative ability to flow influences the degree of mixing and, thus, composition in nature.

The environment provides a perfect demonstration of these differences in ability to flow *(see photo)*. Atmospheric gases mix so well that the lowest 80 km of air has a uniform composition. Much less mixing in the oceans allows the composition at various depths to support different species. And rocks intermingle so little that adjacent strata remain separated for millions of years.

Types of Phase Changes and Their Enthalpies When we consider phase changes, understanding the effect of temperature is critical:

- As *temperature increases,* the average kinetic energy does too, so the particles move faster and overcome attractions more easily.
- As *temperature decreases,* the average kinetic energy does too, so particles move more slowly and attractions can pull them together more easily.

Pressure also affects phase changes, most dramatically when gases are involved and to a lesser extent with liquids. Each phase change has a name and an associated enthalpy change:

1. *Gas to liquid, and vice versa.* As the temperature drops (and/or the pressure rises), the molecules in the gas phase come together and form a liquid in the

process of **condensation;** the opposite process, changing from a liquid to a gas, is **vaporization.**

2. *Liquid to solid, and vice versa*. As the temperature drops further, the particles move more slowly and become fixed in position in the process of **freezing;** the opposite change is called **melting,** or **fusion.** (For most substances, an increase in pressure supports freezing as well.) In common speech, *freezing* implies low temperature because we think of water. But, for example, molten metals freeze (solidify) at much higher temperatures, which gives them many medical, industrial, and artistic applications, such as gold dental crowns, steel auto bodies, and bronze statues.

3. *Gas to solid, and vice versa.* All three states of water are familiar because they are stable under ordinary conditions. Carbon dioxide, on the other hand, is familiar as a gas and a solid (dry ice), but liquid CO_2 occurs only at pressures of 5.1 atm or greater. At ordinary conditions, solid CO_2 changes directly to a gas, a process called **sublimation.** Freeze-dried foods are prepared by freezing the food and subliming the water. The opposite process, changing from a gas directly into a solid, is called **deposition**—ice crystals form on a cold window from the deposition of water vapor (Figure 12.1A).

The accompanying enthalpy changes are either exothermic or endothermic:

- *Exothermic changes*. As the molecules of a gas attract each other into a liquid, and then become fixed in a solid, the system of particles *loses* energy, which is released as heat. Thus, *condensing, freezing, and depositing are exothermic changes.*
- *Endothermic changes*. Heat must be absorbed by the system to overcome the attractive forces that keep the particles fixed in place in a solid or near each other in a liquid. Thus, *melting, vaporizing, and subliming are endothermic changes.*

Sweating has a cooling effect because heat from your body vaporizes the water. To achieve this cooling, cats lick themselves and dogs pant (Figure 12.1B).

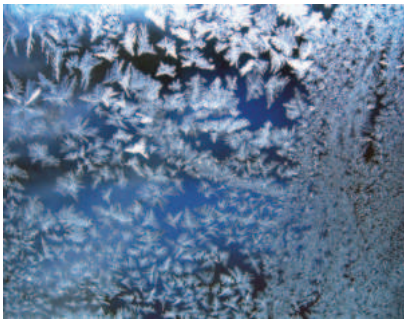
For a pure substance, each phase change is accompanied by a standard enthalpy change, given in units of *kilojoules per mole* (measured at 1 atm and the temperature of the change). For vaporization, it is the **heat** (or *enthalpy*) **of vaporization (ΔH°_{vap}),** and for fusion (melting), it is the **heat** (or *enthalpy*) **of fusion (ΔH°_{fus}).** In the case of water, we have

$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H = \Delta H^\circ_{vap} = 40.7 \text{ kJ/mol (at } 100^\circ\text{C)}$$
$$H_2O(s) \longrightarrow H_2O(l) \qquad \Delta H = \Delta H^\circ_{fus} = 6.02 \text{ kJ/mol (at } 0^\circ\text{C)}$$

The reverse processes, condensing and freezing, have enthalpy changes of the *same magnitude but opposite sign:*

$$H_2O(g) \longrightarrow H_2O(l) \qquad \Delta H = -\Delta H^\circ_{vap} = -40.7 \text{ kJ/mol}$$
$$H_2O(l) \longrightarrow H_2O(s) \qquad \Delta H = -\Delta H^\circ_{fus} = -6.02 \text{ kJ/mol}$$

Water behaves typically in that it takes much less energy to melt the solid than to vaporize the liquid: $\Delta H^\circ_{fus} < \Delta H^\circ_{vap}$; that is, it takes less energy to reduce the intermolecular forces enough for the molecules to move out of their fixed positions (melt a solid) than to separate them completely (vaporize a liquid) (Figure 12.2).



A Deposition

B Vaporization

Figure 12.1 Two familiar phase changes.

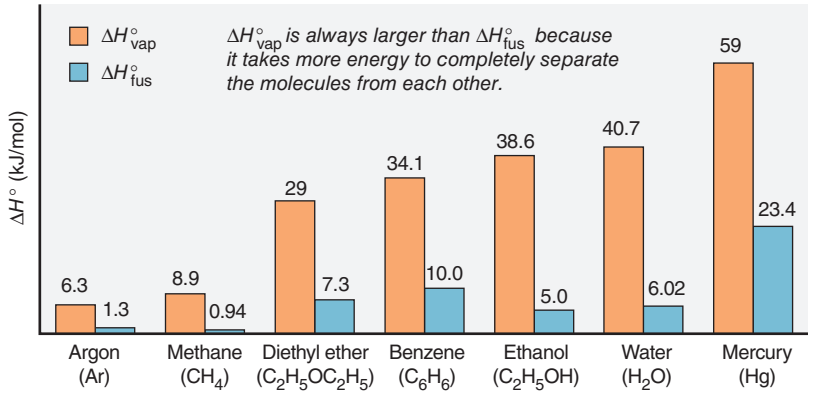


Figure 12.2 Heats of vaporization and fusion for several common substances.

The **heat** (or *enthalpy*) **of sublimation** (ΔH°_{subl}) is the enthalpy change when 1 mol of a substance sublimes, and the negative of this value is the change when 1 mol of the substance deposits. Since sublimation can be considered a combination of melting and vaporizing steps, Hess's law (Section 6.5) says that the heat of sublimation equals the sum of the heats of fusion and vaporization:

$$\begin{array}{rll} \text{Solid} \longrightarrow \text{liquid} & & \Delta H^\circ_{fus} \\ \text{Liquid} \longrightarrow \text{gas} & & \Delta H^\circ_{vap} \\ \hline \text{Solid} \longrightarrow \text{gas} & & \Delta H^\circ_{subl} \end{array}$$

Figure 12.3 summarizes the phase changes and their enthalpy changes.

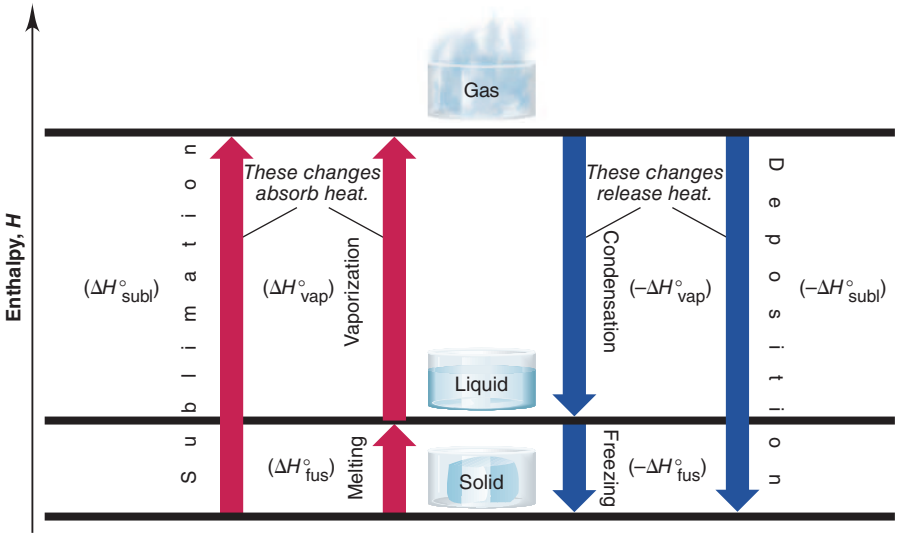

Figure 12.3 Phase changes and their enthalpy changes. Fusion (or melting), vaporization, and sublimation are endothermic changes (positive ΔH°), whereas freezing, condensation, and deposition are exothermic changes (negative ΔH°).

Summary of Section 12.1

- Because of the relative magnitudes of intermolecular forces (potential energy) and average speed (kinetic energy), the particles in a gas are far apart and moving randomly, those in a liquid are in contact and moving relative to each other, and those in a solid are in contact and in fixed positions. These molecular-level differences account for macroscopic differences in shape, compressibility, and ability to flow.
- When a solid becomes a liquid (melting, or fusion), a liquid becomes a gas (vaporization), or a solid becomes a gas (sublimation), energy is absorbed to overcome intermolecular forces and increase the average distance between particles. As particles come closer together in the reverse changes (freezing, condensation, and deposition), energy is released. Each phase change is associated with a given enthalpy change under specified conditions.

12.2 QUANTITATIVE ASPECTS OF PHASE CHANGES

Of course, many phase changes of water occur around you every day, accompanied by the release or absorption of heat. When it rains, water vapor has condensed to a liquid, which changes back to a gas as puddles dry up. In the spring, solid water melts, and in winter, it freezes again. And the same phase changes take place whenever you make a pot of tea or a tray of ice cubes. In this section, we quantify the heat involved in a phase change and examine the equilibrium nature of the process.

Heat Involved in Phase Changes

We apply a kinetic-molecular approach to phase changes with a **heating-cooling curve,** which shows the changes in temperature of a sample when heat is absorbed or released at a constant rate. Let's examine what happens when 2.50 mol of gaseous water in a closed container undergoes a change from 130°C to −40°C at a constant pressure of 1 atm. We'll divide this process into five heat-releasing (exothermic) stages (Figure 12.4):

Stage 1. Gaseous water cools. Water molecules zoom chaotically at a range of speeds, smashing into each other and the container walls. At the starting temperature, the most probable speed of the molecules, and thus their average kinetic energy (E_k), is high enough to overcome the potential energy (E_p) of attractions. As the temperature falls, the average E_k decreases and attractions become more important. The change is

$$H_2O(g)\,[130°C] \longrightarrow H_2O(g)\,[100°C]$$

The heat (q) is the product of the amount (number of moles, n) of water, the molar heat capacity of *gaseous* water, $C_{water(g)}$, and the temperature change during this step, ΔT ($T_{final} - T_{initial}$):

$$\begin{aligned} q &= n \times C_{water(g)} \times \Delta T = (2.50\ \text{mol})\,(33.1\ \text{J/mol}\cdot°\text{C})\,(100°\text{C} - 130°\text{C}) \\ &= -2482\ \text{J} = -2.48\ \text{kJ} \end{aligned}$$

The minus sign indicates that heat is released. (For purposes of canceling, the units for molar heat capacity, C, include °C rather than K, but this doesn't affect the magnitude of C because 1°C and 1 K represent the same temperature increment.)

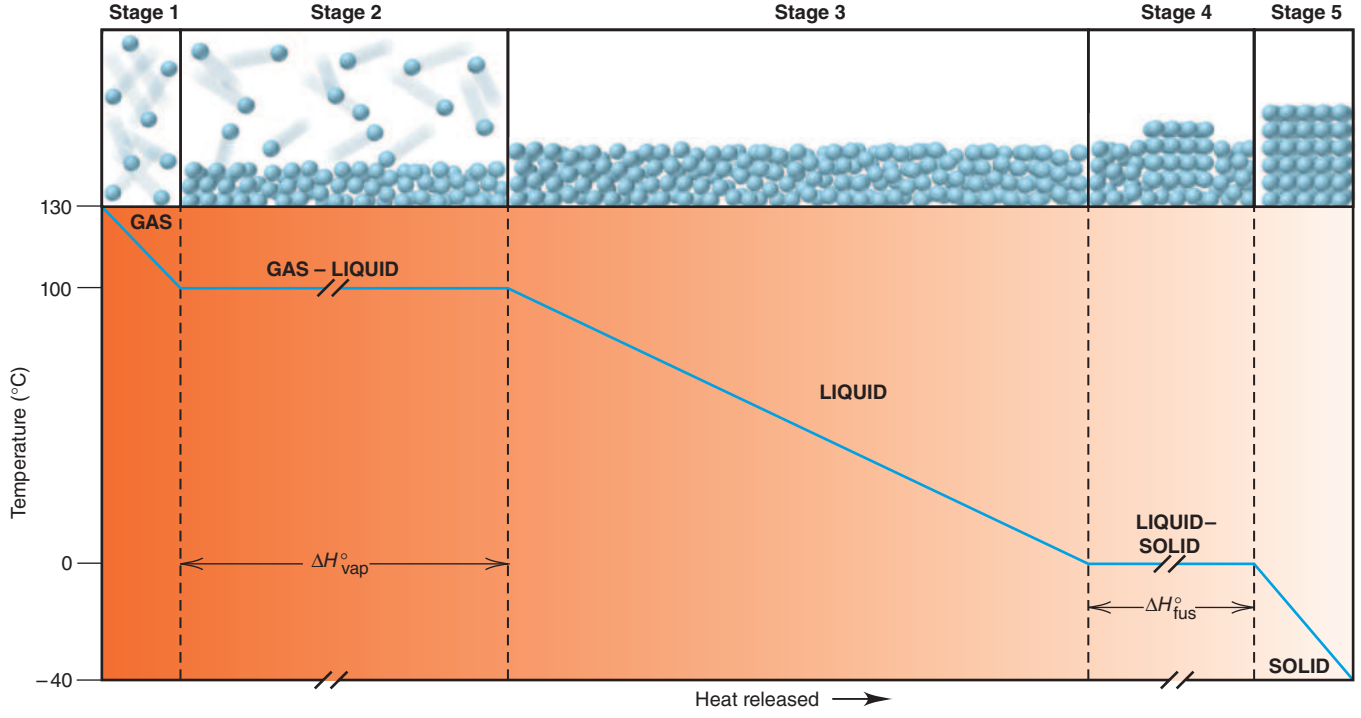

Figure 12.4 A cooling curve for the conversion of gaseous water to ice. A plot of temperature vs. heat released as gaseous water changes to ice is shown, with a molecular-level depiction for each stage. The slopes of the lines in stages 1, 3, and 5 reflect the molar heat capacities of the phases. Although not drawn to scale, the line in stage 2 is longer than the line in stage 4 because ΔH°_{vap} of water is greater than ΔH°_{fus}. A plot of temperature vs. heat absorbed starting at −40°C would have the same steps but in reverse order.

Stage 2. Gaseous water condenses. At the condensation point, intermolecular attractions cause the slowest of the molecules to aggregate into microdroplets and then a bulk liquid. Note that, during the phase change,

- The temperature of the sample, and thus its average E_k, is constant. At the same temperature, molecules move farther between collisions in a gas than in a liquid, but their *average* speed is the same.
- Releasing heat from the sample decreases the average E_p as the molecules approach and attract each other.

Thus, at 100°C, gaseous and liquid water have the same average E_k, but the liquid has lower average E_p. The change is

$$H_2O(g)\,[100°C] \longrightarrow H_2O(l)\,[100°C]$$

The heat is the amount (n) times the negative of the heat of vaporization ($-\Delta H^\circ_{vap}$):

$$q = n(-\Delta H^\circ_{vap}) = (2.50\text{ mol})\,(-40.7\text{ kJ/mol}) = -102\text{ kJ}$$

This stage contributes the *greatest portion of the total heat released* because of the large decrease in E_p as the molecules become so much closer in the liquid than they were in the gas.

Stage 3. Liquid water cools. The molecules in the liquid state continue to lose heat, and the loss appears as a decrease in temperature, that is, as a decrease in the most probable molecular speed and, thus, the average E_k. The temperature decreases as long as the sample remains liquid. The change is

$$H_2O(l)\,[100°C] \longrightarrow H_2O(l)\,[0°C]$$

The heat depends on amount (n), the molar heat capacity of *liquid* water, and ΔT:

$$q = n \times C_{water(l)} \times \Delta T = (2.50\text{ mol})\,(75.4\text{ J/mol}\cdot°C)\,(0°C - 100°C)$$
$$= -18{,}850\text{ J} = -18.8\text{ kJ}$$

Stage 4. Liquid water freezes. At 0°C, the sample loses E_p as increasing intermolecular attractions cause the molecules to align themselves into the crystalline structure of ice. Molecular motion continues only as random jiggling about fixed positions. As we saw during condensation, temperature and average E_k are constant during freezing. The change is

$$H_2O(l)\,[0°C] \longrightarrow H_2O(s)\,[0°C]$$

The heat is equal to n times the negative of the heat of fusion ($-\Delta H^\circ_{fus}$):

$$q = n(-\Delta H^\circ_{fus}) = (2.50\text{ mol})\,(-6.02\text{ kJ/mol}) = -15.0\text{ kJ}$$

Stage 5. Solid water cools. With motion restricted to jiggling in place, further cooling merely reduces the average speed of this jiggling. The change is

$$H_2O(s)\,[0°C] \longrightarrow H_2O(s)\,[-40°C]$$

The heat depends on n, the molar heat capacity of *solid* water, and ΔT:

$$q = n \times C_{water(s)} \times \Delta T = (2.50\text{ mol})\,(37.6\text{ J/mol}\cdot°C)\,(-40°C - 0°C)$$
$$= -3760\text{ J} = -3.76\text{ kJ}$$

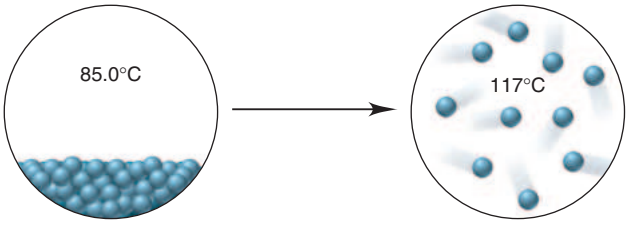
According to Hess's law, the total heat released is the sum of the heats released for the individual stages. The sum of q for stages 1 to 5 is −142 kJ. Two key points stand out for this or any similar process, whether exothermic or endothermic:

- *Within a phase,* heat flow is accompanied by *a change in temperature,* which is associated with a change in average E_k, as *the most probable speed of the molecules changes.* The heat released or absorbed depends on the amount of substance, the molar heat capacity *for that phase,* and the change in temperature.
- *During a phase change,* heat flow occurs at a *constant temperature,* which is associated with a change in average E_p, as *the average distance between molecules changes.* Both phases are present and (as you'll see) are in equilibrium during the change. The heat released or absorbed depends on the amount of substance and the enthalpy change for that phase change.

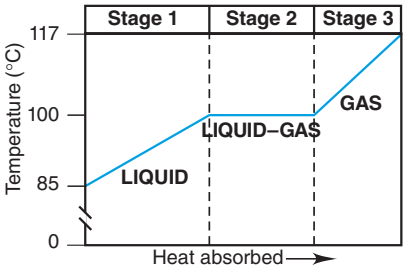
Let's work a molecular-scene sample problem to make sure these ideas are clear.

SAMPLE PROBLEM 12.1 Finding the Heat of a Phase Change Depicted by Molecular Scenes

Problem The scenes below represent a phase change of water. Select data from the previous discussion to find the heat (in kJ) released or absorbed when 24.3 g of H_2O undergoes this change.



Plan From the molecular scenes, data in the text, and the given mass (24.3 g) of water, we have to find the heat that accompanies this change. The scenes show a disorderly, condensed phase at 85.0°C changing to separate molecules at 117°C. Thus, the phase change they depict is vaporization, an endothermic process. The text data are given per mole, so we first convert the mass (g) of water to amount (mol). There are three stages: (1) heating the liquid from 85.0°C to 100.°C, (2) converting liquid water at 100.°C to gaseous water at 100.°C, and (3) heating the gas from 100.°C to 117°C *(see margin)*. We add the values of q for these stages to obtain the total heat.



Solution Converting from mass (g) of H_2O to amount (mol):

$$\text{Amount (mol) of } H_2O = 24.3 \text{ g } H_2O \times \frac{1 \text{ mol}}{18.02 \text{ g } H_2O} = 1.35 \text{ mol}$$

Finding the heat accompanying stage 1, $H_2O(l)\,[85.0°C] \longrightarrow H_2O(l)\,[100.°C]$:

$$q = n \times C_{\text{water}(l)} \times \Delta T = (1.35 \text{ mol})\,(75.4 \text{ J/mol·°C})\,(100.°C - 85.0°C)$$
$$= 1527 \text{ J} = 1.53 \text{ kJ}$$

Finding the heat accompanying stage 2, $H_2O(l)\,[100.°C] \longrightarrow H_2O(g)\,[100.°C]$:

$$q = n(\Delta H^\circ_{\text{vap}}) = (1.35 \text{ mol})\,(40.7 \text{ kJ/mol}) = 54.9 \text{ kJ}$$

Finding the heat accompanying stage 3, $H_2O(g)\,[100.°C] \longrightarrow H_2O(g)\,[117°C]$:

$$q = n \times C_{\text{water}(g)} \times \Delta T = (1.35 \text{ mol})\,(33.1 \text{ J/mol·°C})\,(117°C - 100.°C)$$
$$= 759.6 \text{ J} = 0.760 \text{ kJ}$$

Adding the three heats together to find the total heat of the process:

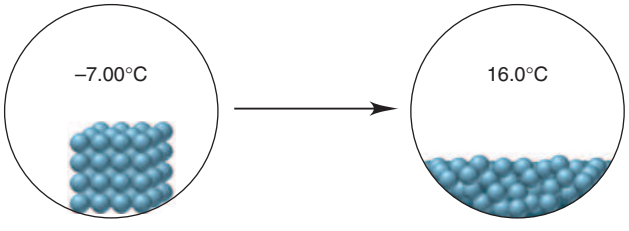
$$\text{Total heat (kJ)} = 1.53 \text{ kJ} + 54.9 \text{ kJ} + 0.760 \text{ kJ} = \boxed{57.2 \text{ kJ}}$$

Check The heat should have a positive value because it is absorbed. Be sure to round to check each value of q; for example, in stage 1, 1.33 mol × 75 J/mol·°C × 15°C = 1500 J. Note that the phase change itself (stage 2) requires the most energy and, thus, dominates the final answer. The $\Delta H^\circ_{\text{vap}}$ units include kJ, whereas the molar heat capacity units include J, which is a thousandth as large.

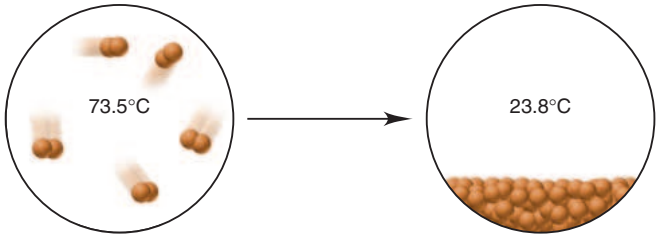
FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

12.1A The scenes below represent a phase change of water. Select data from the text discussion to find the heat (in kJ) released or absorbed when 2.25 mol of H_2O undergoes this change.



12.1B The scenes below represent a phase change of bromine, Br_2. Use the following data to find the heat (in kJ) released or absorbed when 47.94 g of bromine undergoes this change: C_{liquid} = 75.7 J/mol·°C; C_{gas} = 36.0 J/mol·°C; ΔH°_{fus} = 10.6 kJ/mol; ΔH°_{vap} = 29.6 kJ/mol; mp = −7.25°C; bp = 59.5°C.



SOME SIMILAR PROBLEMS 12.19 and 12.20

The Equilibrium Nature of Phase Changes

In everyday experience, phase changes take place in *open* containers—the outdoors, a pot on a stove, the freezer compartment of a refrigerator—so they are not reversible. But, in a *closed* container, *phase changes **are** reversible and reach equilibrium,* just as chemical changes do. In this discussion, we examine the three phase equilibria.

Liquid-Gas Equilibria Vaporization and condensation are familiar events. Let's see how these processes differ in open and closed systems of a liquid in a flask:

1. *Open system: nonequilibrium process*. Picture an *open* flask containing a pure liquid at constant temperature. Within their range of speeds, some molecules at the surface have a high enough E_k to overcome attractions and vaporize. Nearby molecules fill the gap, and with heat supplied by the constant-temperature surroundings, the process continues until the entire liquid phase is gone.

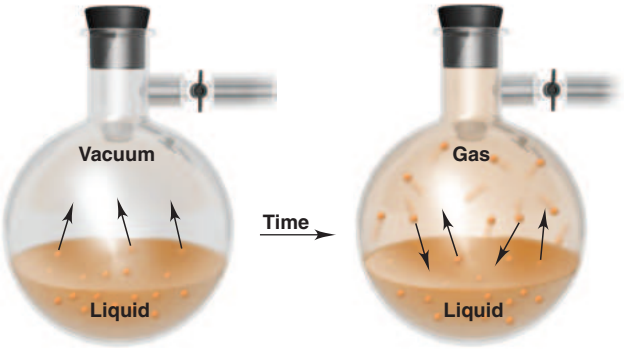
2. *Closed system: equilibrium process*. Now picture a *closed* flask at constant temperature and assume a vacuum exists above a liquid (Figure 12.5A). Two processes take place: Some molecules at the surface have a high enough E_k to *vaporize*. After a short time, molecules in the vapor collide with the surface, and the slower ones are attracted strongly enough to *condense.*

At first, these two processes occur at different rates. The number of molecules in a given surface area is constant, so the number of molecules leaving the surface per unit time—the rate of vaporization—is also constant, and the pressure increases. With time, the number of molecules colliding with and entering the surface—the rate of condensation—increases as the vapor becomes more populated, so the increase in pressure slows. Eventually, the rate of condensation equals the rate of vaporization; from this time onward, *the pressure is constant* (Figure 12.5B).

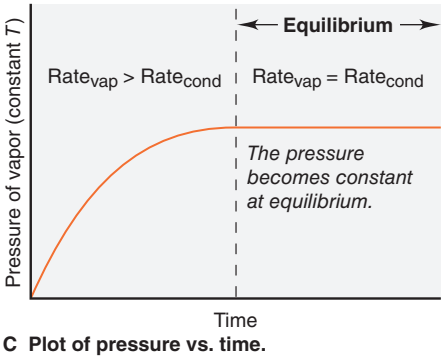
Macroscopically, the situation at this point seems static, but at the molecular level, molecules are entering and leaving the liquid at equal rates. The system has reached a state of *dynamic equilibrium:*

$$\text{liquid} \rightleftharpoons \text{gas}$$

Figure 12.5 **Liquid-gas equilibrium.** **A,** Molecules leave the surface at a constant rate and the pressure rises. **B,** At equilibrium, the same number of molecules leave and enter the liquid in a given time. **C,** Pressure increases until, at equilibrium, it is constant.



A Molecules in the liquid vaporize. **B** Molecules vaporize and condense at the same rate.



C Plot of pressure vs. time.

The pressure exerted by the vapor at equilibrium is called the *equilibrium vapor pressure,* or just the **vapor pressure,** of the liquid at that temperature. Figure 12.5C depicts the entire process graphically. If we started with a larger flask, the number of molecules in the vapor would be greater at equilibrium. But, as long as the temperature is constant and some liquid is present, the vapor pressure will be the same.

3. *Disturbing a system at equilibrium.* Let's see what happens if we alter certain conditions, called "disturbing" the system:

- *Decrease in pressure*. Suppose we pump some vapor out of the flask, immediately lowering the pressure. (In a cylinder fitted with a piston, we lower the pressure by moving the piston outward, thus increasing the volume.) The rate of condensation temporarily falls below the rate of vaporization (the forward process is faster) because fewer molecules enter the liquid than leave it. The pressure rises until, after a short time, the condensation rate increases enough for equilibrium to be reached again.
- *Increase in pressure*. Suppose we pump more vapor in (or move the piston inward, thus decreasing the volume), thereby immediately raising the pressure. The rate of condensation temporarily exceeds the rate of vaporization because more molecules enter the liquid than leave it (the reverse process is faster). Soon, however, the condensation rate decreases until the pressure again reaches the equilibrium value.

This general behavior of a liquid and its vapor is seen in any system at equilibrium: *when a system at equilibrium is disturbed, it counteracts the disturbance until it re-establishes equilibrium.* We'll return to this key idea often in later chapters.

The Effects of Temperature and Intermolecular Forces on Vapor Pressure

The vapor pressure is affected by two factors—a change in temperature and a change in the gas itself, that is, in the type and/or strength of intermolecular forces:

1. *Effect of temperature*. Temperature has a major effect on vapor pressure because it changes the fraction of molecules moving fast enough to escape the liquid and, by the same token, the fraction moving slowly enough to be recaptured. In Figure 12.6, we see the familiar skewed bell-shaped curve of the distribution of molecular speeds (see also Figure 5.20, p. 228). At the higher temperature, T_2, more molecules have enough energy to leave the surface. Thus, in general, *the higher the temperature is, the higher the vapor pressure:*

$$\text{higher } T \Longrightarrow \text{higher } P$$

2. *Effect of intermolecular forces*. At a given T, all substances have the same average E_k. Therefore, molecules with weaker intermolecular forces are held less tightly

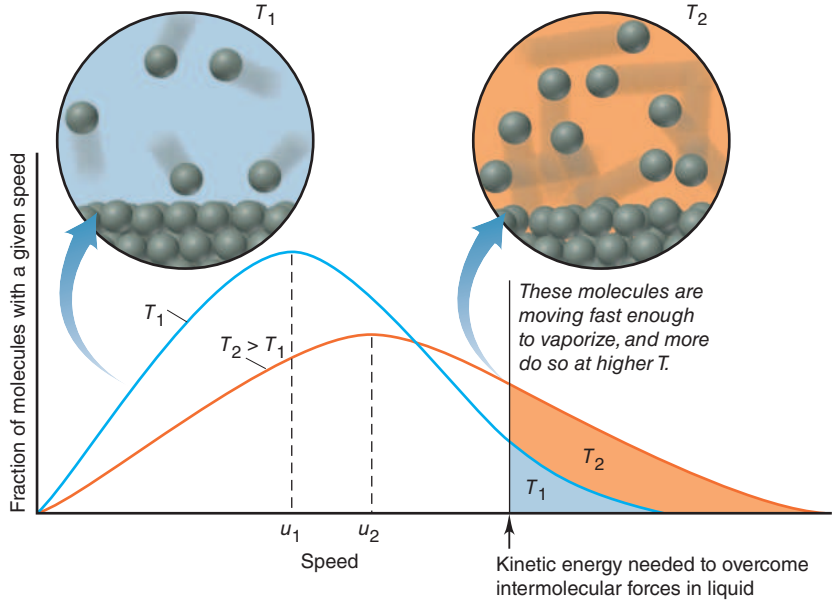


Figure 12.6 The effect of temperature on the distribution of molecular speeds.

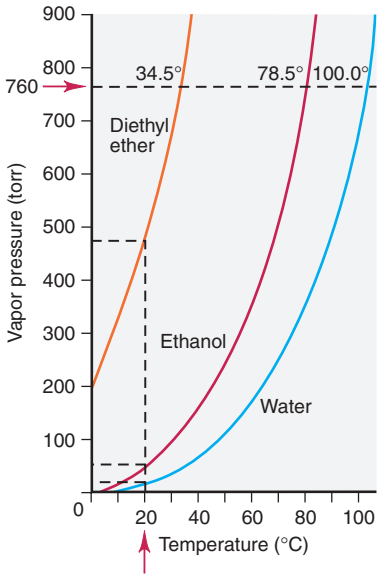

Figure 12.7 **Vapor pressure as a function of temperature and intermolecular forces.**

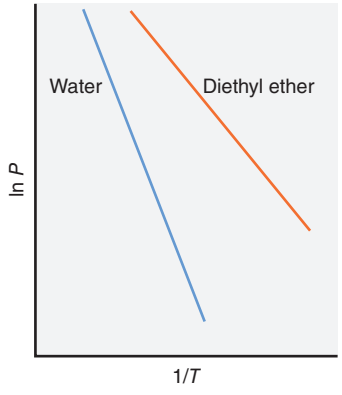

Figure 12.8 **Linear plots of the relationship between vapor pressure and temperature.** The slope is steeper for water because its ΔH_{vap} is greater.

at the surface and vaporize more easily. In general, *the weaker the intermolecular forces are, the higher the vapor pressure:*

$$\text{weaker forces} \Longrightarrow \text{higher } P$$

Figure 12.7 shows the vapor pressure of three liquids as a function of temperature:

- The effect of temperature is seen in the steeper rise as the temperature increases.
- The effect of intermolecular forces is seen in the values of the vapor pressure, the short, horizontal dashed lines intersecting the vertical (pressure) axis at a given temperature *(vertical dashed line at 20°C):* the intermolecular forces in diethyl ether (highest vapor pressure) are weaker than those in ethanol, which are weaker than those in water (lowest vapor pressure).

Quantifying the Effect of Temperature The nonlinear relationship between P and T is converted to a linear one with the **Clausius-Clapeyron equation:**

$$\ln P = \frac{-\Delta H_{vap}}{R}\left(\frac{1}{T}\right) + C$$
$$y \;=\; m \quad x \;+\; b$$

where ln P is the natural logarithm of the vapor pressure, ΔH_{vap} is the heat of vaporization, R is the universal gas constant (8.314 J/mol·K), T is the absolute temperature, and C is a constant (not related to heat capacity). The equation is often used to find the heat of vaporization. The equation for a straight line is shown under it in blue, with y = ln P, $x = 1/T$, m (the slope) $= -\Delta H_{vap}/R$, and b (the y-axis intercept) $= C$. A plot of ln P vs. $1/T$ gives a straight line, as shown for diethyl ether and water in Figure 12.8.

A two-point version of the Clausius-Clapeyron equation allows us to calculate ΔH_{vap} if vapor pressures at two temperatures are known:

$$\ln\frac{P_2}{P_1} = \frac{-\Delta H_{vap}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) \qquad \textbf{(12.1)}$$

If ΔH_{vap} and P_1 at T_1 are known, we can also calculate the vapor pressure (P_2) at any other temperature (T_2) or the temperature at any other pressure.

SAMPLE PROBLEM 12.2 Applying the Clausius-Clapeyron Equation

Problem The vapor pressure of ethanol is 115 torr at 34.9°C. If ΔH_{vap} of ethanol is 38.6 kJ/mol, calculate the temperature (in °C) when the vapor pressure is 760 torr.

Plan We are given ΔH_{vap}, P_1, P_2, and T_1 and substitute them into Equation 12.1 to solve for T_2. The value of R here is 8.314 J/mol·K, so we must convert T_1 to K to obtain T_2, and then convert T_2 back to °C.

Solution Substituting the values into Equation 12.1 and solving for T_2:

$$\ln\frac{P_2}{P_1} = \frac{-\Delta H_{vap}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$
$$T_1 = 34.9°\text{C} + 273.15 = 308.0\ \text{K}$$
$$\ln\frac{760\ \text{torr}}{115\ \text{torr}} = \left(-\frac{38.6\times10^3\ \text{J/mol}}{8.314\ \text{J/mol·K}}\right)\left(\frac{1}{T_2} - \frac{1}{308.0\ \text{K}}\right)$$
$$1.888 = (-4.64\times10^3\ \text{K})\left[\frac{1}{T_2} - (3.247\times10^{-3}\ \text{K}^{-1})\right]$$
$$T_2 = 352\ \text{K}$$

Converting T_2 from K to °C:

$$T_2 = 352\ \text{K} - 273.15 = \boxed{79°\text{C}}$$

Check Round off to check the math. The change is in the right direction: higher P should occur at higher T. As we discuss next, a substance has a vapor pressure of 760 torr at its *normal boiling point.* Checking the *CRC Handbook of Chemistry and Physics* shows that the boiling point of ethanol is 78.5°C, very close to our answer.

FOLLOW-UP PROBLEMS

12.2A At 34.1°C, the vapor pressure of water is 40.1 torr. What is the vapor pressure at 85.5°C? The ΔH_{vap} of water is 40.7 kJ/mol.

12.2B Acetone is essential as an industrial solvent and a starting reactant in the manufacturing of countless products, from films to synthetic fibers. At 20.2°C, the vapor pressure of acetone is 24.50 kPa. If its ΔH_{vap} is 30.99 kJ/mol, what is the temperature (in °C) when the vapor pressure is 10.00 kPa?

SOME SIMILAR PROBLEMS 12.21–12.24

Vapor Pressure and Boiling Point Let's discuss what is happening when a liquid boils and then see the effect of pressure on boiling point.

1. *How a liquid boils.* In an *open* container, the weight of the atmosphere bears down on a liquid surface. As the temperature rises, molecules move more quickly throughout the liquid. At some temperature, the average E_k of the molecules in the liquid is great enough for them to form bubbles of vapor *in the interior,* and the liquid boils. At any lower temperature, the bubbles collapse as soon as they start to form because the external pressure is greater than the vapor pressure inside the bubbles. Thus, the **boiling point** *is the temperature at which the vapor pressure equals the external pressure,* which is usually that of the atmosphere. As in condensation and freezing, once boiling begins, the temperature of the liquid remains constant until all of the liquid is gone.

2. *Effect of pressure on boiling point.* The boiling point of a liquid varies with elevation. At high elevations, a lower atmospheric pressure is exerted on the liquid surface, so molecules in the interior need less kinetic energy to form bubbles. Therefore, in mountainous regions, food takes *more* time to cook because the boiling point is lower and the boiling liquid is not as hot; for instance, in Boulder, Colorado (elevation 5430 ft, or 1655 m), water boils at 94°C. On the other hand, in a pressure cooker, food takes *less* time to cook because the boiling point is higher at the higher pressure. Thus, *the boiling point is directly proportional to the applied pressure.* The *normal boiling point* is observed at standard atmospheric pressure (760 torr, or 101.3 kPa; *long, horizontal dashed line* in Figure 12.7).

Solid-Liquid Equilibria The particles in a crystal are continually jiggling about their fixed positions. As the temperature rises, the particles jiggle more rapidly, until some have enough kinetic energy to break free of their positions. At this point, melting begins. As more molecules enter the liquid (molten) phase, some collide with the solid and become fixed in position again. Because the phases remain in contact, a dynamic equilibrium is established when the melting rate equals the freezing rate. The temperature at which this occurs is called the **melting point.** The temperature remains fixed at the melting point until all the solid melts.

Because liquids and solids are nearly incompressible, pressure has little effect on the rates of melting and freezing: a plot of pressure vs. temperature for a solid-liquid phase change is typically a *nearly* vertical straight line.

Solid-Gas Equilibria Sublimation is not very familiar because solids have *much* lower vapor pressures than liquids. A substance sublimes rather than melts because the intermolecular attractions are not great enough to keep the molecules near each other when they leave the solid state. Some solids *do* have high enough vapor pressures to sublime at ordinary conditions, including dry ice (carbon dioxide), iodine (Figure 12.9), and moth repellants, all nonpolar molecules with weak intermolecular forces.

The plot of pressure vs. temperature for a solid-gas phase change reflects the large effect of temperature on vapor pressure; thus, it resembles the liquid-gas curve in rising steeply with higher temperatures.

Figure 12.9 Iodine subliming. As the solid sublimes, I_2 vapor deposits on a cold surface (water-filled inner test tube).

Phase Diagrams: Effect of Pressure and Temperature on Physical State

The **phase diagram** of a substance combines the liquid-gas, solid-liquid, and solid-gas curves and gives the conditions of temperature and pressure at which each phase is stable and where phase changes occur.

The Phase Diagram for Carbon Dioxide and Most Substances

The diagram for CO_2, which is typical of most substances, has four general features (Figure 12.10):

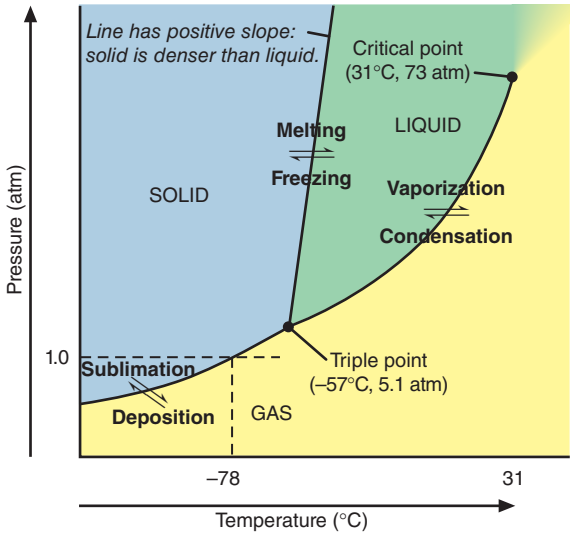

Figure 12.10 **Phase diagram for CO_2.** (The slope of the solid-liquid line is exaggerated, and the axes are not linear in both this figure and Figure 12.11.)

1. *Regions of the diagram.* Each region presents the conditions of pressure and temperature for which the phase is stable. If another phase is placed under those conditions, it will change to the stable phase. In general, the solid is stable at low temperature and high pressure, the gas at high temperature and low pressure, and the liquid at intermediate conditions.

2. *Lines between regions.* The lines are the phase-transition curves discussed earlier. Any point along a line shows the pressure and temperature at which the phases are in equilibrium. The solid-liquid line has a slightly *positive* slope (slants to the *right* with increasing pressure) because, for most substances, the solid is more dense than the liquid: an increase in pressure converts the liquid to the solid. (Water is *the* major exception.)

3. *The triple point.* The three phase-transition curves meet at the **triple point,** at which all three phases are in equilibrium. As strange as it sounds, at the triple point in Figure 12.10, CO_2 is subliming and depositing, melting and freezing, and vaporizing and condensing simultaneously! Substances with several solid and/or liquid forms can have more than one triple point.

The CO_2 phase diagram shows why dry ice (solid CO_2) doesn't melt under ordinary conditions. The triple-point pressure is 5.1 atm, so liquid CO_2 doesn't occur at 1 atm because it is not stable. The horizontal dashed line at 1.0 atm crosses the solid-gas line, so when solid CO_2 is heated, it sublimes at $-78°C$ rather than melts. If our normal atmospheric pressure were 5.2 atm, liquid CO_2 *would* occur.

4. *The critical point.* Heat a liquid in a closed container and its density decreases. At the same time, more of the liquid vaporizes, so the density of the vapor increases. At the **critical point,** the two densities become equal and the phase boundary disappears. The temperature at the critical point is the *critical temperature* (T_c), and the pressure is the *critical pressure* (P_c). The average E_k is so high at this point that the vapor cannot be condensed at any pressure. The two most common gases in air have critical temperatures far below room temperature: O_2 cannot be condensed above $-119°C$, and N_2 above $-147°C$.

Beyond the critical temperature, a *supercritical fluid* (SCF) exists rather than separate liquid and gaseous phases. An SCF expands and contracts like a gas and has unusual solvent properties. Supercritical CO_2 is used to extract caffeine from coffee beans, nicotine from tobacco, and fats from potato chips, and acts as a dry cleaning agent. Lower the pressure, and the SCF disperses as a harmless gas. Supercritical H_2O dissolves nonpolar substances, even though liquid water cannot. Studies are under way to use supercritical H_2O for removing nonpolar organic toxins, such as PCBs, from industrial waste.

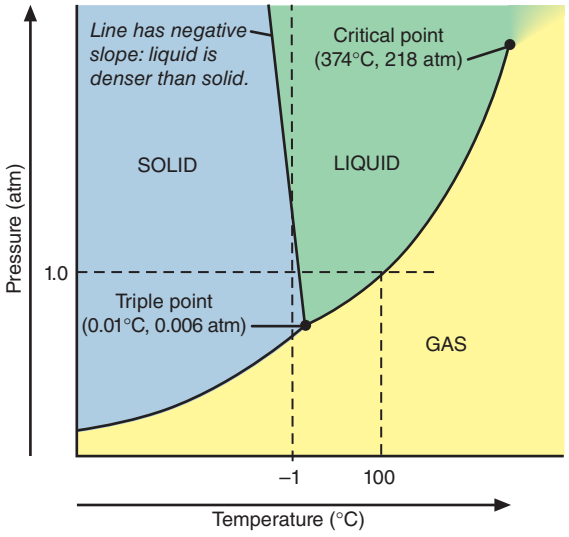

Figure 12.11 **Phase diagram for H_2O.**

The Solid-Liquid Line for Water

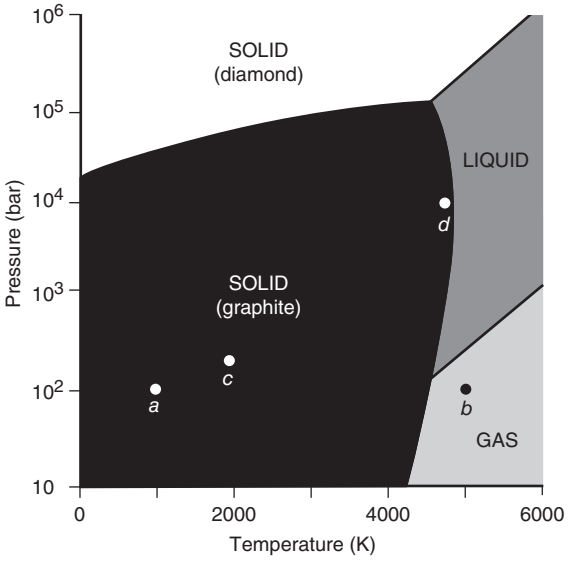
The phase diagram for water differs from others in one major respect that reveals a key property. Unlike almost any other substance, the solid form is *less dense* than the liquid; that is, *water expands upon freezing.* Thus, the solid-liquid line has a *negative* slope (slants to the *left* with increasing pressure): an increase in pressure converts the solid to the liquid, and the higher the pressure, the lower the temperature at which water freezes (Figure 12.11).

The vertical dashed line at −1°C crosses the solid-liquid line, which means that ice melts with only an increase in pressure.

The triple point of water occurs at low pressure (0.006 atm). Therefore, when solid water is heated at 1.0 atm *(horizontal dashed line),* the solid-liquid line is crossed at 0°C, the normal melting point. Thus, ice melts rather than sublimes. The horizontal dashed line then crosses the liquid-gas curve at 100°C, the normal boiling point.

SAMPLE PROBLEM 12.3 Using a Phase Diagram to Predict Phase Changes

Problem Use the phase diagram for carbon *(shown at right)* to describe the phase changes that a sample of carbon undergoes during the following:
(a) The sample is heated at 10^2 bar (99 atm) from 1000 K to 5000 K.
(b) The sample is then compressed at 5000 K to 10^6 bar (990,000 atm).



Plan We have to describe the phase changes due to heating at constant pressure (10^2 bar) and then compressing at constant temperature (5000 K).
(a) Using the phase diagram, we find the starting conditions (10^2 bar and 1000 K), labeled point *a*, and draw a horizontal line from there to point *b*, indicating the ending conditions (10^2 bar and 5000 K). We note any phase-transition curves that the line crosses.
(b) Then, from the new starting conditions at point *b* (10^2 bar and 5000 K), we draw a vertical line to the ending pressure (10^6 bar) and note any phase-transition curves that this line crosses.

Solution **(a)** At 10^2 bar and 1000 K, the sample is in the form of graphite. As it is heated, the graphite sublimes and becomes carbon gas (at around 4400 K).
(b) As it is compressed at 5000 K, the gas first condenses to liquid carbon (at around 300 bar), which then solidifies to diamond (at around 3×10^5 bar).

Check **(a)** From the phase diagram, the first triple point occurs above 10^2 bar, so graphite will vaporize before it liquefies. **(b)** The liquid carbon will solidify to diamond because graphite does not exist at 5000 K under any pressure.

Comment Synthetic diamonds are made by compressing graphite at approximately 7×10^4 bar and 2300 K. The process occurs at a commercially useful rate when carried out in molten nickel. Traces of nickel remain in the diamonds, which are used for grinding tools and are not of gem quality.

FOLLOW-UP PROBLEMS

12.3A Describe the phase changes that a sample of carbon undergoes when it is heated at 3×10^2 bar from 2000 K (point *c* on the phase diagram in the sample problem) to 6000 K.

12.3B Describe the phase changes that a sample of carbon undergoes when it is compressed at 4600 K from 10^4 bar (point *d* on the phase diagram in the sample problem) to 10^6 bar.

SOME SIMILAR PROBLEMS 12.27 and 12.28

Summary of Section 12.2

- A heating-cooling curve depicts the change in temperature when a substance absorbs or releases heat at a constant rate. Within a phase, temperature (and average E_k) changes. During a phase change, temperature (and average E_k) is constant, but E_p changes. The total enthalpy change for the system is found using Hess's law.
- In a closed container, the liquid and gas phases of a substance reach equilibrium. The vapor pressure, the pressure of the gas at equilibrium, *increases* with temperature and *decreases* with the strength of the intermolecular forces.
- The Clausius-Clapeyron equation relates the vapor pressure to the temperature and is often used to find ΔH_{vap}.

- A liquid in an open container boils when its vapor pressure equals the external pressure.
- Solid-liquid equilibrium occurs at the melting point. Some solids sublime because they have very weak intermolecular forces.
- The phase diagram of a substance shows the phase that is stable at any *P* and *T*, the conditions at which phase changes occur, and the conditions at the critical point and the triple point. Water differs from most substances in that its solid phase is less dense than its liquid phase, so its solid-liquid line has a negative slope.

12.3 TYPES OF INTERMOLECULAR FORCES

In Chapter 9, we saw that bonding (*intra*molecular) forces are due to the attraction between cations and anions (ionic bonding), nuclei and electron pairs (covalent bonding), or metal cations and delocalized electrons (metallic bonding). But the physical nature of the phases and their changes are due primarily to *inter*molecular (nonbonding) forces, which arise from the attraction between molecules with partial charges or between ions and molecules. Coulomb's law explains the relative strength of these forces:

- *Bonding forces are relatively strong* because larger charges are closer together.
- *Intermolecular forces are relatively weak* because smaller charges are farther apart.

How Close Can Molecules Approach Each Other?

To see the minimum distance *between* molecules, consider solid Cl_2. When we measure the distances between two Cl nuclei, we obtain two different values (Figure 12.12A):

- *Bond length and covalent radius*. The shorter distance, called the *bond length,* is between *two bonded Cl atoms in the* ***same*** *molecule*. One-half this distance is the *covalent radius*.
- *Van der Waals distance and radius*. The longer distance is between *two nonbonded Cl atoms in* ***adjacent*** *molecules*. It is called the *van der Waals (VDW) distance*. At this distance, intermolecular attractions balance electron-cloud repulsions; thus, the VDW distance is as close as one Cl_2 molecule can approach another. The **van der Waals radius** is one-half the closest distance between nuclei of identical *nonbonded* atoms. The VDW radius of an atom is *always larger than its covalent radius.* Like covalent radii, VDW radii decrease across a period and increase down a group (Figure 12.12B).

As we discuss intermolecular forces (also called *van der Waals forces*), consult Table 12.2, which compares them with bonding forces.

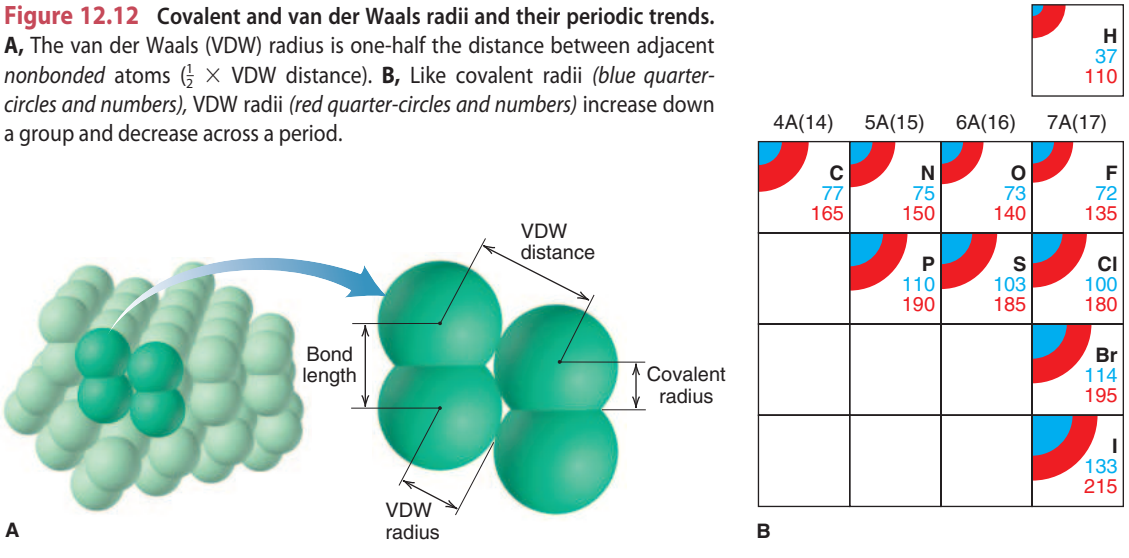


Figure 12.12 **Covalent and van der Waals radii and their periodic trends.** **A,** The van der Waals (VDW) radius is one-half the distance between adjacent *nonbonded* atoms ($\frac{1}{2}$ × VDW distance). **B,** Like covalent radii *(blue quarter-circles and numbers),* VDW radii *(red quarter-circles and numbers)* increase down a group and decrease across a period.

Table 12.2 Comparison of Bonding and Nonbonding (Intermolecular) Forces

Force	Model	Basis of Attraction	Energy (kJ/mol)	Example
Bonding				
Ionic		Cation–anion	400–4000	NaCl
Covalent		Nuclei–shared e^- pair	150–1100	H—H
Metallic		Cations–delocalized electrons	75–1000	Fe
Nonbonding (Intermolecular)				
Ion-dipole		Ion charge–dipole charge	40–600	H bond		Polar bond to H–dipole charge (high EN of N, O, F)	10–40	Dipole-dipole		Dipole charges	5–25	Ion–induced dipole		Ion charge–polarizable e^- cloud	3–15	Dipole–induced dipole		Dipole charge–polarizable e^- cloud	2–10	Dispersion (London)		Polarizable e^- clouds	0.05–40	
Ion-Dipole Forces

When an ion and a nearby polar molecule (dipole) attract each other, an **ion-dipole force** results. The most important example takes place when an ionic compound dissolves in water. As you'll see in Chapter 13, one main reason the ions become separated is because the attractions between the ions and the oppositely charged poles of the H_2O molecules are stronger than the attractions between the ions themselves.

Dipole-Dipole Forces

In Figure 10.13 (p. 417), an external electric field orients gaseous polar molecules. The polar molecules in liquids and solids lie near each other, and their partial charges act as tiny electric fields and give rise to **dipole-dipole forces:** the positive pole *(blue)* of one molecule attracts the negative pole *(red)* of another (Figure 12.13). The orientation is more orderly in a solid than in a liquid because the average kinetic energy is lower.

These forces depend on the magnitude of the molecular dipole moment. For compounds of similar molar mass, the greater the molecular dipole moment, the greater the dipole-dipole forces, so the more energy it takes to separate the molecules; thus, the boiling point is higher. Methyl chloride, for instance, has a smaller dipole moment than acetaldehyde and boils at a lower temperature (Figure 12.14, *next page*).

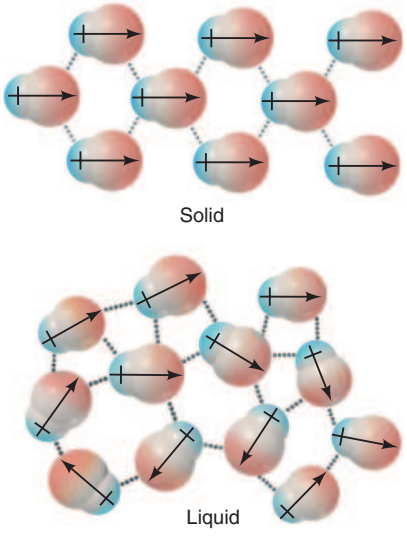

Figure 12.13 Polar molecules and dipole-dipole forces. (Spaces between the molecules are exaggerated.)

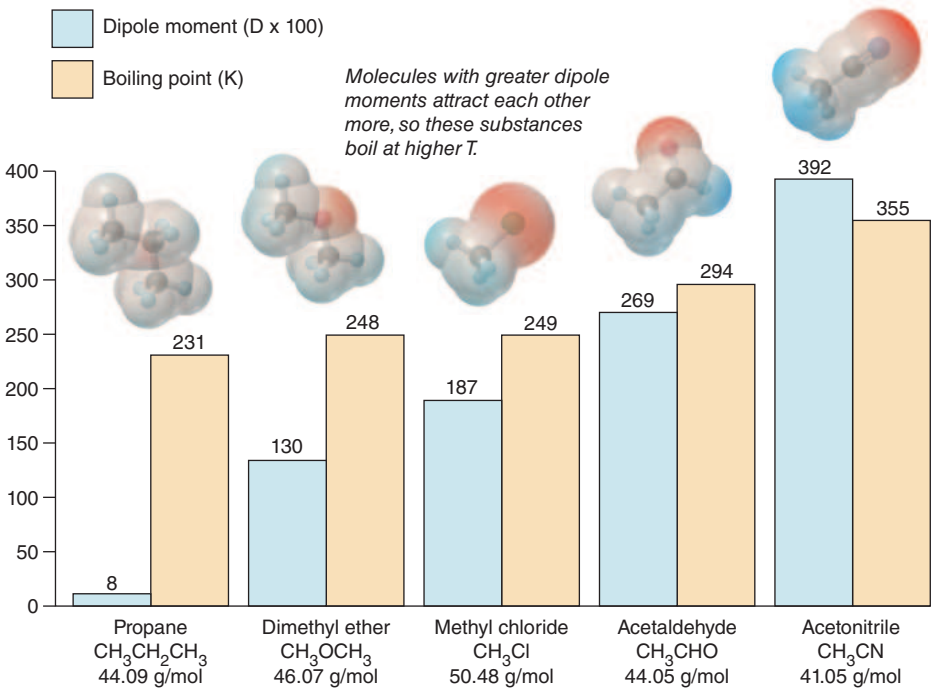

Figure 12.14 **Dipole moment and boiling point.**

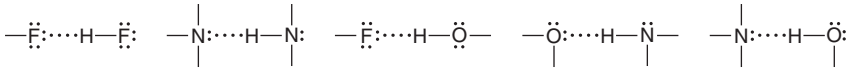
The Hydrogen Bond

A special type of dipole-dipole force arises between molecules that have *an H atom bonded to a small, highly electronegative atom with lone electron pairs, specifically N, O, or F*. The H—N, H—O, and H—F bonds are very polar. When the partially positive H of one molecule is attracted to the partially negative lone pair on the N, O, or F of another molecule, a **hydrogen bond (H bond)** forms. Thus, the atom sequence of an H bond (dotted line) is —B:····H—A—, where A *and* B are N, O, or F. Some examples are



The first two are found in pure samples of HF and NH_3, respectively.

The small sizes of N, O, and F are essential to H bonding for two reasons:

1. The atoms are so electronegative that their covalently bonded H is highly positive.
2. The lone pair on the N, O, or F of the other molecule can come close to the H.

The Significance of Hydrogen Bonding Hydrogen bonding has a profound impact in many systems. We'll examine one effect on physical properties and preview its importance in biological systems, which we address in Chapters 13 and 15.

Figure 12.15 shows the effect of H bonding on the boiling points of the binary hydrides of Groups 4A(14) through 7A(17). For reasons we'll discuss shortly, boiling points rise with molar mass, as the Group 4A(14) hydrides show. However, the first member in each of the other groups—NH_3, H_2O, and HF—deviates enormously from this expected trend. Within samples of these substances, the molecules form strong H bonds, so it takes more energy for the molecules to separate and enter the gas phase. For example, on the basis of molar mass alone, we would expect water to boil about 200°C lower than it actually does *(red dashed line)*. (In Section 12.5 we'll discuss the effects that H bonds in water have in nature.)

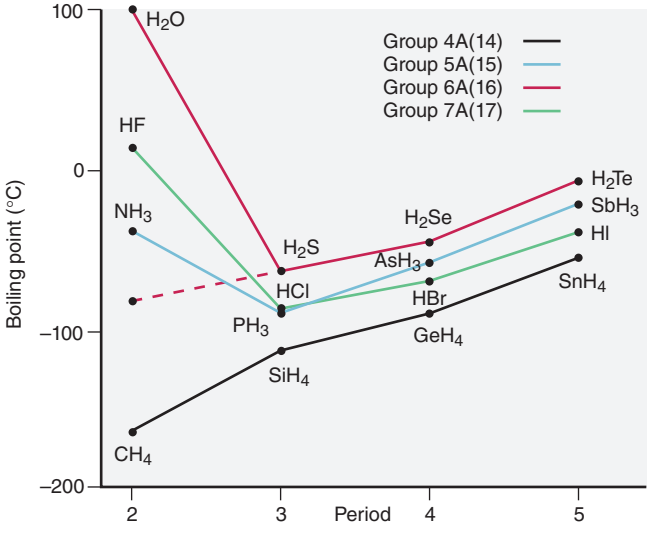


Figure 12.15 **Hydrogen bonding and boiling point.** NH_3, H_2O, and HF have exceptionally high boiling points because they form H bonds.

The significance of hydrogen bonding in biological systems cannot be emphasized too strongly. In Chapter 13, you'll see that it is a key feature in the structure and function of the biological macromolecules. As such, it is responsible for the action of many *enzymes*—the proteins that speed metabolic reactions—and for the functioning of genes, not to mention the strength of wood and texture of cotton.

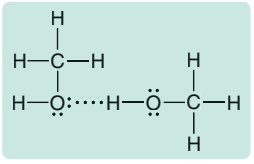
SAMPLE PROBLEM 12.4 Drawing Hydrogen Bonds Between Molecules of a Substance

Problem Which of these substances exhibits H bonding? Draw examples of the H bonds between two molecules of each substance that does.

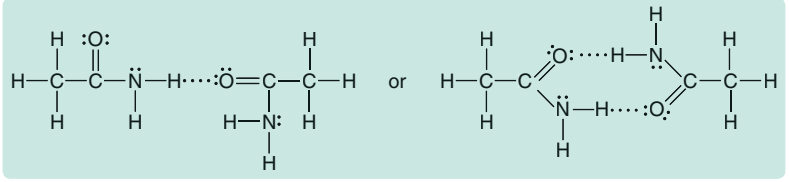
(a) C_2H_6 **(b)** CH_3OH **(c)** $CH_3\overset{\overset{O}{\|}}{C}-NH_2$

Plan If the molecule does *not* contain N, O, or F, it cannot form H bonds. If it contains any of these atoms covalently bonded to H, we draw two molecules in the —B:····H—A— pattern.

Solution **(a)** For C_2H_6. No N, O, or F, so no H bonds can form.
(b) For CH_3OH. The H covalently bonded to the O in one molecule forms an H bond to the lone pair on the O of an adjacent molecule:



(c) For $CH_3\overset{\overset{O}{\|}}{C}-NH_2$. Two of these molecules can form one H bond between an H bonded to N and the O, or they can form two such H bonds:



A third possibility (not shown) could be between an H attached to N in one molecule and the lone pair of N in another molecule.

Check The —B:····H—A— sequence (with A and B either N, O, or F) is present.

Comment Note that H covalently bonded to C *does not form H bonds* because carbon is not electronegative enough to make the C—H bond sufficiently polar.

FOLLOW-UP PROBLEMS

12.4A Which of these substances exhibits H bonding? Draw one possible example of the H bond(s) between two molecules of each substance that does.

(a) $CH_3\overset{\overset{O}{\|}}{C}-OH$ **(b)** CH_3CH_2OH **(c)** $CH_3\overset{\overset{O}{\|}}{C}CH_3$

12.4B Which of these substances exhibits H bonding? Draw one possible example of the H bond(s) between two molecules of each substance that does.

(a) $H_2C{=}O$ **(b)** H_2NOH **(c)** $O{=}CHCH_2OH$

SOME SIMILAR PROBLEMS 12.43 and 12.44

Polarizability and Induced Dipole Forces

Even though electrons are attracted to nuclei and localized in bonding and lone pairs, we often picture them as "clouds" of negative charge because they are in constant motion. A nearby electric field can *induce* a distortion in the cloud, pulling

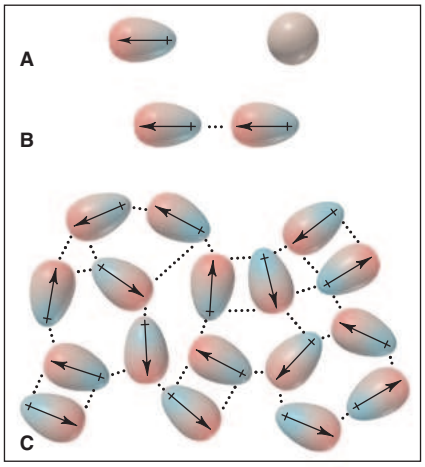


Figure 12.16 Dispersion forces among nonpolar particles. A, When atoms are far apart, an instantaneous dipole in one atom *(left)* doesn't influence another. **B,** When atoms are close together, the instantaneous dipole in one atom induces a dipole in the other. **C,** The process occurs through the sample.

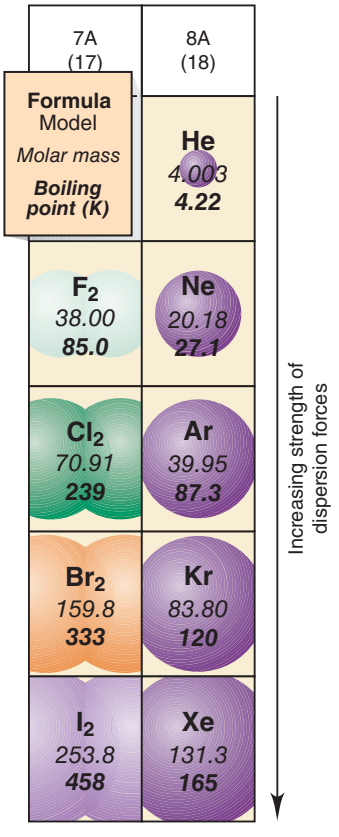

Figure 12.17 Molar mass and trends in boiling point.

electron density toward a positive pole of a field or pushing it away from a negative one:

- *For a nonpolar molecule,* the distortion induces a temporary dipole moment.
- *For a polar molecule,* the distortion induces an increase in the already existing dipole moment.

In addition to charged plates connected to a battery, the source of the electric field can be the charge of an ion or the partial charges of a polar molecule.

How easily the electron cloud of an atom (or ion) can be distorted is called its **polarizability.** Smaller particles are less polarizable than larger ones because their electrons are closer to the nucleus and therefore held more tightly. Thus, we observe several trends:

- Polarizability *increases down a group* because atomic size increases and larger electron clouds are easier to distort.
- Polarizability *decreases across a period* because increasing Z_{eff} makes the atoms smaller and holds the electrons more tightly.
- Cations are *less* polarizable than their parent atoms because they are smaller; anions are *more* polarizable because they are larger.

Ion–induced dipole and dipole–induced dipole forces are the two types of charge-induced dipole forces; they are most important in solution, so we'll focus on them in Chapter 13. Nevertheless, *polarizability affects all intermolecular forces.*

Dispersion (London) Forces

So far, we've discussed forces that depend on the existing charge of an ion or a polar molecule. But what forces cause nonpolar substances like octane, chlorine, and argon to condense and solidify? As you'll see, polarizability plays the central role in the most universal intermolecular force.

The intermolecular force responsible for the condensed states of nonpolar substances is the **dispersion force** (or **London force,** for Fritz London, the physicist who explained its quantum-mechanical basis). *Dispersion forces are present between all particles (atoms, ions, and molecules) because they result from the motion of electrons in atoms.* Let's examine key aspects of this force:

1. *Origin*. Picture one atom in a sample of, say, argon gas. Over time, its 18 electrons are distributed uniformly, so the atom is nonpolar. But at any instant, there may be more electrons on one side of the nucleus than the other, which gives the atom an *instantaneous dipole*. When a pair of argon atoms is far apart, they don't influence each other, but when close together, *the instantaneous dipole in one atom induces a dipole in its neighbor,* and they attract each other. This process spreads to other atoms and throughout the sample. At low temperatures, these attractions keep the atoms together (Figure 12.16). Thus, dispersion forces are *instantaneous dipole–induced dipole forces*.

2. *Universal presence*. While they are the *only* force existing between nonpolar particles, *dispersion forces contribute to the energy of attraction in all substances* because they exist between *all* particles. In fact, except for the forces between small, highly polar molecules or between molecules forming H bonds, the *dispersion force is the dominant intermolecular force.* Calculations show, for example, that 85% of the attraction between HCl molecules is due to dispersion forces and only 15% to dipole-dipole forces. Even for water, 75% of the attraction comes from H bonds and 25% from dispersion forces.

3. *Relative strength*. The relative strength of dispersion forces depends on the polarizability of the particles, so they are weak for small particles, like H_2 and He, but stronger for larger particles, like I_2 and Xe. *Polarizability depends on the number of electrons, which correlates closely with molar mass* because heavier particles are either larger atoms or molecules with more atoms and, thus, more electrons. For this reason, as molar mass increases down the Group 4A(14) hydrides (see Figure 12.15), or down the halogens or the noble gases, dispersion forces increase and so do boiling points (Figure 12.17).

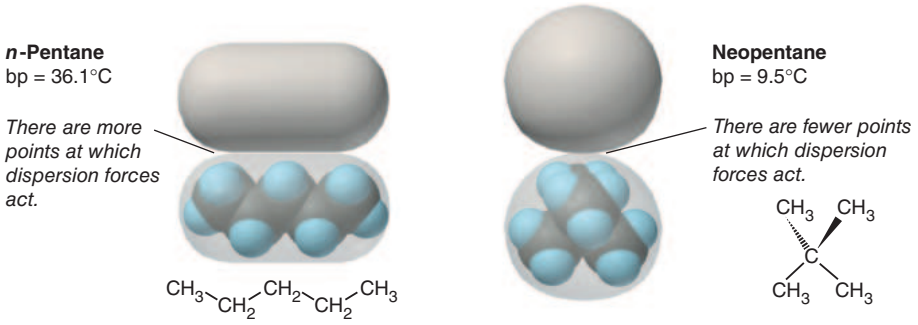

Figure 12.18 Molecular shape, intermolecular contact, and boiling point.

4. *Effect of molecular shape*. For a pair of nonpolar substances with the same molar mass, a molecular shape that has more area over which electron clouds can be distorted allows stronger attractions. For example, the two five-carbon alkanes, *n*-pentane and neopentane (2,2-dimethylpropane) are isomers—same molecular formula (C_5H_{12}) but different structures and properties. *n*-Pentane is more cylindrical and neopentane more spherical (Figure 12.18). Thus, two *n*-pentane molecules make more contact than do two neopentane molecules, so dispersion forces act at more points, and *n*-pentane has a higher boiling point.

Figure 12.19 shows how to decide on intermolecular forces in a sample.

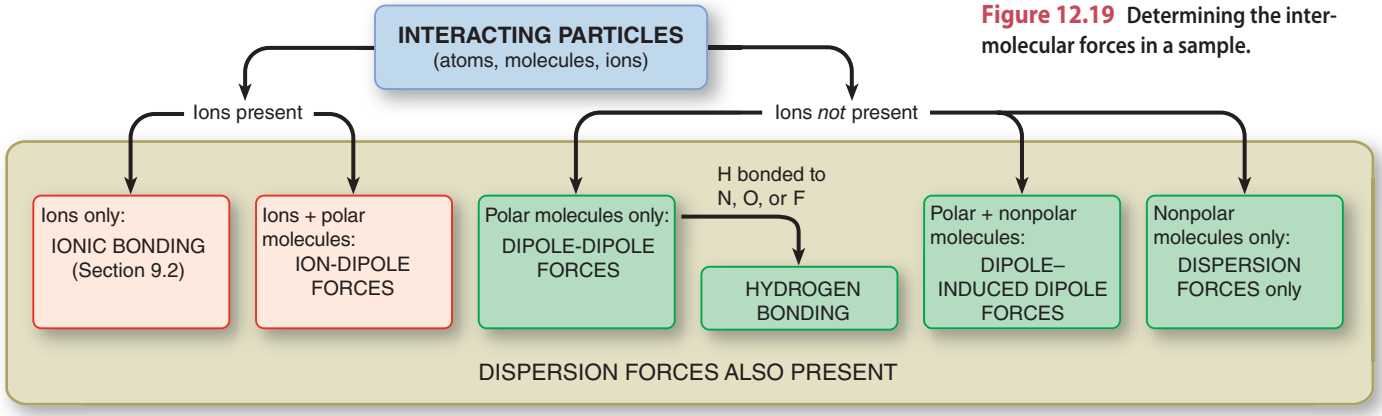

Figure 12.19 Determining the intermolecular forces in a sample.

SAMPLE PROBLEM 12.5 Identifying the Types of Intermolecular Forces

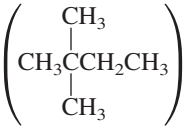
Problem For each substance, identify the key bonding and/or intermolecular force(s), and predict which one of the pair has the higher boiling point:

(a) $MgCl_2$ or PCl_3

(b) CH_3NH_2 or CH_3F

(c) CH_3OH or CH_3CH_2OH

(d) Hexane ($CH_3CH_2CH_2CH_2CH_2CH_3$) or 2,2-dimethylbutane

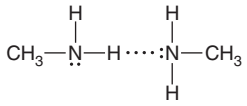


Plan We examine the formulas and structures for key differences between members of the pair: Are ions present? Are molecules polar or nonpolar? Is N, O, or F bonded to H? Do the molecules have different masses or shapes?

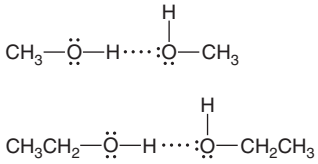
To rank boiling points, we consult Figure 12.19 and Table 12.2. Remember that

- Bonding forces are stronger than intermolecular forces.
- Hydrogen bonding is a strong type of dipole-dipole force.
- Dispersion forces are decisive when the difference is molar mass or molecular shape.

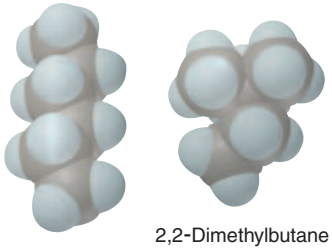
(b)



(c)



(d)



Hexane 2,2-Dimethylbutane

Solution **(a)** $MgCl_2$ consists of Mg^{2+} and Cl^- ions held together by ionic bonding forces; PCl_3 consists of polar molecules, so intermolecular dipole-dipole forces are present. The forces in $MgCl_2$ are stronger, so it should have a higher boiling point.
(b) CH_3NH_2 and CH_3F both consist of polar molecules of about the same molar mass. CH_3NH_2 has N—H bonds, so it can form H bonds *(see margin)*. CH_3F contains a C—F bond but no H—F bond, so dipole-dipole forces occur but not H bonds. Therefore, CH_3NH_2 should have the higher boiling point.
(c) CH_3OH and CH_3CH_2OH molecules both contain an O—H bond, so they can form H bonds *(see margin)*. CH_3CH_2OH has an additional $—CH_2—$ group and thus a larger molar mass, which correlates with stronger dispersion forces; therefore, it should have a higher boiling point.
(d) Hexane and 2,2-dimethylbutane are nonpolar molecules of the same molar mass but different molecular shapes *(see margin)*. Cylindrical hexane molecules make more intermolecular contact than more compact 2,2-dimethylbutane molecules do, so hexane should have stronger dispersion forces and a higher boiling point.

Check The actual boiling points show that our predictions are correct:
(a) $MgCl_2$ (1412°C) and PCl_3 (76°C)
(b) CH_3NH_2 (−6.3°C) and CH_3F (−78.4°C)
(c) CH_3OH (64.7°C) and CH_3CH_2OH (78.5°C)
(d) Hexane (69°C) and 2,2-dimethylbutane (49.7°C)

Comment Dispersion forces are *always* present, but in parts (a) and (b), they are much less significant than the other forces that occur.

FOLLOW-UP PROBLEMS

12.5A In each pair, identify the intermolecular forces present for each substance, and predict which substance has the *higher* boiling point:
(a) CH_3Br or CH_3F **(b)** $CH_3CH_2CH_2OH$ or $CH_3CH_2OCH_3$ **(c)** C_2H_6 or C_3H_8

12.5B In each pair, identify the intermolecular forces present for each substance, and predict which substance has the *lower* boiling point:
(a) CH_3CHO or CH_3CH_2OH **(b)** $CHCl_3$ or CHI_3
(c) $H_2N—\overset{\overset{O}{\|}}{C}CH_2CH_3$ or $(CH_3)_2N—\overset{\overset{O}{\|}}{C}H$

SOME SIMILAR PROBLEMS 12.49–12.54

Summary of Section 12.3

- The van der Waals radius determines the shortest distance over which intermolecular forces operate; it is always larger than the covalent radius.
- Intermolecular forces are much weaker than bonding (intramolecular) forces.
- Ion-dipole forces occur between ions and polar molecules.
- Dipole-dipole forces occur between oppositely charged poles on polar molecules.
- Hydrogen bonding, a special type of dipole-dipole force, occurs when H bonded to N, O, or F is attracted to the lone pair of N, O, or F in another molecule.
- Electron clouds can be distorted (polarized) in an electric field.
- Ion– and dipole–induced dipole forces arise between a charge and the dipole it induces in another molecule.
- Dispersion (London) forces are instantaneous dipole–induced dipole forces that occur among all particles and increase with number of electrons (molar mass). Molecular shape determines the extent of contact between molecules and can be a factor in the strength of dispersion forces.

12.4 PROPERTIES OF THE LIQUID STATE

Of the three states, only liquids combine the ability to flow with the effects of strong intermolecular forces. We understand this state least at the molecular level. Because of the *random* arrangement of the particles in a gas, any region of the sample is virtually identical to any other. And, different regions of a crystalline solid are identical because of the *orderly* arrangement of the particles (Section 12.6). Liquids, however, have regions that are orderly one moment and random the next. Nevertheless, many macroscopic properties, such as surface tension, capillarity, and viscosity, are well understood.

Surface Tension

Intermolecular forces have different effects on a molecule at the surface than on one in the interior (Figure 12.20):

- An interior molecule is attracted by others on all sides.
- A surface molecule is only attracted by others below and to the sides, so it experiences a *net attraction downward.*

Therefore, to increase attractions and become more stable, a surface molecule tends to move into the interior. For this reason, *a liquid surface has the fewest molecules and, thus, the smallest area possible*. In effect, the surface behaves like a "taut skin" covering the interior.

The only way to increase the surface area is for molecules to move up by breaking attractions in the interior, which requires energy. The **surface tension** is the energy required to increase the surface area and has units of J/m^2 (Table 12.3). In general, *the stronger the forces between particles, the more energy it takes to increase the surface area, so the greater the surface tension.* Water has a high surface tension because its molecules form multiple H bonds. *Surfactants* (*surface-active agents*), such as soaps, petroleum recovery agents, and fat emulsifiers, decrease the surface tension of water by congregating at the surface and disrupting the H bonds.

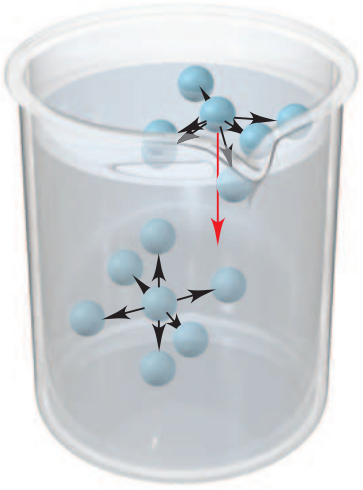


Figure 12.20 The molecular basis of surface tension.

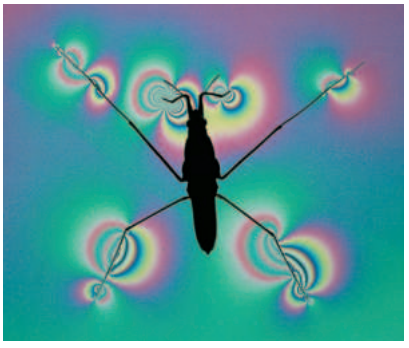
Table 12.3 Surface Tension and Forces Between Particles

Substance	Formula	Surface Tension (J/m^2) at 20°C	Major Force(s)
Diethyl ether	$CH_3CH_2OCH_2CH_3$	1.7×10^{-2}	Dipole-dipole; dispersion
Ethanol	CH_3CH_2OH	2.3×10^{-2}	H bonding
Butanol	$CH_3CH_2CH_2CH_2OH$	2.5×10^{-2}	H bonding; dispersion
Water	H_2O	7.3×10^{-2}	H bonding
Mercury	Hg	48×10^{-2}	Metallic bonding



Because of its widespread legs, a water strider doesn't exert enough pressure to exceed the surface tension.

Surface tension is the cause of many familiar phenomena. Bubbles are round because this shape minimizes the surface area around the gas, and surface tension is the reason some insects can walk on water *(see photo).*

Capillarity

The rising of a liquid against the pull of gravity through a narrow space, such as a thin tube, is called *capillary action,* or **capillarity.** Capillarity results from a competition between the intermolecular forces within the liquid (cohesive forces) and those between the liquid and the tube walls (adhesive forces). Let's look at the difference between the capillarities of water and mercury in glass:

1. *Water in glass*. When you place a narrow glass tube in water, why does the liquid rise up the tube and form a concave meniscus? Glass is mostly silicon dioxide (SiO_2), so water molecules form adhesive H-bonding forces with the O atoms of the glass. As a result, a thin film of water creeps up the wall. At the same time, cohesive H-bonding forces between water molecules, which give rise to surface tension, make the surface taut. These adhesive and cohesive forces combine to raise the water level and produce the concave meniscus (Figure 12.21A, *next page*). The liquid rises until gravity pulling down is balanced by adhesive forces pulling up.

2. *Mercury in glass*. When you place a glass tube in a dish of mercury, why does the liquid drop below the level in the dish and form a convex meniscus? The cohesive forces among the mercury atoms are metallic bonds, so they are *much* stronger than the mostly dispersion adhesive forces between mercury and glass. As a result, the liquid pulls away from the walls. At the same time, the surface atoms are being

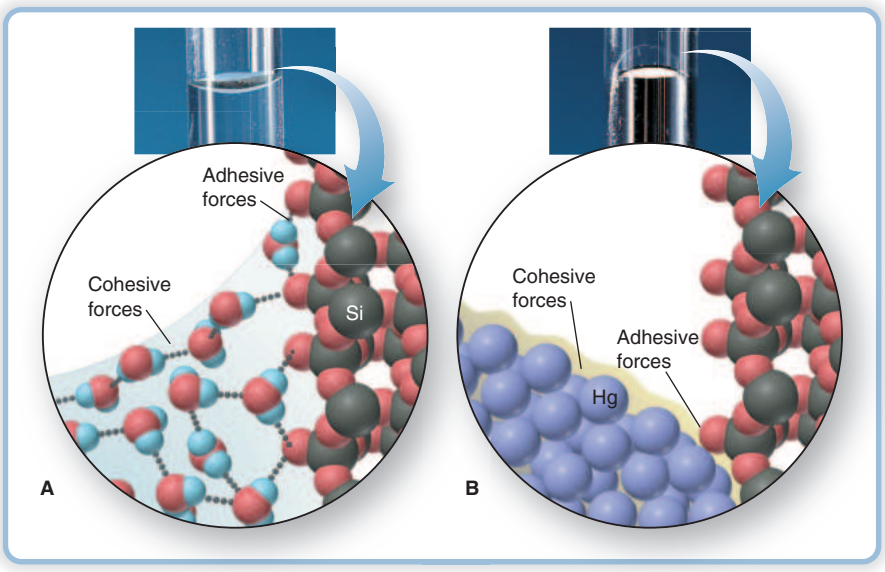


Figure 12.21 **Capillary action and the shape of the water or mercury meniscus in glass. A,** Water displays a concave meniscus. **B,** Mercury displays a convex meniscus.

pulled toward the interior by mercury's high surface tension, so the level drops. These combined forces produce the convex meniscus seen in a laboratory barometer (Figure 12.21B).

Capillarity plays a key role in many everyday events. The adhesive (dipole–induced dipole) forces between water and a nonpolar surface are much weaker than the cohesive (H-bond) forces within water. As a result, water pulls away from a nonpolar surface and forms beaded droplets, as on a freshly waxed car or on the waxy coating of a leaf after a rainfall. Even more familiar, after a shower, capillary action draws water away from your body through the closely spaced fibers in the cotton towel, which is made of cellulose molecules, so the water molecules also form H bonds with the —OH groups of cellulose.

Viscosity

Viscosity is the resistance of a fluid to flow, and it results from intermolecular attractions that impede the movement of molecules around and past each other. Both gases and liquids flow, but liquid viscosities are *much* higher because the much shorter distances between the particles of a liquid result in many more points for intermolecular forces to act. Let's examine two factors—temperature and molecular shape—that influence viscosity:

- *Effect of temperature*. *Viscosity decreases with heating* (Table 12.4). Faster moving molecules overcome intermolecular forces more easily, so the resistance to flow decreases. Next time you heat cooking oil, watch the oil flow more easily and spread out in the pan as it warms.
- *Effect of molecular shape*. Small, spherical molecules make little contact and pour easily, like buckshot from a bowl. Long molecules make more contact and become entangled and pour slowly, like cooked spaghetti from a bowl. Thus, given the same types of intermolecular forces, liquids consisting of longer molecules have higher viscosities.

To protect engine parts during long drives, motor oils contain *polymeric viscosity improvers*. As the oil warms, these additive molecules change from compact spheres to long strands that become tangled with the long hydrocarbon molecules of the oil. Greater dispersion forces increase the viscosity to compensate for the thinning of the oil due to heating.

Table 12.4 **Viscosity of Water at Several Temperatures**

Temperature (°C)	Viscosity ($N \cdot s/m^2$)*
20	1.00×10^{-3}
40	0.65×10^{-3}
60	0.47×10^{-3}
80	0.35×10^{-3}

*The units of viscosity are newton-seconds per square meter.

Summary of Section 12.4

- Surface tension is a measure of the energy required to increase a liquid's surface area. Greater intermolecular forces within a liquid create higher surface tension.
- Capillarity, the rising of a liquid through a narrow space, occurs when the forces between a liquid and a surface (adhesive) are greater than those in the liquid (cohesive).
- Viscosity, the resistance to flow, depends on molecular shape and decreases with temperature. Stronger intermolecular forces create higher viscosity.

12.5 THE UNIQUENESS OF WATER

Water is absolutely amazing stuff, with some of the most unusual properties of any substance, but it is so familiar we take it for granted. Like any substance, its properties arise inevitably from those of its atoms. Each O and H atom attains a filled outer level by sharing electrons in single bonds. With two bonding pairs and two lone pairs around O and a large electronegativity difference in each O—H bond, the H_2O molecule is bent and highly polar. This arrangement is crucial because it allows each molecule to engage in four H bonds with its neighbors (Figure 12.22). From these basic atomic and molecular facts emerges some unique and remarkable macroscopic behavior.

Figure 12.22 H-bonding ability of water. One H_2O molecule can form four H bonds to other molecules, resulting in a tetrahedral arrangement.

Solvent Properties of Water

The *great solvent power* of water results from its polarity and H-bonding ability:

- It dissolves ionic compounds through ion-dipole forces that separate the ions from the solid and keep them in solution (see Figure 4.2, p. 140).
- It dissolves polar nonionic substances, such as ethanol (CH_3CH_2OH) and glucose ($C_6H_{12}O_6$), by H bonding.
- It dissolves nonpolar atmospheric gases to a limited extent through dipole–induced dipole and dispersion forces.

Water is the environmental and biological solvent, forming the complex solutions we know as oceans, lakes, and cellular fluid. Aquatic animals could not survive without dissolved O_2, nor could aquatic plants without dissolved CO_2. Tiny marine animals form coral reefs made of carbonates from dissolved CO_2 and HCO_3^-. Life began in a "primordial soup," an aqueous mixture of simple molecules from which emerged larger molecules capable of self-sustaining reactions. From a chemical point of view, all organisms, from bacteria to humans, are highly organized systems of membranes enclosing and compartmentalizing complex aqueous solutions.

Thermal Properties of Water

When a substance is heated, some of the added energy increases average molecular speed, some increases molecular vibration and rotation, and some is used to overcome intermolecular forces.

1. *Specific heat capacity*. Because water has so many strong H bonds, its *specific heat capacity* is higher than any common liquid. With oceans covering 70% of Earth's surface, daytime energy from the Sun causes relatively small changes in temperature, allowing life to survive. On the waterless, airless Moon, temperatures range from 100°C to −150°C during a complete lunar day. Even in Earth's deserts, day-night temperature differences of 40°C are common.

2. *Heat of vaporization*. Numerous strong H bonds give water a very *high heat of vaporization*. Two examples show why this is crucial. The average adult has 40 kg of body water and generates about 10,000 kJ of heat a day from metabolism. If this heat were used to increase the average E_k of water molecules in the body, the rise in body temperaure of tens of degrees would mean immediate death. Instead, the heat is converted to E_p as it breaks H bonds and evaporates sweat, resulting in a stable body temperature and minimal loss of body fluid. On a planetary scale, the Sun's energy vaporizes ocean water in warm latitudes, and the potential energy is released as heat to warm cooler regions when the vapor condenses to rain. This global-scale cycling of water powers many weather patterns.

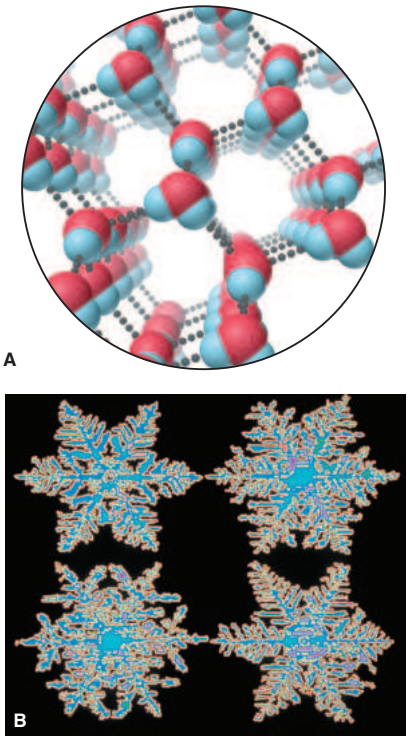

Figure 12.23 The hexagonal structure of ice. A, The open, hexagonal molecular structure of ice. **B,** The beauty of six-pointed snowflakes reflects this hexagonal structure.

Surface Properties of Water

Hydrogen bonding is also responsible for water's *high surface tension* and *high capillarity*. Except for some molten metals and salts, water has the highest surface tension of any liquid. It keeps plant debris resting on a pond surface, providing shelter and nutrients for fish and insects. High capillarity means water rises through the tiny spaces between soil particles, so plant roots can absorb deep groundwater during dry periods.

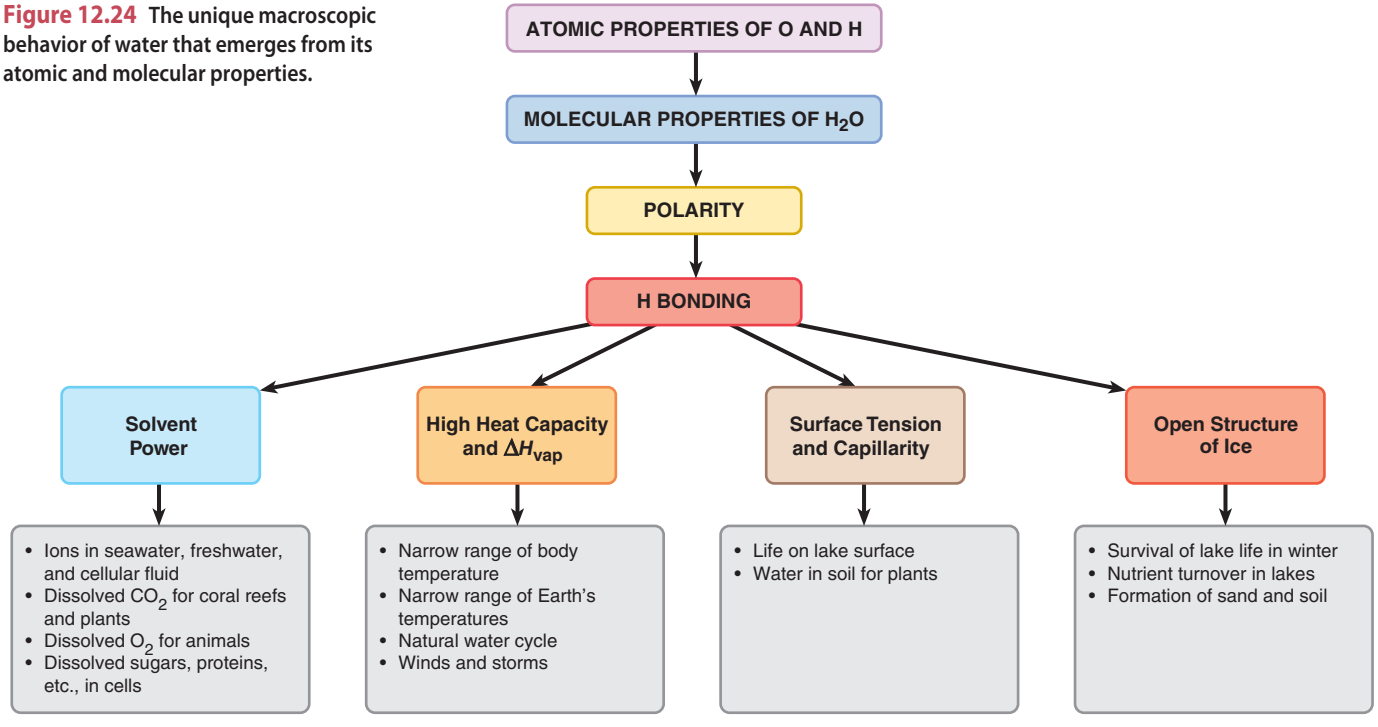
The Unusual Density of Solid Water

In the solid state, the tetrahedral arrangement of H-bonded water molecules (see Figure 12.22) leads to the hexagonal, *open structure* of ice (Figure 12.23A), and the symmetrical beauty of snowflakes (Figure 12.23B) reflects this hexagonal organization. The large spaces within ice make *the solid less dense than the liquid* and explain the negative slope of the solid-liquid line in the phase diagram for water (see Figure 12.11, p. 466). As pressure is applied, some H bonds break, so the crystal structure is disrupted, and the ice liquefies. When ice melts at 0°C, the loosened molecules pack much more closely, filling spaces in the collapsing solid structure. As a result, liquid water is most dense (1.000 g/mL) at around 4°C (3.98°C). With more heating, the density decreases through normal thermal expansion. This behavior has major effects in nature:

- *Surface ice of lakes*. When the surface of a lake freezes in winter, the ice floats. If the solid were denser than the liquid, as is true for nearly every other substance, the surface water would freeze and sink until the entire lake was solid. Aquatic life would not survive from year to year.
- *Nutrient turnover*. As lake water becomes colder in early winter, it becomes more dense *before* it freezes. Similarly, in spring, less dense ice thaws to form more dense water *before* the water expands. During both of these seasonal density changes, the top layer of water reaches maximum density first and sinks. The next layer of water rises because it is slightly less dense, reaches 4°C, and likewise sinks. This alternation of sinking and rising distributes nutrients and dissolved oxygen.
- *Soil formation*. When rain fills crevices in rocks and freezes, an outward force is applied that is relieved when the ice melts. In time, this repeated freeze-thaw stress cracks the rock. Over eons, this effect helps produce sand and soil.

The far-reaching consequences of the properties of water illustrate chemistry's central theme: the macroscopic world we know is the cumulative outcome of the atomic world we seek to know (Figure 12.24).

Figure 12.24 The unique macroscopic behavior of water that emerges from its atomic and molecular properties.



Summary of Section 12.5

- The atomic properties of H and O result in water's bent molecular shape, polarity, and H-bonding ability.
- These properties give water the ability to dissolve many ionic and polar compounds.
- Water's high specific heat capacity and heat of vaporization give Earth and its organisms a narrow temperature range.
- Water's high surface tension and capillarity are essential to plants and animals.
- Because water expands on freezing, lake life survives in winter, nutrients mix from seasonal density changes, and soil forms through freeze-thaw stress on rocks.

12.6 THE SOLID STATE: STRUCTURE, PROPERTIES, AND BONDING

Stroll through a museum's mineral collection, and you'll be struck by the variety and beauty of crystalline solids. In this section, we discuss the structural features of these and other solids and the intermolecular forces that create them. We also consider the main bonding model that explains many properties of solids.

Structural Features of Solids

We can divide solids into two broad categories:

- **Crystalline solids** have well-defined shapes because their particles—atoms, molecules, or ions—occur in an orderly arrangement (Figure 12.25).
- **Amorphous solids** have poorly defined shapes because their particles lack an orderly arrangement throughout the sample.

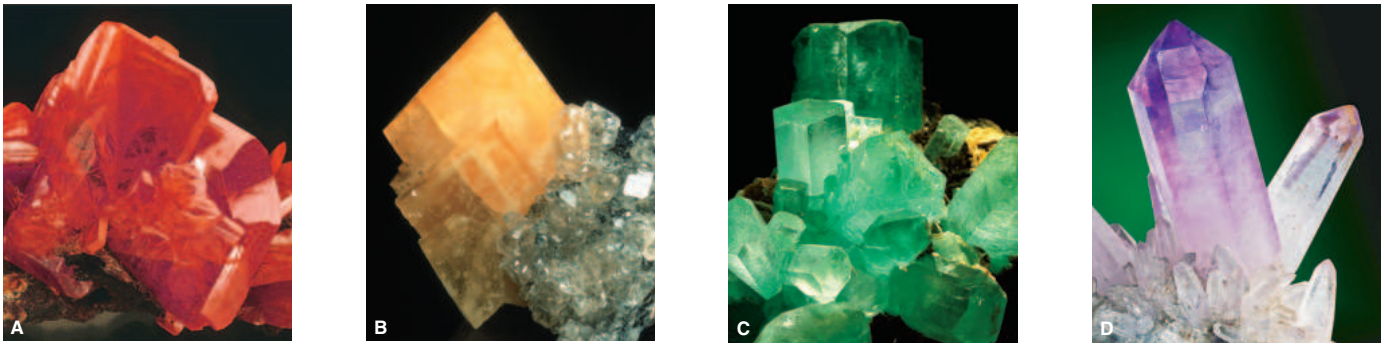


Figure 12.25 The beauty of crystalline solids. A, Wulfanite. **B,** Barite *(left)* on calcite *(right)*. **C,** Beryl (emerald). **D,** Quartz (amethyst).

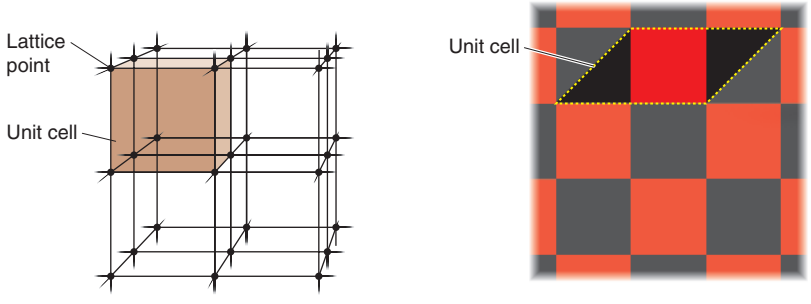
The Crystal Lattice and the Unit Cell The particles in a crystal are packed tightly in an orderly, three-dimensional array. As the simplest case, consider the particles as *identical* spherical atoms, and imagine a point at the center of each. The collection of points forms a regular pattern called the crystal **lattice.** The lattice consists of *all points with identical surroundings;* that is, there would be no way to tell if you moved from one lattice point to another.

Figure 12.26A shows a portion of a lattice and the **unit cell,** the *smallest* portion that gives the crystal if it is repeated in all directions. A two-dimensional analogy for a unit cell and the resulting crystal lattice appears in a checkerboard (Figure 12.26B), a section of tiled floor, or any pattern that is constructed from a repeating unit.



A Portion of 3-D lattice **B 2-D analogy for unit cell and lattice**

Figure 12.26 The crystal lattice and the unit cell. A, A small portion of a lattice is shown as points connected by lines, with a unit cell *(colored)*. **B,** A checkerboard analogy for a lattice.

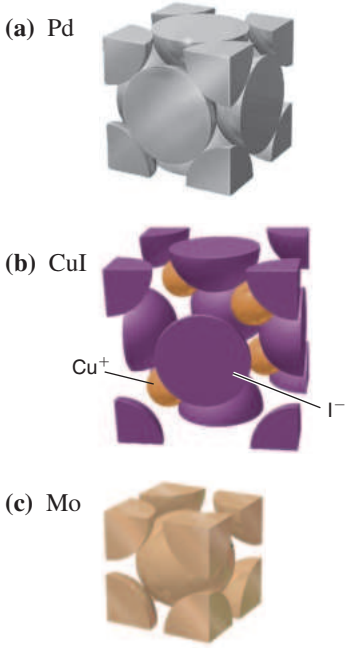
There are 7 crystal systems and 14 types of unit cells that occur in nature, but we will be concerned primarily with the *cubic system*. The solid states of a majority of metallic elements, some covalent compounds, and many ionic compounds occur as cubic lattices. A key parameter of any lattice is the **coordination number,** the number of *nearest* neighbors of a particle. There are three types of cubic unit cells:

1. In the **simple cubic unit cell** (Figure 12.27A), the centers of eight identical particles define the corners of a cube (shown in the expanded view, *top row*). The particles touch along the cube edges (see the space-filling view, *second row*), but they do not touch diagonally along the cube faces or through its center. An expanded portion of the crystal *(third row)* shows that the coordination number of each particle is 6: four in its own layer, one in the layer above, and one in the layer below.
2. In the **body-centered cubic unit cell** (Figure 12.27B), identical particles lie at each corner *and* in the center of the cube. Those at the corners do not touch each other, but they all touch the one in the center. Each particle is surrounded by eight nearest neighbors, four above and four below, so the coordination number is 8.
3. In the **face-centered cubic unit cell** (Figure 12.27C), identical particles lie at each corner *and* in the center of each face but not in the center of the cube. Particles at the corners touch those in the faces but not each other. The coordination number is 12.

How many particles make up a unit cell? For particles of the same size, *the higher the coordination number, the greater the number of particles in a given volume.* Since one unit cell touches another, with no gaps, a particle at a corner or face is *shared* by adjacent cells. In the cubic unit cells, the particle at each corner is part of eight adjacent cells (Figure 12.27, *third row*), so one-eighth of each particle belongs to each cell *(bottom row).* There are eight corners in a cube, so

- A simple cubic unit cell contains $8 \times \frac{1}{8}$ particle $= 1$ particle.
- A body-centered cubic unit cell contains $8 \times \frac{1}{8}$ particle $= 1$ particle plus 1 particle in the center, for a total of 2 particles.
- A face-centered cubic unit cell contains $8 \times \frac{1}{8}$ particle $= 1$ particle plus one-half particle in each of the six faces, or $6 \times \frac{1}{2}$ particle $= 3$ particles, for a total of 4 particles.

SAMPLE PROBLEM 12.6 Determining the Number of Particles per Unit Cell and the Coordination Number



Problem For each of the crystalline solids shown in the margin, determine the number of atoms (or ions) per unit cell and the coordination number.

Plan To determine the number of particles (atoms or ions) in a unit cell, we count the number of particles at the corners, in the faces, and within the body of the cell. The eight corners are shared by eight other cells for a total of 8 corners $\times \frac{1}{8}$ particle per corner, or 1 particle; particles in the body of a cell are in that cell only; particles in the faces are shared by two cells, 6 faces $\times \frac{1}{2}$ particle per face, or 3 particles. We count the number of nearest neighboring particles to obtain the coordination number.

Solution **(a)** Palladium metal adopts a face-centered cubic unit cell:

$$\text{Atoms/unit cell} = (8 \times \tfrac{1}{8}) + (6 \times \tfrac{1}{2}) = \boxed{4 \text{ atoms}}$$

The coordination number is $\boxed{12.}$

(b) Copper(I) iodide has a unit cell that can be viewed as a face-centered cubic array of Cu^+ ions interpenetrating a face-centered cubic array of I^- ions:

$$Cu^+ \text{ ions within the body of the unit cell} = 4$$

$$I^- \text{ ions/unit cell} = (8 \times \tfrac{1}{8}) + (6 \times \tfrac{1}{2}) = \boxed{4\ Cu^+ \text{ and } 4\ I^- \text{ ions}}$$

Each ion is surrounded by four of the oppositely charged ions: coordination number is $\boxed{4.}$

(c) Molybdenum metal adopts a body-centered cubic cell:

$$\text{Atoms/unit cell} = (8 \times \tfrac{1}{8}) + (1 \times 1) = \boxed{2 \text{ atoms}}$$

The coordination number is $\boxed{8.}$

Check Using Figure 12.27, we see that the values are correct.

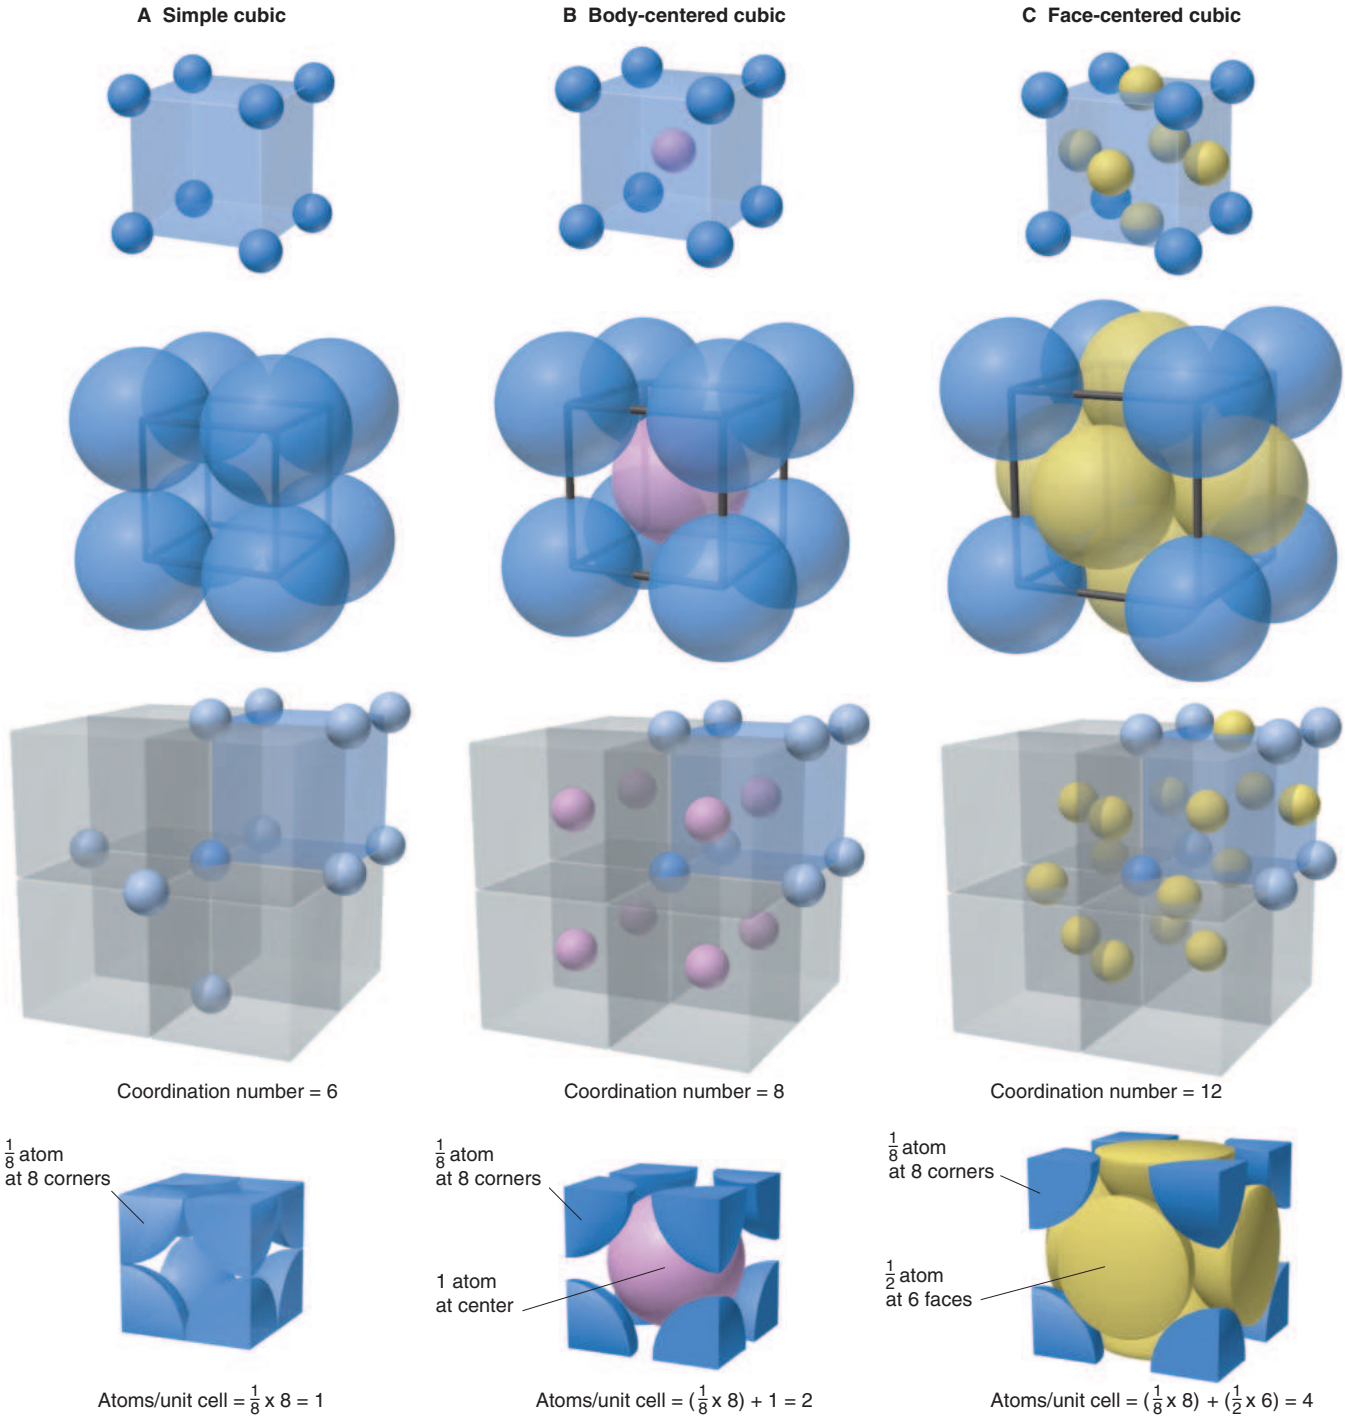


Figure 12.27 The three cubic unit cells. A, Simple cubic unit cell. **B,** Body-centered cubic unit cell. **C,** Face-centered cubic unit cell. *Top row:* Cubic arrangements of atoms in expanded view. *Second row:* Space-filling view of these cubic arrangements. All atoms are identical but, for clarity, corner atoms are blue, body-centered atoms pink, and face-centered atoms yellow. *Third row:* A unit cell *(shaded blue)* in an expanded portion of the crystal. The number of nearest neighbors around one particle *(dark blue in center)* is the coordination number. *Bottom row:* The total numbers of atoms in the actual unit cell. The simple cubic has one atom, the body-centered has two, and the face-centered has four.

SOME SIMILAR PROBLEMS 12.87, 12.96, 12.97, 12.98(a), and 12.99(a)

The efficient packing of fruit.

Packing Efficiency and the Creation of Unit Cells Unit cells result from the ways atoms pack together, which are similar to the ways that macroscopic spheres—marbles, golf balls, fruit—are packed *(see photo).* Let's pack *identical* spheres to create the three cubic unit cells and the hexagonal unit cell and determine the **packing efficiency,** the percentage of the total volume occupied by the spheres themselves:

1. *The simple cubic unit cell.* When we arrange the first layer of spheres in vertical and horizontal rows, large diamond-shaped spaces are formed (Figure 12.28A, *cutaway portion*). If we place the next layer of spheres *directly above* the first, we obtain an arrangement based on the *simple* cubic unit cell (Figure 12.28B). The spheres occupy only 52% of the unit-cell volume, so 48% is empty space between them. This is a very inefficient way to pack spheres, so neither fruit nor atoms are typically packed this way.

2. *The body-centered cubic unit cell.* Rather than placing the second layer (colored *green* for clarity) directly above the first, we use space more efficiently by placing its spheres over the diamond-shaped spaces in the first layer (Figure 12.28C). Then we pack the third layer onto the diamond-shaped spaces in the second, which makes the first and third layers line up vertically. This arrangement is based on the *body-centered* cubic unit cell, and its packing efficiency is much higher at 68%. Several metallic elements, including chromium, iron, and all the Group 1A(1) elements, have a crystal structure based on this unit cell.

3. *The hexagonal and face-centered cubic unit cells.* Spheres are packed most efficiently in these cells. First, in the bottom layer (labeled *a, orange*), we shift every other row laterally so that the large diamond-shaped spaces become smaller triangular spaces. Then we place the second layer *(b, green)* over these spaces (Figure 12.28D).

In layer *b,* notice that some spaces are orange because they lie above *spheres* in layer *a,* whereas other spaces are white because they lie above *spaces* in layer *a*. We can place the third layer in either of two ways, giving rise to two different unit cells:

- *Hexagonal unit cell.* If we place the third layer of spheres *(orange)* over the orange spaces (look down and left to Figure 12.28E), they lie directly over the spheres in layer *a*. Every other layer is placed identically (an *abab. . .* layering pattern), and we obtain **hexagonal closest packing,** which is based on the *hexagonal* unit cell.
- *Face-centered unit cell.* If we place the third layer of spheres *(blue)* over the white spaces in layer *b* (look down and right to Figure 12.28F), the placement is different from layers *a* and *b* (an *abcabc. . .* pattern) and we obtain **cubic closest packing,** which is based on the *face-centered cubic* unit cell.

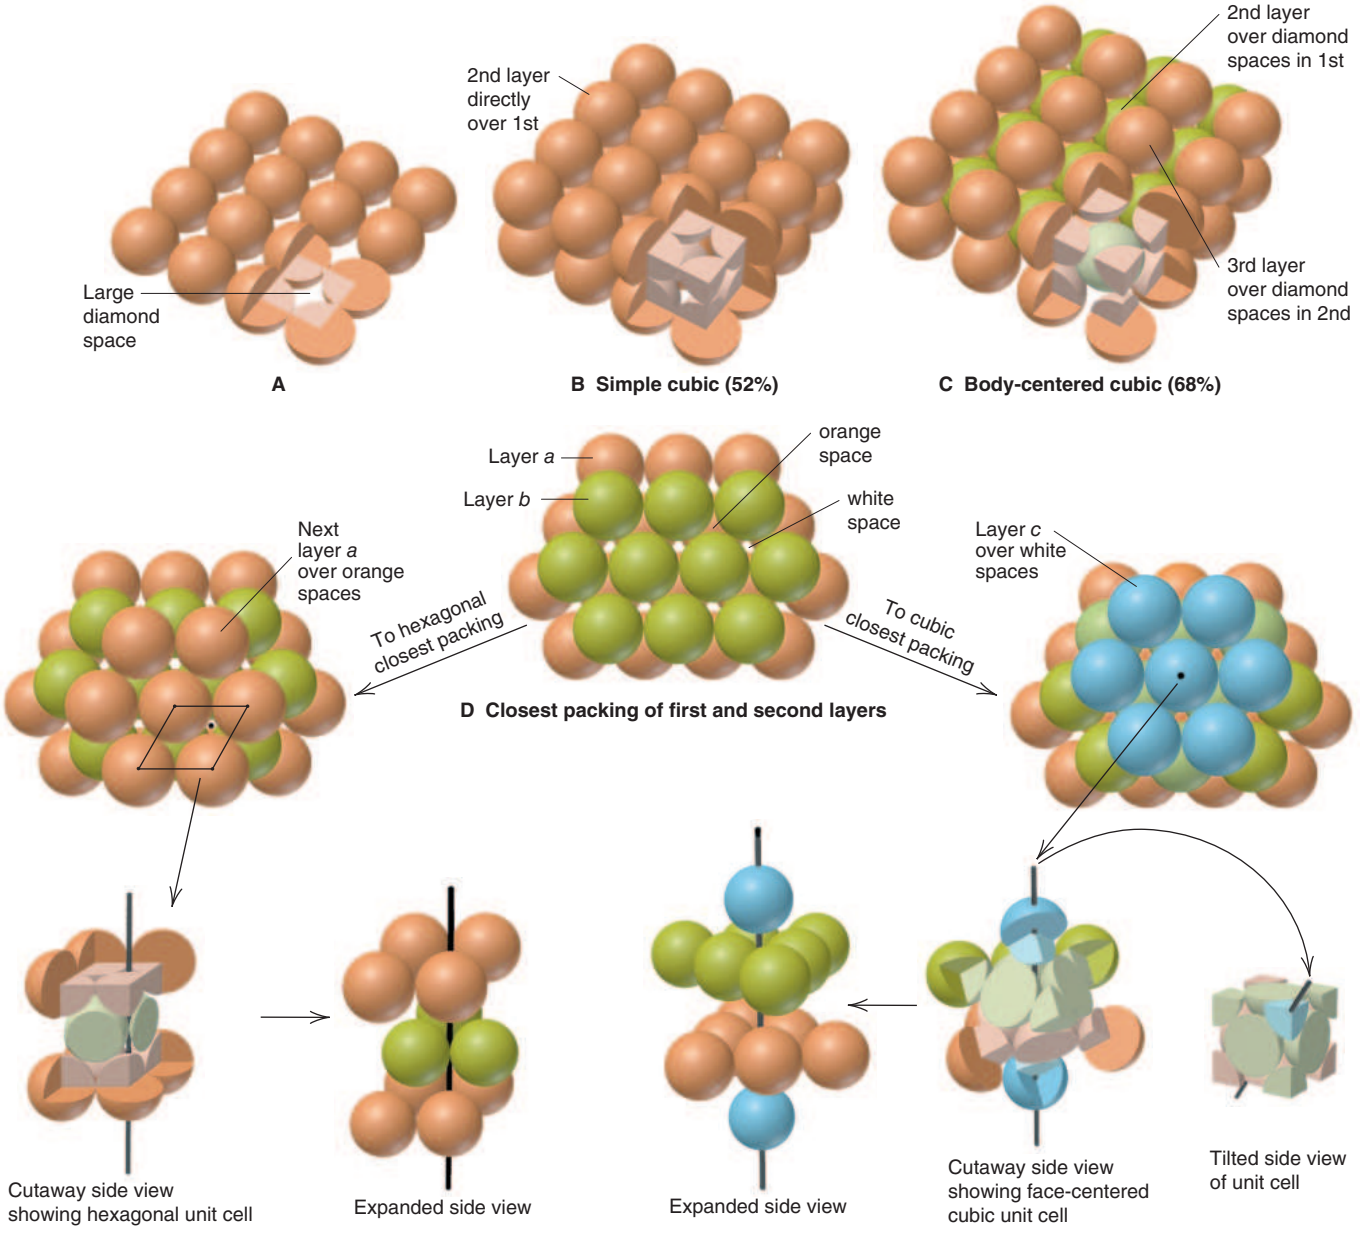

Figure 12.28 **Packing spheres to obtain three cubic and hexagonal unit cells. A,** In the first layer, each sphere lies next to another horizontally and vertically; note the large diamond-shaped spaces *(see cutaway)*. **B,** If the spheres in the next layer lie directly over those in the first, the packing is based on the simple cubic unit cell *(pale orange cube, lower right corner)*. **C,** If the spheres in the next layer lie in the diamond-shaped spaces of the first layer, the packing is based on the *body-centered cubic* unit cell *(lower right corner)*. **D,** The closest possible packing of the first layer *(layer a, orange)* is obtained by shifting every other row in part A to obtain smaller triangular spaces. The spheres of the second layer *(layer b, green)* are placed above these spaces; note the orange and white spaces that result. **E,** When the third layer *(next layer a, orange)* is placed over the orange spaces, we obtain an *abab*. . . pattern and the hexagonal unit cell. **F,** When the third layer *(layer c, blue)* covers the white spaces, we get an *abcabc*. . . pattern and the face-centered cubic unit cell.

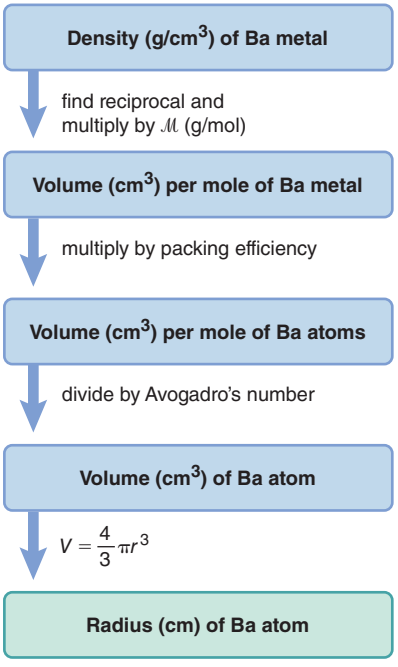
The packing efficiency of both hexagonal and cubic closest packing is 74%, and the coordination number of both is 12. Most metallic elements crystallize in one or the other of these arrangements. Magnesium, titanium, and zinc are some that adopt the hexagonal structure; nickel, copper, and lead adopt the cubic structure, as do many ionic compounds and other substances, such as CO_2, CH_4, and most noble gases.

In Sample Problem 12.7, we use density and our knowledge of unit cells to find an atomic radius.

SAMPLE PROBLEM 12.7 Determining Atomic Radius

Problem Barium is the largest nonradioactive alkaline earth metal. It has a body-centered cubic unit cell and a density of 3.62 g/cm^3. What is the atomic radius of barium? (Volume of a sphere: $V = \frac{4}{3}\pi r^3$.)

Road Map



Plan An atom is spherical, so we can find its radius from its volume. If we multiply the reciprocal of density (volume/mass) by the molar mass (mass/mole), we find the volume/mole of Ba metal. The metal crystallizes in the body-centered cubic structure, so 68% of this volume is occupied by 1 mol of the Ba atoms themselves (see Figure 12.28C). Dividing by Avogadro's number gives the volume of one Ba atom, from which we find the radius. (See the road map.)

Solution Combining steps to find the volume of 1 mol of Ba metal:

$$\text{Volume/mole of Ba metal} = \frac{1}{\text{density}} \times \mathcal{M} = \frac{1\ \text{cm}^3}{3.62\ \text{g Ba}} \times \frac{137.3\ \text{g Ba}}{1\ \text{mol Ba}} = 37.9\ \text{cm}^3/\text{mol Ba}$$

Finding the volume (cm^3) of 1 mol of Ba *atoms:*

$$\begin{aligned}\text{Volume/mole of Ba atoms} &= \text{cm}^3/\text{mol Ba} \times \text{packing efficiency}\\ &= 37.9\ \text{cm}^3/\text{mol Ba} \times 0.68\\ &= 26\ \text{cm}^3/\text{mol Ba atoms}\end{aligned}$$

Finding the volume of one Ba atom:

$$\begin{aligned}\text{Volume of Ba atom} &= \frac{26\ \text{cm}^3}{1\ \text{mol Ba atoms}} \times \frac{1\ \text{mol Ba atoms}}{6.022\times10^{23}\ \text{Ba atoms}}\\ &= 4.3\times10^{-23}\ \text{cm}^3/\text{Ba atom}\end{aligned}$$

Finding the atomic radius of Ba from the volume of a sphere:

$$V \text{ of Ba atom} = \tfrac{4}{3}\pi r^3 \qquad \text{so} \qquad r^3 = \frac{3V}{4\pi}$$

Thus,
$$r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3(4.3\times10^{-23}\ \text{cm}^3)}{4 \times 3.14}} = 2.2\times10^{-8}\ \text{cm}$$

Check The order of magnitude is correct for an atom ($\sim10^{-8}$ cm $\approx 10^{-10}$ m). The actual value for barium is, in fact, 2.22×10^{-8} cm (see Figure 8.13, p. 337).

FOLLOW-UP PROBLEMS

12.7A Cobalt has a face-centered cubic unit cell and an atomic radius of 125 pm. Calculate the density of cobalt metal.

12.7B Iron crystallizes in a body-centered cubic structure. The volume of one Fe atom is 8.38×10^{-24} cm^3, and the density of Fe is 7.874 g/cm^3. Calculate an approximate value for Avogadro's number.

SOME SIMILAR PROBLEMS 12.88 and 12.89

Our understanding of crystal structures comes from our ability to "see" them. Two techniques for visualizing crystal structures are described in Tools of the Laboratory on pages 486–487.

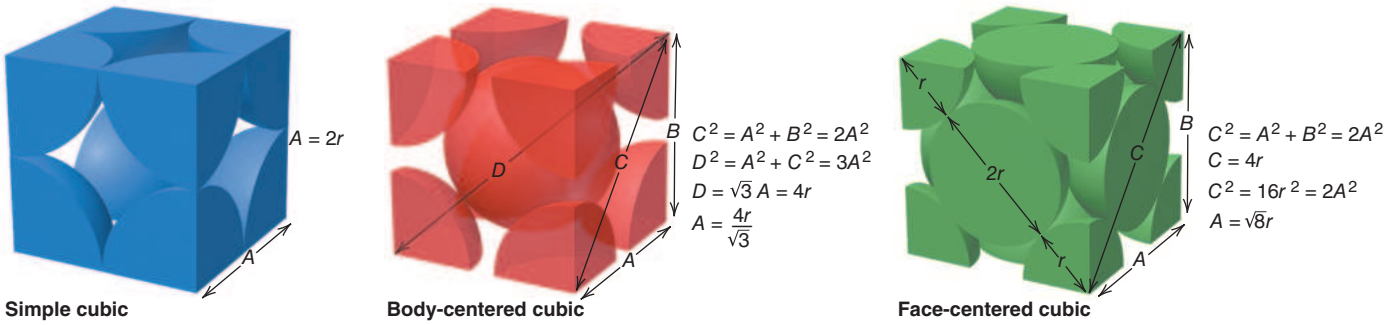


Figure 12.29 Edge length and atomic (ionic) radius in the three cubic unit cells.

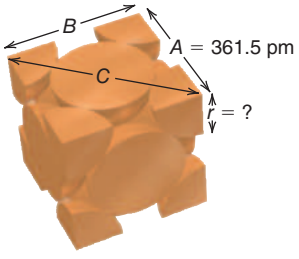
The edge length of the unit cell is obtained from x-ray crystallography. We can then apply the Pythagorean theorem and some arithmetic to find atomic (or ionic) radii in the three cubic unit cells (Figure 12.29). Sample Problem 12.8 shows this approach.

SAMPLE PROBLEM 12.8 Determining Atomic Radius from the Unit Cell

Problem Copper adopts cubic closest packing, and the edge length of the unit cell is 361.5 pm. What is the atomic radius of copper?

Plan Cubic closest packing gives a face-centered cubic unit cell, and we know the edge length. From Figure 12.29 with $A = 361.5$ pm, we solve for r.



Solution Using the Pythagorean theorem to find C, the diagonal of the cell's face:

$$C = \sqrt{A^2 + B^2}$$

The unit cell is a cube, so $A = B$. Therefore,

$$C = \sqrt{2A^2} = \sqrt{2(361.5\text{ pm})^2} = 511.2\text{ pm}$$

Finding r: $C = 4r$. Therefore,

$$r = 511.2\text{ pm}/4 = 127.8\text{ pm}.$$

Check Rounding and quickly checking the math gives

$$C = \sqrt{2(4\times10^2\text{ pm})^2} = \sqrt{2(16\times10^4\text{ pm}^2)}$$

or ~500–600 pm; thus, $r \approx$ 125–150 pm. The actual value for copper is 128 pm (see Figure 8.13, p. 337).

FOLLOW-UP PROBLEMS

12.8A Iron crystallizes in a body-centered cubic structure. If the atomic radius of Fe is 126 pm, find the edge length (in nm) of the unit cell.

12.8B Aluminum crystallizes in a cubic closest packed structure. If the edge length of the unit cell is 0.405 nm, find the atomic radius (in pm).

SOME SIMILAR PROBLEMS 12.92 and 12.93

X-Ray Diffraction Analysis and Scanning Tunneling Microscopy

Various tools exist for measuring atomic-scale dimensions, and two of the most powerful are **x-ray diffraction analysis** and **scanning tunneling microscopy.**

X-Ray Diffraction Analysis

In Chapter 7, we saw how diffraction patterns of bright and dark regions appear when light passes through slits spaced as far apart as the wavelength (see Figure 7.5, p. 291). X-ray wavelengths are about the same size as the spaces between layers of spheres in a crystal, so we use the spaces as "slits" to diffract x-rays.

As one example, let's use this approach to measure the distance (d) between two adjacent layers of atoms in a simplified lattice (Figure B12.1). Two waves impinge on the crystal at an angle θ and are diffracted at that angle by the layers. When the first wave strikes the top layer and the second strikes the next layer, they are *in phase* (peaks aligned with peaks and troughs with troughs). If they are still in phase after being diffracted, they form a spot on a photographic plate. This will occur only if the additional distance traveled by the second wave ($DE + EF$ in the figure) is a whole number of wavelengths, $n\lambda$, where n is a positive integer referred to as the *order* of the diffraction. From trigonometry, we find that

$$n\lambda = 2d \sin \theta$$

where θ is the angle of incoming light and d, the unknown, is the distance between layers. This is the *Bragg equation,* named for W. H. Bragg and his son W. L. Bragg, who shared the Nobel Prize in physics in 1915 for their work on crystal structure analysis.

Rotating the crystal changes θ and produces different sets of spots. Eventually, the complete diffraction pattern reveals distances and angles in the lattice (Figure B12.2). X-ray diffraction analysis is used in many studies, but its greatest recent impact is uncovering the structures of DNA and proteins.

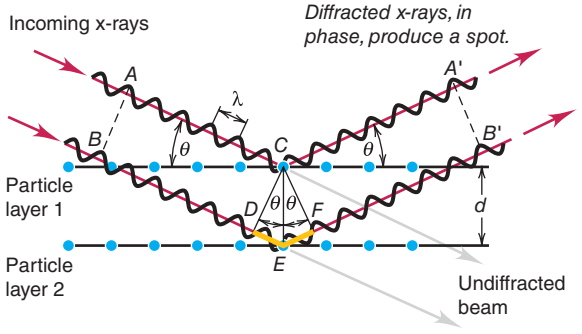


Figure B12.1 **Diffraction of x-rays by crystal planes.**

Scanning Tunneling Microscopy

This technique, invented by Gerd Binnig and Heinrich Rohrer, who won the Nobel Prize in physics in 1986, is used to observe surfaces. It is based on the idea that an electron has a small, but finite, probability of being so far from its nucleus that it can move ("tunnel") closer to another atom.

In practice, an extremely sharp tungsten-tipped probe, the source of the tunneling electrons, is placed very close (about

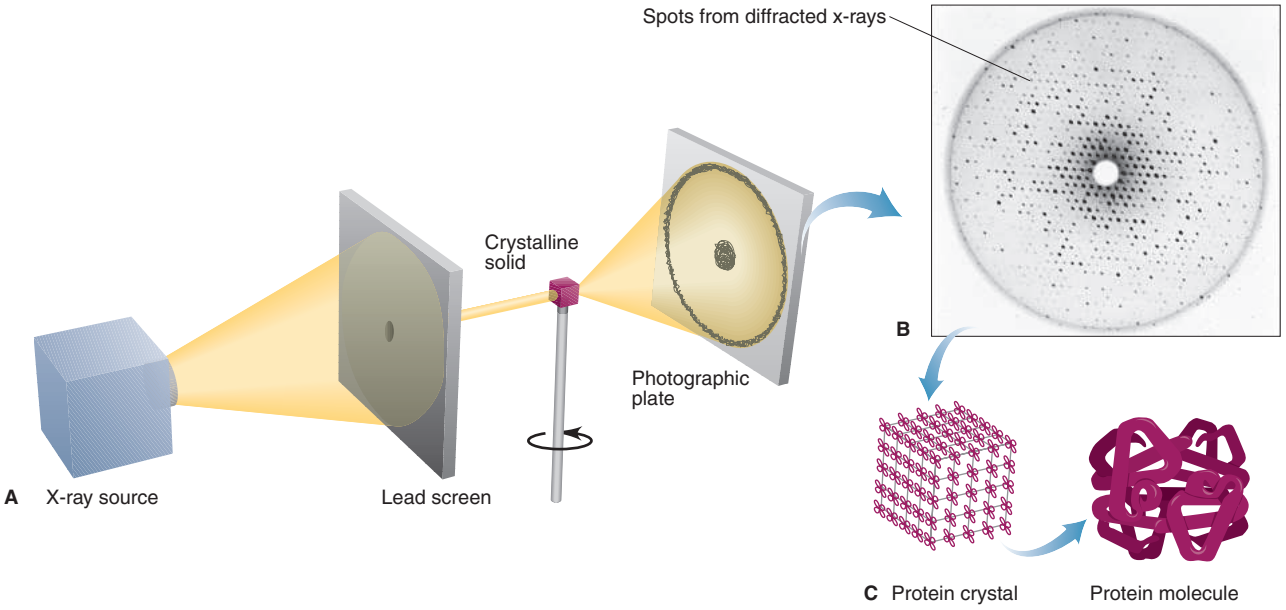

Figure B12.2 **Formation of an x-ray diffraction pattern of the protein hemoglobin.** **A,** A sample of crystalline protein is rotated to obtain different angles of incoming and diffracted x-rays. **B,** The diffraction pattern is a complex series of spots. **C,** Computerized analysis provides a picture of the molecule.

0.5 nm) to the surface under study. A small applied electric potential increases the probability that the electrons will tunnel across this minute gap. The probe moves tiny distances up and down to maintain the constant current across the gap, thus following the surface at the atomic scale. This movement is monitored electronically, and after many scans, a three-dimensional map of the surface is obtained. The method has revealed images of atoms and molecules coated on surfaces and is being used to study the nature of defects and many other surface features (Figure B12.3).

Problems

B12.1 X-rays of wavelength $\lambda = 0.709 \times 10^{-10}$ m undergo a first-order ($n = 1$) diffraction of 11.6° when aimed at crystalline nickel. What is the spacing between layers of Ni atoms?

B12.2 A first-order ($n = 1$) diffraction of x-rays aimed at a crystal of NaCl occurs at 15.9°.
(a) What is the wavelength (in pm) of the x-rays?
(b) At what angle would a second-order ($n = 2$) diffraction appear?

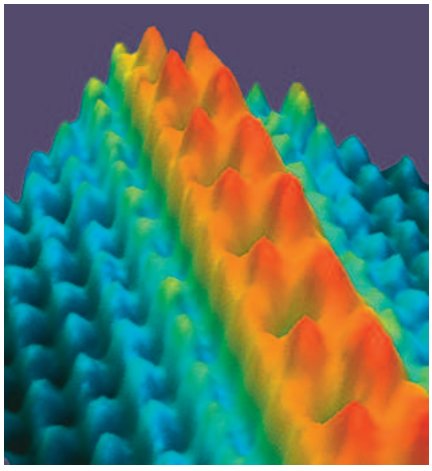

Figure B12.3 A scanning tunneling micrograph of cesium atoms *(red)* on gallium arsenide.

Types and Properties of Crystalline Solids

The five most important types of solids are defined by the type(s) of particle(s) in the crystal (Table 12.5). We'll highlight interparticle forces and physical properties.

Table 12.5 Characteristics of the Major Types of Crystalline Solids

Type	Particle(s)	Interparticle Forces	Physical Properties	Examples [mp, °C]
Atomic	Atoms	Dispersion	Soft, very low mp, poor thermal and electrical conductors	Group 8A(18) (Ne [−249] to Rn [−71])
Molecular	Molecules	Dispersion, dipole-dipole, H bonds	Fairly soft, low to moderate mp, poor thermal and electrical conductors	*Nonpolar** O_2 [−219], C_4H_{10} [−138] Cl_2 [−101], C_6H_{14} [−95], P_4 [44.1] *Polar* SO_2 [−73], $CHCl_3$ [−64], HNO_3 [−42], H_2O [0.0], CH_3COOH [17]
Ionic	Positive and negative ions	Ion-ion attraction	Hard and brittle, high mp, good thermal and electrical conductors when molten	NaCl [801] CaF_2 [1423] MgO [2852]
Metallic	Atoms	Metallic bond	Soft to hard, low to very high mp, excellent thermal and electrical conductors, malleable and ductile	Na [97.8] Zn [420] Fe [1535]
Network covalent	Atoms	Covalent bond	Very hard, very high mp, usually poor thermal and electrical conductors	SiO_2 (quartz) [1610] C (diamond) [~4000]

*Nonpolar molecular solids are arranged in order of increasing molar mass. Note the correlation with increasing melting point (mp).

Figure 12.30 Cubic closest packing of argon (face-centered cubic unit cell).

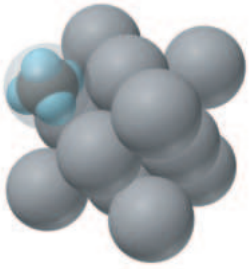

Figure 12.31 Cubic closest packing (face-centered unit cell) of CH_4.

Atomic Solids Individual atoms held together only by *dispersion forces* form an **atomic solid,** and the noble gases [Group 8A(18)] are the only substances that form such solids. The very weak forces among the atoms mean melting and boiling points and heats of vaporization and fusion are all very low, rising smoothly with increasing molar mass. Argon crystallizes in a cubic closest packed structure (Figure 12.30), as do the other noble gases.

Molecular Solids In the many thousands of **molecular solids,** individual molecules occupy the lattice points. Various combinations of dipole-dipole, dispersion, and H-bonding forces account for a wide range of physical properties. Dispersion forces in nonpolar substances lead to melting points that generally increase with molar mass (Table 12.5). Among polar molecules, dipole-dipole forces and, where possible, H bonding occur. Most molecular solids have much higher melting points than atomic solids (noble gases) but much lower melting points than other types of solids. Methane crystallizes in a face-centered cubic structure with the center of each carbon as the lattice point (Figure 12.31).

Ionic Solids To maximize attractions in a binary **ionic solid,** cations are surrounded by as many anions as possible, and vice versa, with *the smaller of the ions (usually the cation) lying in the spaces (holes) formed by the packing of the larger (usually the anion).* The unit cell is the smallest portion that maintains the composition; that is, *the unit cell has the same cation/anion ratio as the empirical formula.*

As a result of cation-anion contact, the interparticle forces (ionic bonds) are *much* stronger than the van der Waals forces in atomic or molecular solids. The properties of ionic solids are a direct consequence of the *fixed ion positions* and *very strong attractive forces,* which create a high lattice energy. Thus, ionic solids typically have high melting points and low electrical conductivities. When a large quantity of heat is supplied and the ions gain enough kinetic energy to break free of their positions, the solid melts and the mobile ions conduct a current. Ionic compounds are hard because only a strong external force can change the relative positions of the huge number of ions attracting one another. If enough force *is* applied to move them, ions of like charge are brought near each other, and their repulsions crack the crystal (see Figure 9.9, p. 367).

Ionic solids often adopt cubic closest packed crystal structures. We'll describe two examples with a 1/1 ratio of ions and then two with a 2/1 (or 1/2) ratio:

1. The *sodium chloride structure* is found in many ionic compounds, including most alkali [Group 1A(1)] halides and hydrides, alkaline earth [Group 2A(2)] oxides and sulfides, and several transition metal oxides and sulfides. To visualize this structure, imagine Cl^- anions and Na^+ cations in separate face-centered cubic arrays. Now picture the two arrays penetrating each other, the smaller Na^+ ions ending up in the holes between the larger Cl^- ions (Figure 12.32A). Thus, each Na^+ is surrounded by six Cl^-, and vice versa (coordination number = 6). Figure 12.32B is a space-filling depiction of the unit cell: four Cl^- $[(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4\ Cl^-]$ and four Na^+ $[(12 \times \frac{1}{4}) + 1$ in the center $= 4\ Na^+]$, give a 1/1 ion ratio.

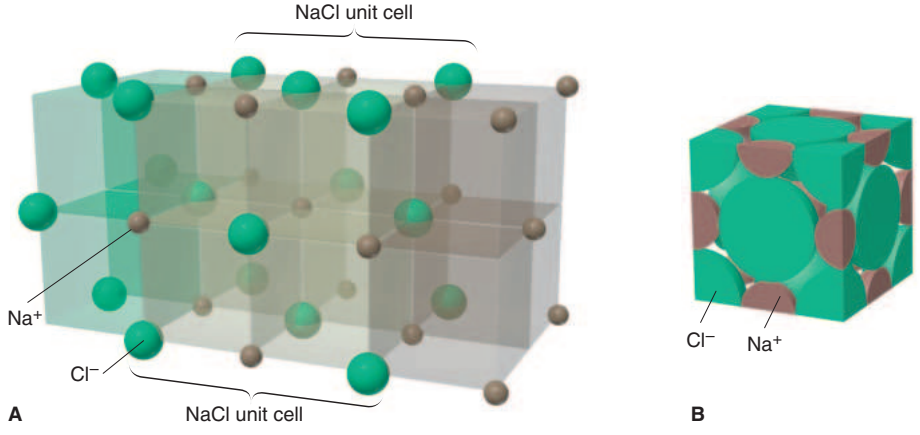

Figure 12.32 The sodium chloride structure. **A,** Expanded view. **B,** Space-filling model of the NaCl unit cell.

2. The *zinc blende (ZnS) structure* can be pictured as two face-centered cubic arrays, one of Zn^{2+} ions *(gray)* and the other of S^{2-} ions *(yellow),* penetrating each other such that each ion is tetrahedrally surrounded by four of the other ions (coordination number = 4) (Figure 12.33). There are four $\left[(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4\right] S^{2-}$ ions and four Zn^{2+} ions for a 1/1 ion ratio. Many other compounds, including AgI, CdS, and the copper(I) halides, adopt the zinc blende structure.

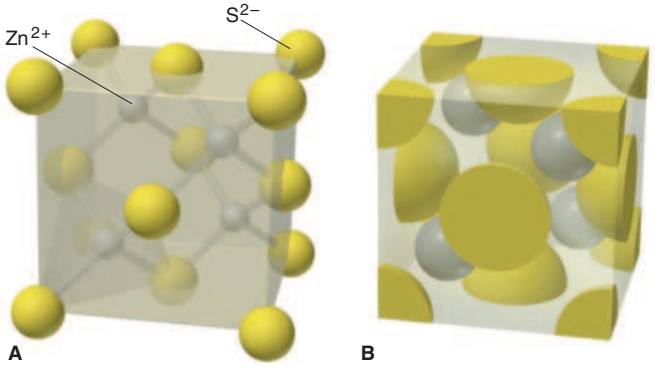

Figure 12.33 **The zinc blende structure.** **A,** Expanded view (with bonds shown for clarity). **B,** The unit cell is expanded a bit to show interior ions.

3. The *fluorite (CaF_2) structure* is common among salts with a 1/2 cation/anion ratio that have relatively large cations and small anions, such as SrF_2 and $BaCl_2$. In CaF_2, the unit cell is a face-centered cubic array of Ca^{2+} ions with F^- ions occupying *all* eight available holes (Figure 12.34). This results in a Ca^{2+}/F^- ratio of 4/8, or 1/2.

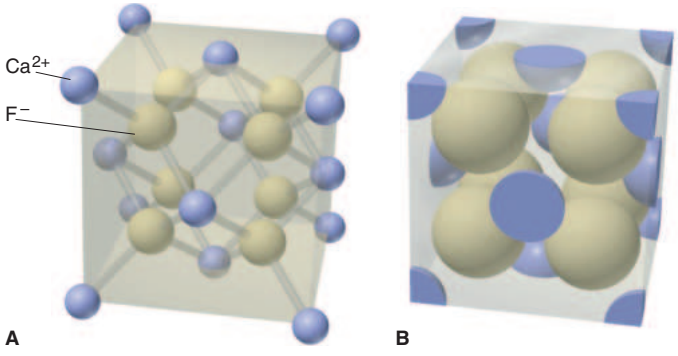

Figure 12.34 **The fluorite structure.** **A,** Expanded view (with bonds shown for clarity). **B,** The unit cell is expanded a bit to show interior ions.

4. The *antifluorite structure* is common in compounds with a 2/1 cation/anion ratio and a relatively large anion (such as K_2S). The ion arrangement is the opposite of that in the fluorite structure: the cations occupy all eight holes formed by the cubic closest packing of the anions.

Metallic Solids Most metallic elements crystallize in one of the two closest packed structures (Figure 12.35). In contrast to the weak dispersion forces in atomic solids, powerful metallic bonding forces hold atoms together in **metallic solids.** The properties of metals—high electrical and thermal conductivity, luster, and malleability—result from their delocalized electrons (Section 9.6). Melting points and hardnesses are related to the packing efficiency and number of valence electrons. For example, Group 2A metals are harder and melt higher than Group 1A metals (see Figure 9.28, p. 386), because the 2A metals have twice as many delocalized valence electrons.

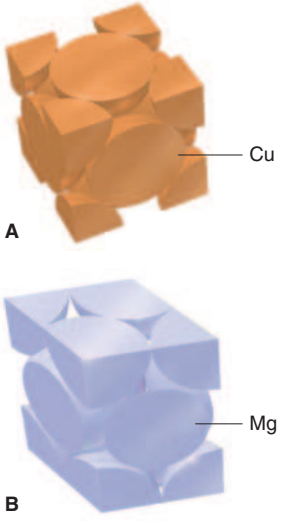

Figure 12.35 **Crystal structures of metals.** **A,** Copper adopts cubic closest packing. **B,** Magnesium adopts hexagonal closest packing.

Network Covalent Solids Strong covalent bonds link the atoms together in a **network covalent solid;** thus, separate particles are not present. These substances adopt a variety of crystal structures depending on the details of their bonding.

Table 12.6 Comparison of the Properties of Diamond and Graphite

Property	Graphite		Diamond	
Density (g/cm^3)	2.27		3.51	Hardness	<1 (very soft)		10 (hardest)	
Melting point (K)	4100		4100	
Color	Shiny black		Colorless transparent	
Electrical conductivity	High (along sheet)		None	
ΔH°_{rxn} for combustion (kJ/mol)	−393.5		−395.4	
ΔH°_f (kJ/mol)	0 (standard state)		1.90	

As a consequence of strong bonding, all network covalent solids have extremely high melting and boiling points, but their conductivity and hardness vary. Two examples with the same composition but strikingly different properties are the two common crystalline forms of elemental carbon, graphite and diamond:

- *Graphite* occurs as stacked flat sheets of hexagonal carbon rings with a strong σ-bond framework and delocalized π bonds, reminiscent of benzene; the arrangement looks like chicken wire or honeycomb. Whereas the π-bonding electrons of benzene are delocalized over one ring, those of graphite are delocalized over the entire sheet. Thus, graphite conducts electricity well—it is a common electrode material—but only in the plane of the sheets. The sheets interact via dispersion forces, and impurities, such as O_2, between the sheets allow them to slide past each other, which explains why graphite is soft and used as a lubricant.
- *Diamond* adopts a face-centered cubic unit cell, with each C tetrahedrally bonded to four others in an endless array. Throughout the crystal, strong single bonds make diamond the hardest natural substance known. Like most network covalent solids, diamond does not conduct electricity because the bonding electrons are localized.

These properties are compared in Table 12.6.

The most important network covalent solids are the *silicates,* which consist of extended arrays of covalently bonded silicon and oxygen atoms. Quartz (SiO_2) is a common example. We'll discuss silicates, which form the structure of clays, rocks, and many minerals, when we consider the chemistry of silicon in Chapter 14.

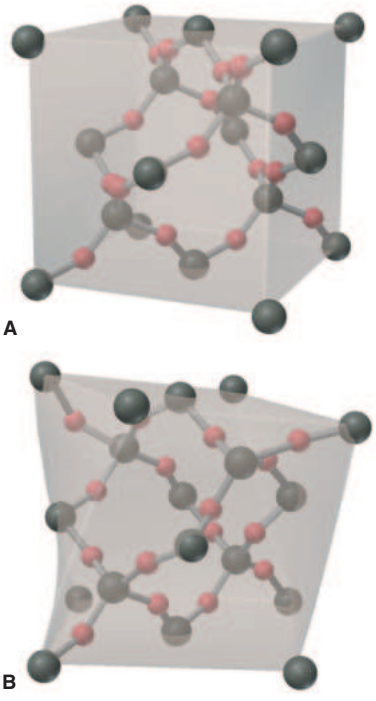

Figure 12.36 Crystalline and amorphous silicon dioxide. A, Cristobalite, a crystalline form of silica (SiO_2), shows cubic closest packing. **B,** Quartz glass is amorphous with a generally disordered structure.

Amorphous Solids

Amorphous solids are noncrystalline. Many have small, somewhat ordered regions interspersed among large disordered regions. Charcoal, rubber, and glass are examples.

The process that forms quartz glass is typical of many amorphous solids. Crystalline quartz (SiO_2), which adopts cubic closest packing, is melted and the viscous liquid is cooled rapidly to prevent it from recrystallizing. The chains of Si and O atoms cannot orient themselves quickly enough, so they solidify in a distorted jumble containing gaps and misaligned rows (Figure 12.36). The absence of regularity confers some properties of a liquid; in fact, glasses are sometimes referred to as *supercooled liquids.*

Bonding in Solids: Molecular Orbital Band Theory

Chapter 9 introduced a qualitative model of metallic bonding, with metal ions submerged in a "sea" of delocalized valence electrons. Molecular orbital (MO) theory offers a more quantitative, and therefore more useful, model called **band theory.** We'll focus on bonding in metals and the resulting conductivity of metals, metalloids, and nonmetals.

Formation of Valence and Conduction Bands Recall from Section 11.3 that when two atoms form a diatomic molecule, their atomic orbitals (AOs) combine to form an equal number of molecular orbitals (MOs). Figure 12.37 shows the formation of MOs in lithium. To form Li_2, each Li atom has four valence orbitals (one 2*s* and three 2*p*) that combine to form eight MOs, four bonding and four antibonding. The order of MOs shows 2*s*–2*p* mixing (Figure 11.20B, p. 444). Two more Li atoms form Li_4, a slightly larger aggregate, with 16 delocalized MOs. As more Li atoms join the cluster, more MOs are created, and their energy levels lie closer and closer together. Extending this process to 7 g (1 mol) of lithium results in 6×10^{23} Li atoms (Li_{N_A}) combining to form an extremely large number (4 × Avogadro's number) of delocalized MOs. *The energies of the MOs are so close that they form a continuum, or band, of MOs.*

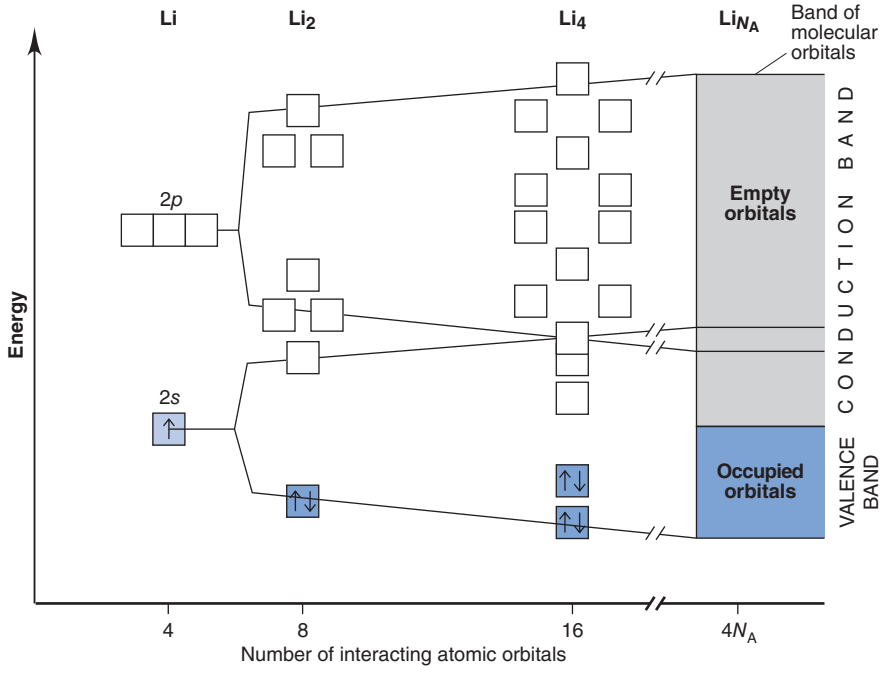

Figure 12.37 **The band of molecular orbitals in lithium metal.**

The lower energy MOs are occupied by the $2s^1$ valence electrons and make up the **valence band.** The empty MOs that are higher in energy make up the **conduction band.** In Li metal, the valence band is derived from the 2*s* AOs, and the conduction band is derived from 2*s* and mostly 2*p* AOs. In Li_2, two valence electrons fill the lowest energy bonding MO and leave the antibonding MO empty. In Li metal, 1 mol of valence electrons fills the valence band and leaves the conduction band empty.

How Band Theory Explains Metallic Properties The key to understanding the properties of metals is that *the valence and conduction bands are contiguous,* that is, the highest level of one touches the lowest of the other. This means that, given an infinitesimal quantity of energy, electrons jump from the filled valence band to the unfilled conduction band: the electrons are completely delocalized and free to move.

- *Electrical conductivity*. Metals conduct so well because an applied field easily excites the highest energy valence electrons into empty conduction orbitals, allowing them to move through the sample.
- *Luster*. With so many closely spaced levels available, electrons absorb and release photons of many frequencies as they move between the valence and conduction bands.
- *Malleability*. Under an applied force, layers of positive metal ions move past each other, always protected from mutual repulsions by the delocalized electrons.
- *Thermal conductivity.* When a metal wire is heated, the highest energy electrons are excited and their extra energy is transferred as kinetic energy along the wire's length.

Conductivity of Solids and the Size of the Energy Gap Like metal atoms, large numbers of nonmetal and metalloid atoms can form bands of MOs. Band theory explains differences in electrical conductivity and the effect of temperature among these three classes of substances in terms of the presence of an energy gap between their valence and conduction bands (Figure 12.38):

1. *Conductors (metals).* The valence and conduction bands of a **conductor** have *no energy gap* between them, so electrons flow when a tiny electrical potential difference is applied. When the temperature is raised, greater random motion of the atoms hinders electron movement: conductivity *decreases* when a metal is heated.
2. *Semiconductors (metalloids).* In a **semiconductor,** a *small energy gap* exists between the valence and conduction bands. Thermally excited electrons can cross the gap, allowing a small current to flow: in contrast to a conductor, conductivity *increases* when a semiconductor is heated.
3. *Insulators (nonmetals).* In an **insulator,** a *large energy gap* exists between the bands: no current is observed even when the substance is heated.

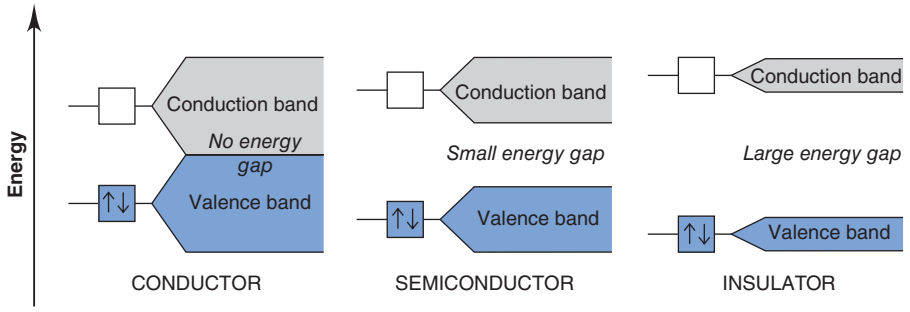

Figure 12.38 Electrical conductivity in a conductor, semiconductor, and insulator.

Another type of electrical conductivity, called **superconductivity,** has been the focus of intensive research for the past few decades. When metals conduct at ordinary temperatures, moving electrons collide with vibrating atoms; the reduction in their flow appears as resistive heating and represents a loss of energy.

For many years, to conduct with no energy loss—to superconduct—required minimizing atom movement by cooling with liquid helium (bp = 4 K; price ≈ \$11/L). Then, in 1986, certain ionic oxides that superconduct near the boiling point of liquid nitrogen (bp = 77 K; price = \$0.06/L) were prepared. Like metal conductors, oxide superconductors, such as $YBa_2Cu_3O_7$, have no gap between bands. In 1989, oxides with Bi and Tl instead of Y and Ba were synthesized and found to superconduct at 125 K; and in 1993, an oxide with Hg, Ba, and Ca, in addition to Cu and O, superconducted at 133 K. Such materials could transmit electricity with no loss of energy, allowing power plants to be located far from cities. They could be part of ultrasmall microchips for ultrafast computers, electromagnets to levitate superfast trains, and inexpensive medical diagnostic equipment with superb image clarity. However, the oxides are brittle and not easy to machine, and when warmed, the superconductivity may disappear and not return on cooling. Addressing these and related problems will involve chemists, physicists, and engineers for many years.

Summary of Section 12.6

- Particles in crystalline solids lie at points that form a structure of repeating unit cells.
- The three types of unit cells of the cubic system are simple, body-centered, and face-centered. The highest packing efficiency occurs with cubic (face-centered) and hexagonal closest packing.

- Bond angles and distances in a crystal are determined with x-ray diffraction analysis and scanning tunneling microscopy. These data are used to determine atomic radii.
- Atomic [Group 8A(18)] solids adopt cubic closest packing, with atoms held together by weak dispersion forces.
- Molecular solids have molecules at the lattice points and often adopt cubic closest packing. Combinations of intermolecular forces (dispersion, dipole-dipole, and H bonding) result in physical properties that vary greatly.
- Ionic solids crystallize with one ion filling holes in the cubic closest packed array of the other. High melting points, hardness, and low conductivity arise from strong ionic attractions.
- Most metals have a closest packed structure. Their physical properties result from the high packing efficiency and the presence of delocalized electrons.
- Atoms of network covalent solids are covalently bonded throughout the sample, so these substances have very high melting and boiling points.
- Amorphous solids have little regularity in their structure.
- Band theory proposes that atomic orbitals of many atoms combine to form a continuum, or band, of molecular orbitals. Metals are electrical conductors because electrons move freely from the filled (valence) band to the empty (conduction) band. Insulators have a large energy gap between the two portions, and semiconductors have a small gap, which can be bridged by heating.

12.7 ADVANCED MATERIALS

In the last few decades, the exciting field of materials science has applied concepts from solid-state chemistry, physics, and engineering. Objects that were once considered futuristic fantasies have become realities: powerful, ultrafast computers smaller than a cell phone; cars powered by sunlight and made of nonmetallic parts stronger than steel and lighter than aluminum; ultrasmall machines constructed by manipulating individual atoms and molecules. In this section, we briefly discuss some of these remarkable materials.

Electronic Materials

The ideal of a perfectly ordered crystal is attainable only if the crystal is grown very slowly under carefully controlled conditions. When crystals form more rapidly, **crystal defects** inevitably form. Planes of particles are misaligned, particles are out of place or missing entirely, and foreign particles replace those that belong in the lattice. Although defects usually weaken a substance, they can be introduced intentionally to improve materials, giving them increased strength, hardness, or conductivity. Centuries of metal-working exemplify the traditional importance of crystal defects, which is the basis of modern electronic materials.

Introducing Crystal Defects in Welding and Alloying In the process of *welding* two metals together, *vacancies* form near the surface when atoms vaporize, and then these vacancies move deeper as atoms from lower rows rise to fill the gaps. Welding causes the two types of metal atoms to intermingle and fill each other's vacancies. Metal *alloying* introduces several kinds of crystal defects, as when some atoms of a second metal occupy lattice sites of the first. Often, the alloy is harder than the pure metal; an example is brass, an alloy of copper with zinc. One reason the welded metals are stronger and the alloy is harder is that the second metal contributes additional valence electrons for metallic bonding.

Doped Semiconductors By controlling the number of valence electrons through the creation of specific types of crystal defects, chemists and engineers can greatly increase the conductivity of a semiconductor. For example, pure silicon [Si; Group 4A(14)],

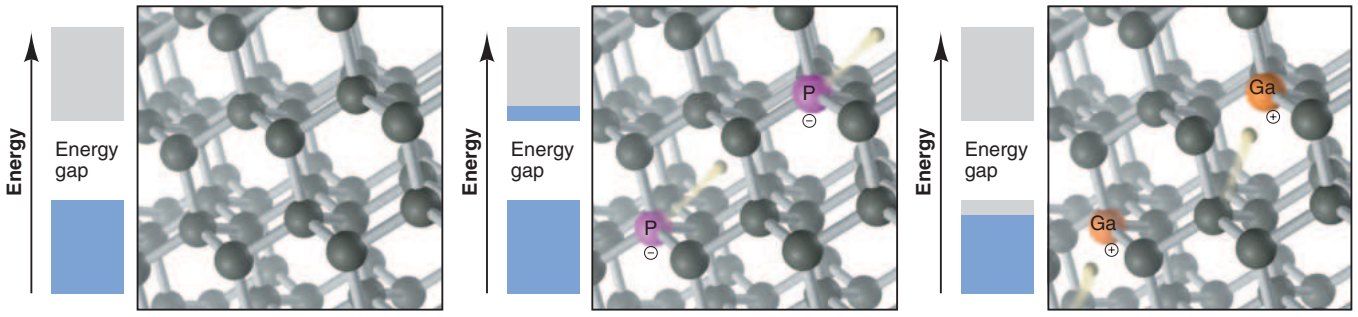

Figure 12.39 Crystal structures and band representations of doped semiconductors. A, Pure silicon has an energy gap between its valence and conduction bands, which keeps conductivity low at room temperature. **B,** Doping silicon with phosphorus *(purple)* adds additional valence electrons. **C,** Doping silicon with gallium *(orange)* removes electrons from the valence band and introduces positive holes.

conducts poorly at room temperature because an energy gap separates its filled valence band from its conduction band (Figure 12.39A). Its conductivity can be greatly enhanced by **doping,** adding small amounts of other elements to increase or decrease the number of valence electrons in the bands:

- *n-Type semiconductor: increasing the number of valence electrons.* When Si is doped with phosphorus [or another Group 5A(15) element], P atoms occupy some of the lattice sites. Since P has one more valence electron than Si, this additional electron must enter an empty orbital in the conduction band, thus bridging the energy gap and increasing conductivity. Such doping creates an *n-type semiconductor,* so called because extra *n*egative charges (electrons) are present (Figure 12.39B).
- *p-Type semiconductor: decreasing the number of valence electrons.* When Si is doped with gallium [or another Group 3A(13) element], Ga atoms occupy some sites (Figure 12.39C). Since Ga has one fewer valence electron than Si, some of the orbitals in the valence band are empty, which creates a positive site. Si electrons can migrate to these empty orbitals, thereby increasing conductivity. Such doping creates a *p-type semiconductor,* so called because the empty orbitals act as *p*ositive holes.

In contact with each other, an n-type and a p-type semiconductor form a *p-n junction.* When the negative terminal of a battery is connected to the n-type portion and the positive terminal to the p-type portion, electrons *(yellow, negative spheres)* flow freely in the n-to-p direction, which has the simultaneous effect of moving holes *(white, positive spheres)* in the p-to-n direction (Figure 12.40A). No current flows if the terminals are reversed (Figure 12.40B). Such unidirectional current flow makes a p-n junction act as a *rectifier,* a device that converts alternating current into direct current. A p-n junction in a modern integrated circuit can be made smaller than a square 10 μm on a side.

A modern computer chip the size of a nickel may incorporate millions of p-n junctions in the form of *transistors*. One of the most common types, an n-p-n transistor,

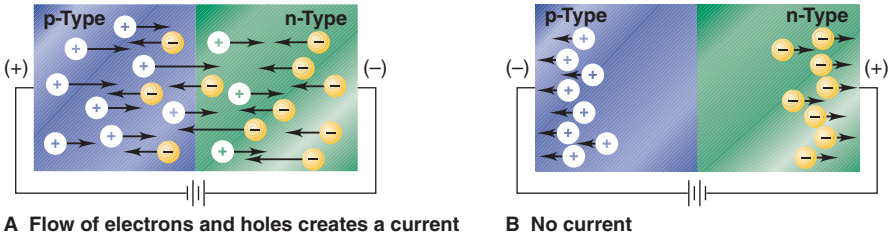

Figure 12.40 The p-n junction. Placing a p-type semiconductor adjacent to an n-type creates a p-n junction.

is made by sandwiching a p-type portion between two n-type portions to form adjacent p-n junctions. The current flowing through one junction controls the current flowing through the other and results in an amplified signal.

One of the more common types of *solar cell* is, in essence, a p-n junction with an n-type surface exposed to a light source. Light provides the energy to free electrons from the n-type region and accelerate them through an external circuit into the p-type region, thus producing a current.

Liquid Crystals

Incorporated in the membrane of every cell in your body and in the display of every electronic device are **liquid crystals.** These materials flow like liquids but, like crystalline solids, pack with a high degree of order at the molecular level.

Ordering of the Particles Let's examine how particles are ordered in the three physical states and how this affects their properties. Both gases and liquids are *isotropic*—their physical properties are the same in every direction within the phase. For example, the viscosity of a gas or a liquid is the same regardless of direction. Glasses and other amorphous solids are also isotropic because they have no regular lattice structure.

In contrast, crystalline solids have a high degree of order among their particles. The properties of a crystal *do* depend on direction, so a crystal is *anisotropic*. The facets in a cut diamond, for instance, arise because the crystal cracks in one direction more easily than in another. Liquid crystals are anisotropic in several physical properties, including electrical and optical properties, which differ with direction through the phase.

Molecular Characteristics Liquid crystal phases consist of individual molecules with two characteristics: (1) a long, cylindrical shape and (2) a structure that fosters intermolecular attractions but inhibits perfect crystalline packing. Molecules that form liquid crystal phases have rodlike shapes and certain groups—in the cases shown in Figure 12.41, flat, benzene-like ring systems—that keep the molecules extended. Many of these molecules also have polarity associated with the long molecular axis. A strong electric field can orient these polar molecules like compass needles in a magnetic field.

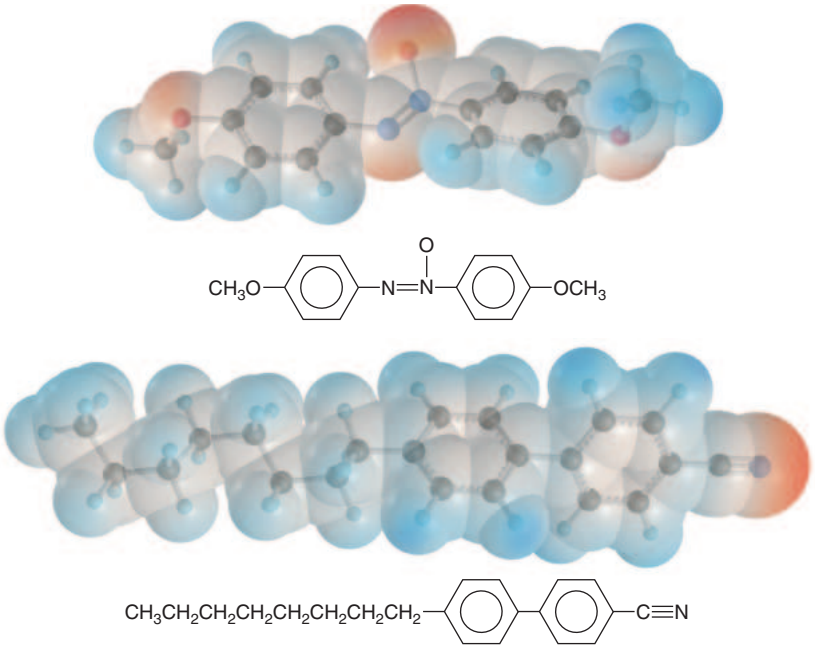

Figure 12.41 Structures of two typical molecules that form liquid crystal phases. Note the long, extended shapes and the regions of high *(red)* and low *(blue)* electron density.

The viscosity of a liquid crystal phase is lowest in the direction parallel to the long axis. Like moistened microscope slides, it is easier for the molecules to slide along each other (because the total attractive force remains the same), than it is for them to pull apart from each other sideways. As a result, the molecules tend to align while the phase flows.

Controlling Conditions to Form Phases Liquid crystal phases can arise in two general ways, and, sometimes, either way can occur in the same substance:

1. *Thermotropic phases* develop as a result of a change in temperature. As a crystalline solid is heated, the molecules leave their lattice sites, but the intermolecular interactions are still strong enough to keep the molecules aligned with each other along their long axes. Like any other phase, the liquid crystal phase has sharp transition temperatures, but they occur over a relatively small temperature range. Further heating provides enough kinetic energy for the molecules to become disordered, as in a normal liquid. The typical range for liquid crystal phases of pure substances is from $<1°C$ to as much as 10°C, but mixing phases of two or more substances can greatly extend this range. For this reason, the liquid crystal phases used within display devices, as well as those within cell membranes, consist of mixtures of molecules.

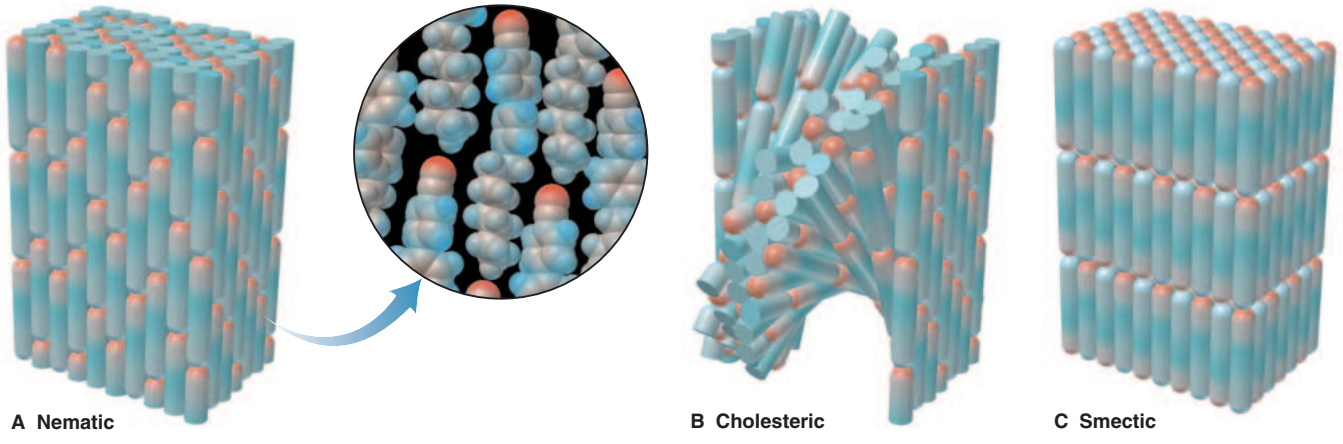
2. *Lyotropic phases* occur in solution as the result of changes in concentration, but the conditions for forming such a phase vary for different substances. For example, when purified, some biomolecules that exist in cell membranes form lyotropic phases in water at the temperature that occurs within the organism. At the other extreme, Kevlar, a fiber used in bulletproof vests and high-performance sports equipment, forms a lyotropic phase in concentrated H_2SO_4 solution.

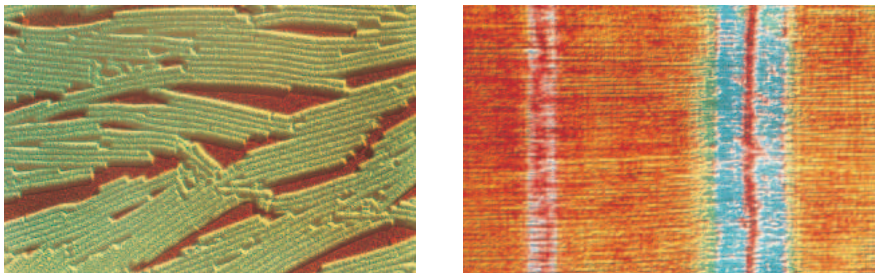
In some cases, a substance that forms a given liquid crystal phase under one set of conditions forms other phases under different conditions. Thus, a given thermotropic liquid crystal substance can pass from disordered liquid through a series of distinct liquid crystal phases to an ordered crystal through a decrease in temperature. A lyotropic substance can undergo similar changes through an increase in concentration.

Types of Order in Liquid Crystal Phases Molecules that form liquid crystal phases can exhibit various types of order. Three common types are nematic, cholesteric, and smectic:

1. In a *nematic phase,* the molecules lie in the same direction but their ends are not aligned, much like a school of fish swimming in synchrony (Figure 12.42A). The nematic phase is the least ordered type of liquid crystal phases.
2. In a *cholesteric phase,* which is somewhat more ordered, the molecules lie in layers that each exhibit nematic-type ordering. Rather than lying in parallel fashion, however, each layer is rotated by a fixed angle with respect to the next layer to give a helical (corkscrew) arrangement. A cholesteric phase is often called a *twisted nematic phase* (Figure 12.42B).

Figure 12.42 The three common types of ordering in liquid crystal phases.





A B

Figure 12.43 Liquid crystal–type phases in biological systems. A, Nematic arrays of tobacco mosaic virus particles within the fluid of a tobacco leaf. **B,** The smectic-like arrangement of actin and myosin protein filaments in voluntary muscle cells.

3. In a *smectic phase,* which is the most ordered, the molecules lie parallel to each other, *with* their ends aligned, in layers that are stacked directly over each other (Figure 12.42C). The long molecular axis has a well-defined angle (shown in the figure as 90°) with respect to the plane of the layer. The molecules in Figure 12.41 form nematic or smectic phases. Liquid crystal–type phases appear in many biological systems (Figure 12.43).

Applications of Liquid Crystals The ability to control the orientation of the molecules in a liquid crystal allows us to produce materials with high strength or unique optical properties:

1. *High-strength applications* involve the use of extremely long molecules called *polymers.* While in a thermotropic liquid crystal phase and during their flow through the processing equipment, these molecules become highly aligned, like the fibers in wood. Cooling solidifies them into fibers, rods, and sheets that can be shaped into materials with superior mechanical properties. Sporting equipment, supersonic aircraft parts, and the sails used in the America's Cup races are fabricated from these polymeric materials. (We discuss the structure and physical behavior of polymers later in this section and their synthesis in Chapter 15.)

2. *Optical applications* include the liquid crystal displays (LCDs) used in countless devices, such as watches, calculators, cell phones, and tablets. All depend on *changes in molecular orientation in an electric field*. Figure 12.44 shows a small portion of a wristwatch LCD. Layers of nematic phases are sandwiched between thin glass plates that incorporate transparent electrodes. The long molecular axis lies parallel to the plane of the plates. The distance between plates (6–8 μm) allows the molecular axis within each succeeding layer to twist just enough for the molecular orientation at the bottom plate to be 90° from that at the top plate. Above and below this "sandwich" are thin polarizing filters that allow light waves oriented in only one direction to pass through. The filters are placed in a "crossed" arrangement, so that light passing through the top filter must twist 90° to pass through the bottom filter. This whole grouping of filters, plates, and liquid crystal phase lies on a mirror.

A current generated by the watch battery controls the orientation of the molecules. With the current on in one region of the display, the molecules become oriented *toward* the field, and thus block the light from passing through to the bottom filter, so that region appears dark. With the current off in another region, light passes through the molecules and bottom filter to the mirror and back again, so that region appears bright.

Cholesteric liquid crystals are used in applications that involve color changes with temperature. The twisted molecular orientation "unwinds" with heating, and the extent of the unwinding determines the color. Liquid crystal thermometers include a mixture of substances to widen their range of temperatures. Newer uses include "mapping" the area of a tumor, detecting faulty connections in electronic circuit boards, and nondestructive testing of materials under stress.

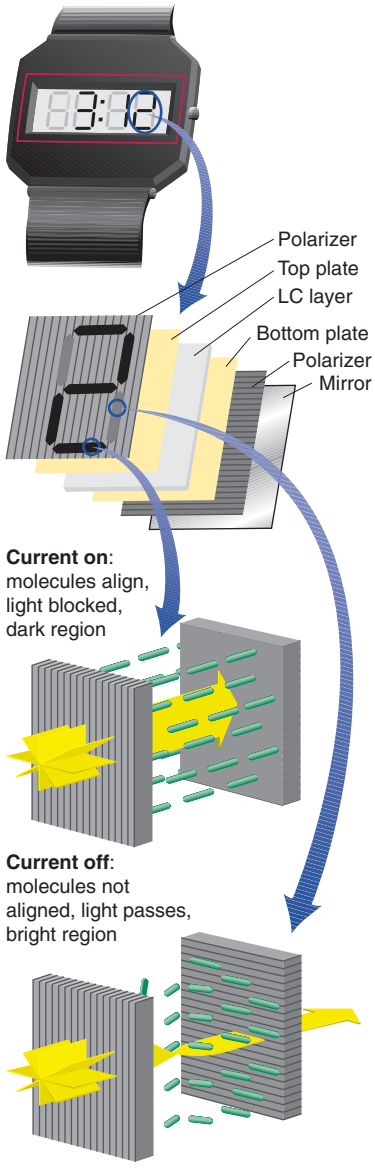


Figure 12.44 A liquid crystal display (LCD). A close-up of the "2" on a wristwatch LCD reveals two polarizers sandwiching two glass plates, which sandwich a liquid crystal (LC) layer, all lying on a mirror. When light waves enter the first polarizer, waves oriented in one direction emerge to enter the LC layer. Enlarging a dark region *(top blow-up)* shows the LC molecules aligned, keeping light waves from passing through; thus, the viewer sees no light. Enlarging a bright region *(bottom blow-up)* shows the LC molecules rotating the plane of the light waves, which can then pass through and reach the viewer.

Ceramic Materials

First developed by Stone Age people, **ceramics** are nonmetallic, nonpolymeric solids hardened by high temperature. Clay ceramics consist of silicate microcrystals suspended in a glassy cementing medium. In "firing" a ceramic pot, for example, a kiln heats the object, made of an aluminosilicate clay, such as kaolinite, to 1500°C and the clay loses water:

$$Si_2Al_2O_5(OH)_4(s) \longrightarrow Si_2Al_2O_7(s) + 2H_2O(g)$$

During the heating process, the structure rearranges to an extended network of Si-centered and Al-centered tetrahedra of O atoms (Section 14.6).

Bricks, porcelain, glazes, and other clay ceramics are hard and resistant to heat and chemicals. Today's high-tech ceramics have these characteristics in addition to superior electrical and magnetic properties (Table 12.7). As just one example, consider the unusual electrical behavior of certain zinc oxide (ZnO) composites. Ordinarily a semiconductor, ZnO can be doped so that it becomes a conductor. Imbedding particles of the doped oxide into an insulating ceramic produces a variable resistor: at low voltage, the material conducts poorly, but at high voltage, it conducts well. The changeover voltage can be "preset" by controlling the size of the ZnO particles and the thickness of the insulating medium.

Table 12.7 Some Uses of Modern Ceramics and Ceramic Mixtures

Ceramic	Applications
SiC, Si_3N_4, TiB_2, Al_2O_3	Whiskers (fibers) to strengthen Al and other ceramics
Si_3N_4	Car engine parts; turbine rotors for "turbo" cars; electronic sensor units
Si_3N_4, BN, Al_2O_3	Support or layering materials (as insulators) in electronic microchips
SiC, Si_3N_4, TiB_2, ZrO_2, Al_2O_3, BN	Cutting tools, edge sharpeners (as coatings and whole devices), scissors, surgical tools, industrial "diamond"
BN, SiC	Armor-plating reinforcement fibers (as in Kevlar composites)
ZrO_2, Al_2O_3	Surgical implants (hip and knee joints)

Preparing Modern Ceramics Among the important modern ceramics are silicon carbide (SiC) and nitride (Si_3N_4), boron nitride (BN), and the superconducting oxides. They are prepared by standard chemical methods that involve driving off a volatile component during the reaction:

1. *SiC ceramics* are made from compounds used in silicone polymer manufacture (we'll discuss these polymers in Section 14.6):

$$n(CH_3)_2SiCl_2(l) + 2n\text{Na}(s) \longrightarrow 2n\text{NaCl}(s) + [(CH_3)_2Si]_n(s)$$

This product is heated to 800°C to form the ceramic:

$$[(CH_3)_2Si]_n \longrightarrow nCH_4(g) + nH_2(g) + n\text{SiC}(s)$$

Silicon carbide can also be prepared by the direct reaction of silicon and graphite under vacuum:

$$\text{Si}(s) + \text{C(graphite)} \xrightarrow{\sim 1500^\circ\text{C}} \text{SiC}(s)$$

The nitride is also prepared by reaction of the elements:

$$3\text{Si}(s) + 2N_2(g) \xrightarrow{>1300^\circ\text{C}} Si_3N_4(s)$$

2. *BN ceramics* are produced through the reaction of boron trichloride or boric acid with ammonia:

$$B(OH)_3(s) + 3NH_3(g) \longrightarrow B(NH_2)_3(s) + 3H_2O(g)$$

Heat drives off some of the bound nitrogen as NH_3 to yield the ceramic:

$$B(NH_2)_3(s) \xrightarrow{\Delta} 2NH_3(g) + \text{BN}(s)$$

3. One type of *superconducting oxide* is made by heating a mixture of barium carbonate with copper and yttrium oxides, followed by further heating in the presence of O_2:

$$4BaCO_3(s) + 6CuO(s) + Y_2O_3(s) \xrightarrow{\Delta} 2YBa_2Cu_3O_{6.5}(s) + 4CO_2(g)$$
$$YBa_2Cu_3O_{6.5}(s) + \tfrac{1}{4}O_2(g) \xrightarrow{\Delta} YBa_2Cu_3O_7(s)$$

Ceramic Structures and Uses Structures of several ceramic materials are shown in Figure 12.45.

1. *Silicon carbide* has a diamond-like structure (Figure 12.45A). Network covalent bonding gives this material great strength. It is made into thin fibers, called *whiskers,* to reinforce other ceramics and prevent cracking in a composite structure, much like steel rods reinforcing concrete.

2. *Silicon nitride* is virtually inert chemically, retains its strength and wear resistance for extended periods above 1000°C, is dense and hard, and acts as an electrical insulator. Many automakers are testing it in high-efficiency car and truck engines because of its low weight, tolerance of high operating temperature, and little need for lubrication.

3. *BN ceramics* exist in two structures, analogous to the common crystalline forms of carbon. In the graphite-like form, BN has extraordinary properties as an electrical insulator. At high temperature and very high pressure (1800°C and 8.5×10^4 atm), BN converts to a diamond-like structure (Figure 12.45B), which is extremely hard and durable. Both forms are virtually invisible to radar.

4. *Superconducting oxides* often contain copper in an unusual oxidation state. In $YBa_2Cu_3O_7$ (Figure 12.45C), for instance, assuming oxidation states of +3 for Y, +2 for Ba, and −2 for O, the three Cu atoms have a total oxidation state of +7. This is allocated as $Cu(II)_2Cu(III)$, with one Cu in the unusual +3 state. X-ray diffraction analysis indicates that a distortion in the structure makes four of the oxide ions unusually close to the Y^{3+} ion, which aligns the Cu ions into chains within the crystal. It is thought that a specific half-filled 3*d* orbital in Cu oriented toward a neighboring O^{2-} ion may be associated with superconductivity.

Because of brittleness, it is difficult to fashion these ceramics into wires, but methods for making films and ribbons have been developed. The brittleness arises from the strength of the ionic-covalent bonding and the resulting inability to deform. Under stress, a microfine defect widens until the material cracks. One new method forms defect-free superconducting oxide ceramics using controlled packing and heat treatment of extremely small, uniform oxide particles coated with organic polymers. Another method is aimed at arresting a widening crack. The ceramics are embedded with zirconia (ZrO_2), whose crystal structure expands up to 5% under mechanical stress. When an advancing crack reaches them, the zirconia particles pinch it shut. A third method prepares the material of precisely grown crystals of Al_2O_3 and $GdAlO_3$, which become entangled during the solidification process. The resulting material bends without cracking above 1800 K.

Figure 12.45 Expanded view of the atom arrangements in some modern ceramic materials.

Polymeric Materials

A **polymer** (Greek, "many parts") is an extremely large molecule, or **macromolecule,** consisting of a covalently linked chain of smaller molecules, called **monomers** (Greek, "one part"). The monomer is the *repeat unit* of the polymer, and a polymer may have hundreds to hundreds of thousands of repeat units. Many types of monomers give polymers the complete repertoire of intermolecular forces.

- *Synthetic* polymers are created in the laboratory.
- *Natural* polymers (or *biopolymers*) are created within organisms.

In this section, we examine the physical nature of synthetic polymers and explore the role of intermolecular forces in their properties and uses. In Chapter 15, we'll examine the types of monomers, the preparation of synthetic polymers, and the monomers, structures, and functions of some biopolymers.

Dimensions of a Polymer Chain Polymers differ from smaller molecules in terms of molar mass, chain length, shape, and size. We'll discuss these, using polyethylene, by far the most common synthetic polymer, as an example.

1. *Polymer mass*. The molar mass of a polymer chain ($\mathcal{M}_{polymer}$, in g/mol, often referred to as the *molecular weight*) depends on the molar mass of the repeat unit ($\mathcal{M}_{repeat}$) and the **degree of polymerization (*n*),** the number of repeat units in the chain:

$$\mathcal{M}_{polymer} = \mathcal{M}_{repeat} \times n$$

For example, the molar mass of the ethylene repeat unit ($—CH_2—CH_2—$) is 28 g/mol. If an individual polyethylene chain in a plastic grocery bag has a degree of polymerization of 7100, the molar mass of that chain is

$$\mathcal{M}_{polymer} = \mathcal{M}_{repeat} \times n = (28 \text{ g/mol})\,(7.1\times10^3) = 2.0\times10^5 \text{ g/mol}$$

Table 12.8 shows some other examples.

Table 12.8 Molar Masses of Some Common Polymers

Name	$\mathcal{M}_{polymer}$ (g/mol)	*n*	Uses
Acrylates	2×10^5	2×10^3	Rugs, carpets
Polyamide (nylons)	1.5×10^4	1.2×10^2	Tires, fishing line
Polycarbonate	1×10^5	4×10^2	Compact discs
Polyethylene	3×10^5	1×10^4	Grocery bags
Polyethylene (ultrahigh molecular weight)	5×10^6	2×10^5	Hip joints
Poly(ethylene terephthalate)	2×10^4	1×10^2	Soda bottles
Polystyrene	3×10^5	3×10^3	Packing, coffee cups
Poly(vinyl chloride)	1×10^5	1.5×10^3	Plumbing

However, even though the monomer repeat unit in any given chain has the same molar mass, the degree of polymerization often varies considerably from chain to chain. Thus, *a sample of a synthetic polymer has a distribution of chain lengths and molar masses*. Polymer chemists use various definitions of the *average* molar mass, and a common one is the *number-average molar mass,* $\mathcal{M}_n$:

$$\mathcal{M}_n = \frac{\text{total mass of all chains}}{\text{number of moles of chains}}$$

If the number-average molar mass of the polyethylene in grocery bags is, for example, 1.6×10^5 g/mol, the chains may vary in molar mass from about 7.0×10^4 to 3.0×10^5 g/mol.

2. *Polymer chain length*. The long axis of a polymer chain is called its *backbone*. The length of an *extended* backbone is simply the number of repeat units (degree of polymerization, n) times the length of each repeat unit (l_0). For instance, the length

of an ethylene repeat unit is about 250 pm, so the extended length of our grocery-bag polyethylene chain is

$$\text{Length of extended chain} = n \times l_0 = (7.1\times10^3)\,(2.5\times10^2\ \text{pm}) = 1.8\times10^6\ \text{pm}$$

Comparing this length with the thickness of the chain, which is about 40 pm, shows the threadlike nature of the extended chain (length about 50,000 times width).

3. *Coiled shape and size.* A polymer molecule, however, whether pure or in solution, doesn't exist as an extended chain. In principle, the shape of the molecule arises from free rotation around all the single bonds. Thus, as each repeat unit rotates randomly, the chain continuously changes direction, turning back on itself many times and eventually arriving at the **random coil** shape that most polymers adopt (Figure 12.46). In reality, rotation is not completely free because intermolecular forces between chain portions, between different chains, and/or between chain and solvent have significant effects on the actual shape of a polymer chain.

The size of the coiled chain is expressed by its **radius of gyration, R_g,** the average distance from the center of mass of the molecule to the outer edge of the coil (Figure 12.46). Even though R_g is reported as a single value for a given polymer, it represents an average value for many chains. The mathematical expression for the radius of gyration includes the length of each repeat unit and the degree of polymerization:*

$$R_g = \sqrt{\frac{nl_0^2}{6}}$$

As expected, the radius of gyration increases with the degree of polymerization, and thus with the molar mass as well. Light-scattering measurements correlate with these calculated results, so for many polymers the radius of gyration can be determined experimentally.

*The mathematical derivation of R_g is beyond the scope of this text, but it is analogous to the two-dimensional "walk of the drunken sailor." With each step, the sailor stumbles in random directions and, given enough time, ends up very close to the starting position. The radius of gyration quantifies how far the end of the polymer chain (the sailor) has gone from the origin.

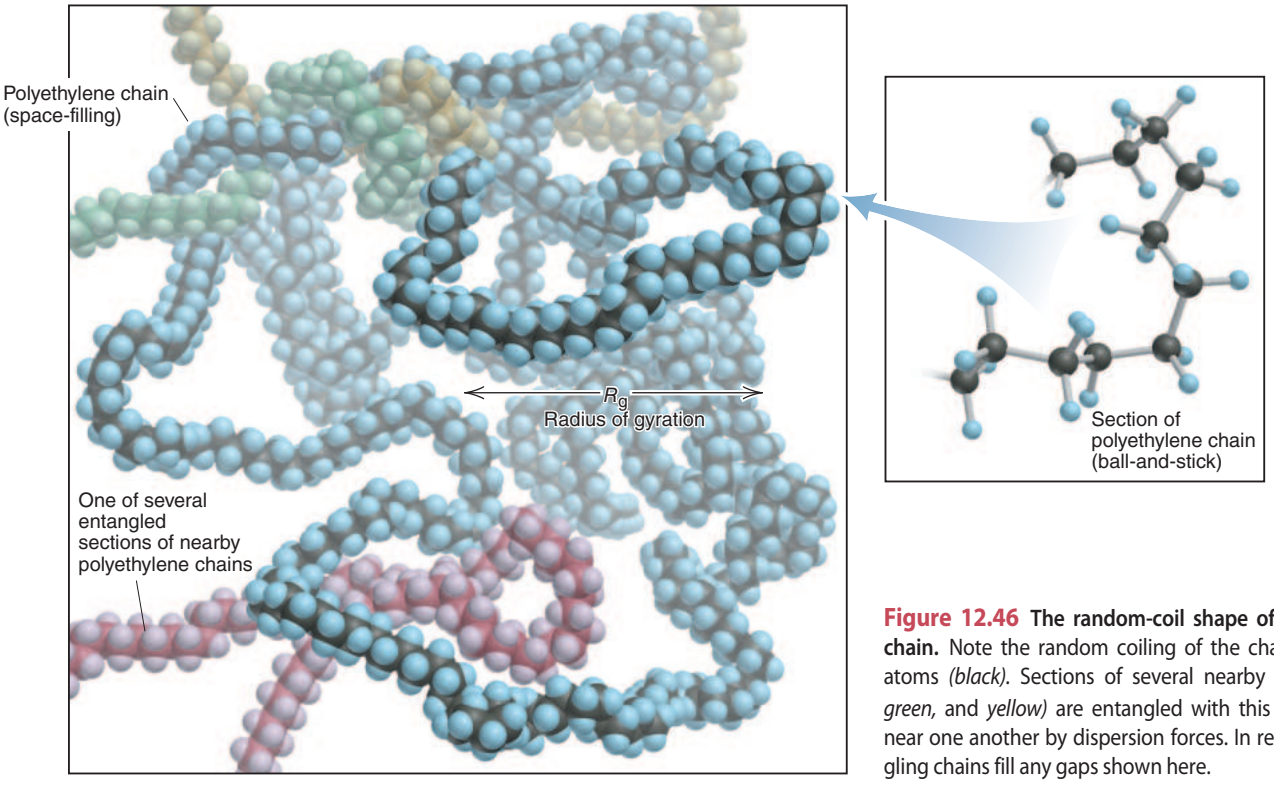

Figure 12.46 The random-coil shape of a polymer chain. Note the random coiling of the chain's carbon atoms *(black)*. Sections of several nearby chains *(red, green,* and *yellow)* are entangled with this chain, kept near one another by dispersion forces. In reality, entangling chains fill any gaps shown here.

For our grocery-bag polyethylene chain, we have

$$R_g = \sqrt{\frac{nl_0^2}{6}} = \sqrt{\frac{(7.1\times10^3)\,(2.5\times10^2\ \text{pm})^2}{6}} = 8.6\times10^3\ \text{pm}$$

Doubling the radius gives a diameter of 1.7×10^4 pm for the coiled chain, less than one-hundredth the length of the extended chain!

Polymer Crystallinity A sample of a given polymer is not just a disorderly jumble of chains. If the molecular structure allows neighboring chains to pack together and if the chemical groups lead to favorable dipole-dipole, H bonding, and/or dispersion forces, portions of the chains can align regularly and exhibit crystallinity.

However, the crystallinity of a polymer is very different from the crystal structures we discussed earlier. In those structures, the orderly array extends over many atoms or molecules, and the unit cell includes at least one atom or molecule. In contrast, the orderly regions of a polymer rarely involve even one whole molecule (Figure 12.47). At best, a polymer is *semicrystalline,* because parts of the molecule align with parts of neighboring molecules (or with other parts of the same chain), while most of the chain remains as a random coil.

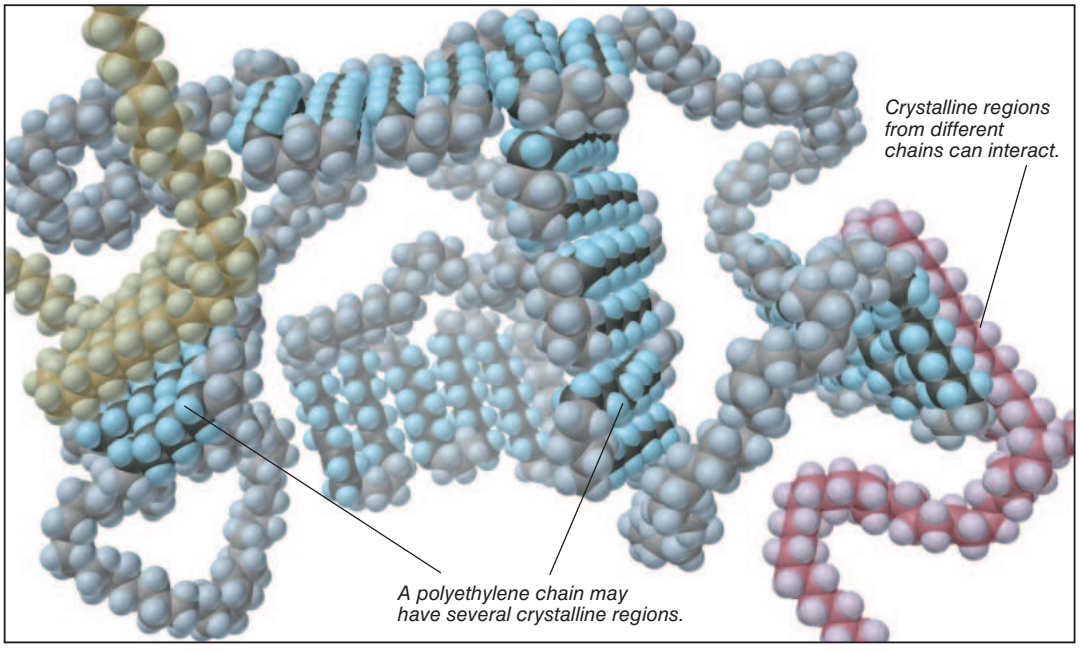

Figure 12.47 The semicrystallinity of a polymer chain. Several crystalline regions *(darker color)* have randomly coiled regions between them. Crystalline regions from nearby chains *(red* and *yellow)* align with those in the main chain.

Viscosity of Pure and Dissolved Polymers Some of the most important uses of polymers arise from their ability to change the viscosity of a solvent in which they are dissolved and to undergo temperature-dependent changes in their own viscosity.

1. *Dissolved polymers.* When an appreciable amount of polymer (approximately 5–15 mass %) dissolves, the viscosity of the solution is much higher than that of the pure solvent. In fact, polymers are added to increase the viscosity of many common materials, such as motor oil, paint, and salad dressing. As the random coil of a polymer moves through a solution, solvent molecules are attracted to it through intermolecular forces (Figure 12.48). Thus, as the solution flows, the polymer coil drags along solvent molecules that are interacting with other solvent molecules and other coils, and flow is reduced. Increasing the polymer concentration increases the viscosity because coils are more likely to become entangled.

Viscosity is a property of a particular polymer-solvent pair at a given temperature. The size (radius of gyration) of a random coil in solution increases with molar mass, and so does the viscosity. To improve polymer manufacture, chemists have developed

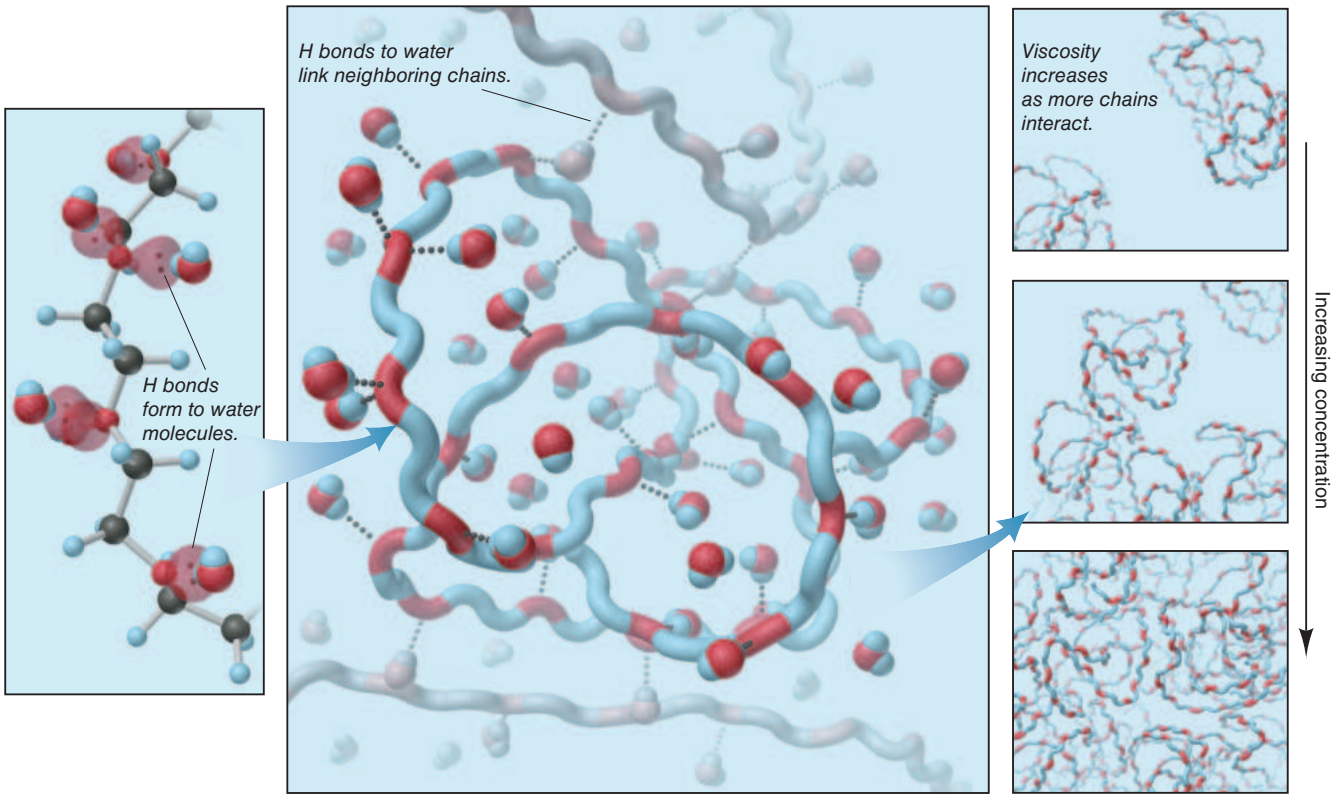

Figure 12.48 The viscosity of a polymer in aqueous solution. A section of a poly(ethylene oxide) chain *(left panel)* forms H bonds between the lone pairs of the chain's O atoms and the H atoms of water molecules. A polymer chain *(blue and red coiled rod, center panel)* forms many H bonds with water molecules that allow the chain to interact with other chains. As the concentration of polymer increases *(three right panels)*, the viscosity of the solution increases.

equations to predict the viscosity of polymers of different molar masses in a variety of solvents (see Problem 12.147).

2. *Pure polymers.* Intermolecular forces also play a major role in the flow of a pure polymer sample. At temperatures high enough to melt them, many polymers exist as viscous liquids, flowing more like honey than water. The forces between the chains, as well as the entangling of chains, hinder the flow. As the temperature decreases, the intermolecular attractions exert a greater effect, and the eventual result is a rigid solid. If the chains don't crystallize, the resulting material is called a *polymer glass.* The transition from a liquid to a glass occurs over a narrow temperature range (10–20°C) for a given polymer; the temperature at the midpoint of the range is called the *glass transition temperature,* T_g. Like window glass, many polymer glasses are transparent, such as polystyrene in drinking cups and polycarbonate in eyeglass lenses.

Plasticity of Polymers The flow-related properties of polymers give rise to their familiar **plastic** mechanical behavior. The word *plastic* refers to a material that, when deformed, retains its new shape; in contrast, when an *elastic* object is deformed, it returns to its original shape. Many polymers can be deformed (stretched, bent, twisted) when warm and retain their deformed shape when cooled. In this way, they are made into milk bottles, car parts, and countless other everyday objects.

Molecular Architecture of Polymers A polymer's architecture—its overall spatial layout and molecular structure—is crucial to its properties. In addition to linear chains, more complex architectures arise through branching and crosslinking:

1. **Branches** are smaller chains appended to a polymer backbone. As the number of branches increases, the chains cannot pack as well, so the degree of crystallinity

decreases and the polymer is less rigid. A small amount of branching occurs as a side reaction in the preparation of high-density polyethylene (HDPE). It is still largely linear and rigid enough for use in milk containers. In contrast, much more branching is intentionally induced to prepare low-density polyethylene (LDPE). The chains cannot pack well, so crystallinity is low. This polymer is used in flexible, transparent food storage bags.

Dendrimers are prepared from monomers with three or more attachment points, so each monomer forms branches. In essence, then, dendrimers have no backbone and consist only of branches. As a dendrimer grows, it has a constantly increasing number of branches and an incredibly large number of end groups at its outer edge. Chemists use dendrimers to bind one polymer to another to create films and fibers and to deliver drugs in medical applications.

Bicycle helmet containing a thermoset polymer.

2. **Crosslinks** can be thought of as branches that link one chain to another. The extent of crosslinking leads to remarkable differences in properties. A small degree of crosslinking often yields a *thermoplastic* polymer, one that still flows at high temperatures. But, as the extent of crosslinking increases, a thermoplastic polymer is transformed into a *thermoset* polymer, one that can no longer flow because it has become a single network. Below their glass transition temperatures, some thermosets are extremely rigid and strong, making them ideal as matrix materials in high-strength composites *(see photo).*

Above their glass transition temperatures, many thermosets become **elastomers,** polymers that can be stretched and immediately spring back to their initial shapes when released, like a trampoline or a rubber band. When you stretch a rubber band, individual polymer chains flow for only a short distance before the connectivity of the network returns them to their original positions. Table 12.9 is a list of some elastomers.

Table 12.9 Some Common Elastomers

Name	T_g (°C)	Uses
Poly(dimethyl siloxane)	−123	Breast implants
Polybutadiene	−106	Rubber bands
Polyisoprene	−65	Surgical gloves
Polychloroprene (neoprene)	−43	Footwear; medical tubing

Impact of Monomer Sequence Differences in monomer sequences influence polymer properties as well. A *homopolymer* consists of one type of monomer (A—A—A—A—A— · · ·), whereas a **copolymer** consists of two or more types. The simplest copolymer is called an *AB block copolymer* because a chain (block) of monomer A and a chain of monomer B are linked at one point:

$$\cdots\text{—A—A—A—A—A—B—B—B—B—B—}\cdots$$

If the intermolecular forces between the A and B portions of the chain are weaker than those between different regions within each portion, the A and B portions form their own random coils. This ability makes AB block copolymers ideal *adhesives* for joining two polymer surfaces covalently. An ABA block copolymer has A chains linked at each end of a B chain:

$$\cdots\text{—A—A—A—B—(B)}_n\text{—B—A—A—A—}\cdots$$

Some of these block copolymers act as *thermoplastic elastomers,* materials shaped at high temperature that become elastomers at room temperature; many are used in the modern footwear industry.

Silicone polymers are described in Chapter 14, and organic reactions that form polymer chains from monomers are examined in Chapter 15.

Nanotechnology: Designing Materials Atom by Atom

Nanotechnology is the science and engineering of nanoscale systems, whose sizes range from 1 to 100 nm. (Recall that 1 nm is 10^{-9} m—about one-billionth the width of your dorm-room desk or one-millionth the width of your pen tip. A nanometer is to a meter as a marble is to Earth!) Nanotechnology joins scientists from physics, materials science, chemistry, biology, environmental science, medicine, and many branches of engineering.

Nanoscale materials behave neither like atoms, which are smaller (about 1×10^1 nm), nor like crystals, which are larger (at least 1×10^5 nm). The different behavior is due to a surface area that is similar to their interior volume—for example, a 5-nm particle has about half of its atoms on its surface. Cut a piece of ordinary aluminum foil into pieces just large enough to see with a light microscope and they still behave like the original piece. But, if you could cut the original piece into 20–30-nm pieces, they would explode. Indeed, aluminum nanoparticles are used in fireworks and propellants.

As so often happens in science, a technological advance allowed this new field to blossom. Nanotechnologists can use the scanning tunneling microscope (see Tools of the Laboratory, pp. 486–487) and the similar scanning probe and atomic force microscopes to examine the chemical and physical properties of nanostructures and build them up, in many cases, atom by atom.

Two features of nanoscale engineering occur routinely in nature:

1. *Self-assembly* is the ability of smaller, simpler parts to organize themselves into a larger, more complex whole. On the molecular scale, self-assembly refers to atoms or small molecules aggregating through intermolecular forces. Oppositely charged regions on two such particles make contact to form a larger particle, which in turn aggregates with another to form a still larger one.
2. *Controlled orientation* is the positioning of two molecules near each other long enough for intermolecular forces to result in a change, often a bond breaking or forming. All enzymes function this way.

Because this field is changing many times faster than a textbook does, we can only provide a glimpse of a few exciting research directions in nanotechnology.

Nanoscale Optical Materials *Quantum dots* are nanoparticles of semiconducting materials, such as gallium arsenide (GaAs) or gallium selenide (GaSe), that are smaller than 10 nm. Rather than having a band of energy levels, the dot has discrete energy levels, much like a single atom. As in atoms, the energy levels can be studied with spectroscopy; unlike atoms, quantum dots can be modified chemically. When high-energy (short-wavelength) UV light irradiates a suspension of quantum dots, they become excited and emit radiation of lower energy (longer wavelength). Most importantly, the emitted wavelengths depend on the size of the dots: the larger the particles, the longer the wavelength emitted. Thus, the color of the emitted light can be "tuned" by varying the dimensions of the nanoparticles (Figure 12.49). One use for quantum dots is the imaging of specific cells. The dot is encapsulated in a coating and then bonded to a particular protein used by a target organ. The cells in the target incorporate the protein, along with its attached quantum dot, and the location of the protein is viewed spectroscopically.

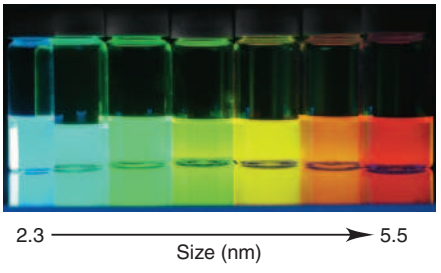

Figure 12.49 The colors of quantum dots. The smaller the dots, the shorter the emitted wavelengths.

Nanostructured Materials *Nanostructuring,* the construction of bulk materials from nanoscale building blocks, increases strength, ductility, plasticity, and many other properties. The resulting *nanocomposites* behave as liquid magnets, ductile cements, conducting elastomers, and many other unique materials.

One example mimics a familiar natural material. Bones are natural nanocomposites of hydroxyapatite (a type of calcium phosphate) and other minerals. Synthetic nanocrystalline hydroxyapatite has weight-bearing properties identical to bone and can be formed into a framework into which natural bone tissue can grow to heal a fracture. Another material, called a *ferrofluid,* consists of magnetic nanoparticles (usually

Figure 12.50 The magnetic behavior of a ferrofluid. Nanoparticles of magnetite (Fe_3O_4) dispersed in a viscous fluid are suspended between the poles of a magnet.

magnetite, Fe_3O_4) dispersed in a viscous fluid. When placed in a magnetic field, the particles align to conform to the shape of the field (Figure 12.50). Ferrofluids find uses in automobile shock absorbers, magnetic plastics, audio speakers, computer hard drives, high-vacuum valves, and many other devices.

High-Surface-Area Materials Carbon nanotubes have remarkable mechanical and electrical properties. But, a possible future application involves storing H_2 gas for hydrogen-powered vehicles. Currently, H_2 is stored in metal cylinders at high pressures (>70 atm). Porous solids, such as carbon nanotubes, can store the same amount of gas at much lower pressures because they have surface areas of 4500 m^2/g—about four football fields per gram of material! Thus, a medium-sized container of nanotubes could store a large amount of H_2 fuel under conditions safe enough for a family car.

Other high-surface-area materials being developed are porous membranes for water purification or batteries and multilayer films that incorporate photosynthetic molecules for high-efficiency solar cells. A very exciting development is the molecule-specific biosensor, which can detect as little as 10^{-14} mol of DNA using color changes in gold nanoparticles. Such biosensors could circulate freely in the bloodstream to measure levels of specific disease-related molecules, deliver drugs to individual cells, and even alter individual genes.

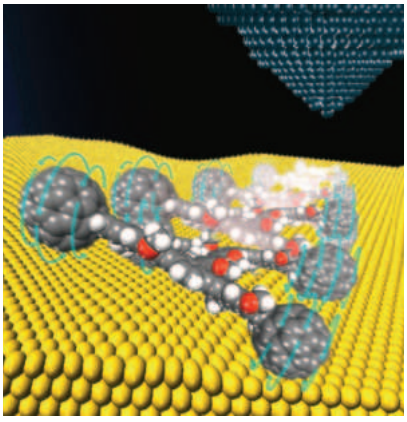

Figure 12.51 Driving a nanocar.

Nanomachines In nature, the virus is a marvel of nanoscale engineering, designed for delivering genetic material to infect a host cell. For example, the T4 virus latches onto a bacterial cell with its tail fibers, bores through the bacterial membrane with its end plate, and then injects the payload of DNA, packaged in its head, into the bacterium. These complex functions are performed by a biological "machine" measuring 60 × 200 nm. Researchers are exploring ways for viruses to deliver medicinal agents to specific cells. In other feats of nanoscale engineering, researchers have created nanovalves, nanopropellers, and even a nanocar, complete with a chassis, axles, and buckyball wheels, that is only 4 nm wide and is "driven" on a gold surface under the direction of an atomic force microscope (Figure 12.51).

Summary of Section 12.7

- Doping increases the conductivity of semiconductors and is essential to modern electronic materials. Doping silicon with Group 5A(15) atoms introduces negative sites (n-type semiconductor) by adding valence electrons to the conduction band, whereas doping with Group 3A(13) atoms adds positive holes (p-type semiconductor) by emptying some orbitals in the valence band. Placing these two types of semiconductors in contact with one another forms a p-n junction. Sandwiching a p-type portion between two n-type portions forms a transistor.
- Liquid crystal phases flow like liquids but have molecules ordered like crystalline solids. Typically, the molecules have rodlike shapes, and their intermolecular forces keep them aligned. Thermotropic phases are prepared by heating the solid; lyotropic phases form when the solvent concentration is varied. The nematic, cholesteric, and smectic phases of liquid crystals differ in their molecular order. Liquid crystal applications depend on controlling the orientation of the molecules.
- Ceramics are very resistant to heat and chemicals. Most are network covalent solids formed at high temperature from simple reactants. They add lightweight strength to other materials.
- Polymers are extremely large molecules that adopt the shape of a random coil, as a result of intermolecular forces. A polymer sample has an average molar mass because it consists of chains with a range of lengths. The high viscosity of a polymer arises from attractions between chains or, in the case of a dissolved polymer, between chains and solvent. By varying the degrees of branching, crosslinking, and ordering (crystallinity), chemists tailor polymers with specific properties.
- Nanoscale materials can be made through construction processes involving self-assembly and controlled orientation of molecules.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How the interplay between kinetic and potential energy underlies the properties of the three states of matter and their phase changes (§12.1)
2. The processes involved, both within a phase and during a phase change, when heat is added or removed from a pure substance (§12.2)
3. The meaning of vapor pressure and how phase changes are dynamic equilibrium processes (§12.2)
4. How temperature and intermolecular forces influence vapor pressure (§12.2)
5. The relation between vapor pressure and boiling point (§12.2)
6. How a phase diagram shows the phases of a substance at differing conditions of pressure and temperature (§12.2)
7. The distinction between bonding and intermolecular forces on the basis of Coulomb's law and the meaning of the van der Waals radius of an atom (§12.3)
8. The types and relative strengths of intermolecular forces acting in a substance (dipole-dipole, H bonding, dispersion), the impact of H bonding on physical properties, and the meaning of polarizability (§12.3)
9. The meanings of surface tension, capillarity, and viscosity and how intermolecular forces influence their magnitudes (§12.4)
10. How the important macroscopic properties of water arise from atomic and molecular properties (§12.5)
11. The meaning of *crystal lattice* and the characteristics of the three types of cubic unit cells (§12.6)
12. How packing of spheres gives rise to the hexagonal and cubic unit cells (§12.6)
13. Types of crystalline solids and how their intermolecular forces give rise to their properties (§12.6)
14. How band theory accounts for the properties of metals and the relative conductivities of metals, nonmetals, and metalloids (§12.6)
15. The structures, properties, and functions of modern materials (doped semiconductors, liquid crystals, ceramics, polymers, and nanostructures) (§12.7)

Master These Skills

1. Calculating the overall enthalpy change when heat is gained or lost by a pure substance (§12.2 and SP 12.1)
2. Using the Clausius-Clapeyron equation to examine the relationship between vapor pressure and temperature (SP 12.2)
3. Using a phase diagram to predict the physical state and/or phase change of a substance (§12.2 and SP 12.3)
4. Determining whether a substance can form H bonds and drawing the H-bonded structures (SP 12.4)
5. Predicting the types and relative strength of the bonding and intermolecular forces acting within a substance from its structure (SP 12.5)
6. Finding the number of particles in a unit cell and the coordination number (§12.6 and SP 12.6)
7. Calculating atomic radius or unit-cell edge length from the crystal structure of an element (SPs 12.7, 12.8)

Key Equations and Relationships

Page numbers appear in parentheses.

12.1 Using the vapor pressure at one temperature to find the vapor pressure at another temperature (two-point form of the Clausius-Clapeyron equation) (464):

$$\ln\frac{P_2}{P_1}=\frac{-\Delta H_{vap}}{R}\left(\frac{1}{T_2}-\frac{1}{T_1}\right)$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

12.1A The scenes represent solid water at −7.00°C melting to liquid water at 16.0°C, so heat is absorbed by the system (q is positive). There are three stages:

Stage 1, $H_2O(s)$ [−7.00°C] ⟶ $H_2O(s)$ [0.00°C]:

$q = n \times C_{water(s)} \times \Delta T = (2.25\text{ mol})\,(37.6\text{ J/mol·°C})\,(7.00\text{°C})$
$= 592\text{ J} = 0.592\text{ kJ}$

Stage 2, $H_2O(s)$ [0.00°C] ⟶ $H_2O(l)$ [0.00°C]:

$q = n(\Delta H^\circ_{fus}) = (2.25\text{ mol})\,(6.02\text{ kJ/mol}) = 13.5\text{ kJ}$

Stage 3, $H_2O(l)$ [0.00°C] ⟶ $H_2O(l)$ [16.0°C]:

$q = n \times C_{water(l)} \times \Delta T = (2.25\text{ mol})\,(75.4\text{ J/mol·°C})\,(16.0\text{°C})$
$= 2714\text{ J} = 2.71\text{ kJ}$

Total heat (kJ) = 0.592 kJ + 13.5 kJ + 2.71 kJ = 16.8 kJ

12.1B The scenes represent gaseous bromine at 73.5°C condensing to liquid bromine at 23.8°C, so heat is released by the system (q is negative). There are three stages:

Stage 1, $Br_2(g)$ [73.5°C] ⟶ $Br_2(g)$ [59.5°C]:

$$q = n \times C_{Br_2(g)} \times \Delta T$$
$$= \left(\frac{47.94\text{ g Br}_2}{159.8\text{ g Br}_2\text{/mol}}\right)(36.0\text{ J/mol·°C})(-14.0\text{°C})$$
$$= -151\text{ J} = -0.151\text{ kJ}$$

Stage 2, $Br_2(g)$ [59.5°C] ⟶ $Br_2(l)$ [59.5°C]:

$q = n(-\Delta H_{vap}) = (0.3000\text{ mol})\,(-29.6\text{ kJ/mol}) = -8.88\text{ kJ}$

Stage 3, $Br_2(l)$ [59.5°C] ⟶ $Br_2(l)$ [23.8°C]:

$q = n \times C_{Br_2(l)} \times \Delta T = (0.3000\text{ mol})(75.7\text{ J/mol·°C})(-35.7\text{°C})$
$= -811\text{ J} = -0.811\text{ kJ}$

Total heat (kJ) = −0.151 kJ + (−8.88 kJ) + (−0.811 kJ)
= −9.84 kJ

12.2A
$$\ln\frac{P_2}{P_1}=\left(\frac{-40.7\times10^3\text{ J/mol}}{8.314\text{ J/mol·K}}\right)\times\left(\frac{1}{273.15+85.5\text{ K}}-\frac{1}{273.15+34.1\text{ K}}\right)$$
$$=(-4.90\times10^3\text{ K})\,(-4.6\times10^{-4}\text{ K}^{-1})=2.28$$

$\frac{P_2}{P_1} = 9.8$; thus, $P_2 = 40.1\text{ torr} \times 9.8 = 3.9\times10^2\text{ torr}$

12.2B
$$\ln\left(\frac{24.50\text{ kPa}}{10.00\text{ kPa}}\right)=\left(\frac{-30.99\times10^3\text{ J/mol}}{8.314\text{ J/mol·K}}\right)\times\left(\frac{1}{273.15\text{ K}+20.2}-\frac{1}{T_1}\right)$$

$$0.8961=(-3.727\times10^3\text{ K})\left(\frac{1}{293.4\text{ K}}-\frac{1}{T_1}\right)-2.404\times10^{-4}\text{ K}^{-1}=3.408\times10^{-3}\text{ K}^{-1}-\frac{1}{T_1}$$

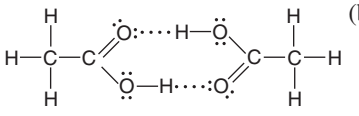
$$\frac{1}{T_1}=3.648\times10^{-3}\text{ K}^{-1}$$

$$T_1=274.1\text{ K}=0.95\text{°C}$$

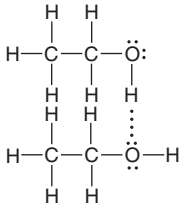
12.3A At the starting conditions (3×10^2 bar and 2000 K; point *c*), the carbon sample is in the form of graphite. As the sample is heated at constant pressure, it melts at around 4500 K, and then vaporizes at around 5000 K.

12.3B At the starting conditions (4600 K and 10^4 bar; point *d*), the carbon sample is in the form of graphite. As the sample is compressed at constant temperature, it melts at around 4×10^4 bar and then solidifies to diamond at around 2×10^5 bar.

12.4A (a)

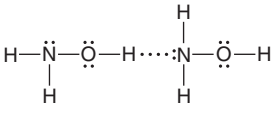


(b)

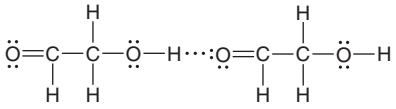


(c) No H bonding

12.4B (a) No H bonding (b)



(c)



12.5A (a) Dipole-dipole, dispersion; CH_3Br
(b) H bonding (in $CH_3CH_2CH_2OH$), dipole-dipole and dispersion in both; $CH_3CH_2CH_2OH$
(c) Dispersion; C_3H_8

12.5B (a) Dispersion and dipole-dipole in both, H bonding (in CH_3CH_2OH); CH_3CHO
(b) Dispersion, dipole-dipole; $CHCl_3$
(c) Dispersion, dipole-dipole, H bonding (in $H_2N{-}\overset{\overset{O}{\|}}{C}CH_2CH_3$); $(CH_3)_2N{-}\overset{\overset{O}{\|}}{C}H$

12.6A (a) PbS: Pb^{2+} ions/unit cell = S^{2-} ions/unit cell = $(8\times\frac{1}{8})+(6\times\frac{1}{2}) = 4\ Pb^{2+}$ and $4\ S^{2-}$ ions; coordination number of each ion is 6.
(b) W: Atoms/unit cell = $(8\times\frac{1}{8})+1=2$; coordination number is 8.
(c) Al: Atoms/unit cell = $(8\times\frac{1}{8})+(6\times\frac{1}{2})=4$; coordination number is 12.

12.6B (a) K: Atoms/unit cell = $(8\times\frac{1}{8})+1=2$; coordination number is 8.
(b) Pt: Atoms/unit cell = $(8\times\frac{1}{8})+(6\times\frac{1}{2})=4$; coordination number is 12.
(c) CsCl: Cs^+ ions/unit cell = $(8\times\frac{1}{8})=1$; Cl^- ions/unit cell = 1; coordination number of each ion is 8.

12.7A V of Co atom $= \frac{4}{3}\pi r^3 = \frac{4}{3}(3.14)\,(125\text{ pm})^3$

$$= \frac{8.18\times10^6\text{ pm}^3}{\text{atom}}$$

V of 1 mol of Co atoms (cm^3)

$$= \frac{8.18\times10^6\text{ pm}^3}{\text{atom}} \times \frac{6.022\times10^{23}\text{ atoms}}{\text{mol atoms}} \times \frac{1\text{ cm}^3}{10^{30}\text{ pm}^3}$$

$$= 4.93\text{ cm}^3/\text{mol atoms}$$

$$V \text{ of 1 mol of Co metal (cm}^3) = \frac{4.93\text{ cm}^3/\text{mol atoms}}{0.74}$$

$$= 6.66\text{ cm}^3/\text{mol Co metal}$$

$$d \text{ of Co metal} = \frac{58.93\text{ g}}{\text{mol}} \times \frac{1\text{ mol}}{6.66\text{ cm}^3} = 8.85\text{ g/cm}^3$$

12.7B Avogadro's no. $= \frac{1\text{ cm}^3}{7.874\text{ g Fe}} \times \frac{55.85\text{ g Fe}}{1\text{ mol Fe}} \times 0.68$

$$\times \frac{1\text{ Fe atom}}{8.38\times10^{-24}\text{ cm}^3}$$

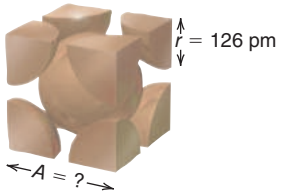
$$= 5.8\times10^{23}\text{ Fe atoms/mol Fe}$$

12.8A From Figure 12.29,

$$A\text{ (nm)} = \frac{4r}{\sqrt{3}} = \frac{4(126\text{ pm})}{\sqrt{3}}$$

$$= 291\text{ pm} \times \frac{1\text{ nm}}{1000\text{ pm}}$$

$$= 0.291\text{ nm}$$



12.8B $A = \sqrt{8}r$

$r = A/\sqrt{8} = 0.405\text{ nm}/\sqrt{8} = 0.143\text{ nm} = 143\text{ pm}$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

An Overview of Physical States and Phase Changes

Concept Review Questions

12.1 How does the energy of attraction between particles compare with their energy of motion in a gas and in a solid? As part of your answer, identify two macroscopic properties that differ between a gas and a solid.

12.2 (a) Why are gases more easily compressed than liquids?
(b) Why do liquids have a greater ability to flow than solids?

12.3 What type of forces, intramolecular or intermolecular:
(a) Prevent ice cubes from adopting the shape of their container?
(b) Are overcome when ice melts?
(c) Are overcome when liquid water is vaporized?
(d) Are overcome when gaseous water is converted to hydrogen gas and oxygen gas?

12.4 (a) Why is the heat of fusion (ΔH_{fus}) of a substance smaller than its heat of vaporization (ΔH_{vap})?
(b) Why is the heat of sublimation (ΔH_{subl}) of a substance greater than its ΔH_{vap}?
(c) At a given temperature and pressure, how does the magnitude of the heat of vaporization of a substance compare with that of its heat of condensation?

Skill-Building Exercises (grouped in similar pairs)

12.5 Which forces are intramolecular and which intermolecular?
(a) Those preventing oil from evaporating at room temperature
(b) Those preventing butter from melting in a refrigerator
(c) Those allowing silver to tarnish
(d) Those preventing O_2 in air from forming O atoms

12.6 Which forces are intramolecular and which intermolecular?
(a) Those allowing fog to form on a cool, humid evening
(b) Those allowing water to form when H_2 is sparked
(c) Those allowing liquid benzene to crystallize when cooled
(d) Those responsible for the low boiling point of hexane

12.7 Name the phase change in each of these events: (a) Dew appears on a lawn in the morning. (b) Icicles change into liquid water. (c) Wet clothes dry on a summer day.

12.8 Name the phase change in each of these events: (a) A diamond film forms on a surface from gaseous carbon atoms in a vacuum. (b) Mothballs in a bureau drawer disappear over time. (c) Molten iron from a blast furnace is cast into ingots ("pigs").

Problems in Context

12.9 Liquid propane, a widely used fuel, is produced by compressing gaseous propane. During the process, approximately 15 kJ of energy is released for each mole of gas liquefied. Where does this energy come from?

12.10 Many heat-sensitive and oxygen-sensitive solids, such as camphor, are purified by warming under vacuum. The solid vaporizes directly, and the vapor crystallizes on a cool surface. What phase changes are involved in this method?

Quantitative Aspects of Phase Changes

(Sample Problems 12.1–12.3)

Concept Review Questions

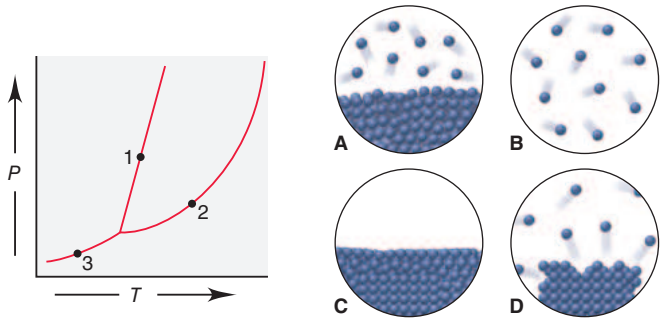
12.11 Describe the changes (if any) in potential energy and in kinetic energy among the molecules when gaseous PCl_3 condenses to a liquid at a fixed temperature.

12.12 When benzene is at its melting point, two processes occur simultaneously and balance each other. Describe these processes on the macroscopic and molecular levels.

12.13 Liquid hexane (bp = 69°C) is placed in a closed container at room temperature. At first, the pressure of the vapor phase increases, but after a short time, it stops changing. Why?

12.14 Explain the effect of strong intermolecular forces on each of these parameters: (a) critical temperature; (b) boiling point; (c) vapor pressure; (d) heat of vaporization.

12.15 Match each numbered point in the phase diagram for compound Q with the correct molecular scene below:



12.16 A liquid is in equilibrium with its vapor in a closed vessel at a fixed temperature. The vessel is connected by a stopcock to an evacuated vessel. When the stopcock is opened, will the final pressure of the vapor be different from the initial value if (a) some liquid remains; (b) all the liquid is first removed? Explain.

12.17 The phase diagram for substance A has a solid-liquid line with a positive slope, and that for substance B has a solid-liquid line with a negative slope. What macroscopic property can distinguish A from B?

12.18 Why does water vapor at 100°C cause a more severe burn than liquid water at 100°C?

Skill-Building Exercises (grouped in similar pairs)

12.19 From the data below, calculate the total heat (in J) needed to convert 22.00 g of ice at −6.00°C to liquid water at 0.500°C:

mp at 1 atm:	0.0°C	ΔH°_{fus}:	6.02 kJ/mol
c_{liquid}:	4.21 J/g·°C	c_{solid}:	2.09 J/g·°C

12.20 From the data below, calculate the total heat (in J) needed to convert 0.333 mol of gaseous ethanol at 300°C and 1 atm to liquid ethanol at 25.0°C and 1 atm:

bp at 1 atm:	78.5°C	ΔH°_{vap}:	40.5 kJ/mol
c_{gas}:	1.43 J/g·°C	c_{liquid}:	2.45 J/g·°C

12.21 A liquid has a ΔH°_{vap} of 35.5 kJ/mol and a boiling point of 122°C at 1.00 atm. What is its vapor pressure at 113°C?

12.22 Diethyl ether has a ΔH°_{vap} of 29.1 kJ/mol and a vapor pressure of 0.703 atm at 25.0°C. What is its vapor pressure at 95.0°C?

12.23 What is the ΔH°_{vap} of a liquid that has a vapor pressure of 621 torr at 85.2°C and a boiling point of 95.6°C at 1 atm?

12.24 Methane (CH_4) has a boiling point of −164°C at 1 atm and a vapor pressure of 42.8 atm at −100°C. What is the heat of vaporization of CH_4?

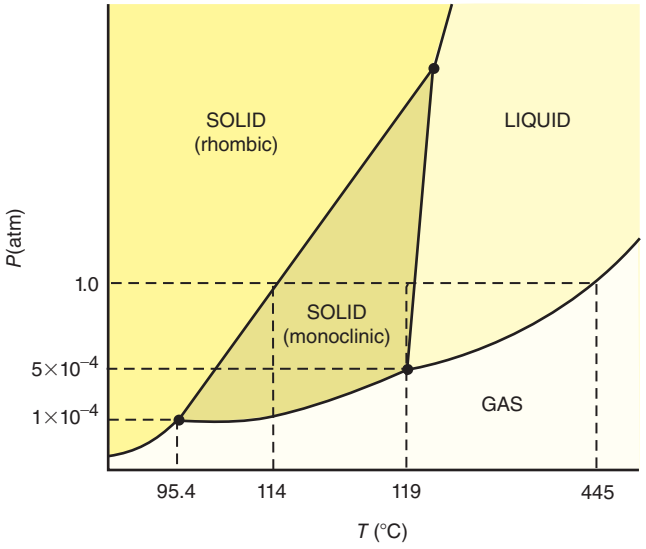
12.25 Use these data to draw a qualitative phase diagram for ethylene (C_2H_4). Is $C_2H_4(s)$ more or less dense than $C_2H_4(l)$?

bp at 1 atm:	−103.7°C
mp at 1 atm:	−169.16°C
Critical point:	9.9°C and 50.5 atm
Triple point:	−169.17°C and 1.20×10^{-3} atm

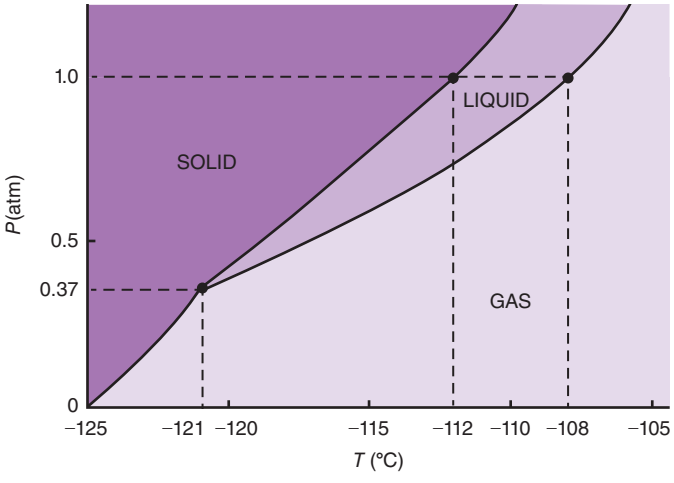
12.26 Use these data to draw a qualitative phase diagram for H_2. Does H_2 sublime at 0.05 atm? Explain.

mp at 1 atm:	13.96 K
bp at 1 atm:	20.39 K
Triple point:	13.95 K and 0.07 atm
Critical point:	33.2 K and 13.0 atm
Vapor pressure of solid at 10 K:	0.001 atm

12.27 The phase diagram for sulfur is shown below.
(a) Give a set of conditions under which it is possible to sublime the rhombic form of solid sulfur.
(b) Describe the phase changes that a sample of sulfur undergoes at 1 atm when it is heated from 90°C to 450°C.



12.28 The phase diagram for xenon is shown below.
(a) What phase is xenon in at room temperature and pressure?
(b) Describe the phase changes that a sample of xenon undergoes at −115°C as it is compressed from 0.5 atm to 25 atm. (The critical pressure of xenon is 58 atm.)



Problems in Context

12.29 Sulfur dioxide is produced in enormous amounts for sulfuric acid production. It melts at −73°C and boils at −10.°C. Its ΔH°_{fus} is 8.619 kJ/mol and its ΔH°_{vap} is 25.73 kJ/mol. The specific heat capacities of the liquid and gas are 0.995 J/g·K and 0.622 J/g·K, respectively. How much heat is required to convert 2.500 kg of solid SO_2 at the melting point to a gas at 60.°C?

12.30 Butane is a common fuel used in cigarette lighters and camping stoves. Normally supplied in metal containers under pressure, the fuel exists as a mixture of liquid and gas, so high temperatures may cause the container to explode. At 25.0°C, the vapor pressure of butane is 2.3 atm. What is the pressure in the container at 135°C (ΔH°_{vap} = 24.3 kJ/mol)?

12.31 Use Figure 12.10, p. 466, to answer the following:
(a) Carbon dioxide is sold in steel cylinders under pressures of approximately 20 atm. Is there liquid CO_2 in the cylinder at room temperature (~20°C)? At 40°C? At −40°C? At −120°C?
(b) Carbon dioxide is also sold as solid chunks, called *dry ice,* in insulated containers. If the chunks are warmed by leaving them in an open container at room temperature, will they melt?
(c) If a container is nearly filled with dry ice and then sealed and warmed to room temperature, will the dry ice melt?
(d) If dry ice is compressed at a temperature below its triple point, will it melt?

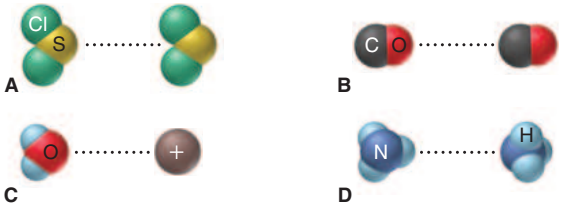
Types of Intermolecular Forces

(Sample Problems 12.4 and 12.5)

Concept Review Questions

12.32 Why are covalent bonds typically much stronger than intermolecular forces?

12.33 (a) Name the type of force depicted in each scene below.
(b) Rank the forces in order of increasing strength.



12.34 Oxygen and selenium are members of Group 6A(16). Water forms H bonds, but H_2Se does not. Explain.

12.35 In solid I_2, is the distance between the two I nuclei of one I_2 molecule longer or shorter than the distance between two I nuclei of adjacent I_2 molecules? Explain.

12.36 Polar molecules exhibit dipole-dipole forces. Do they also exhibit dispersion forces? Explain.

12.37 Distinguish between *polarizability* and *polarity*. How does each influence intermolecular forces?

12.38 How can one nonpolar molecule induce a dipole in a nearby nonpolar molecule?

Skill-Building Exercises (grouped in similar pairs)

12.39 What is the strongest interparticle force in each substance?
(a) CH_3OH (b) CCl_4 (c) Cl_2

12.40 What is the strongest interparticle force in each substance?
(a) H_3PO_4 (b) SO_2 (c) $MgCl_2$

12.41 What is the strongest interparticle force in each substance?
(a) CH_3Cl (b) CH_3CH_3 (c) NH_3

12.42 What is the strongest interparticle force in each substance?
(a) Kr (b) BrF (c) H_2SO_4

12.43 Which member of each pair of compounds forms intermolecular H bonds? Draw the H-bonded structures in each case:
(a) $CH_3\underset{\displaystyle OH}{\underset{|}{C}}HCH_3$ or CH_3SCH_3 (b) HF or HBr

12.44 Which member of each pair of compounds forms intermolecular H bonds? Draw the H-bonded structures in each case:
(a) $(CH_3)_2NH$ or $(CH_3)_3N$ (b) $HOCH_2CH_2OH$ or FCH_2CH_2F

12.45 Which forces oppose vaporization of each substance?
(a) Hexane (b) Water (c) $SiCl_4$

12.46 Which forces oppose vaporization of each substance?
(a) Br_2 (b) SbH_3 (c) CH_3NH_2

12.47 Which has the greater polarizability? Explain.
(a) Br^- or I^- (b) $CH_2{=}CH_2$ or $CH_3{-}CH_3$ (c) H_2O or H_2Se

12.48 Which has the greater polarizability? Explain.
(a) Ca^{2+} or Ca (b) CH_3CH_3 or $CH_3CH_2CH_3$ (c) CCl_4 or CF_4

12.49 Which member in each pair of liquids has the *higher* vapor pressure at a given temperature? Explain.
(a) C_2H_6 or C_4H_{10} (b) CH_3CH_2OH or CH_3CH_2F
(c) NH_3 or PH_3

12.50 Which member in each pair of liquids has the *lower* vapor pressure at a given temperature? Explain.
(a) $HOCH_2CH_2OH$ or $CH_3CH_2CH_2OH$
(b) CH_3COOH or $(CH_3)_2C{=}O$ (c) HF or HCl

12.51 Which substance has the *lower* boiling point? Explain.
(a) LiCl or HCl (b) NH_3 or PH_3 (c) Xe or I_2

12.52 Which substance has the *higher* boiling point? Explain.
(a) CH_3CH_2OH or $CH_3CH_2CH_3$ (b) NO or N_2
(c) H_2S or H_2Te

12.53 Which substance has the *lower* boiling point? Explain.
(a) $CH_3CH_2CH_2CH_3$ or $\begin{matrix}CH_2{-}CH_2\\ |\quad\ \ |\\ CH_2{-}CH_2\end{matrix}$ (b) NaBr or PBr_3
(c) H_2O or HBr

12.54 Which substance has the *higher* boiling point? Explain.
(a) CH_3OH or CH_3CH_3 (b) FNO or ClNO
(c) $\begin{matrix}F\\ \diagdown\\ H\end{matrix}C{=}C\begin{matrix}\diagup F\\ \diagdown H\end{matrix}$ or $\begin{matrix}H\\ \diagdown\\ F\end{matrix}C{=}C\begin{matrix}\diagup F\\ \diagdown H\end{matrix}$

Problems in Context

12.55 For pairs of molecules in the gas phase, average H-bond dissociation energies are 17 kJ/mol for NH_3, 22 kJ/mol for H_2O, and 29 kJ/mol for HF. Explain this increase in H-bond strength.

12.56 Dispersion forces are the only intermolecular forces present in motor oil, yet it has a high boiling point. Explain.

12.57 Why does the antifreeze ingredient ethylene glycol ($HOCH_2CH_2OH$; $\mathcal{M}$ = 62.07 g/mol) have a boiling point of 197.6°C, whereas propanol ($CH_3CH_2CH_2OH$; $\mathcal{M}$ = 60.09 g/mol), a compound with a similar molar mass, has a boiling point of only 97.4°C?

Properties of the Liquid State

Concept Review Questions

12.58 Before the phenomenon of surface tension was understood, physicists described the surface of water as being covered with a "skin." What causes this skinlike phenomenon?

12.59 Small, equal-sized drops of oil, water, and mercury lie on a waxed floor. How does each liquid behave? Explain.

12.60 Why does an aqueous solution of ethanol (CH_3CH_2OH) have a lower surface tension than water?

12.61 Why are units of energy per area (J/m^2) used for surface tension values?

12.62 Does the *strength* of the intermolecular forces in a liquid change as the liquid is heated? Explain. Why does liquid viscosity decrease with rising temperature?

Skill-Building Exercises (grouped in similar pairs)

12.63 Rank the following in order of *increasing* surface tension at a given temperature, and explain your ranking:
(a) $CH_3CH_2CH_2OH$ (b) $HOCH_2CH(OH)CH_2OH$
(c) $HOCH_2CH_2OH$

12.64 Rank the following in order of *decreasing* surface tension at a given temperature, and explain your ranking:
(a) CH_3OH (b) CH_3CH_3 (c) $H_2C{=}O$

12.65 Rank the compounds in Problem 12.63 in order of *decreasing* viscosity at a given temperature; explain your ranking.

12.66 Rank the compounds in Problem 12.64 in order of *increasing* viscosity at a given temperature; explain your ranking.

Problems in Context

12.67 Soil vapor extraction (SVE) is used to remove volatile organic pollutants, such as chlorinated solvents, from soil at hazardous waste sites. Vent wells are drilled, and a vacuum pump is applied to the subsurface. (a) How does this remove pollutants? (b) Why does heating combined with SVE speed the process?

12.68 Use Figure 12.2, p. 457 to answer the following: (a) Does it take more heat to melt 12.0 g of CH_4 or 12.0 g of Hg? (b) Does it take more heat to vaporize 12.0 g of CH_4 or 12.0 g of Hg? (c) What is the principal intermolecular force in each sample?

12.69 Pentanol ($C_5H_{11}OH$; $\mathcal{M}$ = 88.15 g/mol) has nearly the same molar mass as hexane (C_6H_{14}; $\mathcal{M}$ = 86.17 g/mol) but is more than 12 times as viscous at 20°C. Explain.

The Uniqueness of Water

Concept Review Questions

12.70 For what types of substances is water a good solvent? For what types is it a poor solvent? Explain.

12.71 A water molecule can engage in as many as four H bonds. Explain.

12.72 Warm-blooded animals have a narrow range of body temperature because their bodies have a high water content. Explain.

12.73 What property of water keeps plant debris on the surface of lakes and ponds? What is the ecological significance of this?

12.74 A drooping plant can be made upright by watering the ground around it. Explain.

12.75 Describe the molecular basis of the property of water responsible for the presence of ice on the surface of a frozen lake.

12.76 Describe in molecular terms what occurs when ice melts.

The Solid State: Structure, Properties, and Bonding
(Sample Problems 12.6–12.8)

Concept Review Questions

12.77 What is the difference between an amorphous solid and a crystalline solid on the macroscopic and molecular levels? Give an example of each.

12.78 How are a solid's unit cell and crystal structure related?

12.79 For structures consisting of identical atoms, how many atoms are contained in the simple, body-centered, and face-centered cubic unit cells? Explain how you obtained the values.

12.80 An element has a crystal structure in which the width of the cubic unit cell equals the diameter of an atom. What type of unit cell does it have?

12.81 What specific difference in the positioning of spheres gives a crystal structure based on the face-centered cubic unit cell less empty space than one based on the body-centered cubic unit cell?

12.82 Both solid Kr and solid Cu consist of individual atoms. Why do their physical properties differ so much?

12.83 What is the energy gap in band theory? Compare its size in superconductors, conductors, semiconductors, and insulators.

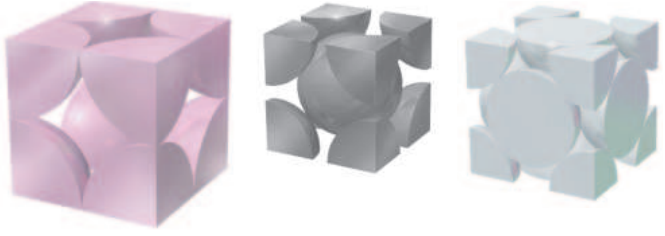
12.84 Predict the effect (if any) of an increase in temperature on the electrical conductivity of (a) a conductor; (b) a semiconductor; (c) an insulator.

12.85 Besides the type of unit cell, what information is needed to find the density of a solid consisting of identical atoms?

Skill-Building Exercises (grouped in similar pairs)

12.86 What type of crystal lattice does each metal form? (The number of atoms per unit cell is given in parentheses.)
(a) Ni (4) (b) Cr (2) (c) Ca (4)

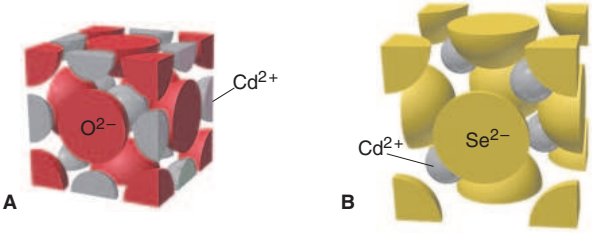
12.87 What is the number of atoms per unit cell for each metal?
(a) Polonium, Po (b) Manganese, Mn (c) Silver, Ag



12.88 Calcium crystallizes through cubic closest packing. If the atomic radius of calcium is 197 pm, find the density of the solid.

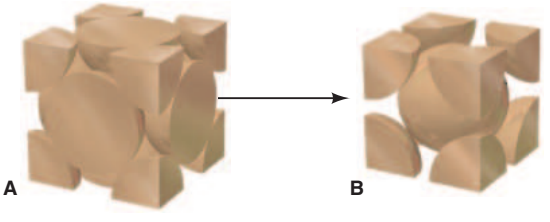
12.89 Chromium adopts the body-centered cubic unit cell in its crystal structure. If the density of chromium is 7.14 g/cm^3, find its atomic radius.

12.90 When cadmium oxide reacts to form cadmium selenide, a change in unit cell occurs, as depicted below:



(a) What is the change in unit cell?
(b) Does the coordination number of cadmium change? Explain.

12.91 As molten iron cools to 1674 K, it adopts one type of cubic unit cell; then, as the temperature drops below 1181 K, it changes to another, as depicted below:



(a) What is the change in unit cell?
(b) Which crystal structure has the greater packing efficiency?

12.92 Potassium adopts the body-centered cubic unit cell in its crystal structure. If the atomic radius of potassium is 227 pm, find the edge length of the unit cell.

12.93 Lead adopts the face-centered cubic unit cell in its crystal structure. If the edge length of the unit cell is 495 pm, find the atomic radius of lead.

12.94 Of the five major types of crystalline solid, which does each of the following form, and why: (a) Ni; (b) F_2; (c) CH_3OH; (d) Sn; (e) Si; (f) Xe?

12.95 Of the five major types of crystalline solid, which does each of the following form, and why: (a) SiC; (b) Na_2SO_4; (c) SF_6; (d) cholesterol ($C_{27}H_{45}OH$); (e) KCl; (f) BN?

12.96 Zinc oxide adopts the zinc blende crystal structure (Figure P12.96). How many Zn^{2+} ions are in the ZnO unit cell?

12.97 Calcium sulfide adopts the sodium chloride crystal structure (Figure P12.97). How many S^{2-} ions are in the CaS unit cell?

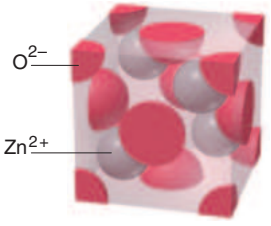


Figure P12.96

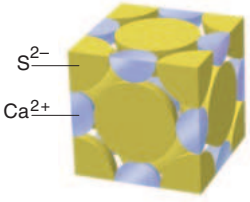

Figure P12.97

12.98 Zinc selenide (ZnSe) crystallizes in the zinc blende structure (see Figure P12.96) and has a density of 5.42 g/cm^3.
(a) How many Zn and Se ions are in each unit cell?
(b) What is the mass of a unit cell?
(c) What is the volume of a unit cell?
(d) What is the edge length of a unit cell?

12.99 An element crystallizes in a face-centered cubic lattice and it has a density of 1.45 g/cm^3. The edge of its unit cell is 4.52×10^{-8} cm.
(a) How many atoms are in each unit cell?
(b) What is the volume of a unit cell?
(c) What is the mass of a unit cell?
(d) Calculate an approximate atomic mass for the element.

12.100 Classify each of the following as a conductor, insulator, or semiconductor: (a) phosphorus; (b) mercury; (c) germanium.

12.101 Classify each of the following as a conductor, insulator, or semiconductor: (a) carbon (graphite); (b) sulfur; (c) platinum.

12.102 Predict the effect (if any) of an increase in temperature on the electrical conductivity of (a) antimony; (b) tellurium; (c) bismuth.

12.103 Predict the effect (if any) of a decrease in temperature on the electrical conductivity of (a) silicon; (b) lead; (c) germanium.

Problems in Context

12.104 Polonium, the Period 6 member of Group 6A(16), is a rare radioactive metal that is the only element with a crystal structure based on the simple cubic unit cell. If its density is 9.142 g/cm^3, calculate an approximate atomic radius for polonium.

12.105 The coinage metals—copper, silver, and gold—crystallize in a cubic closest packed structure. Use the density of copper (8.95 g/cm^3) and its molar mass (63.55 g/mol) to calculate an approximate atomic radius for copper.

12.106 One of the most important enzymes in the world—nitrogenase, the plant protein that catalyzes nitrogen fixation—contains active clusters of iron, sulfur, and molybdenum atoms. Crystalline molybdenum (Mo) has a body-centered cubic unit cell (d of Mo = 10.28 g/cm^3). (a) Determine the edge length of the unit cell. (b) Calculate the atomic radius of Mo.

12.107 Tantalum (Ta; d = 16.634 g/cm^3 and $\mathcal{M}$ = 180.9479 g/mol) has a body-centered cubic structure with a unit-cell edge length of 3.3058 Å. Use these data to calculate Avogadro's number.

Advanced Materials

Concept Review Questions

12.108 When tin is added to copper, the resulting alloy (bronze) is much harder than copper. Explain.

12.109 In the process of doping a semiconductor, certain impurities are added to increase the electrical conductivity. Explain this process for an n-type and a p-type semiconductor.

12.110 State two molecular characteristics of substances that typically form liquid crystals. How is each related to function?

12.111 Distinguish between isotropic and anisotropic substances. To which category do liquid crystals belong?

12.112 How are the properties of high-tech ceramics the same as those of traditional clay ceramics, and how are they different? Refer to specific substances in your answer.

12.113 Why is the average molar mass of a polymer sample different from the molar mass of an individual chain?

12.114 How does the random coil shape relate to the radius of gyration of a polymer chain?

12.115 What factor(s) influence the viscosity of a polymer solution? What factor(s) influence the viscosity of a molten polymer? What is a polymer glass?

12.116 Use an example to show how branching and crosslinking can affect the physical behavior of a polymer.

Skill-Building Exercises (grouped in similar pairs)

12.117 Silicon and germanium are both semiconducting elements from Group 4A(14) that can be doped to improve their conductivity. Would each of the following form an n-type or a p-type semiconductor: (a) Ge doped with P; (b) Si doped with In?

12.118 Would each of the following form an n-type or a p-type semiconductor: (a) Ge doped with As; (b) Si doped with B?

12.119 The repeat unit in a polystyrene coffee cup has the formula $C_6H_5CHCH_2$. If the molar mass of the polymer is 3.5×10^5 g/mol, what is the degree of polymerization?

12.120 The monomer of poly(vinyl chloride) has the formula C_2H_3Cl. If there are 1565 repeat units in a single chain of the polymer, what is the molecular mass (in amu) of that chain?

12.121 The polypropylene (repeat unit CH_3CHCH_2) in a plastic toy has a molar mass of 2.8×10^5 g/mol and a repeat unit length of 0.252 pm. Calculate the radius of gyration.

12.122 The polymer that is used to make 2-L soda bottles [poly(ethylene terephthalate)] has a repeat unit with molecular formula $C_{10}H_8O_4$ and length 1.075 nm. Calculate the radius of gyration of a chain with a molar mass of 2.30×10^4 g/mol.

Comprehensive Problems

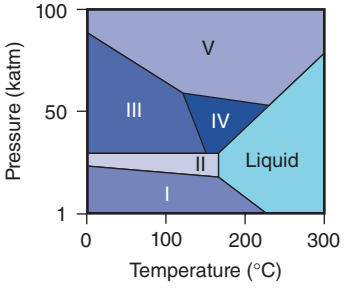
12.123 A 0.75-L bottle is cleaned, dried, and closed in a room where the air is 22°C and has 44% relative humidity (that is, the water vapor in the air is 0.44 of the equilibrium vapor pressure at 22°C). The bottle is then brought outside and stored at 0.0°C.
(a) What mass of liquid water condenses inside the bottle?
(b) Would liquid water condense at 10°C? (See Table 5.2, p. 220.)

12.124 In an experiment, 5.00 L of N_2 is saturated with water vapor at 22°C and then compressed to half its volume at constant T. (a) What is the partial pressure of H_2O in the compressed gas mixture? (b) What mass of water vapor condenses to liquid?

12.125 Barium is the largest nonradioactive alkaline earth metal. It has a body-centered cubic unit cell and a density of 3.62 g/cm^3. What is the atomic radius of barium? (Volume of a sphere: $V = \frac{4}{3}\pi r^3$.)

12.126 Two important characteristics used to evaluate the risk of fire or explosion are a compound's *lower flammable limit* (LFL) and *flash point.* The LFL is the minimum percentage by volume in air that is ignitable. Below that, the mixture is too "lean" to burn. The flash point is the temperature at which the air over a confined liquid becomes ignitable. *n*-Hexane boils at 68.7°C at 1 atm. At 20.0°C, its vapor pressure is 121 mmHg. The LFL of *n*-hexane is 1.1%. Calculate the flash point of *n*-hexane.

12.127 Bismuth is used to calibrate instruments employed in high-pressure studies because it has several well-characterized crystalline phases. Its phase diagram *(right)* shows the liquid phase and five solid phases that are stable above 1 katm (1000 atm) and up to 300°C. (a) Which solid phases are stable at 25°C? (b) Which phase is stable at 50 katm and 175°C? (c) As the pressure is reduced from 100 to 1 katm at 200°C, what phase transitions does bismuth undergo? (d) What phases are present at each of the triple points?



12.128 In making computer chips, a 4.00-kg cylindrical ingot of ultrapure n-type doped silicon that is 5.20 inches in diameter is sliced into wafers 1.12×10^{-4} m thick.
(a) Assuming no waste, how many wafers can be made?
(b) What is the mass of a wafer (d of Si = 2.34 g/cm^3; V of a cylinder = $\pi r^2 h$)?
(c) A key step in making p-n junctions for the chip is chemical removal of the oxide layer on the wafer through treatment with gaseous HF. Write a balanced equation for this reaction.
(d) If 0.750% of the Si atoms are removed during the treatment in part (c), how many moles of HF are required per wafer, assuming 100% reaction yield?

12.129 Methyl salicylate, $C_8H_8O_3$, the odorous constituent of oil of wintergreen, has a vapor pressure of 1.00 torr at 54.3°C and 10.0 torr at 95.3°C. (a) What is its vapor pressure at 25°C? (b) What is the minimum number of liters of air that must pass over a sample of the compound at 25°C to vaporize 1.0 mg of it?

12.130 Mercury (Hg) vapor is toxic and readily absorbed from the lungs. At 20.°C, mercury (ΔH_{vap} = 59.1 kJ/mol) has a vapor pressure of 1.20×10^{-3} torr, which is high enough to be hazardous. To reduce the danger to workers in processing plants, Hg is cooled to lower its vapor pressure. At what temperature would the vapor pressure of Hg be at the safer level of 5.0×10^{-5} torr?

12.131 Polytetrafluoroethylene (Teflon) has a repeat unit with the formula $F_2C{-}CF_2$. A sample of the polymer consists of fractions with the following distribution of chains:

Fraction	Average no. of Repeat Units	Amount (mol) of Polymer
1	273	0.10
2	330	0.40
3	368	1.00
4	483	0.70
5	525	0.30
6	575	0.10

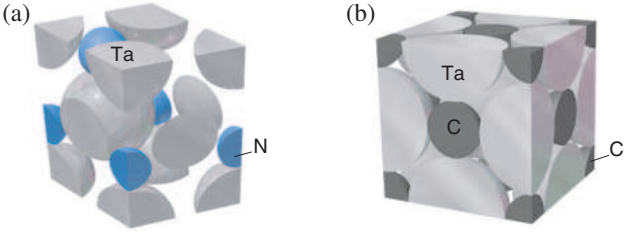
(a) Determine the molar mass of each fraction.
(b) Determine the number-average molar mass of the sample.
(c) Another type of average molar mass of a polymer sample is called the *weight-average molar mass,* $\mathcal{M}_w$:

$$\mathcal{M}_w = \frac{\Sigma\ (\mathcal{M}\text{ of fraction} \times \text{mass of fraction})}{\text{total mass of all fractions}}$$

Calculate the weight-average molar mass of the above sample.

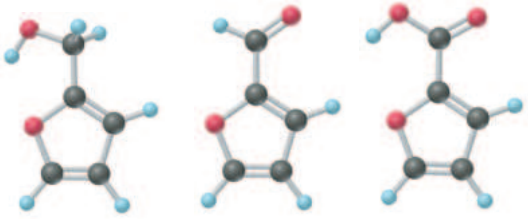
12.132 A greenhouse contains 256 m^3 of air at a temperature of 26°C, and a humidifier in it vaporizes 4.20 L of water. (a) What is the pressure of water vapor in the greenhouse, assuming that none escapes and that the air was originally completely dry (d of H_2O = 1.00 g/mL)? (b) What total volume of liquid water would have to be vaporized to saturate the air (that is, achieve 100% relative humidity)? (See Table 5.2, p. 220.)

12.133 Like most transition metals, tantalum (Ta) exhibits several oxidation states. Give the formula of each tantalum compound whose unit cell is depicted below:



12.134 KF has the same type of crystal structure as NaCl. The unit cell of KF has an edge length of 5.39 Å. Find the density of KF.

12.135 Furfural, which is prepared from corncobs, is an important solvent in synthetic rubber manufacturing, and it is reduced to furfuryl alcohol, which is used to make polymer resins. Furfural can also be oxidized to 2-furoic acid.



(a) Which of these compounds can form H bonds? Draw structures in each case.
(b) The molecules of some substances can form an "internal" H bond, that is, an H bond *within* a molecule. This takes the form of a polygon with atoms as corners and bonds as sides and an H bond as one of the sides. Which of these molecules is (are) likely to form a stable internal H bond? Draw the structure. (*Hint:* Structures with 5 or 6 atoms as corners are most stable.)

12.136 On a humid day in New Orleans, the temperature is 22.0°C, and the partial pressure of water vapor in the air is 31.0 torr. The 9000-ton air-conditioning system in the Louisiana Superdome maintains an inside air temperature of 22.0°C also, but a partial pressure of water vapor of 10.0 torr. The volume of air in the dome is 2.4×10^6 m^3, and the total pressure is 1.0 atm both inside and outside the dome.
(a) What mass of water (in metric tons) must be removed every time the inside air is completely replaced with outside air? (*Hint:* How many moles of gas are in the dome? How many moles of water vapor? How many moles of dry air? How many moles of outside air must be added to the air in the dome to simulate the composition of outside air?)
(b) Find the heat released when this mass of water condenses.

12.137 The boiling point of amphetamine, $C_9H_{13}N$, is 201°C at 760 torr and 83°C at 13 torr. What is the concentration (in g/m^3) of amphetamine when it is in contact with 20.°C air?

12.138 Diamond has a face-centered cubic unit cell, with four more C atoms in tetrahedral holes within the cell. Densities of diamonds vary from 3.01 g/cm^3 to 3.52 g/cm^3 because C atoms are missing from some holes. (a) Calculate the unit-cell edge length of the densest diamond. (b) Assuming the cell dimensions are fixed, how many C atoms are in the unit cell of the diamond with the lowest density?

12.139 Is it possible for a salt of formula AB_3 to have a face-centered cubic unit cell of anions with cations in all eight of the available holes? Explain.

12.140 The density of solid gallium at its melting point is 5.9 g/cm^3, whereas that of liquid gallium is 6.1 g/cm^3. Is the temperature at the triple point higher or lower than the normal melting point? Is the slope of the solid-liquid line for gallium positive or negative?

12.141 A 4.7-L sealed bottle containing 0.33 g of liquid ethanol, C_2H_6O, is placed in a refrigerator and reaches equilibrium with its vapor at −11°C. (a) What mass of ethanol is present in the vapor? (b) When the container is removed and warmed to room temperature, 20.°C, will all the ethanol vaporize? (c) How much liquid ethanol would be present at 0.0°C? The vapor pressure of ethanol is 10. torr at −2.3°C and 40. torr at 19°C.

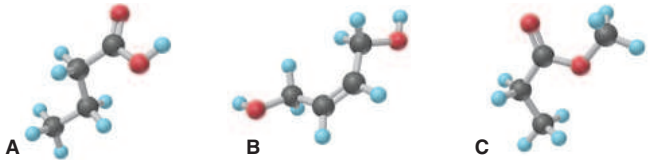
12.142 Substance A has the following properties.

mp at 1 atm:	−20.°C	bp at 1 atm:	85°C
ΔH_{fus}:	180. J/g	ΔH_{vap}:	500. J/g
c_{solid}:	1.0 J/g·°C	c_{liquid}:	2.5 J/g·°C
c_{gas}:	0.5 J/g·°C		

At 1 atm, a 25-g sample of A is heated from −40.°C to 100.°C at a constant rate of 450. J/min. (a) How many minutes does it take to heat the sample to its melting point? (b) How many minutes does it take to melt the sample? (c) Perform any other necessary calculations, and draw a curve of temperature vs. time for the entire heating process.

12.143 An aerospace manufacturer is building a prototype experimental aircraft that cannot be detected by radar. Boron nitride is chosen for incorporation into the body parts, and the boric acid/ammonia method is used to prepare the ceramic material. Given 85.5% and 86.8% yields for the two reaction steps, how much boron nitride can be prepared from 1.00 metric ton of boric acid and 12.5 m^3 of ammonia at 275 K and 3.07×10^3 kPa? Assume that ammonia does not behave ideally under these conditions and is recycled completely in the reaction process.

12.144 The ball-and-stick models below represent three compounds with the same molecular formula, $C_4H_8O_2$:



(a) Which compound(s) can form intermolecular H bonds?
(b) Which has the highest viscosity?

12.145 The ΔH_f° of gaseous dimethyl ether (CH_3OCH_3) is −185.4 kJ/mol; the vapor pressure is 1.00 atm at −23.7°C and 0.526 atm at −37.8°C. (a) Calculate ΔH_{vap}° of dimethyl ether. (b) Calculate ΔH_f° of liquid dimethyl ether.

12.146 The crystal structure of sodium is based on the body-centered cubic unit cell. What is the mass of one unit cell of Na?

12.147 The *intrinsic viscosity* of a polymer solute in a solvent, $[\eta]_{solvent}$, is the portion of the total viscosity due to the solute and is related to solute shape. It has also been found to relate to intermolecular interactions between solvent and polymer: higher $[\eta]_{solvent}$ means stronger interaction. The $[\eta]_{solvent}$ values of polymers in solution are given by the Mark-Houwink equation, $[\eta]_{solvent} = K\mathcal{M}^a$, where $\mathcal{M}$ is the molar mass of the polymer and K and a are constants specific to the polymer and solvent. Use the data below for substances at 25°C to answer the following questions:

Polymer	Solvent	K (mL/g)	a
Polystyrene	Benzene	9.5×10^{-3}	0.74
	Cyclohexane	8.1×10^{-2}	0.50
Polyisobutylene	Benzene	8.3×10^{-2}	0.50
	Cyclohexane	2.6×10^{-1}	0.70

(a) A polystyrene sample has a molar mass of 104,160 g/mol. Calculate the intrinsic viscosity in benzene and in cyclohexane. Which solvent has stronger interactions with the polymer?
(b) A different polystyrene sample has a molar mass of 52,000 g/mol. Calculate its $[\eta]_{benzene}$. Given a polymer standard of known $\mathcal{M}$, how could you use its measured $[\eta]$ in a given solvent to determine the molar mass of any sample of that polymer?
(c) Compare $[\eta]$ of a polyisobutylene sample [repeat unit $(CH_3)_2CCH_2$] with a molar mass of 104,160 g/mol with that of the polystyrene in part (a). What does this suggest about the solvent-polymer interactions of the two samples?

12.148 One way of purifying gaseous H_2 is to pass it under high pressure through the holes of a metal's crystal structure. Palladium, which adopts a cubic closest packed structure, absorbs more H_2 than any other element and is one of the metals used for this purpose. How the metal and H_2 interact is unclear, but it is estimated that the density of absorbed H_2 approaches that of liquid hydrogen (70.8 g/L). What volume (in L) of gaseous H_2 (at STP) can be packed into the spaces of 1 dm^3 of palladium metal?

13.7 Structure and Properties of Colloids

Concepts and Skills to Review Before You Study This Chapter

- separation of mixtures (Section 2.9)
- calculations involving mass percent (Section 3.1) and molarity (Section 4.1)
- electrolytes; water as solvent (Sections 4.1 and 12.5)
- mole fraction and Dalton's law (Section 5.4)
- intermolecular forces and polarizability (Section 12.3)
- monomers and polymers (Section 12.7)
- equilibrium nature of phase changes and vapor pressure of liquids; phase diagrams (Section 12.2)

Virtually all the gases, liquids, and solids in the real world are *mixtures*—two or more substances mixed together physically, not combined chemically. Synthetic mixtures, such as glass *(see photo)* and soap, usually contain only a dozen or so components, but natural mixtures, such as seawater and soil, often contain over 50. Living mixtures, such as trees and students, are the most complex—even a simple bacterial cell contains nearly 6000 different compounds (Table 13.1).

Recall from Chapter 2 that a mixture has two defining characteristics: *its composition is variable,* and *it retains some properties of its components.* We focus here on two common types of mixtures—solutions and colloids—whose main differences relate to particle size and number of phases:

Table 13.1 Approximate Composition of a Bacterium

Substance	Mass % of Cell	Number of Types	Number of Molecules
Water	~70	1	5×10^{10}
Ions	1	20	?
Sugars*	3	200	3×10^{8}
Amino acids*	0.4	100	5×10^{7}
Lipids*	2	50	3×10^{7}
Nucleotides*	0.4	200	1×10^{7}
Other small molecules	0.2	~200	?
Macromolecules (proteins, nucleic acids, polysaccharides)	23	~5000	6×10^{6}

*Includes precursors and metabolites.

- A *solution* is a *homogeneous* mixture; that is, it exists as one phase. In a solution, the particles are individual atoms, ions, or small molecules.
- A *colloid* is a type of *heterogeneous* mixture. A heterogeneous mixture has two or more phases. They may be visibly distinct, like pebbles in concrete, or not, like the much smaller particles in the colloids smoke and milk. In a colloid, the particles are typically macromolecules or aggregations of small molecules that are dispersed so finely they don't settle out.

IN THIS CHAPTER . . . *We focus on how intermolecular forces and other energy considerations affect a solute dissolving in a solvent, how we calculate concentration, and how solutions differ from pure substances. We also briefly consider the behavior and applications of colloids.*

- We survey intermolecular forces between solute and solvent and find that substances with similar types of forces form a solution.
- We see how the dual polarity of some organic molecules gives rise to these same intermolecular forces, and we find that they determine the structures and functions of soaps, antibiotics, biological macromolecules, and cell membranes.
- We use a stepwise cycle to see why a substance dissolves and examine the heat involved and the dispersal of matter that occurs when a solution forms. To understand the latter factor, we introduce the concept of entropy.
- We examine the equilibrium nature of solubility and see how temperature and pressure affect it.
- We define various solution concentration units and see how to interconvert them mathematically.
- We see why the physical properties of solutions are different from those of pure substances and learn how to apply those differences.
- We investigate colloids and apply solution and colloid chemistry to the purification of water.

13.1 TYPES OF SOLUTIONS: INTERMOLECULAR FORCES AND SOLUBILITY

A **solute** dissolves in a **solvent** to form a solution. In general, *the solvent is the most abundant component,* but in some cases, the substances are **miscible**—soluble in each other in any proportion—so the terms "solute" and "solvent" lose their meaning. *The physical state of the solvent usually determines the physical state of the solution.* Solutions can be gaseous, liquid, or solid, but we focus mostly on liquid solutions because they are by far the most important.

The **solubility (*S*)** of a solute is the maximum amount that dissolves in a fixed quantity of a given solvent at a given temperature, when an excess of the solute is present. Different solutes have different solubilities:

- Sodium chloride (NaCl), S = 39.12 g/100. mL water at 100.°C.
- Silver chloride (AgCl), S = 0.0021 g/100. mL water at 100.°C.

Solubility is a *quantitative* term, but *dilute* and *concentrated* are qualitative, referring to the *relative* amounts of dissolved solute; the NaCl solution above is concentrated, and the AgCl solution is dilute.

A given solute may dissolve in one solvent and not another. The explanation lies in the relative strengths of the intermolecular forces within both solute and solvent and between them. The useful rule-of-thumb **"like dissolves like"** says that *substances with similar types of intermolecular forces dissolve in each other.* Thus, by knowing the forces, we can often predict whether a solute will dissolve in a solvent.

Intermolecular Forces in Solution

All the intermolecular forces we discussed for pure substances also occur in solutions (Figure 13.1; also see Section 12.3):

1. *Ion-dipole forces* are the principal force involved when an ionic compound dissolves in water. Two events occur simultaneously:
   - *Forces compete*. When a soluble salt is added to water, the ions attract the oppositely charged pole of a water molecule. These attractions compete with and overcome attractions between the ions, and the crystal structure breaks down.
   - *Hydration shells form*. As an ion separates, water molecules cluster around it in **hydration shells.** The number of water molecules in the innermost shell depends on the ion's size: four fit tetrahedrally around small ions like Li^+, while the larger Na^+ and F^- have six water molecules surrounding them octahedrally (Figure 13.2). In the innermost shell, normal H bonding is disrupted to form the ion-dipole forces. But these water molecules are H bonded to others in the next shell, and those are H bonded to others still farther away.
2. *Hydrogen bonding* is the principal force in solutions of polar, O- and N-containing organic and biological compounds, such as alcohols, amines, and amino acids.
3. *Dipole-dipole forces,* in the absence of H bonding, allow polar molecules like propanal (CH_3CH_2CHO) to dissolve in polar solvents like dichloromethane (CH_2Cl_2).
4. **Ion–induced dipole forces,** one type of *charge-induced dipole force,* rely on polarizability. They arise when an ion's charge distorts the electron cloud of a nearby nonpolar molecule. This type of force initiates the binding of the Fe^{2+} ion in hemoglobin to an O_2 molecule entering a red blood cell.
5. **Dipole–induced dipole forces,** also based on polarizability, arise when a polar molecule distorts the electron cloud of a nonpolar molecule. They are weaker than ion–induced dipole forces because the charge of each pole is less than an ion's (Coulomb's law). The solubility in water of atmospheric O_2, N_2, and noble gases, while limited, is due in part to these forces. Paint thinners and grease solvents also rely on them.
6. *Dispersion forces* contribute to the solubility of all solutes in all solvents, but they are the *principal* intermolecular force in solutions of nonpolar substances, such as petroleum and gasoline.

The same forces maintain the shapes of biological macromolecules (Section 13.2).

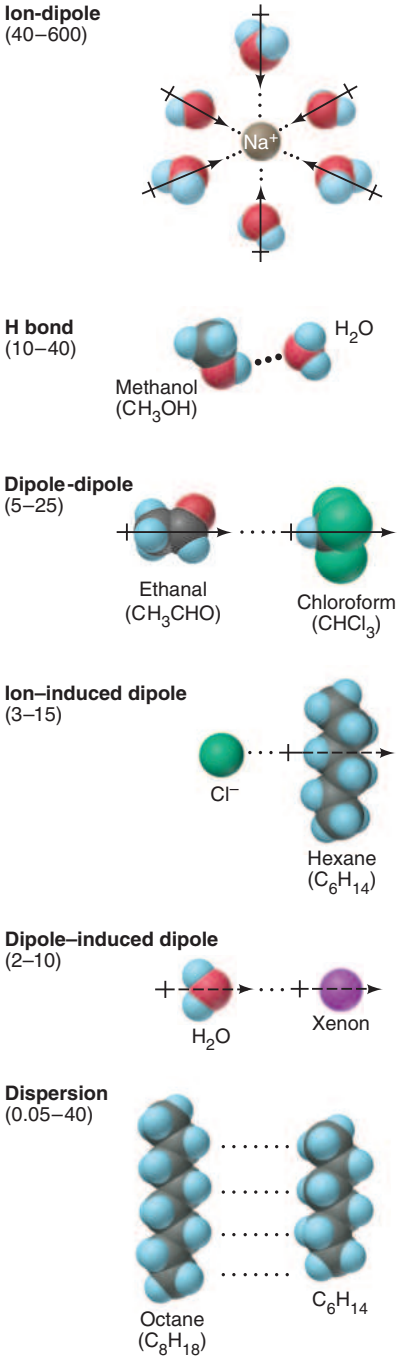

Figure 13.1 Types of intermolecular forces in solutions. Forces are listed in order of decreasing strength (values are in kJ/mol), with an example of each.

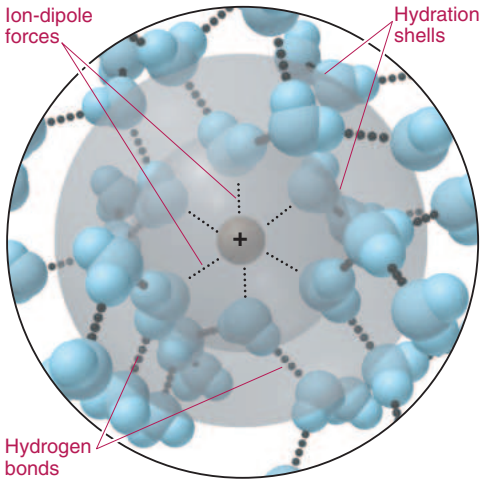

Figure 13.2 Hydration shells around an Na^+ ion. Ion-dipole forces orient water molecules around an ion. In the innermost shell here, six water molecules surround the cation octahedrally.

Liquid Solutions and the Role of Molecular Polarity

From cytoplasm to tree sap, gasoline to cleaning fluid, iced tea to urine, liquid solutions are very familiar. Water is the most prominent solvent, but there are many other liquid solvents, with polarities from very polar to nonpolar.

Applying the Like-Dissolves-Like Rule The like-dissolves-like rule says that when the forces *within* the solute are *similar* to those *within* the solvent, the forces can *replace* each other and a solution forms. Thus,

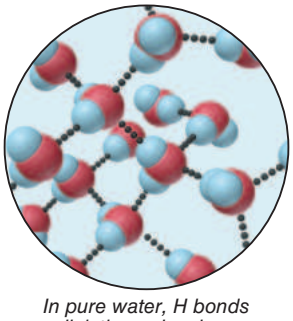
- *Salts are soluble in water* because the ion-dipole attractions between ion and water are similar in strength to the strong attractions between the ions and the strong H bonds between water molecules, so they *can* replace each other.
- *Salts are insoluble in hexane (C_6H_{14})* because the ion–induced dipole forces between ion and nonpolar hexane are very weak and *cannot* replace the strong attractions between the ions.
- *Oil is insoluble in water* because the weak dipole–induced dipole forces between oil and water molecules *cannot* replace the strong H bonds between water molecules or the extensive dispersion forces within the oil.
- *Oil is soluble in hexane* because dispersion forces in one *can* replace the similar dispersion forces in the other.

Dual Polarity and Effects on Solubility To examine these ideas further, let's compare the solubilities of a series of alcohols in water and in hexane, two solvents with very different intermolecular forces. Alcohols are organic compounds that have a dual polarity, a polar hydroxyl (—OH) group bonded to a nonpolar hydrocarbon group:

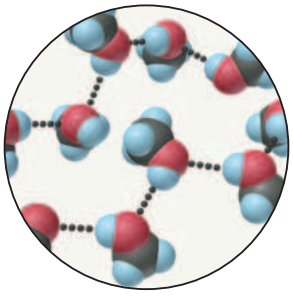
- The —OH portion interacts through strong H bonds with water and through weak dipole–induced dipole forces with hexane.
- The hydrocarbon portion interacts through dispersion forces with hexane and through very weak dipole–induced dipole forces with water.

The general formula for an alcohol is $CH_3(CH_2)_nOH$, and we'll look at straight-chain examples with one to six carbons (n = 0 to 5):

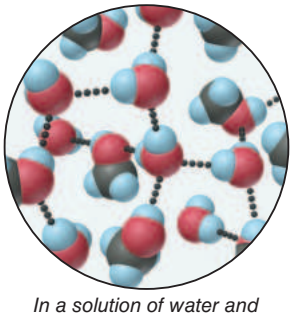
1. *Solubility in water is high for smaller alcohols*. From the models in Table 13.2 *(next page),* we see that the —OH group is a relatively large portion of the alcohols with one to three carbons (n = 0 to 2). These molecules interact with each other through H bonding, just as water molecules do. When they mix with water, H bonding *within* solute and *within* solvent is replaced by H bonding *between* solute and solvent (Figure 13.3). As a result, these smaller alcohols are miscible with water.



In pure water, H bonds link the molecules.



In pure methanol, H bonds link the molecules.



In a solution of water and methanol, H bonds link the two types of molecules.

Figure 13.3 Like dissolves like: solubility of methanol in water.

Table 13.2 Solubility* of a Series of Alcohols in Water and in Hexane

Alcohol	Model	Solubility in Water	Solubility in Hexane
CH_3OH (methanol)		∞	1.2
CH_3CH_2OH (ethanol)		∞	∞
$CH_3(CH_2)_2OH$ (1-propanol)		∞	∞
$CH_3(CH_2)_3OH$ (1-butanol)		1.1	∞
$CH_3(CH_2)_4OH$ (1-pentanol)		0.30	∞
$CH_3(CH_2)_5OH$ (1-hexanol)		0.058	∞

*Expressed in mol alcohol/1000 g solvent at 20°C.

2. *Solubility in water is low for larger alcohols*. Solubility decreases dramatically for alcohols larger than three carbons ($n > 2$); in fact, those with chains longer than six carbons ($n > 5$) are insoluble in water. For larger alcohols to dissolve, the nonpolar chains have to move among the water molecules, replacing the strong H-bond attractions between water molecules with the weak attractions of the chains for water. While the —OH portion of such an alcohol forms H bonds to water, these cannot make up for all the other H bonds between water molecules that have to break to make room for the long hydrocarbon portion.

Table 13.2 shows that the opposite trend occurs with hexane:

1. *Solubility in hexane is low for the smallest alcohol.* For alcohols in hexane, in addition to dispersion forces, weak dipole–induced dipole forces exist between the —OH of methanol (CH_3OH) and hexane. These cannot replace the strong H bonding between CH_3OH molecules, so solubility is relatively low.

2. *Solubility in hexane is high for larger alcohols.* In any larger alcohol ($n > 0$), dispersion forces between the hydrocarbon portion and hexane *can* replace dispersion forces between hexane molecules. With only weak forces within the solvent to be replaced, even ethanol, with a two-carbon chain, has enough dispersion forces between it and hexane to be miscible.

Many organic molecules have polar and nonpolar portions, which determine their solubility. For example, carboxylic acids and amines behave like alcohols: methanoic acid (HCOOH, formic acid) and methanamine (CH_3NH_2) are miscible with water and slightly soluble in hexane, whereas hexanoic acid [$CH_3(CH_2)_4COOH$] and 1-hexanamine [$CH_3(CH_2)_5NH_2$] are slightly soluble in water and very soluble in hexane.

SAMPLE PROBLEM 13.1 **Predicting Relative Solubilities**

Problem Predict which solvent will dissolve more of the given solute:
(a) Sodium chloride in methanol (CH_3OH) or in 1-propanol ($CH_3CH_2CH_2OH$)
(b) Ethylene glycol ($HOCH_2CH_2OH$) in hexane ($CH_3CH_2CH_2CH_2CH_2CH_3$) or in water
(c) Diethyl ether ($CH_3CH_2OCH_2CH_3$) in water or in ethanol (CH_3CH_2OH)
