Plan We examine the formulas of solute and solvent to determine the forces in and between solute and solvent. A solute is more soluble in a solvent whose intermolecular forces are similar to, and therefore can replace, its own.

Solution **(a)** Methanol. NaCl is ionic, so it dissolves through ion-dipole forces. Both methanol and 1-propanol have a polar —OH group, but the hydrocarbon portion of each alcohol interacts only weakly with the ions and 1-propanol has a longer hydrocarbon portion than methanol.
(b) Water. Ethylene glycol molecules have two —OH groups, so they interact with each other through H bonding. H bonds formed with H_2O can replace these H bonds between solute molecules better than dipole–induced dipole forces with hexane can.
(c) Ethanol. Diethyl ether molecules interact through dipole-dipole and dispersion forces. They can form H bonds to H_2O or to ethanol. But ethanol can also interact with the ether effectively through dispersion forces because it has a hydrocarbon chain.

FOLLOW-UP PROBLEMS
Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*
13.1A State which solute is more soluble in the given solvent and which forces are most important: **(a)** 1-butanol ($CH_3CH_2CH_2CH_2OH$) or 1,4-butanediol ($HOCH_2CH_2CH_2CH_2OH$) in water; **(b)** chloroform ($CHCl_3$) or carbon tetrachloride (CCl_4) in water.
13.1B State which solvent can dissolve more of the given solute and which forces are most important: **(a)** chloromethane (CH_3Cl) in chloroform ($CHCl_3$) or in methanol (CH_3OH); **(b)** pentanol ($C_5H_{11}OH$) in water or in hexane (C_6H_{14}).
SOME SIMILAR PROBLEMS 13.13 and 13.14

Gas-Liquid Solutions A substance with very weak intermolecular attractions should have a low boiling point and, thus, would be a gas under ordinary conditions. Also, it would not be very soluble in water because of weak solute-solvent forces. Thus, for nonpolar or slightly polar gases, boiling point generally correlates with solubility in water (Table 13.3).

The small amount of a nonpolar gas that *does* dissolve may be vital. At 25°C and 1 atm, the solubility of O_2 is only 3.2 mL/100. mL of water, but aquatic animal life requires it. At times, the solubility of a nonpolar gas may *seem* high because it is also *reacting* with the solvent. Oxygen seems more soluble in blood than in water because it bonds chemically to hemoglobin in red blood cells. Carbon dioxide, which is essential for aquatic plants and coral-reef growth, seems very soluble in water (~81 mL of CO_2/100. mL of H_2O at 25°C and 1 atm) because it is dissolving *and* reacting:

$$CO_2(g) + H_2O(l) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$

Table 13.3 **Correlation Between Boiling Point and Solubility in Water**

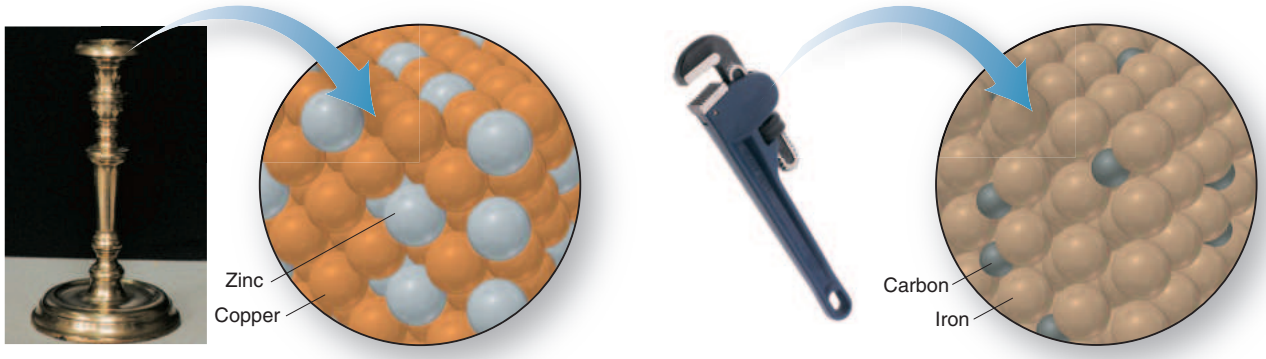
Gas	Solubility (*M*)*	bp (K)
He	4.2×10^{-4}	4.2
Ne	6.6×10^{-4}	27.1
N_2	10.4×10^{-4}	77.4
CO	15.6×10^{-4}	81.6
O_2	21.8×10^{-4}	90.2
NO	32.7×10^{-4}	121.4

*At 273 K and 1 atm.

Gas Solutions and Solid Solutions

Gas solutions and solid solutions also have vital importance and numerous applications.

Gas-Gas Solutions *All gases are miscible with each other.* Air is the classic example of a gaseous solution, consisting of about 18 gases in widely differing proportions. Anesthetic gas proportions are finely adjusted to the needs of the patient and the length of the surgical procedure. The proportions of many industrial gas mixtures, such as CO/H_2 in syngas production or N_2/H_2 in ammonia production, are controlled to optimize product yield under varying conditions of temperature and pressure.



A Brass, a substitutional alloy

B Carbon steel, an interstitial alloy

Figure 13.4 The arrangement of atoms in two types of alloys.

Gas-Solid Solutions *When a gas dissolves in a solid, it occupies the spaces between the closely packed particles.* Hydrogen gas can be purified by passing an impure sample through palladium. Only H_2 molecules are small enough to fit between the Pd atoms, where they form Pd—H bonds. The H atoms move from one Pd atom to another and emerge from the metal as H_2 molecules (see Figure 14.2, p. 570).

The ability of gases to dissolve in a solid also has disadvantages. The electrical conductivity of copper is greatly reduced by the presence of O_2, which dissolves into the crystal structure and reacts to form copper(I) oxide. High-conductivity copper is prepared by melting and recasting the metal in an O_2-free atmosphere.

Solid-Solid Solutions Solids diffuse so little that their mixtures are usually heterogeneous. Some solid-solid solutions can be formed by melting the solids and then mixing them and allowing them to freeze. Many **alloys,** mixtures of elements that have a metallic character, are solid-solid solutions (although several have microscopic heterogeneous regions). In a *substitutional alloy* like brass (Figure 13.4A), atoms of zinc *replace* atoms of the main element, copper, at some sites in the cubic closest packed array. In an *interstitial alloy* like carbon steel (Figure 13.4B), atoms of carbon (a nonmetal is typical in this type of alloy) *fill some spaces (interstices)* between atoms of the main element, iron, in the body-centered array.

Waxes are also solid-solid solutions. Most are amorphous solids with some small regions of crystalline regularity. A *wax* is defined as a solid of biological origin that is insoluble in water and soluble in nonpolar solvents. Beeswax, which bees secrete to build their combs, is a homogeneous mixture of fatty acids, long-chain carboxylic acids, and hydrocarbons in which some of the molecules are more than 40 carbon atoms long. Carnauba wax, from a South American palm, is a mixture of compounds, each consisting of a fatty acid bound to a long-chain alcohol. It is hard but forms a thick gel in nonpolar solvents, so it is perfect for waxing cars.

Summary of Section 13.1

- A solution is a homogeneous mixture of a solute dissolved in a solvent through the action of intermolecular forces.
- Ion-dipole, ion–induced dipole, and dipole–induced dipole forces occur in solutions, in addition to all the intermolecular forces that also occur in pure substances.
- If similar intermolecular forces occur in solute and solvent, they replace each other when the substances mix and a solution is likely to form ("like dissolves like").
- When ionic compounds dissolve in water, the ions become surrounded by hydration shells of H-bonded water molecules.
- Solubility of organic molecules in various solvents depends on the relative sizes of their polar and nonpolar portions.
- The solubility of nonpolar gases in water is low because of weak intermolecular forces. Gases are miscible with one another and dissolve in solids by fitting into spaces in the crystal structure.
- Solid-solid solutions include alloys (some of which are formed by mixing molten components) and waxes.

13.2 INTERMOLECULAR FORCES AND BIOLOGICAL MACROMOLECULES

We discuss the shapes of proteins, nucleic acids, and cell membranes, as well as the functions of soaps and antibiotics, in a chapter on solutions because they depend on intermolecular forces too. They are explained by two ideas:

- Polar and ionic groups attract water, but nonpolar groups do not.
- Just as separate molecules attract each other, so do distant groups on the same molecule.

The Structures of Proteins

Proteins are unbranched polymers formed from about 20 different monomers called **amino acids.** They range in size from about 50 amino acids ($\mathcal{M} \approx 5\times10^3$ g/mol) to several thousand ($\mathcal{M} \approx 5\times10^5$ g/mol). Proteins with a few types of amino acids in repeating patterns have extended helical or sheetlike shapes and give structure to hair, skin, and so forth. Proteins with many types of amino acids have complex, globular shapes and function as antibodies, enzymes, and so forth. Let's see how intermolecular forces among amino acids influence the shapes of globular proteins.

The Polarity of Amino-Acid Side Chains In a cell, a free amino acid has four groups bonded to one C, which is called the α-carbon (Figure 13.5): charged carboxyl ($—COO^-$) and amine ($—NH_3^+$) groups, an H atom, and a *side chain,* which ranges from another H atom to a two-ringed C_9H_8N group. In a protein, the carboxyl group of one amino acid is linked covalently to the amine group of the next by a *peptide* bond. (We discuss amino acid structures and peptide bond formation in Chapter 15.) Thus, as Figure 13.6 shows, the *backbone* of a protein is a polypeptide chain: an *α-carbon connected through a peptide bond (orange screen) to the next* α*-carbon,* and so forth. The various side chains *(gray screens)* dangle off the α-carbons on alternate sides of the chain.

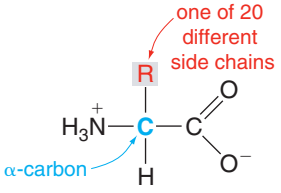


Figure 13.5 **The charged form of an amino acid under physiological conditions.**

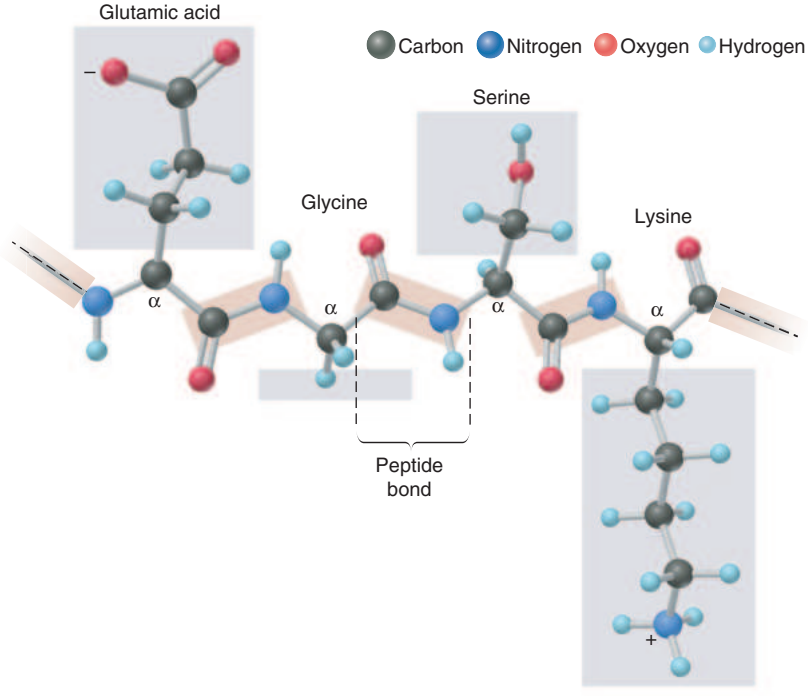

Figure 13.6 **A portion of a polypeptide chain.** Three peptide bonds *(orange screens)* join four amino acids in this chain portion.

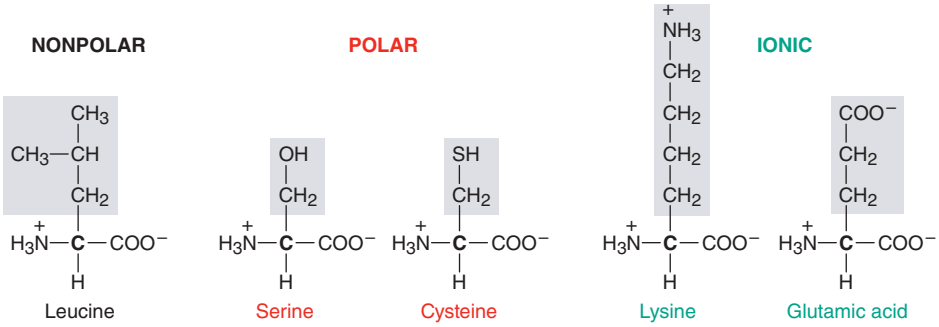
Amino acids can be classified by the polarity or charge of their side chains: nonpolar, polar, and ionic. A few examples are



Intermolecular Forces and Protein Shape The same forces that act between separate molecules are responsible for a protein's shape, because *distant groups on the protein chain end up near each other as the chain bends.* Figure 13.7 depicts the forces within a small portion of a protein and between the protein and the aqueous medium of the cell. In general order of importance, they are

- Covalent peptide bonds create the backbone (polypeptide chain).
- Helical and sheetlike segments arise from *H bonds between the C═O of one peptide bond and the N—H of another.*
- Polar and ionic side chains protrude into the surrounding cell fluid, interacting with water through ion-dipole forces and H bonds.
- Nonpolar side chains interact through dispersion forces within the nonaqueous protein interior.

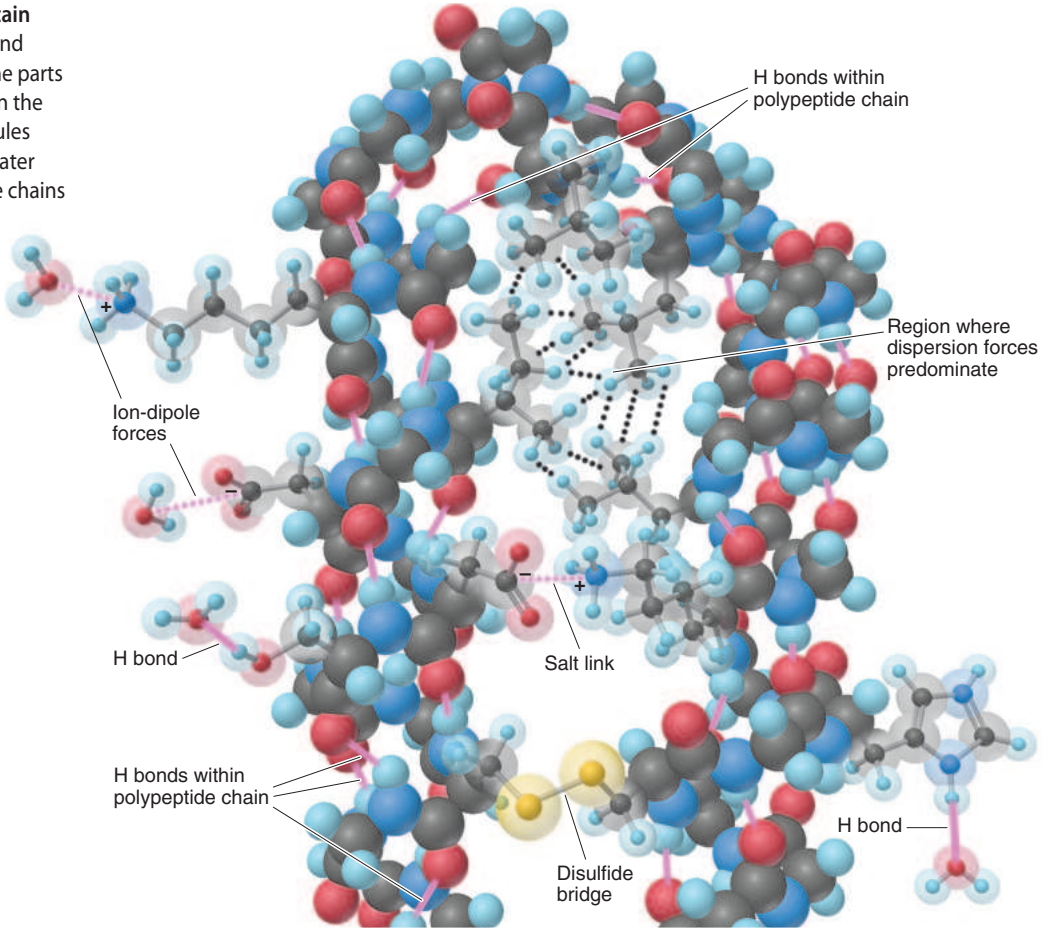


Figure 13.7 The forces that maintain protein structure. Covalent, ionic, and intermolecular forces act between the parts of a portion of a protein and between the protein and surrounding H_2O molecules to determine the protein's shape. (Water molecules and some amino-acid side chains are shown as ball-and-stick models within space-filling contours.)

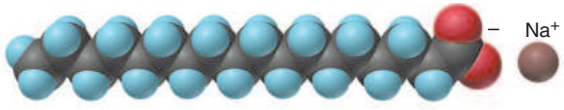
- The —SH ends of two cysteine side chains form a covalent —S—S— bond, a *disulfide bridge,* between distant parts of the chain that fixes a bend.
- Oppositely charged ends of ionic side chains, $—COO^-$ and $—NH_3^+$ groups, that lie near each other form an electrostatic *salt link* (or *ion pair*) that creates bend in the protein chain.
- Other H bonds between side chains keep distant chain portions near each other.

Thus, *soluble proteins have polar-ionic exteriors and nonpolar interiors.* As we emphasize in Chapter 15, the amino acid *sequence* of a protein determines its *shape,* which determines its *function.*

Dual Polarity in Soaps, Membranes, and Antibiotics

Dual polarity, which we discussed in regard to the solubility of alcohols, also helps explain how soaps, cell membranes, and antibiotics function.

Action of Soaps A **soap** is the salt formed when a strong base (a metal hydroxide) reacts with a *fatty acid,* a carboxylic acid with a long hydrocarbon chain. A typical soap molecule is made up of a nonpolar "tail" 15–19 carbons long and a polar-ionic "head" consisting of a $—COO^-$ group and the cation of the strong base. The cation greatly influences a soap's properties. Lithium soaps are hard and high melting and used in car lubricants. Potassium soaps are low melting and used in liquid form. Several sodium soaps, including sodium stearate, $CH_3(CH_2)_{16}COONa$, are components of common bar soaps:



Sodium stearate, $C_{17}H_{35}COONa$

When grease on your hands or clothes is immersed in soapy water, the soap molecules' nonpolar tails interact with the nonpolar grease molecules through dispersion forces, while the polar-ionic heads attract water molecules through ion-dipole forces and H bonds. Tiny aggregates of grease molecules, embedded with soap molecules whose polar-ionic heads stick into the water, are flushed away by added water (Figure 13.8).

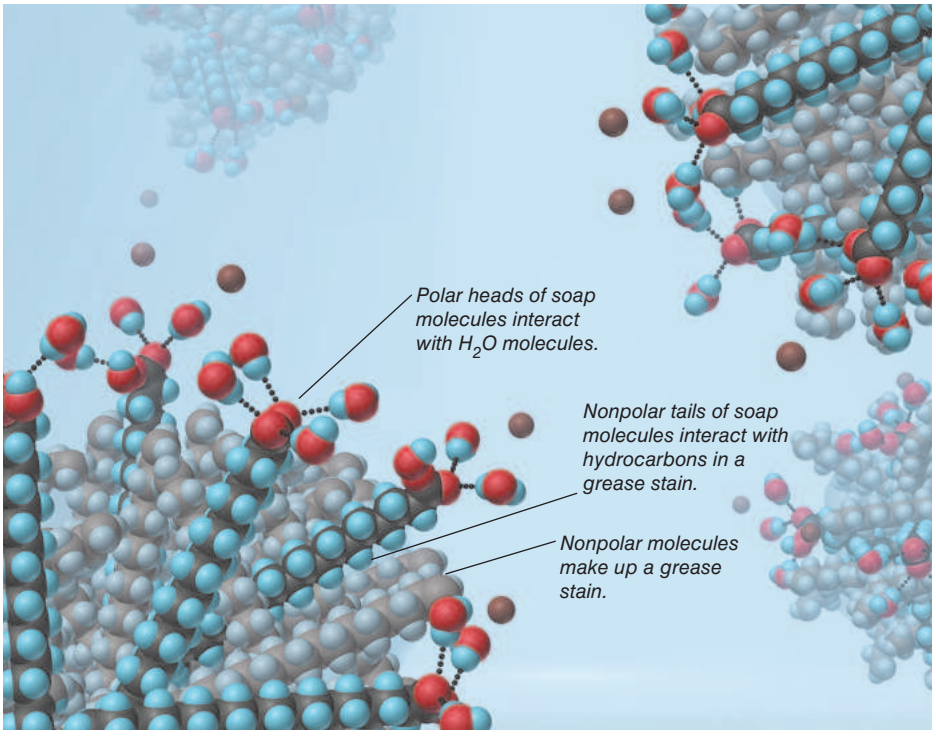


Figure 13.8 The cleaning ability of a soap depends on the dual polarity of its molecules.

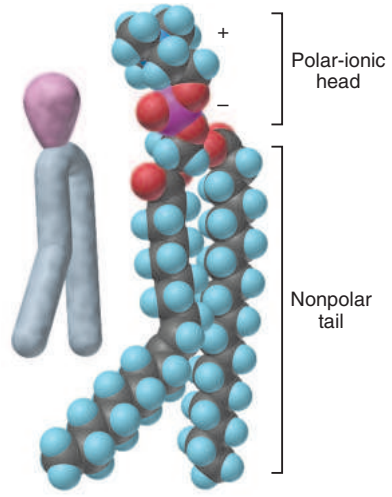

Figure 13.9 **A membrane phospholipid.** Lecithin (phosphatidylcholine), a phospholipid, is shown as a space-filling model and as a simplified purple-and-gray shape.

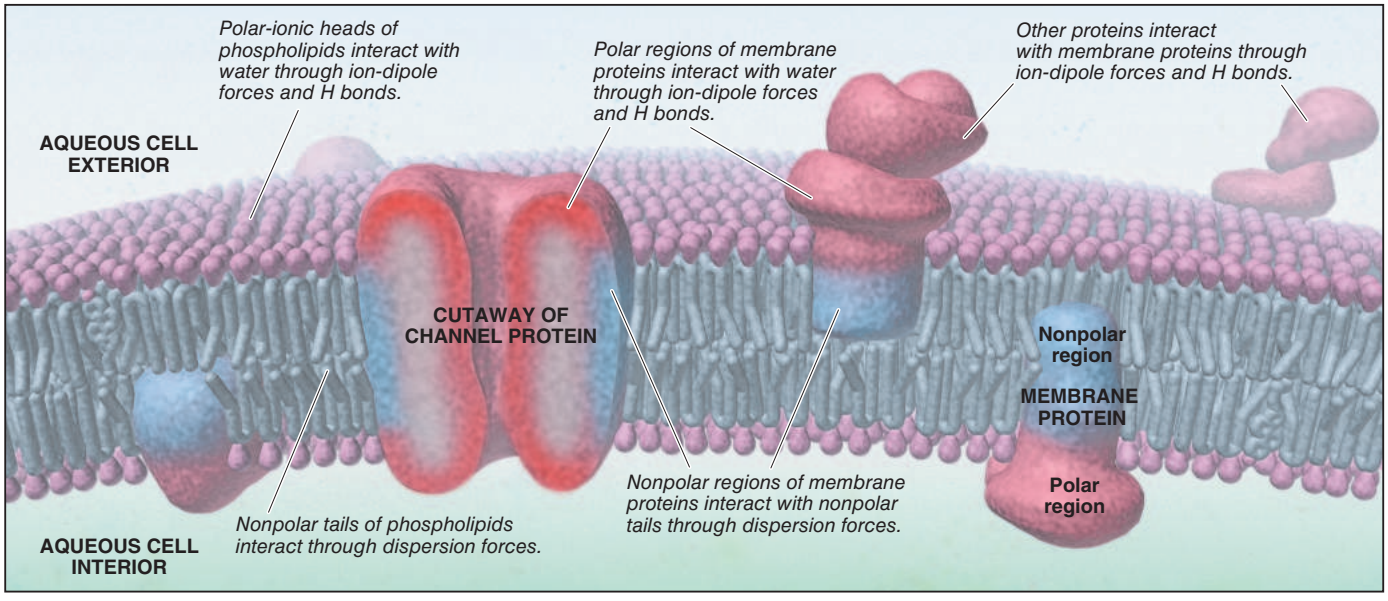
Lipid Bilayers and the Structure of the Cell Membrane The most abundant molecules in cell membranes are *phospholipids.* Like soaps, they have a dual polarity—a nonpolar tail consists of two fatty acid chains, and an organophosphate group is the polar-ionic head (Figure 13.9). Remarkably, phospholipids self-assemble in water into a sheetlike double layer called a **lipid bilayer,** with the tails of the two layers touching and the heads in the water. In the laboratory, bilayers form spherical vesicles that trap water inside. These structures are favored energetically because of their intermolecular forces:

- Ion-dipole forces occur between polar heads and water inside and outside.
- Dispersion forces occur between nonpolar tails within the bilayer interior.
- Minimal contact exists between nonpolar tails and water.

A typical animal cell membrane consists of a phospholipid bilayer with proteins partially embedded in it, and a small portion of a membrane appears in Figure 13.10. Membrane proteins, which play countless essential roles, differ fundamentally from soluble proteins in terms of their dual polarity:

- Soluble proteins have polar exteriors and nonpolar interiors. They form ion-dipole and H-bonding forces between water and *polar groups on the exterior* and dispersion forces between *nonpolar groups in the interior* (see Figure 13.7).
- Membrane proteins have exteriors that are partially polar *(red)* and partially nonpolar *(blue)*. They have polar groups on the *exterior portion that juts into the aqueous surroundings* and nonpolar groups on *the exterior portion embedded in the membrane*. These nonpolar groups form dispersion forces with the phospholipid tails of the bilayer. Channel proteins also have polar groups lining the aqueous channel.

Figure 13.10 **Intermolecular forces and cell membrane structure.**



Action of Antibiotics A key function of the membrane is to balance internal and external ion concentrations: Na^+ is excluded from the cell, and K^+ is kept inside. Gramicidin A and similar antibiotics act by forming channels in the bacterial membrane through which ions flow (Figure 13.11). Two helical gramicidin A molecules, their nonpolar groups outside and polar groups inside, lie end to end to form a channel through the membrane. The nonpolar outside stabilizes the molecule in the membrane through dispersion forces, and the polar inside passes the ions along using ion-dipole forces, like a "bucket brigade." Over 10^7 ions pass through each of these channels per second, which disrupts the vital ion balance, and the microorganism dies.

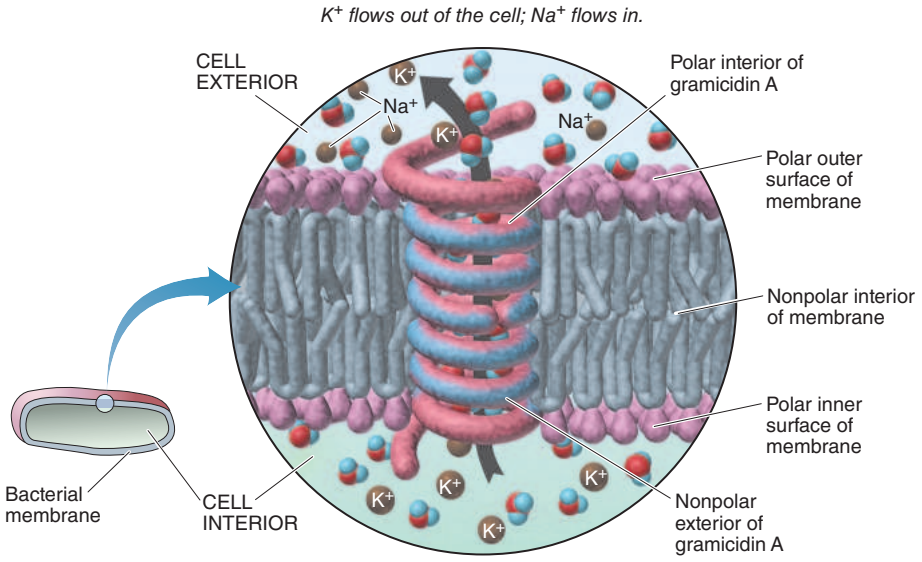


Figure 13.11 The mode of action of the antibiotic gramicidin A. The K^+ ions are shown leaving the cell. At the same time (not shown), Na^+ ions enter the cell.

The Structure of DNA

The chemical information that guides the design and construction, and therefore the function, of all proteins is contained in **nucleic acids,** unbranched polymers made up of monomers called **mononucleotides.** Each mononucleotide consists of an N-containing base, a sugar, and a phosphate group (Figure 13.12). In DNA *(**d**eoxy-ribo**n**ucleic **a**cid),* the sugar is *2-deoxyribose,* in which —H substitutes for —OH on the second C atom of the five-C sugar ribose.

The repeating pattern of the DNA chain is *sugar linked to phosphate linked to sugar linked to phosphate,* and so on. Attached to each sugar is one of four N-containing bases, flat ring structures that dangle off the polynucleotide chain, similar to the way amino-acid side chains dangle off the polypeptide chain.

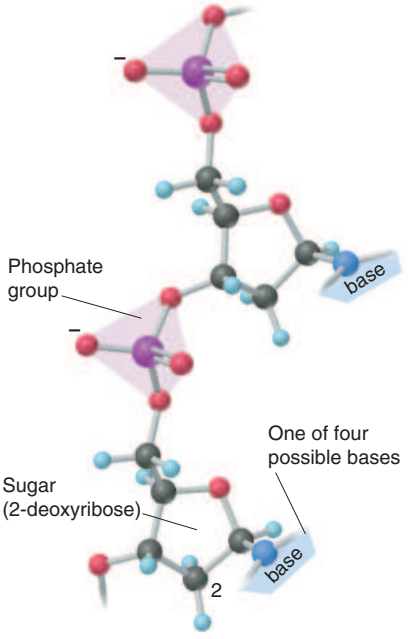

Figure 13.12 A short portion of the polynucleotide chain of DNA.

Intermolecular Forces and the Double Helix DNA exists as two chains wrapped around each other in a **double helix** stabilized by intermolecular forces (Figure 13.13):

- *On the more polar exterior,* negatively charged sugar-phosphate groups interact with the aqueous surroundings via ion-dipole forces and H bonds.
- *In the less polar interior,* flat, N-containing bases stack above each other and interact by dispersion forces.
- *Bases form specific interchain H bonds;* that is, each base in one chain is always H bonded with its complementary base in the other chain. Thus, *the base sequence of one chain is the H-bonded complement of the base sequence of the other.*

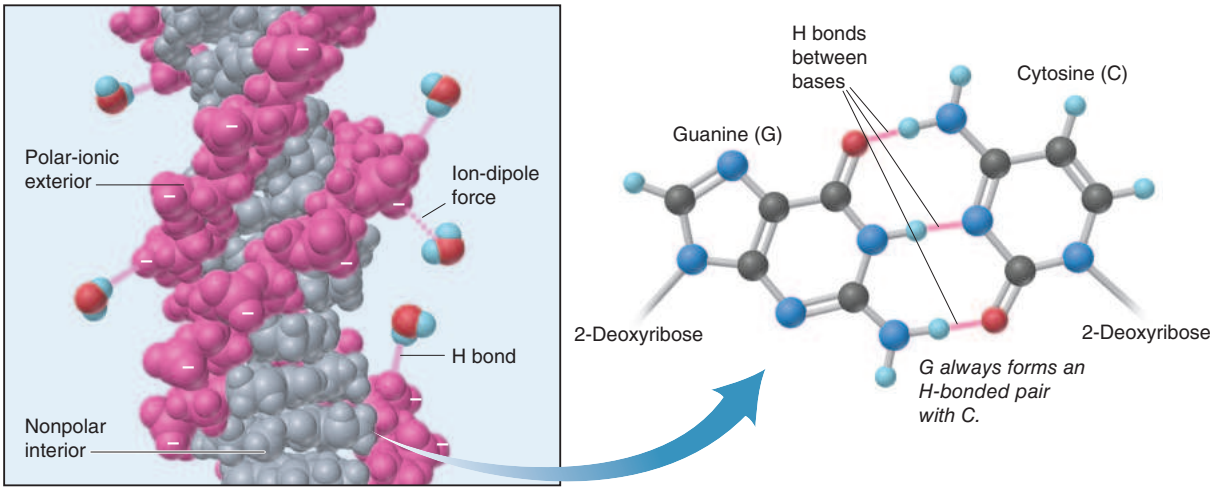

Figure 13.13 The double helix of DNA. A segment of DNA *(left)* has its polar-ionic sugar-phosphate portion *(pink)* facing the water and the nonpolar bases *(gray)* stacking in the interior. The expanded portion *(right)* shows an H-bonded pair of the bases guanine and cytosine.

A DNA molecule contains millions of H bonds linking bases in these prescribed pairs. The *total* energy of the H bonds keeps the chains together, but each H bond is weak enough (around 5% of a typical covalent single bond) that a few at a time can break as the chains separate during crucial cellular processes. (In Chapter 15, we'll see how H-bonded base pairs are essential for protein synthesis and DNA replication.)

Summary of Section 13.2

- In soluble proteins, polar and ionic amino-acid side chains on the exterior interact with surrounding water, and nonpolar side chains in the interior interact with each other.
- With polar-ionic heads *and* nonpolar tails, a soap dissolves grease *and* interacts with water.
- Like soaps, phospholipids have dual polarity. They assemble into a water-impermeable lipid bilayer. In a cell membrane, the embedded portions of membrane proteins have exterior nonpolar side chains that interact with the nonpolar tails in the lipid bilayer through dispersion forces. Some antibiotics form channels with nonpolar exteriors and polar interiors that shuttle ions through the cell membrane.
- DNA forms a double helix with a sugar-phosphate, polar-ionic exterior. In the interior, N-containing bases H bond in specific pairs and stack through dispersion forces.

13.3 WHY SUBSTANCES DISSOLVE: BREAKING DOWN THE SOLUTION PROCESS

The qualitative *macroscopic* rule "like dissolves like" is based on *molecular* interactions between the solute and the solvent. To see *why* like dissolves like, we'll break down the solution process conceptually into steps and examine each of them quantitatively.

The Heat of Solution and Its Components

Before a solution forms, solute particles (ions or molecules) are attracting each other, as are solvent particles (molecules). For one to dissolve in the other, three steps must take place, each accompanied by an enthalpy change:

Step 1. Solute particles separate from each other. This step involves overcoming intermolecular (or ionic) attractions, so it is *endothermic:*

$$\text{Solute (aggregated)} + \textit{heat} \longrightarrow \text{solute (separated)} \qquad \Delta H_{\text{solute}} > 0$$

Step 2. Solvent particles separate from each other. This step also involves overcoming attractions, so it is *endothermic,* too:

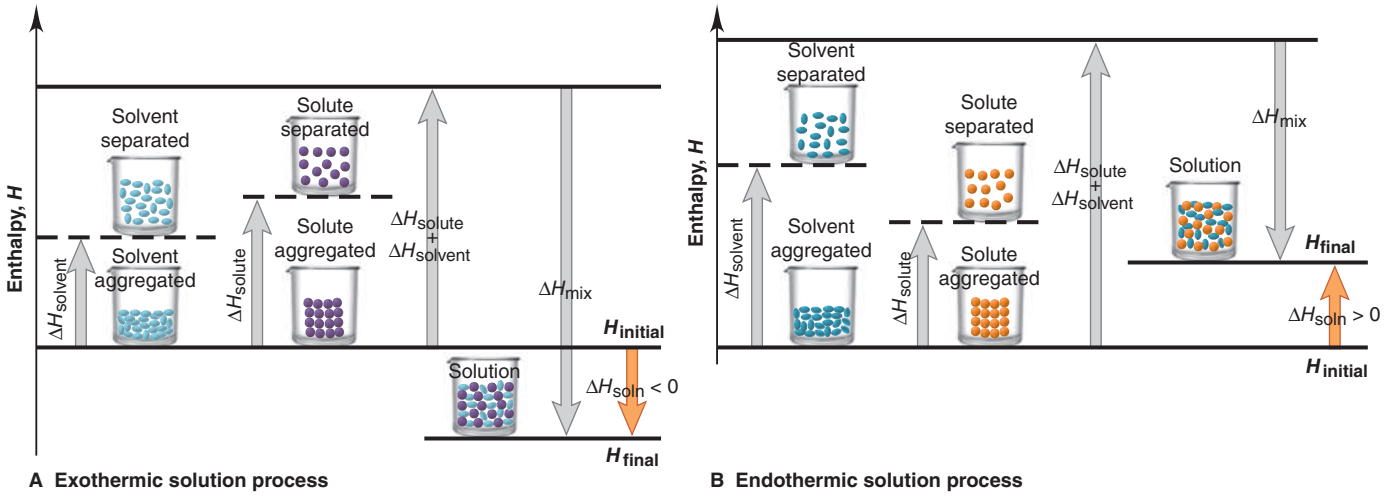
$$\text{Solvent (aggregated)} + \textit{heat} \longrightarrow \text{solvent (separated)} \qquad \Delta H_{\text{solvent}} > 0$$

Step 3. Solute and solvent particles mix and form a solution. The different particles attract each other and come together, so this step is *exothermic:*

$$\text{Solute (separated)} + \text{solvent (separated)} \longrightarrow \text{solution} + \textit{heat} \qquad \Delta H_{\text{mix}} < 0$$

The overall process is called a *thermochemical solution cycle,* and in yet another application of Hess's law, we combine the three individual enthalpy changes to find the **heat** (or enthalpy) **of solution (ΔH_{soln}),** the total enthalpy change that occurs when solute and solvent form a solution:

$$\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{solvent}} + \Delta H_{\text{mix}} \qquad \textbf{(13.1)}$$



A Exothermic solution process **B Endothermic solution process**

Figure 13.14 Enthalpy components of the heat of solution. A, ΔH_{mix} is larger than the sum of ΔH_{solute} and $\Delta H_{solvent}$, so ΔH_{soln} is negative. **B,** ΔH_{mix} is smaller than the sum of ΔH_{solute} and $\Delta H_{solvent}$, so ΔH_{soln} is positive.

Overall solution formation is exothermic or endothermic, and ΔH_{soln} is either negative or positive, depending on the relative sizes of the individual ΔH values:

- *Exothermic process:* $\Delta H_{soln} < 0$. If the sum of the endothermic terms ($\Delta H_{solute} + \Delta H_{solvent}$) is *smaller* than the exothermic term (ΔH_{mix}), the process is exothermic and ΔH_{soln} is negative (Figure 13.14A).
- *Endothermic process:* $\Delta H_{soln} > 0$. If the sum of the endothermic terms is *larger* than the exothermic term, the process is endothermic and ΔH_{soln} is positive (Figure 13.14B). If ΔH_{soln} is highly positive, the solute may not dissolve significantly in that solvent.

The Heat of Hydration: Dissolving Ionic Solids in Water

The $\Delta H_{solvent}$ and ΔH_{mix} components of the solution cycle are difficult to measure individually. Combined, they equal the enthalpy change for **solvation,** the process of surrounding a solute particle with solvent particles:

$$\Delta H_{solvation} = \Delta H_{solvent} + \Delta H_{mix}$$

Solvation in water is called **hydration.** Thus, enthalpy changes for separating the water molecules ($\Delta H_{solvent}$) and mixing the separated solute with them (ΔH_{mix}) are combined into the **heat** (or enthalpy) **of hydration (ΔH_{hydr}).** In water, Equation 13.1 becomes

$$\Delta H_{soln} = \Delta H_{solute} + \Delta H_{hydr}$$

The heat of hydration is a key factor in dissolving an ionic solid. Breaking the H bonds in water is more than compensated for by forming the stronger ion-dipole forces, so hydration of an ion is *always* exothermic. The ΔH_{hydr} of an ion is defined as the enthalpy change for the hydration of 1 mol of separated (gaseous) ions:

$$M^+(g)\ [\text{or } X^-(g)] \xrightarrow{H_2O} M^+(aq)\ [\text{or } X^-(aq)] \qquad \Delta H_{\text{hydr of the ion}}\ (\text{always} < 0)$$

Importance of Charge Density Heats of hydration exhibit trends based on the ion's **charge density,** the ratio of its charge to its volume. In general, the higher the charge density, the more negative ΔH_{hydr} is. Coulomb's law says that the higher the charge of an ion and the smaller its radius, the closer it gets to the oppositely charged pole of an H_2O molecule (see Figure 2.12, p. 62), and the stronger the attraction. Thus,

- A 2+ ion attracts H_2O molecules more strongly than a 1+ ion of similar size.
- A small 1+ ion attracts H_2O molecules more strongly than a large 1+ ion.

Table 13.4 Trends in Ionic Heats of Hydration

Ion	Ionic Radius (pm)	ΔH_{hydr} (kJ/mol)
Group 1A(1)		
Na^+	102	−410
K^+	138	−336
Rb^+	152	−315
Cs^+	167	−282
Group 2A(2)		
Mg^{2+}	72	−1903
Ca^{2+}	100	−1591
Sr^{2+}	118	−1424
Ba^{2+}	135	−1317
Group 7A(17)		
F^-	133	−431
Cl^-	181	−313
Br^-	196	−284
I^-	220	−247

Periodic trends in ΔH_{hydr} values are based on trends in charge density (Table 13.4):

- *Down a group,* the charge stays the same and the size increases; thus, the charge densities decrease, as do the ΔH_{hydr} values.
- *Across a period,* say, from Group 1A(1) to Group 2A(2), the 2A ion has a smaller radius *and* a higher charge, so its charge density and ΔH_{hydr} are greater.

Components of Aqueous Heats of Solution To separate an ionic solute, MX, into gaseous ions requires a lot of energy (ΔH_{solute}); recall from Chapter 9 that this is the lattice energy, and it is highly positive:

$$MX(s) \longrightarrow M^+(g) + X^-(g) \qquad \Delta H_{solute}\ (\text{always} > 0) = \Delta H_{lattice}$$

Thus, for ionic compounds in water, the heat of solution is the lattice energy (always positive) plus the combined heats of hydration of the ions (always negative):

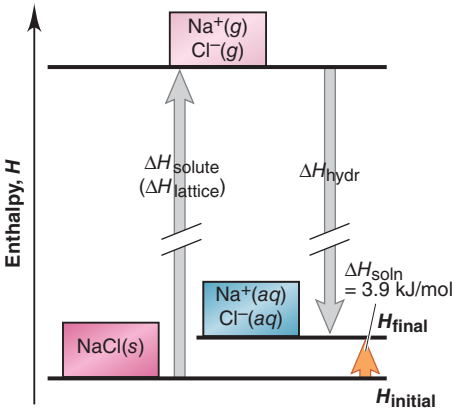
$$\Delta H_{soln} = \Delta H_{lattice} + \Delta H_{hydr\ of\ the\ ions} \qquad (13.2)$$

Once again, the sizes of the individual terms determine the sign of ΔH_{soln}.

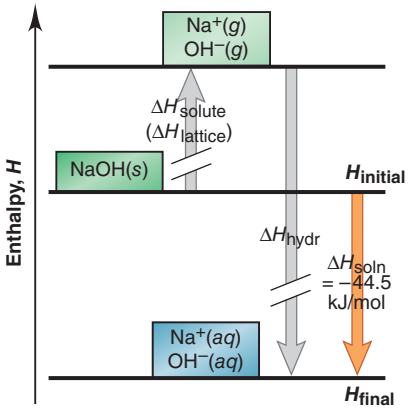
Figure 13.15 shows qualitative enthalpy diagrams for three ionic solutes dissolving in water:

- *NaCl.* Sodium chloride has a small positive ΔH_{soln} (3.9 kJ/mol) because its lattice energy is only slightly greater than the combined ionic heats of hydration: if you dissolve NaCl in water in a flask, you don't feel the small temperature change.
- *NaOH.* Sodium hydroxide has a large negative ΔH_{soln} (−44.5 kJ/mol) because its lattice energy is much *smaller* than the combined ionic heats of hydration: if you dissolve NaOH in water, the flask feels hot.
- *NH_4NO_3.* Ammonium nitrate has a large positive ΔH_{soln} (25.7 kJ/mol) because its lattice energy is much *larger* than the combined ionic heats of hydration: if you dissolve NH_4NO_3 in water, the flask feels cold.

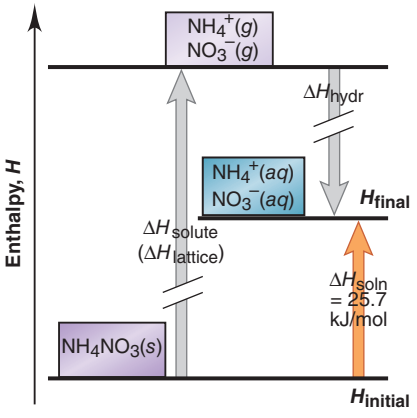
Hot and cold "packs" consist of a thick outer pouch of water and a thin inner pouch of a salt. A squeeze breaks the inner pouch, and the salt dissolves. Most hot packs use anhydrous $CaCl_2$ ($\Delta H_{soln} = -82.8$ kJ/mol). In Japan, some soup is sold in double-walled cans with a salt in a packet immersed in water between the walls. Open the can and the packet breaks, the salt dissolves, and the soup quickly warms to about 90°C. Cold packs use NH_4NO_3 ($\Delta H_{soln} = 25.7$ kJ/mol). A cold pack can keep the solution at 0°C for about half an hour, long enough to soothe a sprain.



A NaCl. *$\Delta H_{lattice}$ is slightly larger than ΔH_{hydr}: ΔH_{soln} is small and positive.*



B NaOH. *ΔH_{hydr} dominates: ΔH_{soln} is large and negative.*



C NH_4NO_3. *$\Delta H_{lattice}$ dominates: ΔH_{soln} is large and positive.*

Figure 13.15 Enthalpy diagrams for three ionic compounds dissolving in water.

SAMPLE PROBLEM 13.2 Calculating an Aqueous Ionic Heat of Solution

Problem With secondary applications ranging from sedative to fire retardant, calcium bromide is used primarily in concentrated solution as an industrial drilling fluid.
(a) Use Table 13.4 and the lattice energy (2132 kJ/mol) to find the heat of solution (kJ/mol) of calcium bromide.
(b) Draw an enthalpy diagram for this solution process.

(a) Calculating the heat of solution of $CaBr_2$.

Plan We are given, or can look up, the individual enthalpy components for a salt dissolving in water and have to determine their signs to calculate the overall heat of solution (ΔH_{soln}). The components are the lattice energy (the heat absorbed when the solid separates into gaseous ions) and the heat of hydration for each ion (the heat released when the ion becomes hydrated). The lattice energy is always positive, so $\Delta H_{lattice} = 2132$ kJ/mol. Heats of hydration are always negative, so from Table 13.4, ΔH_{hydr} of $Ca^{2+} = -1591$ kJ/mol and ΔH_{hydr} of $Br^- = -284$ kJ/mol. We use Equation 13.2, noting that there are 2 mol of Br^-, to obtain ΔH_{soln}.

Solution

$$\begin{aligned}\Delta H_{soln} &= \Delta H_{lattice} + \Delta H_{hydr\ of\ the\ ions}\\ &= \Delta H_{lattice} + \Delta H_{hydr}\ of\ Ca^{2+} + 2(\Delta H_{hydr}\ of\ Br^-)\\ &= 2132\ kJ/mol + (-1591\ kJ/mol) + 2(-284\ kJ/mol)\\ &= \boxed{-27\ kJ/mol}\end{aligned}$$

Check Rounding to check the math gives

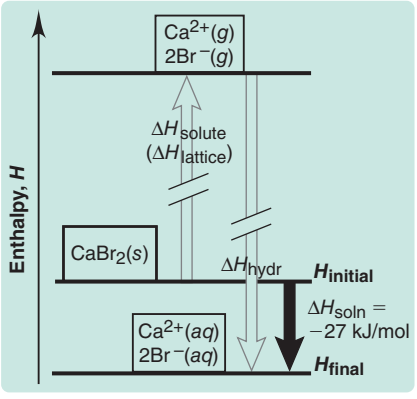
$$2100\ kJ/mol - 1600\ kJ/mol - 560\ kJ/mol = -60\ kJ/mol$$

This small negative sum indicates that our answer is correct.

(b) Drawing an enthalpy diagram for the process of dissolving $CaBr_2$.

Plan Along a vertical enthalpy axis, the lattice energy (endothermic) is represented by an upward arrow leading from solid salt to gaseous ions. The hydration of the ions (exothermic) is represented by a downward arrow from gaseous to hydrated ions. From part (a), ΔH_{soln} is small and negative, so the downward arrowhead is slightly below the tail of the upward arrow.

Solution The enthalpy diagram is shown in the margin.



FOLLOW-UP PROBLEMS

13.2A Use the following data to find the combined heat of hydration for the ions in KNO_3: $\Delta H_{soln} = 34.89$ kJ/mol and $\Delta H_{lattice} = 685$ kJ/mol.
13.2B Use the following data to find the heat of hydration of CN^-: ΔH_{soln} of NaCN = 1.21 kJ/mol, $\Delta H_{lattice}$ of NaCN = 766 kJ/mol, and ΔH_{hydr} of $Na^+ = -410.$ kJ/mol.
SOME SIMILAR PROBLEMS 13.30, 13.31, 13.36, and 13.37

The Solution Process and the Change in Entropy

The heat of solution (ΔH_{soln}) is one of two factors that determine whether a solute dissolves. The other factor is the natural tendency of a system of particles to spread out, which results in the system's kinetic energy becoming more dispersed or more widely distributed. A thermodynamic variable called **entropy (*S*)** is directly related to the number of ways a system can distribute its energy, which involves the freedom of motion of the particles.

Let's see what it means for a system to "distribute its energy." We'll first compare the three physical states and then compare solute and solvent with solution.

Entropy and the Three Physical States The states of matter differ significantly in their entropy.

- In a solid, the particles are fixed in their positions with little freedom of motion. In a liquid, they can move around each other and so have greater freedom of motion. And in a gas, the particles have little restriction and much more freedom of motion.

- The more freedom of motion the particles have, the more ways they can distribute their kinetic energy; thus, a liquid has higher entropy than a solid, and a gas has higher entropy than a liquid:

$$S_{gas} > S_{liquid} > S_{solid}$$

- Thus, there is a *change* in entropy (ΔS) associated with a phase change, and it can be positive or negative. For example, the change in entropy when a liquid vaporizes ($\Delta S_{vap} = S_{gas} - S_{liquid}$) is positive ($\Delta S_{vap} > 0$), the change in entropy when a liquid freezes (fusion) ($\Delta S_{fus} = S_{solid} - S_{liquid}$) is negative ($\Delta S_{fus} < 0$), and so forth.

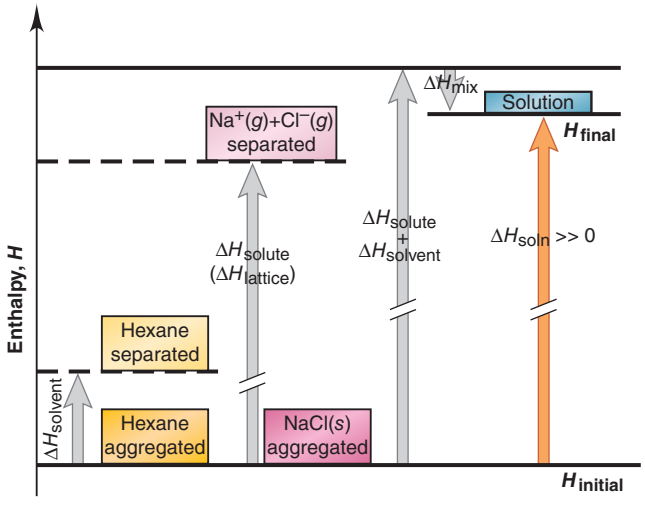
Entropy and the Formation of Solutions The formation of solutions also involves a change in entropy. *A solution usually has higher entropy than the pure solute and pure solvent* because the number of ways to distribute the energy is related to the number of interactions between different molecules. There are far more interactions possible when solute and solvent are mixed than when they are pure; thus,

$$S_{soln} > (S_{solute} + S_{solvent}) \qquad \text{or} \qquad \Delta S_{soln} > 0$$

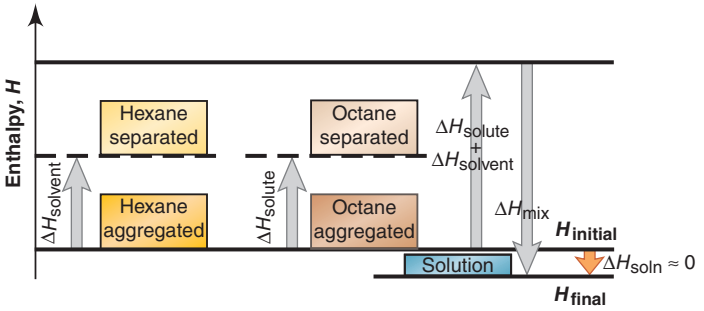
You know from everyday experience that solutions form naturally, but pure solutes and solvents don't: you've seen sugar dissolve in water, but you've never seen a sugar solution separate into pure sugar and water. In Chapter 20, we'll see that energy is needed to reverse the natural tendency of systems to distribute their energy—to get "mixed up." Water treatment plants, oil refineries, steel mills, and many other industrial facilities expend a lot of energy to separate mixtures into pure components.

Enthalpy vs. Entropy Changes in Solution Formation Solution formation involves the interplay of two factors: systems change toward a state of *lower enthalpy* and *higher entropy,* so the relative sizes of ΔH_{soln} and ΔS_{soln} determine whether a solution forms. Let's consider three solute-solvent pairs to see which factor dominates:

1. *NaCl in hexane*. Given their very different intermolecular forces, we predict that sodium chloride does *not* dissolve in hexane (C_6H_{14}). An enthalpy diagram (Figure 13.16A) shows that separating the solvent is easy because the dispersion forces are weak ($\Delta H_{solvent} \geq 0$), but separating the solute requires supplying the very large $\Delta H_{lattice}$ ($\Delta H_{solute} >> 0$). Mixing releases little heat because ion–induced dipole forces between Na^+ (or Cl^-) and hexane are weak ($\Delta H_{mix} \leq 0$). Because the sum of the endothermic terms is *much* larger than the exothermic term, $\Delta H_{soln} >> 0$. *A solution does not form because the entropy increase from mixing solute and solvent would be much smaller than the enthalpy increase required to separate the solute:* $\Delta S_{mix} << \Delta H_{solute}$.



A NaCl. *ΔH_{mix} is **much** smaller than ΔH_{solute}: ΔH_{soln} is so much larger than the entropy increase due to mixing that NaCl does **not** dissolve.*



B Octane. *ΔH_{soln} is very small, but the entropy increase due to mixing is large, so octane **does** dissolve.*

Figure 13.16 **Enthalpy diagrams for dissolving (A) NaCl and (B) octane in hexane.**

2. *Octane in hexane*. We predict that octane (C_8H_{18}) is soluble in hexane because both are held together by dispersion forces of similar strength; in fact, they are miscible. That is, both ΔH_{solute} and $\Delta H_{solvent}$ are around zero. The similar forces mean that ΔH_{mix} is around zero also. And a lot of heat is not released; in fact, ΔH_{soln} is around zero (Figure 13.16B). So why does a solution form so readily? *With no enthalpy change driving the process, octane dissolves in hexane because the entropy increases greatly when the pure substances mix:* $\Delta S_{mix} >> \Delta H_{soln}$.

3. *NH_4NO_3 in water.* A large enough increase in entropy can sometimes cause a solution to form even when the enthalpy increase is large ($\Delta H_{soln} >> 0$). As we saw previously, in Figure 13.15C (p. 530), when ammonium nitrate dissolves in water, the process is highly endothermic; that is, $\Delta H_{lattice} >> \Delta H_{hydr\ of\ the\ ions}$. Nevertheless, *the increase in entropy that occurs when the crystal breaks down and the ions mix with water molecules is greater than the increase in enthalpy:* $\Delta S_{soln} > \Delta H_{soln}$.

In Chapter 20, we'll return in depth to the relation between enthalpy and entropy to understand physical and chemical systems.

Summary of Section 13.3

- In a thermochemical solution cycle, the heat of solution is the sum of the endothermic separations of solute and of solvent and the exothermic mixing of their particles.
- In water, solvation (surrounding solute particles with solvent) is called hydration. For ions, heats of hydration depend on the ion's charge density but are always negative because ion-dipole forces are strong. Charge density exhibits periodic trends.
- Systems naturally increase their entropy (distribute their energy in more ways). A gas has higher entropy than a liquid, which has higher entropy than a solid, and a solution has higher entropy than the pure solute and solvent.
- Relative sizes of the enthalpy and entropy changes determine solution formation. A substance with a positive ΔH_{soln} dissolves *only* if ΔS_{soln} is larger than ΔH_{soln}.

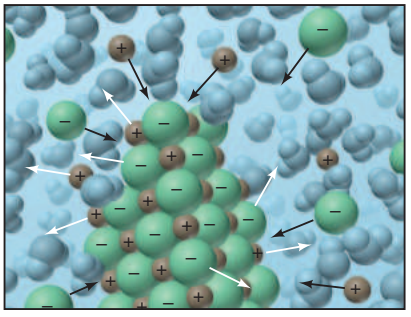


Figure 13.17 Equilibrium in a saturated solution. At some temperature, the number of solute particles dissolving *(white arrows)* per unit time equals the number recrystallizing *(black arrows)*.

13.4 SOLUBILITY AS AN EQUILIBRIUM PROCESS

When an excess amount of solid is added to a solvent, particles leave the crystal, are surrounded by solvent, and move away. Some dissolved solute particles collide with undissolved solute and recrystallize, but, as long as the rate of dissolving is greater than the rate of recrystallizing, the concentration rises. At a given temperature, when solid is dissolving at the same rate as dissolved particles are recrystallizing, the concentration remains constant and *undissolved solute is in equilibrium with dissolved solute:*

$$\text{Solute (undissolved)} \rightleftharpoons \text{solute (dissolved)}$$

Figure 13.17 shows an ionic solid in equilibrium with dissolved cations and anions. (We learned about the concept of equilibrium in Section 4.7 and saw how it occurs between phases in Section 12.2.)

Three terms express the extent of this solution process:

- A **saturated solution** is *at* equilibrium and contains the maximum amount of dissolved solute at a given temperature in the presence of undissolved solute. Therefore, if you filter off the solution and add more solute, it doesn't dissolve.
- An **unsaturated solution** contains *less* than the equilibrium concentration of dissolved solute; add more solute, and more dissolves until the solution is saturated.
- A **supersaturated solution** contains *more* than the equilibrium concentration and is unstable relative to the saturated solution. You can often prepare a supersaturated solution if the solute is more soluble at higher temperature. While heating, dissolve more than the amount required for saturation at some lower temperature, and then slowly cool the solution. If the excess solute remains dissolved, the solution is supersaturated. Add a "seed" crystal of solute or tap the container, and the excess solute crystallizes immediately, leaving behind a saturated solution (Figure 13.18).

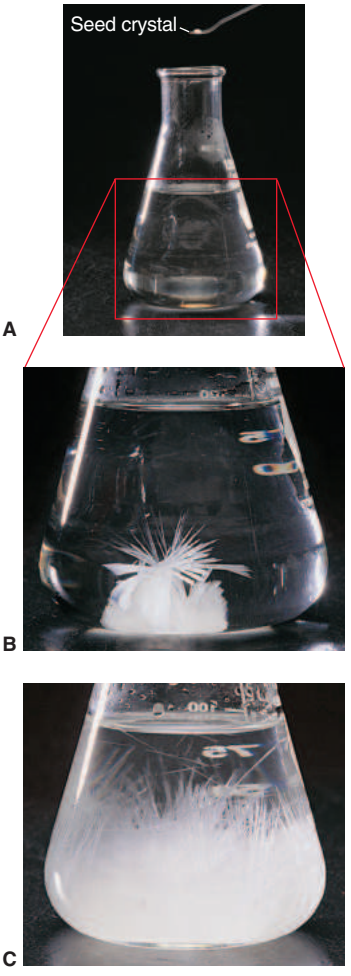

Figure 13.18 Sodium acetate crystallizing from a supersaturated solution. When a seed crystal of sodium acetate is added to a supersaturated solution of it **(A),** solute begins to crystallize **(B)** and continues until the remaining solution is saturated **(C).**

Effect of Temperature on Solubility

You know that more sugar dissolves in hot tea than in iced tea; in fact, temperature affects the solubility of most substances. Let's examine the effects of temperature on the solubility of solids and gases.

Temperature and the Solubility of Solids in Water Like sugar, *most solids are more soluble at higher temperatures* (Figure 13.19). Note that cerium sulfate is one of several exceptions, mostly other sulfates. Some salts have higher solubility up to a certain temperature and then lower solubility at still higher temperatures.

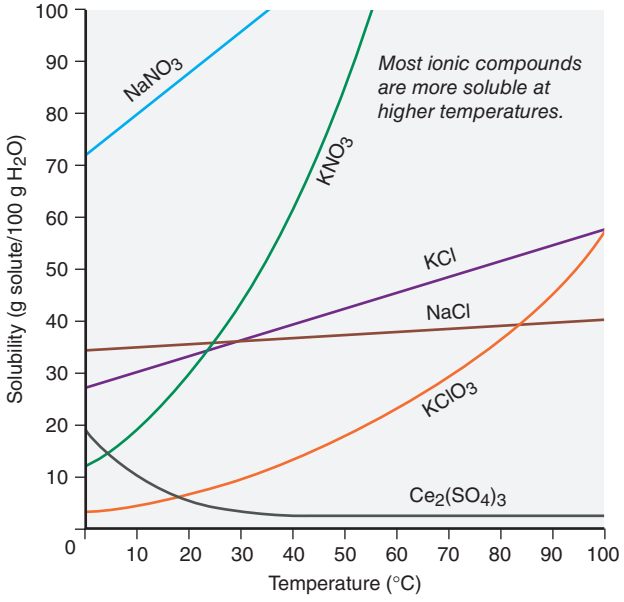

Figure 13.19 Relation between solubility and temperature for several ionic compounds.

The effect of temperature on solubility is a complex phenomenon, and the sign of ΔH_{soln} does not reflect that complexity. Tabulated ΔH_{soln} values give the enthalpy change for making a solution at the standard state of 1 *M*; but in order to understand the effect of temperature, we need to know the sign of the enthalpy change very close to the point of saturation, which may differ from the sign of the tabulated value. For example, tables give a negative ΔH_{soln} for NaOH and a positive one for NH_4NO_3, yet both compounds are more soluble at higher temperatures. Thus, even though the effect of temperature indicates the equilibrium nature of solubility, no single measure can predict the effect for a given solute.

Temperature and the Solubility of Gases in Water The effect of temperature on *gas* solubility is much more predictable. When a solid dissolves in a liquid, the solute particles must separate, so $\Delta H_{solute} > 0$. In contrast, gas particles are already separated, so $\Delta H_{solute} \approx 0$. Because hydration is exothermic ($\Delta H_{hydr} < 0$), the sum of these two terms is negative. Thus, $\Delta H_{soln} < 0$ for all gases in water:

$$\text{Solute}(g) + \text{water}(l) \rightleftharpoons \text{saturated solution}(aq) + \text{heat}$$

Thus, *gas solubility in water* ***decreases*** *with rising temperature (addition of heat).* Gases have weak intermolecular forces with water. When the temperature rises, the average kinetic energy increases, allowing the gas particles to easily overcome these forces and re-enter the gas phase.

This behavior leads to *thermal pollution.* Many electric power plants use large amounts of water from a nearby river or lake for cooling, and the warmed water is

returned to the source. The metabolic rates of fish and other aquatic animals increase in this warmer water, increasing their need for O_2. But the concentration of dissolved O_2 is lower in warm water, so they become "oxygen deprived." Also, the less dense warm water floats and prevents O_2 from reaching the cooler water below. Thus, even creatures at deeper levels become oxygen deprived. Farther from the plant, the water temperature and O_2 solubility return to normal. To mitigate the problem, cooling towers lower the temperature of the water before it exits the plant (Figure 13.20); nuclear power plants use a similar approach (Section 24.7).

Figure 13.20 Preventing thermal pollution with cooling towers.

Effect of Pressure on Solubility

Pressure has little effect on the solubility of liquids and solids because they are almost incompressible. But it has a *major* effect on the solubility of gases. Consider a piston-cylinder assembly with a gas above a saturated aqueous solution of the gas (Figure 13.21A). At equilibrium, at a given pressure, the same number of gas molecules enter and leave the solution per unit time:

$$\text{Gas} + \text{solvent} \rightleftharpoons \text{saturated solution}$$

Push down on the piston, and you disturb the equilibrium: gas volume decreases, so gas pressure (and concentration) increases, and gas particles collide with the liquid surface more often. Thus, more particles enter than leave the solution per unit time (Figure 13.21B). More gas dissolves to reduce this disturbance (a shift to the right in the preceding equation) until the system re-establishes equilibrium (Figure 13.21C).

The relation between gas pressure and solubility has many familiar applications. In a closed can of cola, dissolved CO_2 is in equilibrium with 4 atm of CO_2 in the small volume above the solution. Open the can and the dissolved CO_2 bubbles out of solution until the drink goes "flat" because its CO_2 concentration reaches equilibrium with CO_2 in air ($P_{CO_2} = 4\times10^{-4}$ atm). In a different situation *(see photo),* scuba divers who breathe compressed air have a high concentration of N_2 dissolved in their blood. If they ascend too quickly, they may suffer decompression sickness (the "bends"), in which lower external pressure allows the dissolved N_2 to form bubbles in the blood that block capillaries.

What happens to gases dissolved in the blood of a scuba diver?

Henry's law expresses the quantitative relationship between gas pressure and solubility: *the solubility of a gas (S_{gas}) is directly proportional to the partial pressure of the gas (P_{gas}) above the solution:*

$$S_{gas} = k_H \times P_{gas} \qquad \textbf{(13.3)}$$

where k_H is the *Henry's law constant* and is specific for a given gas-solvent combination at a given temperature. With S_{gas} in mol/L and P_{gas} in atm, the units of k_H are mol/L·atm, or mol·L^{-1}·atm^{-1}.

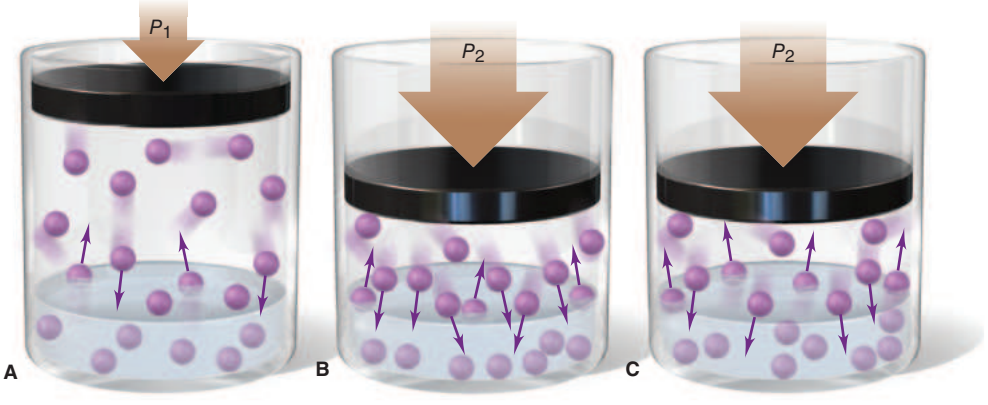

Figure 13.21 The effect of pressure on gas solubility.

SAMPLE PROBLEM 13.3 Using Henry's Law to Calculate Gas Solubility

Problem The partial pressure of carbon dioxide gas inside a bottle of cola is 4 atm at 25°C. What is the solubility of CO_2? The Henry's law constant for CO_2 in water is 3.3×10^{-2} mol/L·atm at 25°C.

Plan We know P_{CO_2} (4 atm) and the value of k_H (3.3×10^{-2} mol/L·atm), so we substitute them into Equation 13.3 to find S_{CO_2}.

Solution $S_{CO_2} = k_H \times P_{CO_2} = (3.3\times10^{-2}\ \text{mol/L·atm})(4\ \text{atm}) =$ 0.1 mol/L

Check The units are correct. We rounded to one significant figure to match the number in the pressure value. A 0.5-L bottle of cola has about 2 g (0.05 mol) of dissolved CO_2.

FOLLOW-UP PROBLEMS

13.3A If air contains 78% N_2 by volume, what is the solubility of N_2 in water at 25°C and 1 atm (k_H for N_2 in H_2O at 25°C $= 7\times10^{-4}$ mol/L·atm)?

13.3B Dinitrogen monoxide (N_2O), commonly known as *laughing gas,* is mixed with oxygen for use as an analgesic during dental surgery. If a mixture of N_2O and O_2 is 40.% N_2O by volume and has a total pressure of 1.2 atm, what is the solubility (mol/L) of N_2O in water at 25°C (k_H for N_2O in H_2O at 25°C is 2.5×10^{-2} mol/L·atm)?

SOME SIMILAR PROBLEMS 13.46 and 13.47

Summary of Section 13.4

- A solution that contains the maximum amount of dissolved solute in the presence of excess undissolved solute is saturated. A saturated solution is in equilibrium with excess solute, because solute particles are entering and leaving the solution at the same rate. An unsaturated solution contains less than this amount.
- Most solids are more soluble at higher temperatures.
- All gases have a negative ΔH_{soln} in water, so heating lowers gas solubility in water.
- Henry's law says that the solubility of a gas is directly proportional to its partial pressure above the solution.

13.5 CONCENTRATION TERMS

Concentration is the *proportion* of a substance in a mixture, so it is an *intensive* property (like density and temperature), one that does not depend on the quantity of mixture: 1.0 L or 1.0 mL of 0.1 *M* NaCl have the same concentration. Concentration is a ratio of quantities (Table 13.5), most often solute to *solution,* but sometimes solute to *solvent.* Both parts of the ratio can be given in units of mass, volume, or amount (mol), and chemists express concentration by several terms, including molarity, molality, and various expressions of "parts of solute per part by solution."

Table 13.5 Concentration Definitions

Concentration Term	Ratio
Molarity (*M*)	$\dfrac{\text{amount (mol) of solute}}{\text{volume (L) of solution}}$
Molality (*m*)	$\dfrac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}}$
Parts by mass	$\dfrac{\text{mass of solute}}{\text{mass of solution}}$
Parts by volume	$\dfrac{\text{volume of solute}}{\text{volume of solution}}$
Mole fraction (*X*)	$\dfrac{\text{amount (mol) of solute}}{\text{amount (mol) of solute + amount (mol) of solvent}}$

Molarity and Molality

Two very common concentration terms are molarity and molality:

1. Molarity (M) is the *number of moles of solute dissolved in 1 L of solution:*

$$\text{Molarity } (M) = \frac{\text{amount (mol) of solute}}{\text{volume (L) of solution}} \qquad \textbf{(13.4)}$$

In Chapter 4, we used molarity to convert liters of solution into amount of dissolved solute. Molarity has two drawbacks that affect its use in precise work:

- *Effect of temperature*. A liquid expands when heated, so a unit volume of hot solution contains less solute than one of cold solution; thus, the molarity is different.
- *Effect of mixing*. Because of solute-solvent interactions that are difficult to predict, *volumes may not be additive:* adding 500. mL of one solution to 500. mL of another may not give 1000. mL of final solution.

2. **Molality (*m*)** does not contain volume in its ratio; it is *the number of moles of solute dissolved in 1000 g (1 kg) of solvent:*

$$\text{Molality } (m) = \frac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}} \qquad \textbf{(13.5)}$$

Note that molality includes the quantity of *solvent,* not solution. For precise work, molality has two advantages over molarity:

- *Effect of temperature*. Molal solutions are based on *masses* of components, not *volume*. Since mass does not change with temperature, neither does molality.
- *Effect of mixing*. Unlike volumes, masses *are* additive: adding 500. g of one solution to 500. g of another *does* give 1000. g of final solution.

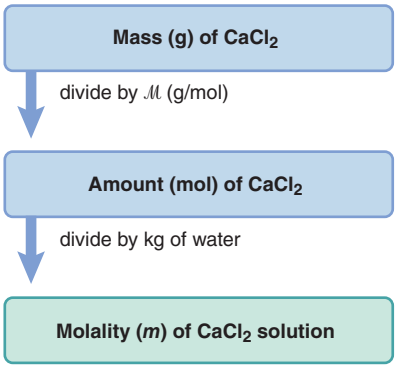
For these reasons, molality is the preferred term when temperature, and hence density, may change, as in a study of physical properties. Note that, in the case of water, 1 L has a mass of 1 kg, so *molality and molarity are nearly the same for dilute aqueous solutions.*

SAMPLE PROBLEM 13.4 Calculating Molality

Problem What is the molality of a solution prepared by dissolving 32.0 g of $CaCl_2$ in 271 g of water?

Plan To use Equation 13.5, we convert the mass of $CaCl_2$ (32.0 g) to amount (mol) using the molar mass (g/mol) and then divide by the mass of water (271 g), being sure to convert from grams to kilograms (see the road map).

Road Map



Solution Converting from grams of solute to moles:

$$\text{Amount (mol) of } CaCl_2 = 32.0 \text{ g } CaCl_2 \times \frac{1 \text{ mol } CaCl_2}{110.98 \text{ g } CaCl_2} = 0.288 \text{ mol } CaCl_2$$

Finding molality:

$$\text{Molality} = \frac{\text{mol solute}}{\text{kg solvent}} = \frac{0.288 \text{ mol } CaCl_2}{271 \text{ g} \times \dfrac{1 \text{ kg}}{10^3 \text{ g}}}$$

$$= 1.06\ m\ CaCl_2$$

Check The answer seems reasonable: the given amount (mol) of $CaCl_2$ and mass (kg) of H_2O are about the same, so their ratio is about 1.

FOLLOW-UP PROBLEMS

13.4A How many grams of glucose ($C_6H_{12}O_6$) must be dissolved in 563 g of ethanol (C_2H_5OH) to prepare a 2.40×10^{-2} m solution?

13.4B What is the molality of a solution made by dissolving 15.20 g of I_2 in 1.33 mol of diethyl ether, $(CH_3CH_2)_2O$?

SOME SIMILAR PROBLEMS 13.64 and 13.65

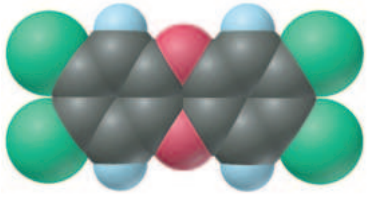
Parts of Solute by Parts of Solution

Several concentration terms relate the parts of solute (or solvent) to the parts of *solution*. Both can be expressed in units of mass, volume, or amount (mol).

Parts by Mass The most common of these terms is **mass percent, % (w/w),** which you encountered in Chapter 3. The word *percent* means "per hundred," so mass percent means mass of solute dissolved in 100. parts by mass of solution:

$$\text{Mass percent} = \frac{\text{mass of solute}}{\text{mass of solute} + \text{mass of solvent}} \times 100 = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100 \qquad (13.6)$$

Mass percent values appear commonly on jars of solid laboratory chemicals to indicate impurities.



Is this deadly toxin in your body?

Two very similar terms are parts per million (ppm) by mass and parts per billion (ppb) by mass, or grams of solute per million or per billion grams of solution: in Equation 13.6, you multiply by 10^6 or by 10^9, respectively, instead of by 100, to obtain these much smaller concentrations. Environmental toxicologists use these units to measure pollutants. For example, TCDD (*t*etrachloro*d*ibenzo*d*ioxin) *(see margin),* a byproduct of paper bleaching, is unsafe at soil levels above 1 ppb. From normal contact with air, water, and soil, North Americans have an average of 0.01 ppb TCDD in their tissues.

Parts by Volume The most common parts-by-volume term is **volume percent, % (v/v),** the volume of solute in 100. volumes of solution:

$$\text{Volume percent} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100 \qquad (13.7)$$

For example, rubbing alcohol is an aqueous solution of isopropanol (a three-carbon alcohol) that contains 70 volumes of alcohol in 100. volumes of solution, or 70% (v/v).

Parts by volume is often used to express tiny concentrations of liquids or gases. Minor atmospheric components occur in parts per million by volume (ppmv). For example, about 0.05 ppmv of the toxic gas carbon monoxide (CO) is in clean air, 1000 times as much (50 ppmv of CO) in air over urban traffic, and 10,000 times as much (500 ppmv of CO) in cigarette smoke. *Pheromones* are compounds secreted by members of a species to signal food, danger, sexual readiness, and so forth. Many organisms, including dogs and monkeys, release pheromones, and researchers suspect that humans do as well. Some insect pheromones, such as the sexual attractant of the gypsy moth, are active at a few hundred molecules per milliliter of air, 100 parts per quadrillion by volume.

A concentration term often used in health-related facilities for aqueous solutions is % (w/v), a ratio of solute *weight* (actually mass) to solution *volume.* Thus, a 1.5% (w/v) NaCl solution contains 1.5 g of NaCl per 100. mL of *solution.*

Parts by Mole: Mole Fraction The **mole fraction (*X*)** of a solute is the ratio of the number of moles of solute to the total number of moles (solute plus solvent):

$$\text{Mole fraction } (X) = \frac{\text{amount (mol) of solute}}{\text{amount (mol) of solute} + \text{amount (mol) of solvent}} \qquad (13.8)$$

Put another way, the mole fraction gives the proportion of solute (or solvent) particles in solution. The *mole percent* is the mole fraction expressed as a percentage:

$$\text{Mole percent (mol \%)} = \text{mole fraction} \times 100$$

SAMPLE PROBLEM 13.5 Expressing Concentrations in Parts by Mass, Parts by Volume, and Mole Fraction

Problem **(a)** Find the concentration of calcium ion (in ppm) in a 3.50-g pill that contains 40.5 mg of Ca^{2+}.
(b) The label on a 0.750-L bottle of Italian chianti says "11.5% alcohol by volume." How many liters of alcohol does the wine contain?
(c) A sample of rubbing alcohol contains 142 g of isopropyl alcohol (C_3H_7OH) and 58.0 g of water. What are the mole fractions of alcohol and water?

Plan **(a)** We know the mass of Ca^{2+} (40.5 mg) and the mass of the pill (3.50 g). We convert the mass of Ca^{2+} from mg to g, find the mass ratio of Ca^{2+} to pill, and multiply by 10^6 to obtain ppm. **(b)** We know the volume % (11.5%, or 11.5 parts by volume of alcohol to 100. parts of chianti) and the total volume (0.750 L), so we use Equation 13.7 to find liters of alcohol. **(c)** We know the mass and formula of each component, so we convert masses to amounts (mol) and apply Equation 13.8 to find the mole fractions.

Solution **(a)** Finding parts per million by mass of Ca^{2+}. Combining the steps, we have

$$\text{ppm } Ca^{2+} = \frac{\text{mass of } Ca^{2+}}{\text{mass of pill}} \times 10^6 = \frac{40.5 \text{ mg } Ca^{2+} \times \dfrac{1 \text{ g}}{10^3 \text{ mg}}}{3.50 \text{ g}} \times 10^6$$

$$= 1.16 \times 10^4 \text{ ppm } Ca^{2+}$$

(b) Finding volume (L) of alcohol:

$$\text{Volume (L) of alcohol} = 0.750 \text{ L chianti} \times \frac{11.5 \text{ L alcohol}}{100. \text{ L chianti}}$$

$$= 0.0862 \text{ L}$$

(c) Finding mole fractions. Converting from mass (g) to amount (mol):

$$\text{Amount (mol) of } C_3H_7OH = 142 \text{ g } C_3H_7OH \times \frac{1 \text{ mol } C_3H_7OH}{60.09 \text{ g } C_3H_7OH} = 2.36 \text{ mol } C_3H_7OH$$

$$\text{Amount (mol) of } H_2O = 58.0 \text{ g } H_2O \times \frac{1 \text{ mol } H_2O}{18.02 \text{ g } H_2O} = 3.22 \text{ mol } H_2O$$

Calculating mole fractions:

$$X_{C_3H_7OH} = \frac{\text{moles of } C_3H_7OH}{\text{total moles}} = \frac{2.36 \text{ mol}}{2.36 \text{ mol} + 3.22 \text{ mol}}$$

$$= 0.423$$

$$X_{H_2O} = \frac{\text{moles of } H_2O}{\text{total moles}} = \frac{3.22 \text{ mol}}{2.36 \text{ mol} + 3.22 \text{ mol}}$$

$$= 0.577$$

Check **(a)** The mass ratio is about 0.04 g/4 g = 10^{-2}, and $10^{-2} \times 10^6 = 10^4$ ppm, so it seems correct. **(b)** The volume % is a bit more than 10%, so the volume of alcohol should be a bit more than 75 mL (0.075 L). **(c)** Always check that the *mole fractions add up to 1:* 0.423 + 0.577 = 1.000.

FOLLOW-UP PROBLEMS

13.5A An alcohol solution contains 35.0 g of 1-propanol (C_3H_7OH) and 150. g of ethanol (C_2H_5OH). Calculate the mass percent and the mole fraction of each alcohol.

13.5B A sample of gasoline contains 1.87 g of ethanol (C_2H_5OH), 27.4 g of 2,2,4-trimethylpentane (iso-octane, C_8H_{18}), and 4.10 g of heptane (C_7H_{16}). Calculate the mass percent and the mole percent of each component.

SOME SIMILAR PROBLEMS 13.70 and 13.71

Interconverting Concentration Terms

All the terms we just discussed represent different ways of expressing concentration, so they are interconvertible. Keep these points in mind:

- To convert a term based on amount to one based on mass, you need the molar mass. These conversions are similar to the mass-mole conversions you've done earlier.
- To convert a term based on mass to one based on volume, you need the solution *density*. Given the mass of solution, the density (mass/volume) gives the volume, or vice versa.
- Molality includes quantity of *solvent;* the other terms include quantity of *solution.*

SAMPLE PROBLEM 13.6 Interconverting Concentration Terms

Problem Hydrogen peroxide is a powerful oxidizing agent; it is used in concentrated solution in rocket fuel and in dilute solution in hair bleach. An aqueous solution of H_2O_2 is 30.0% by mass and has a density of 1.11 g/mL. Calculate the **(a)** molality, **(b)** mole fraction of H_2O_2, and **(c)** molarity.

Plan We know the mass % (30.0) and the density (1.11 g/mL). **(a)** For molality, we need the amount (mol) of solute and the mass (kg) of *solvent.* If we assume 100.0 g of solution, the mass % equals the grams of H_2O_2, which we subtract to obtain the grams of solvent. To find molality, we convert grams of H_2O_2 to moles and divide by mass of solvent (converting g to kg). **(b)** To find the mole fraction, we use the moles of H_2O_2 [from part (a)] and convert the grams of H_2O to moles. Then we divide the moles of H_2O_2 by the total moles. **(c)** To find molarity, we assume 100.0 g of solution and use the solution density to find the volume. Then we divide the moles of H_2O_2 [from part (a)] by *solution* volume (in L).

Solution **(a)** From mass % to molality. Finding mass of solvent (assuming 100.0 g of solution):

$$\text{Mass (g) of } H_2O = 100.0 \text{ g solution} - 30.0 \text{ g } H_2O_2 = 70.0 \text{ g } H_2O$$

Converting from grams of H_2O_2 to moles:

$$\text{Amount (mol) of } H_2O_2 = 30.0 \text{ g } H_2O_2 \times \frac{1 \text{ mol } H_2O_2}{34.02 \text{ g } H_2O_2} = 0.882 \text{ mol } H_2O_2$$

Calculating molality:

$$\text{Molality of } H_2O_2 = \frac{0.882 \text{ mol } H_2O_2}{70.0 \text{ g} \times \dfrac{1 \text{ kg}}{10^3 \text{ g}}} = \boxed{12.6\ m\ H_2O_2}$$

(b) From mass % to mole fraction:

$$\text{Amount (mol) of } H_2O_2 = 0.882 \text{ mol } H_2O_2 \text{ [from part (a)]}$$

$$\text{Amount (mol) of } H_2O = 70.0 \text{ g } H_2O \times \frac{1 \text{ mol } H_2O}{18.02 \text{ g } H_2O} = 3.88 \text{ mol } H_2O$$

$$X_{H_2O_2} = \frac{0.882 \text{ mol}}{0.882 \text{ mol} + 3.88 \text{ mol}} = \boxed{0.185}$$

(c) From mass % and density to molarity. Converting from solution mass to volume:

$$\text{Volume (mL) of solution} = 100.0 \text{ g} \times \frac{1 \text{ mL}}{1.11 \text{ g}} = 90.1 \text{ mL}$$

Calculating molarity:

$$\text{Molarity} = \frac{\text{mol } H_2O_2}{\text{L soln}} = \frac{0.882 \text{ mol } H_2O_2}{90.1 \text{ mL} \times \dfrac{1 \text{ L soln}}{10^3 \text{ mL}}} = \boxed{9.79\ M\ H_2O_2}$$

Check Rounding shows the sizes of the answers to be reasonable: **(a)** The ratio of ~0.9 mol/0.07 kg is greater than 10. **(b)** ~0.9 mol H_2O_2/(1 mol + 4 mol) ≈ 0.2. **(c)** The ratio of moles to liters (0.9/0.09) is around 10.

FOLLOW-UP PROBLEMS

13.6A Concentrated hydrochloric acid is 11.8 *M* HCl and has a density of 1.190 g/mL. Calculate the mass %, molality, and mole fraction of HCl.

13.6B Concentrated aqueous solutions of calcium bromide are used in drilling oil wells. If a solution is 52.1% $CaBr_2$ by mass and has a density of 1.70 g/mL, find the molality, molarity, and mole percent of $CaBr_2$.

SOME SIMILAR PROBLEMS 13.72–13.75

Summary of Section 13.5

- The concentration of a solution is independent of the quantity of solution and can be expressed as molarity (mol solute/L solution), molality (mol solute/kg solvent), parts by mass (mass solute/mass solution), parts by volume (volume solute/volume solution), or mole fraction [mol solute/(mol solute + mol solvent)] (Table 13.5).
- Molality is based on mass, so it is independent of temperature; the mole fraction gives the proportion of dissolved particles.
- If the quantities of solute and solution as well as the solution density are known, the various ways of expressing concentration are interconvertible.

13.6 COLLIGATIVE PROPERTIES OF SOLUTIONS

The presence of solute gives a solution different physical properties than the pure solvent. But, in the case of four important properties, it is the *number* of solute particles, *not* their chemical identity, that makes the difference. These **colligative properties** (*colligative* means "collective") are vapor pressure lowering, boiling point elevation, freezing point depression, and osmotic pressure. Most of the effects are small, but they have many applications, including some that are vital to organisms.

We predict the magnitude of a colligative property from the solute formula, which shows the number of particles in solution and is closely related to our classification of solutes (Chapter 4) by their ability to conduct an electric current (Figure 13.22):

1. *Electrolytes.* An aqueous solution of an **electrolyte** conducts a current because the solute separates into ions as it dissolves.
   - *Strong electrolytes*—soluble salts, strong acids, and strong bases—dissociate completely, so their solutions conduct well.
   - *Weak electrolytes*—weak acids and weak bases—dissociate very little, so their solutions conduct poorly.
2. *Nonelectrolytes.* Compounds such as sugar and alcohol do not dissociate into ions at all. They are **nonelectrolytes** because their solutions do not conduct a current.

Thus we can predict that

- *For nonelectrolytes,* 1 mol of compound yields 1 mol of particles when it dissolves in solution. For example, 0.35 *M* glucose contains 0.35 mol of solute particles per liter.
- *For strong electrolytes,* 1 mol of compound dissolves to yield the amount (mol) of ions shown in the formula unit: 0.4 *M* Na_2SO_4 has 0.8 mol of Na^+ ions and 0.4 mol of SO_4^{2-} ions, or 1.2 mol of particles, per liter (see Sample Problem 4.1, p. 142).
- *For weak electrolytes,* the calculation is complicated because the solution reaches equilibrium; we examine these systems in Chapters 18 and 19.

In this section, we discuss colligative properties of three types of solute—nonvolatile nonelectrolytes, volatile nonelectrolytes, and strong electrolytes.

A Strong electrolyte

B Weak electrolyte

C Nonelectrolyte

Figure 13.22 Conductivity of three types of electrolyte solutions. A, For strong electrolytes, the number of particles equals the number of ions in a formula unit. **B,** Weak electrolytes form few ions. **C,** For nonelectrolytes, the number of particles equals the number of molecules.

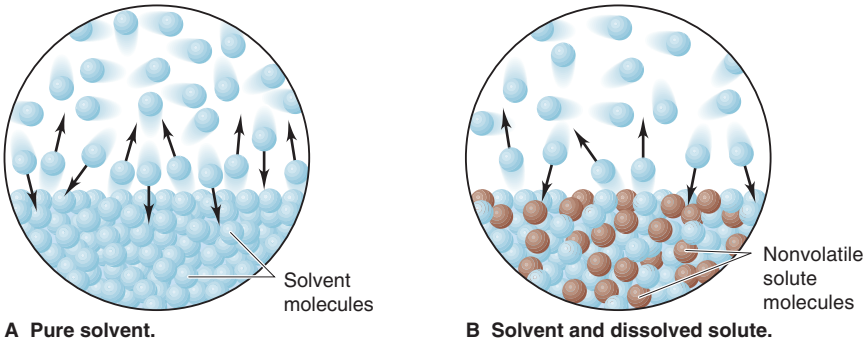
Nonvolatile Nonelectrolyte Solutions

We start with solutions of *nonvolatile nonelectrolytes,* because they provide the clearest examples of the colligative properties. These solutions contain solutes that are not ionic and thus do not dissociate, and they have negligible vapor pressure at the boiling point of the solvent; sucrose (table sugar) dissolved in water is an example.

Vapor Pressure Lowering *The vapor pressure of a nonvolatile nonelectrolyte solution is always lower than the vapor pressure of the pure solvent.* The difference in vapor pressures is the **vapor pressure lowering (ΔP).**

1. *Why the vapor pressure of a solution is lower*. The fundamental reason for this lowering involves entropy, specifically the relative changes in entropies of vaporization of solvent versus solution. A liquid vaporizes because a gas has higher entropy. In a closed container, vaporization continues until the numbers of particles leaving and entering the liquid phase per unit time are equal, that is, when the system reaches equilibrium. But, as we said, the entropy of a solution is already higher than that of a pure solvent, so fewer solvent particles need to vaporize to reach the same entropy. With fewer particles in the gas phase, the vapor above a solution has lower pressure (Figure 13.23).

Figure 13.23 **Effect of solute on the vapor pressure of solution.**



A Pure solvent. *Equilibrium between a liquid and its vapor occurs when equal numbers of molecules vaporize and condense in a given time.*

B Solvent and dissolved solute. *Solute molecules increase the entropy, so equilibrium occurs at a lower vapor pressure.*

2. *Quantifying vapor pressure lowering*. **Raoult's law** says that the vapor pressure of solvent above a solution ($P_{solvent}$) equals the mole fraction of solvent ($X_{solvent}$) times the vapor pressure of the pure solvent ($P^\circ_{solvent}$):

$$P_{solvent} = X_{solvent} \times P^\circ_{solvent} \qquad (13.9)$$

Since $X_{solvent}$ is less than 1 in a solution, $P_{solvent}$ is less than $P^\circ_{solvent}$. An **ideal solution** is one that follows Raoult's law at any concentration. However, just as real gases deviate from ideality, so do real solutions. In practice, Raoult's law works reasonably well for *dilute* solutions and becomes exact at infinite dilution.

Let's see how the *amount* of dissolved solute affects ΔP. The solution consists of solvent and solute, so the sum of their mole fractions equals 1:

$$X_{solvent} + X_{solute} = 1; \quad \text{thus,} \quad X_{solvent} = 1 - X_{solute}$$

From Raoult's law, we have

$$P_{solvent} = X_{solvent} \times P^\circ_{solvent} = (1 - X_{solute}) \times P^\circ_{solvent}$$

Multiplying through on the right side gives

$$P_{solvent} = P^\circ_{solvent} - (X_{solute} \times P^\circ_{solvent})$$

Rearranging and introducing ΔP gives

$$P^\circ_{solvent} - P_{solvent} = \Delta P = X_{solute} \times P^\circ_{solvent} \qquad (13.10)$$

Thus, ΔP equals the mole fraction of solute times the vapor pressure of the pure solvent—a relationship applied in the next sample problem.

SAMPLE PROBLEM 13.7 Using Raoult's Law to Find ΔP

Problem Find the vapor pressure lowering, ΔP, when 10.0 mL of glycerol ($C_3H_8O_3$) is added to 500. mL of water at 50.°C. At this temperature, the vapor pressure of pure water is 92.5 torr and its density is 0.988 g/mL. The density of glycerol is 1.26 g/mL.

Plan To calculate ΔP, we use Equation 13.10. We are given the vapor pressure of pure water ($P^\circ_{H_2O} = 92.5$ torr), so we just need the mole fraction of glycerol, $X_{glycerol}$. We convert the given volume of glycerol (10.0 mL) to mass using the given density (1.26 g/L), find the molar mass from the formula, and convert mass (g) to amount (mol). The same procedure gives amount of H_2O. From these amounts, we find $X_{glycerol}$ and ΔP.

Solution Calculating the amount (mol) of glycerol and of water:

$$\text{Amount (mol) of glycerol} = 10.0 \text{ mL glycerol} \times \frac{1.26 \text{ g glycerol}}{1 \text{ mL glycerol}} \times \frac{1 \text{ mol glycerol}}{92.09 \text{ g glycerol}}$$

$$= 0.137 \text{ mol glycerol}$$

$$\text{Amount (mol) of } H_2O = 500. \text{ mL } H_2O \times \frac{0.988 \text{ g } H_2O}{1 \text{ mL } H_2O} \times \frac{1 \text{ mol } H_2O}{18.02 \text{ g } H_2O}$$

$$= 27.4 \text{ mol } H_2O$$

Calculating the mole fraction of glycerol:

$$X_{glycerol} = \frac{0.137 \text{ mol}}{0.137 \text{ mol} + 27.4 \text{ mol}} = 0.00498$$

Finding the vapor pressure lowering:

$$\Delta P = X_{glycerol} \times P^\circ_{H_2O} = 0.00498 \times 92.5 \text{ torr} = \boxed{0.461 \text{ torr}}$$

Check The amount of each component seems correct: for glycerol, ~10 mL × 1.25 g/mL ÷ 100 g/mol = 0.125 mol; for H_2O, ~500 mL × 1 g/mL ÷ 20 g/mol = 25 mol. The small ΔP is reasonable because the mole fraction of solute is small.

Comment **1.** The calculation assumes that glycerol is nonvolatile. At 1 atm, glycerol boils at 290.0°C, so the vapor pressure of glycerol at 50°C is negligible.
2. We have assumed the solution is close to ideal and that Raoult's law holds.

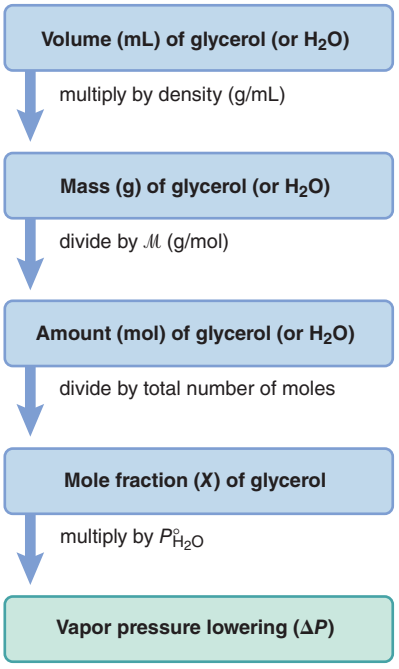
FOLLOW-UP PROBLEMS

13.7A Calculate the vapor pressure lowering of a solution of 2.00 g of aspirin ($\mathcal{M} = 180.15$ g/mol) in 50.0 g of methanol (CH_3OH) at 21.2°C. Methanol has a vapor pressure of 101 torr at this temperature.

13.7B Because menthol ($C_{10}H_{20}O$) has a minty taste and soothes throat soreness, it is added to many medicinal products. Find the vapor pressure lowering (in torr) of a solution that contains 6.49 g of menthol in 25.0 g of ethanol (C_2H_5OH) at 22°C. Ethanol has a vapor pressure of 6.87 kPa at this temperature (101.325 kPa = 1 atm).

SOME SIMILAR PROBLEMS 13.96 and 13.97

Road Map



Boiling Point Elevation *A solution boils at a higher temperature than the pure solvent.* This colligative property results from the vapor pressure lowering:

1. *Why a solution boils at a higher T.* Recall that the boiling point, T_b, of a liquid is the temperature at which its vapor pressure equals the external pressure, P_{ext}. But, the vapor pressure of a solution is always lower than that of the pure solvent. Therefore, it is lower than P_{ext} at T_b of the solvent, so the solution doesn't boil. Thus, the **boiling point elevation (ΔT_b)** results because a higher temperature is needed to raise the solution's vapor pressure to equal P_{ext}.

We superimpose a phase diagram for the solution on one for the solvent to see ΔT_b (Figure 13.24, *next page*): the gas-liquid line for the solution lies *below* the line for the solvent at any T and to the right of it at any P, and the line crosses 1 atm (P_{ext}, or P_{atm}) at a higher T.

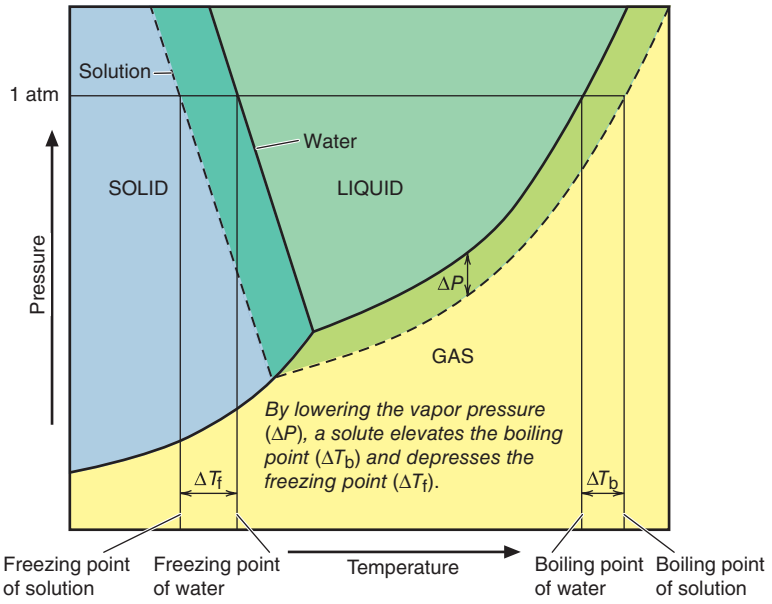


Figure 13.24 Boiling and freezing points of solvent and solution. Phase diagrams of an aqueous solution *(dashed lines)* and of pure water *(solid lines)*. (The slope of the solid-liquid line and the size of ΔP are exaggerated.)

2. *Quantifying boiling point elevation*. Like vapor pressure lowering, boiling point elevation is proportional to the concentration of solute:

$$\Delta T_b \propto m \quad \text{or} \quad \Delta T_b = K_b m \tag{13.11}$$

where m is the solution molality and K_b is the *molal boiling point elevation constant*. Since $\Delta T_b > 0$, we subtract the lower solvent T_b from the higher solution T_b:

$$\Delta T_b = T_{b(\text{solution})} - T_{b(\text{solvent})}$$

Molality is used because it relates to mole fraction and, thus, to particles of solute, and it is not affected by temperature.

The constant K_b has units of degrees Celsius per molal unit (°C/m) and is specific for a given solvent (Table 13.6). The K_b for water is 0.512°C/m, so ΔT_b for aqueous solutions is quite small. For example, if you dissolve 1.00 mol of glucose (180. g; 1.00 mol of particles) or 0.500 mol of NaCl (29.2 g; also 1.00 mol of particles) in 1.00 kg of water at 1 atm, both solutions will boil at 100.512°C instead of 100.000°C.

Table 13.6 Molal Boiling Point Elevation and Freezing Point Depression Constants of Several Solvents

Solvent	Boiling Point (°C)*	K_b (°C/m)	Melting Point (°C)	K_f (°C/m)
Acetic acid	117.9	3.07	16.6	3.90
Benzene	80.1	2.53	5.5	4.90
Carbon disulfide	46.2	2.34	−111.5	3.83
Carbon tetrachloride	76.5	5.03	−23	30.
Chloroform	61.7	3.63	−63.5	4.70
Diethyl ether	34.5	2.02	−116.2	1.79
Ethanol	78.5	1.22	−117.3	1.99
Water	100.0	0.512	0.0	1.86

*At 1 atm.

Freezing Point Depression *A solution freezes at a lower temperature than the pure solvent,* and this colligative property also results from vapor pressure lowering:

1. *Why a solution freezes at a lower T*. Only solvent vaporizes from solution, so solute molecules are left behind. Similarly, *only solvent freezes,* again leaving solute molecules behind. The freezing point of a solution is the temperature at which its vapor pressure equals that of the pure solvent, that is, when solid solvent and liquid

solution are in equilibrium. The **freezing point depression** (ΔT_f) occurs because the vapor pressure of the solution is always lower than that of the solvent, so the solution freezes at a lower temperature; that is, only at a lower temperature will solvent particles leave and enter the solid at the same rate. In Figure 13.24, the solid-liquid line for the solution is to the left of the pure solvent line at 1 atm, or any pressure.

2. *Quantifying freezing point depression*. Like ΔT_b, the freezing point depression is proportional to the molal concentration of solute:

$$\Delta T_f \propto m \quad \text{or} \quad \Delta T_f = K_f m \tag{13.12}$$

where K_f is the *molal freezing point depression constant,* which also has units of °C/*m* (see Table 13.6). Also, like ΔT_b, $\Delta T_f > 0$, but in this case, we subtract the lower solution T_f from the higher solvent T_f:

$$\Delta T_f = T_{f(solvent)} - T_{f(solution)}$$

Here, too, the effect in aqueous solution is small because K_f for water is just 1.86°C/*m*. Thus, at 1 atm, 1 *m* glucose, 0.5 *m* NaCl, and 0.33 *m* K_2SO_4, all solutions with 1 mol of particles per kilogram of water, freeze at −1.86°C instead of at 0.00°C.

SAMPLE PROBLEM 13.8 Determining Boiling and Freezing Points of a Solution

Problem You add 1.00 kg of ethylene glycol ($C_2H_6O_2$) antifreeze to 4450 g of water in your car's radiator. What are the boiling and freezing points of the solution?

Plan To find the boiling and freezing points, we need ΔT_b and ΔT_f. We first find the molality by converting mass of solute (1.00 kg) to amount (mol) and dividing by mass of solvent (4450 g, converted to kg). Then we calculate ΔT_b and ΔT_f from Equations 13.11 and 13.12 (using constants from Table 13.6). We add ΔT_b to the solvent boiling point and subtract ΔT_f from its freezing point. The road map shows the steps.

Solution Calculating the molality:

$$\text{Amount (mol) of } C_2H_6O_2 = 1.00 \text{ kg } C_2H_6O_2 \times \frac{10^3 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol } C_2H_6O_2}{62.07 \text{ g } C_2H_6O_2}$$

$$= 16.1 \text{ mol } C_2H_6O_2$$

$$\text{Molality} = \frac{\text{mol solute}}{\text{kg solvent}} = \frac{16.1 \text{ mol } C_2H_6O_2}{4450 \text{ g } H_2O \times \dfrac{1 \text{ kg}}{10^3 \text{ g}}} = 3.62\ m\ C_2H_6O_2$$

Finding the boiling point elevation and $T_{b(solution)}$, with $K_b = 0.512$°C/*m*:

$$\Delta T_b = \frac{0.512°C}{m} \times 3.62\ m = 1.85°C$$

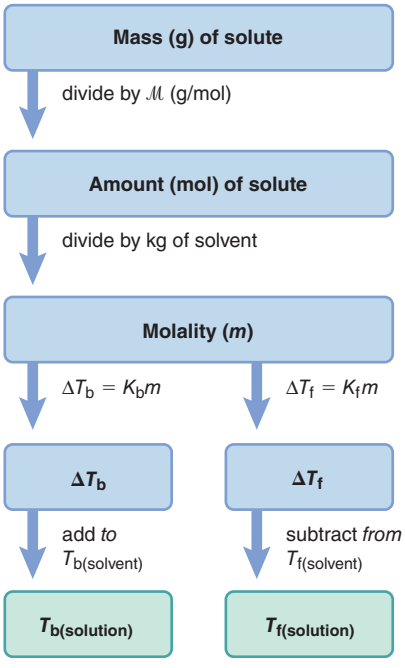
$$T_{b(solution)} = T_{b(solvent)} + \Delta T_b = 100.00°C + 1.85°C = \boxed{101.85°C}$$

Finding the freezing point depression and $T_{f(solution)}$, with $K_f = 1.86$°C/*m*:

$$\Delta T_f = \frac{1.86°C}{m} \times 3.62\ m = 6.73°C$$

$$T_{f(solution)} = T_{f(solvent)} - \Delta T_f = 0.00°C - 6.73°C = \boxed{-6.73°C}$$

Road Map



Check The changes in boiling and freezing points should be in the same proportion as the constants used. That is, $\Delta T_b/\Delta T_f$ should equal K_b/K_f: 1.85/6.73 = 0.275 = 0.512/1.86.

Comment These answers are approximate because the concentration far exceeds that of a *dilute* solution, for which Raoult's law is most accurate.

FOLLOW-UP PROBLEMS

13.8A Carbon disulfide (CS_2) has the unusual ability to dissolve several nonmetals as well as rubbers and resins. What are the boiling and freezing points of a solution consisting of 8.44 g of phosphorus (P_4) dissolved in 60.0 g of CS_2 (see Table 13.6)?

13.8B What is the lowest molality of ethylene glycol solution that will protect your car's coolant from freezing at 0.00°F? (Assume that the solution is ideal.)

SOME SIMILAR PROBLEMS 13.98–13.103

Osmotic Pressure This colligative property is observed when solutions of higher and lower concentrations are separated by a **semipermeable membrane,** one that allows solvent, but *not* solute, to pass through. The phenomenon is called **osmosis:** a net flow of solvent into the more concentrated solution causes a pressure difference known as *osmotic pressure*. Many organisms regulate internal concentrations by osmosis.

1. *Why osmotic pressure arises.* Consider a simple apparatus in which a semipermeable membrane lies at the curve of a U tube and separates an aqueous sugar solution from pure water. Water molecules pass in *either* direction, but the larger sugar molecules do not. Because sugar molecules are on the solution side of the membrane, fewer water molecules touch that side, so fewer leave the solution than enter it in a given time (Figure 13.25A). As a result, the solution maintains higher entropy. This *net flow of water into the solution* increases its volume and thus decreases its concentration.

As the height of the solution column rises and the height of the water column falls, the difference in the weights of the columns produces a pressure difference that resists more water entering and pushes some water back through the membrane. When water is being pushed out of the solution at the same rate it is entering, the system is at equilibrium (Figure 13.25B). The pressure difference at this point is the **osmotic pressure (Π),** which is the same as the pressure that must be applied to *prevent* net movement of water from solvent to solution (or from lower to higher concentration, Figure 13.25C).

2. *Quantifying osmotic pressure.* The osmotic pressure is proportional to the number of solute particles in a given solution *volume,* that is, to the molarity (M):

$$\Pi \propto \frac{n_{\text{solute}}}{V_{\text{soln}}} \qquad \text{or} \qquad \Pi \propto M$$

The proportionality constant is R times the absolute temperature T. Thus,

$$\Pi = \frac{n_{\text{solute}}}{V_{\text{soln}}} RT = MRT \qquad \textbf{(13.13)}$$

The similarity of Equation 13.13 to the ideal gas law ($P = nRT/V$) is not surprising, because both relate the pressure of a system to its concentration and temperature.

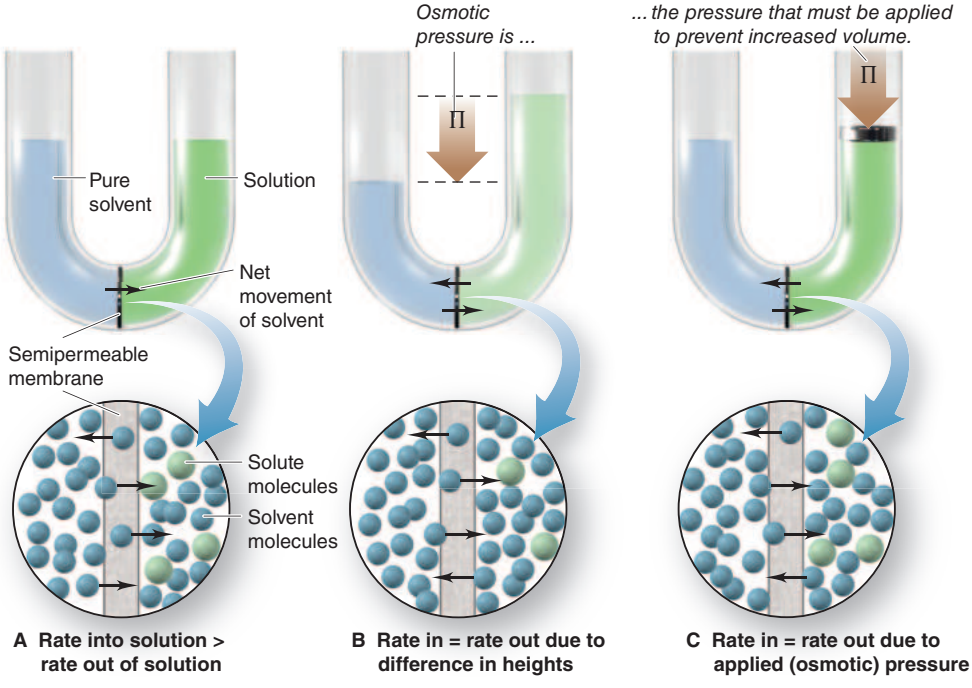


Figure 13.25 The development of osmotic pressure. A, In a given time, more solvent enters the solution through the membrane than leaves. **B,** At equilibrium, solvent flow is equalized. **C,** The *osmotic pressure* (Π) *prevents* the volume change.

The Underlying Theme of Colligative Properties A common theme runs through our explanations of the four colligative properties of nonvolatile solutes. Each property arises because solute particles cannot move between two phases:

- They cannot enter the gas phase, which leads to *vapor pressure lowering* and *boiling point elevation*.
- They cannot enter the solid phase, which leads to *freezing point depression*.
- They cannot cross a semipermeable membrane, which leads to *osmotic pressure*.

In each situation, the presence of solute decreases the mole fraction of solvent, which lowers the number of solvent particles leaving the solution per unit time. This lowering maintains higher entropy and requires a new balance in numbers of particles moving between two phases per unit time, and this new balance results in the measured colligative property.

Using Colligative Properties to Find Solute Molar Mass

Each colligative property is proportional to solute concentration. Thus, by measuring the property—lower freezing point, higher boiling point, and so forth—we determine the amount (mol) of solute particles and, given the mass of solute, the molar mass.

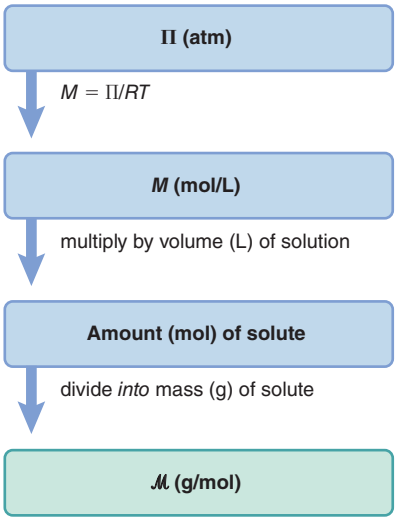
In principle, any of the colligative properties can be used but, of the four, osmotic pressure creates the largest changes and, thus, the most precise measurements. Polymer chemists and biochemists estimate molar masses as great as 10^5 g/mol by measuring osmotic pressure. Because only a tiny fraction of a mole of a macromolecular solute dissolves, the change in the other colligative properties would be too small.

SAMPLE PROBLEM 13.9 Determining Molar Mass from Osmotic Pressure

Problem Biochemists have discovered more than 400 mutant varieties of hemoglobin, the blood protein that binds O_2 and carries it to the body's cells. A physician dissolves 21.5 mg of one variety in water to make 1.50 mL of solution at 5.0°C. She measures an osmotic pressure of 3.61 torr. What is the molar mass of the protein?

Plan We know the osmotic pressure (Π = 3.61 torr), R, and T (5.0°C). We convert Π from torr to atm, and T from °C to K, and then use Equation 13.13 to solve for molarity (M). Then we calculate the amount (mol) of hemoglobin from the known volume (1.50 mL) and use the known mass (21.5 mg) to find $\mathcal{M}$.

Road Map



Solution Combining unit conversion steps and solving for molarity:

$$M = \frac{\Pi}{RT} = \frac{\dfrac{3.61 \text{ torr}}{760 \text{ torr}/1 \text{ atm}}}{\left(0.0821 \dfrac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}}\right)(273.15 \text{ K} + 5.0)} = 2.08\times10^{-4}\ M$$

Finding amount (mol) of solute (after changing mL to L):

$$\text{Amount (mol) of solute} = M \times V = \frac{2.08\times10^{-4} \text{ mol}}{1 \text{ L soln}} \times 0.00150 \text{ L soln} = 3.12\times10^{-7} \text{ mol}$$

Calculating molar mass of hemoglobin (after changing mg to g):

$$\mathcal{M} = \frac{0.0215 \text{ g}}{3.12\times10^{-7} \text{ mol}} = 6.89\times10^{4} \text{ g/mol}$$

Check The small osmotic pressure implies a very low molarity. Hemoglobin is a biopolymer, so we expect a small number of moles [$(\sim2\times10^{-4}$ mol/L$)(1.5\times10^{-3}$ L) = 3×10^{-7} mol] and a high $\mathcal{M}$ ($\sim21\times10^{-3}$ g/3×10^{-7} mol = 7×10^4 g/mol). Mammalian hemoglobin has a molar mass of 64,500 g/mol.

FOLLOW-UP PROBLEMS

13.9A Pepsin is an enzyme in the intestines of mammals that breaks down proteins into amino acids. A 12.0-mL aqueous solution contains 0.200 g of pepsin and has an osmotic pressure of 8.98 torr at 27.0°C. What is the molar mass of pepsin?

13.9B At 37°C, 0.30 M sucrose has about the same osmotic pressure as blood. What is the osmotic pressure of blood?

SOME SIMILAR PROBLEMS 13.104 and 13.105

Volatile Nonelectrolyte Solutions

What is the effect on vapor pressure when the solute *is* volatile, that is, when the vapor consists of solute *and* solvent molecules? From Raoult's law (Equation 13.9),

$$P_{\text{solvent}} = X_{\text{solvent}} \times P^\circ_{\text{solvent}} \qquad \text{and} \qquad P_{\text{solute}} = X_{\text{solute}} \times P^\circ_{\text{solute}}$$

where X_{solvent} and X_{solute} are the mole fractions in the *liquid* phase. According to Dalton's law (p. 224), the total vapor pressure is the sum of the partial vapor pressures:

$$P_{\text{total}} = P_{\text{solvent}} + P_{\text{solute}} = (X_{\text{solvent}} \times P^\circ_{\text{solvent}}) + (X_{\text{solute}} \times P^\circ_{\text{solute}})$$

Thus, just as a nonvolatile solute lowers the vapor pressure of the solvent by making the solvent's mole fraction less than 1, *the presence of each volatile component lowers the vapor pressure of the other* by making each mole fraction less than 1.

Let's examine this idea with a solution of benzene (C_6H_6) and toluene (C_7H_8), which are miscible. The mole fractions of the two solution components in this example are equal: $X_{\text{ben}} = X_{\text{tol}} = 0.500$. At 25°C, the vapor pressures of the pure substances are 95.1 torr for benzene (P°_{ben}) and 28.4 torr for toluene (P°_{tol}). Note that benzene is *more volatile* than toluene. We find the partial pressures from Raoult's law:

$$P_{\text{ben}} = X_{\text{ben}} \times P^\circ_{\text{ben}} = 0.500 \times 95.1 \text{ torr} = 47.6 \text{ torr}$$
$$P_{\text{tol}} = X_{\text{tol}} \times P^\circ_{\text{tol}} = 0.500 \times 28.4 \text{ torr} = 14.2 \text{ torr}$$

Thus, the presence of benzene in the liquid lowers the vapor pressure of toluene, and vice versa.

Now let's calculate the mole fraction of each substance *in the vapor* by applying Dalton's law. Recall from Section 5.4 that $X_A = P_A/P_{\text{total}}$. Therefore, for benzene and toluene in the vapor,

$$X_{\text{ben}} = \frac{P_{\text{ben}}}{P_{\text{total}}} = \frac{47.6 \text{ torr}}{47.6 \text{ torr} + 14.2 \text{ torr}} = 0.770$$
$$X_{\text{tol}} = \frac{P_{\text{tol}}}{P_{\text{total}}} = \frac{14.2 \text{ torr}}{47.6 \text{ torr} + 14.2 \text{ torr}} = 0.230$$

The key point is that *the vapor has a higher mole fraction of the* ***more*** *volatile component.* Through a single vaporization-condensation step, a 50/50 *liquid* ratio of benzene-to-toluene created a 77/23 *vapor* ratio. Condense this vapor into a separate container, and the new *liquid* would have this 77/23 composition, and the new *vapor* above it would be enriched still further in the more volatile benzene.

In the laboratory method of **fractional distillation,** a solution of two or more volatile components is attached to a *fractionating column* packed with glass beads (or ceramic chunks), which increase surface area; the column is connected to a condenser and collection flask. As the solution is heated and the vapor mixture meets the beads, numerous vaporization-condensation steps enrich the mixture until the vapor leaving the column, and thus the liquid finally collected, consists only of the most volatile component. (As we'll see shortly, this method is essential in the oil industry.)

Strong Electrolyte Solutions

For colligative properties of strong electrolyte solutions, the solute formula tells us the number of particles. For instance, the boiling point elevation (ΔT_b) of 0.050 *m* NaCl should be 2 × ΔT_b of 0.050 *m* glucose ($C_6H_{12}O_6$), because NaCl dissociates into two particles per formula unit. Thus, we use a multiplying factor called the *van't Hoff factor (i),* named after the Dutch chemist Jacobus van't Hoff (1852–1911):

$$i = \frac{\text{measured value for electrolyte solution}}{\text{expected value for nonelectrolyte solution}}$$

To calculate colligative properties for strong electrolyte solutions, we include *i*:

For vapor pressure lowering: $\Delta P = i(X_{\text{solute}} \times P^\circ_{\text{solvent}})$
For boiling point elevation: $\Delta T_b = i(K_b m)$
For freezing point depression: $\Delta T_f = i(K_f m)$
For osmotic pressure: $\Pi = i(MRT)$

Nonideal Solutions and Ionic Atmospheres *If* strong electrolyte solutions behaved ideally, the factor *i* would be the amount (mol) of particles in solution divided by the amount (mol) of dissolved solute; that is, *i* would be 2 for KBr, 3 for $Mg(NO_3)_2$, and so forth. However, *most strong electrolyte solutions are* ***not*** *ideal,* and the measured value of *i* is typically *lower* than the value expected from the formula. For example, for the boiling point elevation of 0.050 *m* NaCl, the expected value is 2.0, but, from experiment, we have

$$i = \frac{\Delta T_b \text{ of } 0.050\ m \text{ NaCl}}{\Delta T_b \text{ of } 0.050\ m \text{ glucose}} = \frac{0.049°C}{0.026°C} = 1.9$$

It seems as though the ions are not behaving independently, even though other evidence indicates that soluble salts dissociate completely. One clue to understanding the results is that multiply-charged ions cause a larger deviation (Figure 13.26).

To explain this nonideal behavior, we picture positive ions clustered, on average, near negative ions, and vice versa, to form an **ionic atmosphere** of net opposite charge (Figure 13.27). In effect, each type of ion acts "tied up," so its actual concentration seems *lower*. The *effective* concentration is the *stoichiometric* concentration, which is based on the formula, multiplied by *i*. The greater the charge, the stronger the attractions, which explains the larger deviation for salts with multiply-charged ions.

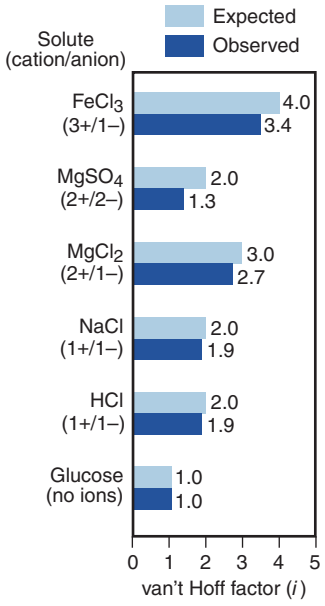


Figure 13.26 Nonideal behavior of strong electrolyte solutions. Van't Hoff factors (*i*) for 0.050 *m* solutions show the largest deviation for salts with multiply-charged ions. Glucose (a nonelectrolyte) behaves as expected.

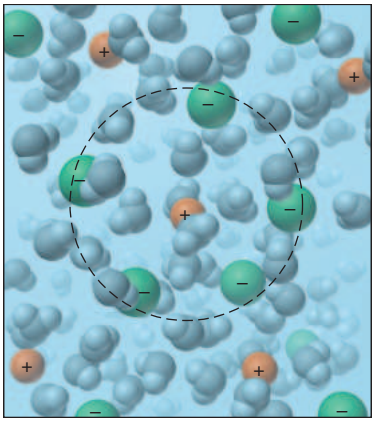

Figure 13.27 An ionic atmosphere model for nonideal behavior of electrolyte solutions.

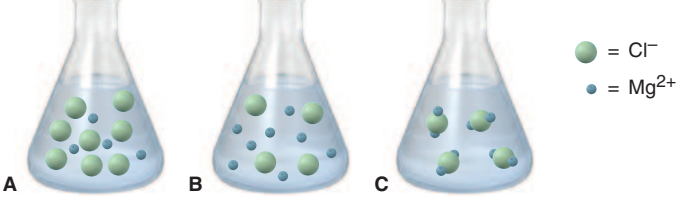
Comparing Real Solutions and Real Gases At ordinary conditions and concentrations, particles are *much* closer together in liquids than in gases. And, as a result, nonideal behavior is much more common, and the deviations much larger. Nevertheless, the two systems have similarities:

- Gases display nearly ideal behavior at low pressures because the distances between particles are large. Similarly, the van't Hoff factor (*i*) approaches the ideal value as the solution becomes more dilute, that is, as the distance between ions increases.
- Attractions between particles cause deviations from the expected pressure in gases and from the expected size of a colligative property in ionic solutions.
- For both real gases and real solutions, we use empirically determined numbers (van der Waals constants or van't Hoff factors) to transform theories (the ideal gas law or Raoult's law) into more useful relations.

SAMPLE PROBLEM 13.10 Depicting Strong Electrolyte Solutions

Problem A 0.952-g sample of magnesium chloride dissolves in 100. g of water in a flask.



(a) Which scene depicts the solution best?
(b) What is the amount (mol) represented by each green sphere?
(c) Assuming the solution is ideal, what is its freezing point (at 1 atm)?

Plan **(a)** We find the numbers of cations and anions per formula unit from the name and compare it with the three scenes. **(b)** We convert the given mass to amount (mol), use the answer from part (a) to find moles of chloride ions *(green spheres),* and divide by the number of green spheres to get moles/sphere. **(c)** We find the molality (*m*) from amount (mol) of solute divided by the given mass of water (changed to kg). We multiply K_f for water (Table 13.6) by *m* to get ΔT_f, and then subtract that from 0.000°C to get the solution freezing point.

Solution **(a)** The formula is $MgCl_2$; only scene A has 1 Mg^{2+} for every 2 Cl^-.

(b) $$\text{Amount (mol) of } MgCl_2 = \frac{0.952 \text{ g } MgCl_2}{95.21 \text{ g/mol } MgCl_2} = 0.0100 \text{ mol } MgCl_2$$

Therefore, $$\text{Amount (mol) of } Cl^- = 0.0100 \text{ mol } MgCl_2 \times \frac{2\ Cl^-}{1\ MgCl_2} = 0.0200 \text{ mol } Cl^-$$

$$\text{Moles/sphere} = \frac{0.0200 \text{ mol } Cl^-}{8 \text{ spheres}} = 2.50 \times 10^{-3} \text{ mol/sphere}$$

(c) $$\text{Molality } (m) = \frac{\text{mol of solute}}{\text{kg of solvent}} = \frac{0.0100 \text{ mol } MgCl_2}{100.\text{ g} \times \frac{1 \text{ kg}}{1000 \text{ g}}} = 0.100\ m\ MgCl_2$$

Assuming an ideal solution, $i = 3$ for $MgCl_2$ (3 ions per formula unit), so we have

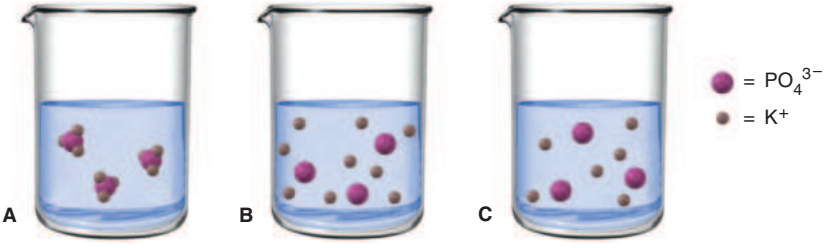
$$\Delta T_f = i(K_f m) = 3(1.86°C/m \times 0.100\ m) = 0.558°C$$

and $$T_f = 0.000°C - 0.558°C = -0.558°C$$

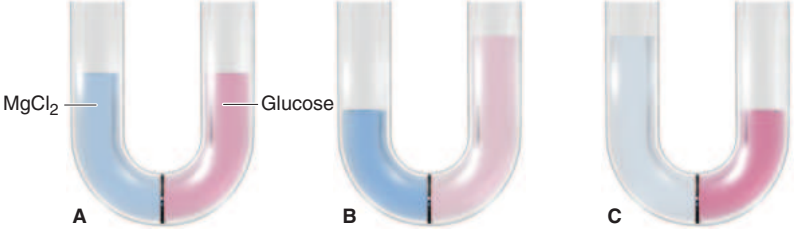
Check Let's quickly check the ΔT_f in part (c): We have 0.01 mol dissolved in 0.1 kg, or 0.1 *m*. Then, rounding K_f, we have about $3(2°C/m \times 0.1\ m) = 0.6°C$.

FOLLOW-UP PROBLEMS

13.10A A solution is made by dissolving 31.2 g of potassium phosphate in 85.0 g of water in a beaker. **(a)** Which scene depicts the solution best? **(b)** Assuming ideal behavior, what is the boiling point of the solution (at 1 atm)?



13.10B The $MgCl_2$ solution in the sample problem has a density of 1.006 g/mL at 20.0°C. **(a)** What is its osmotic pressure? **(b)** A U tube, with semipermeable membrane, is filled with this solution in the left arm and a glucose solution of equal molarity in the right. After time, which scene depicts the U tube best?



SOME SIMILAR PROBLEMS 13.106 and 13.107

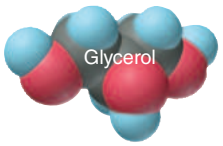
Applications of Colligative Properties

Two colligative properties, freezing point depression (or boiling point elevation) and osmotic pressure, have key applications that involve all three types of solutes we've discussed, nonvolatile and volatile nonelectrolytes and strong electrolytes.

Uses of Freezing Point Depression Applications of this property appear in everyday life, nature, and industry:

- *Plane de-icer and car antifreeze*. The main ingredient in plane de-icer and car antifreeze, ethylene glycol ($C_2H_6O_2$, *see margin*), lowers the freezing point of water in winter and raises its boiling point in summer. Due to extensive H bonding, ethylene glycol is miscible with water and nonvolatile at 100°C.

- *Biological antifreeze.* Structurally similar to ethylene glycol and also miscible with water, glycerol ($C_3H_8O_3$, *see margin*) is produced by some fish and insects, including the common housefly, to lower the freezing point of their blood and thus allow them to survive winters.
- *De-icing sidewalks and roads.* NaCl, or a mixture of it with $CaCl_2$, is used to melt ice on roads. A small amount dissolves in the ice by lowering its freezing point and melting it. More salt dissolves, more ice melts, and so forth. An advantage of $CaCl_2$ is that it has a highly negative ΔH_{soln}, so heat is released when it dissolves, which melts more ice.
- *Refining petroleum and silicon.* In the oil industry, countless vaporization-condensation steps within a 30-m fractionating tower separate the hundreds of volatile compounds in crude oil into a few "fractions" based on boiling point range (Figure 13.28). Impure silicon is refined by continuous melting and refreezing into a sample pure enough for use in computer chips (Chapter 22).



Uses of Osmotic Pressure Of the four colligative properties, this one has the most applications vital to organisms.

- *Tonicity and cell shape.* The term *tonicity* refers to the tone, or firmness, of a cell. Placing the cell in an *isotonic* solution, one that has the same concentration of particles as the cell fluid, maintains the cell's normal shape because water enters and leaves the cell at the same rate (Figure 13.29A). A *hypotonic* solution has a lower concentration of particles, so water enters the cell faster than it leaves, causing the cell to burst (Figure 13.29B). In contrast, a *hypertonic* solution has a higher concentration of particles, so the cell shrinks because water leaves faster than it enters (Figure 13.29C). To maintain cell shape, contact-lens rinse is isotonic saline (0.15 *M* NaCl), as are solutions used to deliver nutrients or drugs intravenously.
- *Absorption of water by trees.* Tree sap is a more concentrated solution than surrounding groundwater, so water passes through root membranes into the tree, creating an osmotic pressure that can exceed 20 atm in the tallest trees.
- *Regulation of water volume in the body.* Of the four major biological cations—Na^+, K^+, Mg^{2+}, and Ca^{2+}—sodium ion has the primary role of regulating water volume. It accounts for over 90 mol % of cations *outside* a cell: high Na^+ draws water out of the cell and low Na^+ leaves more inside. And the primary role of the kidneys is to regulate Na^+ concentration.
- *Food preservation.* Before refrigeration, salt was valued as a preservative. Packed onto food, salt causes microbes on the surface to shrivel as they lose water. In fact, it was so highly prized for this purpose that Roman soldiers were paid in salt, from which comes the word *salary*.

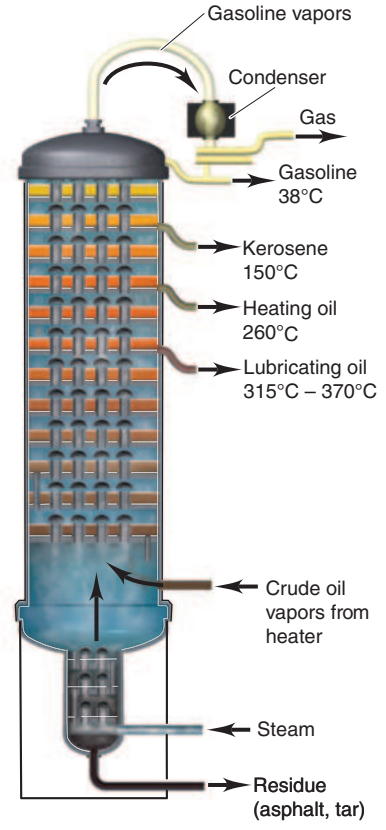


Figure 13.28 **Fractional distillation in petroleum refining.**

Figure 13.29 **Osmotic pressure and cell shape.** Isotonic **(A),** hypotonic **(B),** and hypertonic **(C)** solutions influence the shape of a red blood cell.

Summary of Section 13.6

- Colligative properties arise from the number, not the type, of dissolved solute particles.
- Compared to pure solvent, a solution has higher entropy, which results in lower vapor pressure (Raoult's law), elevated boiling point, and depressed freezing point. A difference in concentration of a solute gives rise to osmotic pressure.
- Colligative properties are used to determine solute molar mass; osmotic pressure gives the most precise measurements.
- When solute *and* solvent are volatile, each lowers the vapor pressure of the other, with the vapor pressure of the more volatile component greater. When the vapor is condensed, the new solution is richer in that component than the original solution.
- Calculating colligative properties of electrolyte solutions requires a factor (*i*) that adjusts for the number of ions per formula unit. These solutions exhibit nonideal behavior because charge attractions effectively reduce the concentration of ions.

13.7 THE STRUCTURE AND PROPERTIES OF COLLOIDS

Particle size plays a defining role in three types of mixtures:

- *Suspensions*. Stir a handful of fine sand into a glass of water, and the particles are suspended at first but gradually settle to the bottom. Sand in water is a **suspension,** a *heterogeneous* mixture containing particles large enough (>1000 nm) to be visibly distinct from the surrounding fluid.
- *Solutions*. In contrast, stirring sugar into water forms a solution, a *homogeneous* mixture in which the particles are invisible, individual sugar molecules (around 1 nm) distributed evenly throughout the surrounding fluid.
- *Colloids*. Between these extremes is a large group of mixtures called *colloidal dispersions,* or **colloids,** in which a dispersed (solute-like) substance is distributed throughout a dispersing (solvent-like) substance. The particles are larger than simple molecules but too small to settle out.

In this section, we examine the classification and key features of colloids.

1. *Particle size and surface area*. Colloidal particles range in diameter from 1 to 1000 nm (10^{-9} to 10^{-6} m). It may be a single macromolecule (natural or synthetic) or an aggregate of many atoms, ions, or molecules. As a result of the small particle size, a colloid has a *very large total surface area*. A cube with 1-cm sides has a total surface area of 6 cm^2. If we divide it equally into 10^{12} cubes, each cube is the size of a large colloidal particle and the total surface area is 60,000 cm^2, or 6 m^2. The enormous surface area of a colloid attracts other particles through various intermolecular forces.

2. *Classification of colloids*. Colloids are commonly classified by the physical state of the dispersed and dispersing substances (Table 13.7). Many familiar commercial products and natural objects are colloids. Whipped cream and shaving cream are *foams,* a gas dispersed in a liquid. Styrofoam is a *solid foam,* a gas dispersed in a

Table 13.7 Types of Colloids

Colloid Type	Dispersed Substance	Dispersing Medium	Example(s)
Aerosol	Liquid	Gas	Fog
Aerosol	Solid	Gas	Smoke
Foam	Gas	Liquid	Whipped cream
Solid foam	Gas	Solid	Marshmallow
Emulsion	Liquid	Liquid	Milk
Solid emulsion	Liquid	Solid	Butter
Sol	Solid	Liquid	Paint, cell fluid
Solid sol	Solid	Solid	Opal

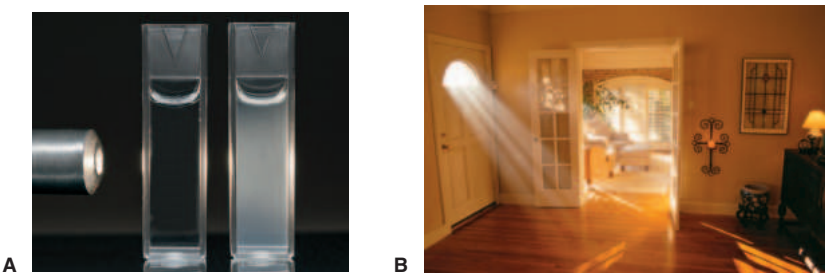

Figure 13.30 Light scattering and the Tyndall effect. A, The narrow, barely visible light beam that passes through a solution *(left),* is scattered and broadened by passing through a colloid *(right).* **B,** Sunlight is scattered by dust in air.

solid. Most biological fluids are aqueous *sols,* solids dispersed in water: proteins and nucleic acids are the colloidal-size particles dispersed in an aqueous fluid of ions and small molecules within a cell. Soaps and detergents work by forming an *emulsion,* a liquid dispersed in another liquid. Other emulsions are mayonnaise and hand cream. Bile salts convert fats to an emulsion in the watery fluid of the small intestine.

3. *Tyndall effect and Brownian motion*. Light passing through a colloid is scattered randomly because the dispersed particles have sizes similar to wavelengths of visible light (400 to 750 nm). The scattered light beam appears broader than one passing through a solution, an example of the **Tyndall effect** (Figure 13.30). Dust scatters sunlight shining through it, as does mist pierced by headlights.

Under low magnification, colloidal particles exhibit *Brownian motion,* an erratic change of speed and direction. Brownian motion results from collisions of the particles with molecules of the dispersing medium, and Einstein's explanation of it in 1905 led many to accept the molecular nature of matter.

4. *Stabilizing and destabilizing colloids*. Why *don't* colloidal particles aggregate and settle out? Colloidal particles dispersed in water have charged surfaces that stabilize the colloid through ion-dipole forces. Molecules with dual polarities, like lipids and soaps, form spherical *micelles,* with the charged heads on the exterior and hydrocarbon tails in the interior (Section 13.2). Aqueous proteins mimic this arrangement, with charged amino acid groups facing the water and nonpolar groups buried within the molecule. Oily particles can be dispersed in water by adding ions, which are adsorbed onto their surfaces. Repulsions between the ions on the oil and partial charges on water molecules prevent the particles from aggregating.

Despite these forces, various methods that coagulate the particles destabilize the colloid. Heating makes the particles collide more often and with enough force to coalesce and settle out. Addition of an electrolyte solution containing oppositely charged ions neutralizes the surface charges, so the particles coagulate and settle. In smokestack gases from a coal-burning power plant, ions become adsorbed onto uncharged colloidal particles, which are then attracted to the charged plates of a device called a *Cotrell precipitator* installed in the stack. At the mouths of rivers, where salt concentrations increase near an ocean or sea, colloidal clay particles coalesce into muddy deltas, like those of the Mississippi and the Nile (Figure 13.31). Thus, the city of New Orleans and the ancient Egyptian empire were made possible by such large-scale colloid chemistry.

The upcoming Chemical Connections essay applies solution and colloid chemistry to the purification of water for residential and industrial use.

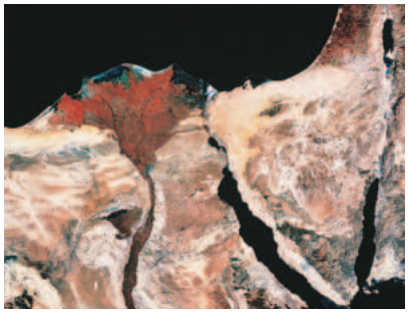

Figure 13.31 The Nile delta (reddish-brown area).

Summary of Section 13.7

- Particles in a colloid are smaller than those in a suspension and larger than those in a solution.
- Colloids are classified by the physical states of the dispersed and dispersing substances and involve many combinations of gas, liquid, and/or solid.
- Colloids have extremely large surface areas, scatter incoming light (Tyndall effect), and exhibit random (Brownian) motion.
- Colloidal particles in water are stabilized by charged surfaces that keep them dispersed, but they can be coagulated by heating or by the addition of ions.
- Solution behavior and colloid chemistry are applied to water treatment and purification.

Solutions and Colloids in Water Purification

Most water destined for human use comes from lakes, rivers, reservoirs, or groundwater. Present in this essential resource may be soluble toxic organic compounds and high concentrations of NO_3^- and Fe^{3+}, colloidal clay and microbes, and suspended debris. Let's see how water is treated to remove these dissolved, dispersed, and suspended particles.

Water Treatment Plants

Treating water involves several steps (Figure B13.1):

Step 1. Screening and settling. As water enters the facility, screens remove debris, and settling removes sand and other particles.

Step 2. Coagulating. This step and the next two remove colloids. These particles have negative surfaces that repel each other. Added aluminum sulfate [cake alum; $Al_2(SO_4)_3$] or iron(III) chloride ($FeCl_3$), which supply Al^{3+} or Fe^{3+} that neutralize the charges, coagulates the particles through intermolecular forces.

Step 3. Flocculating and sedimenting. Mixing water and flocculating agents in large basins causes a fluffy *floc* to form. Added cationic polymers form long-chain bridges between floc particles, which grow bigger and flow into other basins, where they form a sediment and are removed. Some plants use *dissolved air flotation* (DAF) instead: bubbles forced through the water attach to the floc, and the floating mass is skimmed.

Step 4. Filtering. Various filters remove remaining particles. In *slow sand filters,* the water passes through sand and/or gravel of increasing particle size. In *rapid sand filters,* the sand is backwashed with water, and the colloidal mass is removed. Membrane filters *(not shown)* with pore sizes of 0.1–10 μm are thin tubes bundled together inside a vessel. The water is forced into these tubes, and the colloid-free filtrate is collected from a large central tube. Filtration is very effective at removing microorganisms resistant to disinfecting.

Step 5. Disinfecting. Water sources often contain harmful microorganisms that are killed by one of three agents:

- Chlorine, as aqueous bleach (ClO^-) or Cl_2, is most common, but carcinogenic chlorinated organic compounds can form.
- UV light emitted by high-intensity fluorescent tubes disinfects by disrupting microorganisms' DNA.
- Ozone (O_3) gas is a powerful oxidizing agent.

Sodium fluoride (NaF) to prevent tooth decay and phosphate salts to prevent leaching of lead from pipes may then be added.

Step 6 (not shown). Adsorbing onto granular activated carbon (GAC). Petroleum and other organic contaminants are removed by adsorption. GAC is a highly porous agent formed by "activating" wood, coal, or coconut shells with steam: 1 kg of GAC has a surface area of 275 acres!

Water Softening via Ion Exchange

Water with large amounts of 2+ ions, such as Ca^{2+} and Mg^{2+}, is called **hard water.** Combined with fatty-acid anions in soap, these cations form solid deposits on clothes, washing machines, and sinks:

$$Ca^{2+}(aq) + 2C_{17}H_{35}COONa(aq) \longrightarrow \underset{\text{soap}}{} \quad (C_{17}H_{35}COO)_2Ca(s) + 2Na^+(aq)$$
$$\text{insoluble deposit}$$

When a large amount of HCO_3^- is present, the cations form *scale,* a carbonate deposit in boilers and hot-water pipes that interferes with the transfer of heat:

$$Ca^{2+}(aq) + 2HCO_3^-(aq) \longrightarrow CaCO_3(s) + CO_2(g) + H_2O(l)$$

Removing hard-water cations, called **water softening,** is done by exchanging Na^+ ions for Ca^{2+} and Mg^{2+} ions. A domestic **ion exchange** system contains an insoluble polymer *resin* with bonded anionic groups, such as $—SO_3^-$ or $—COO^-$, and Na^+

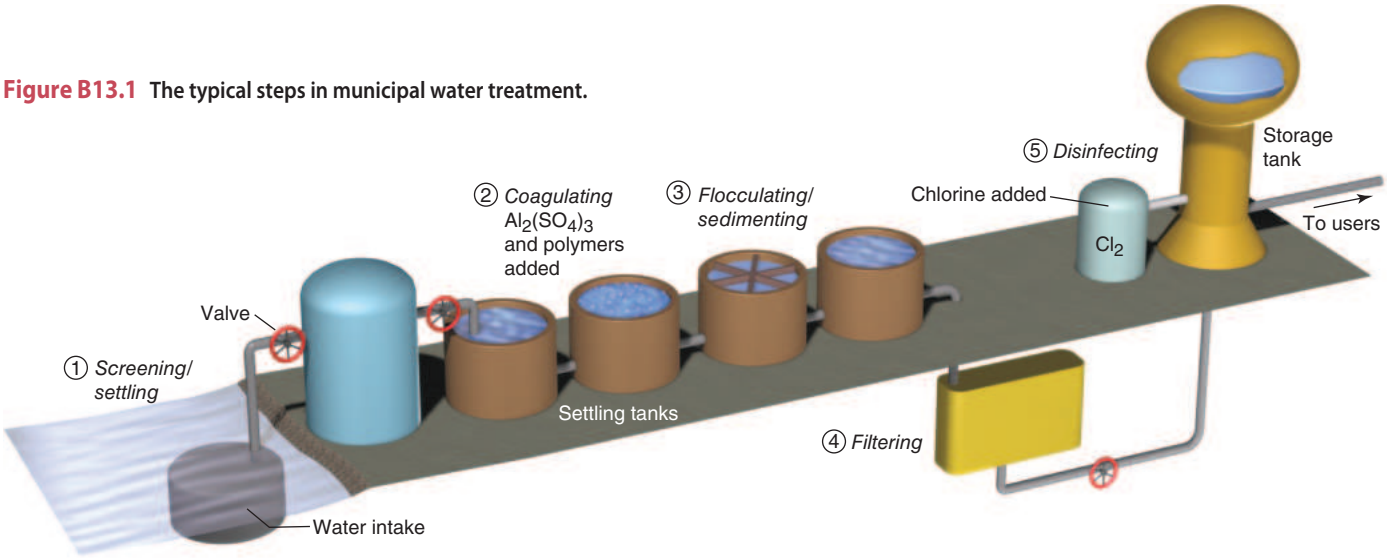

Figure B13.1 The typical steps in municipal water treatment.

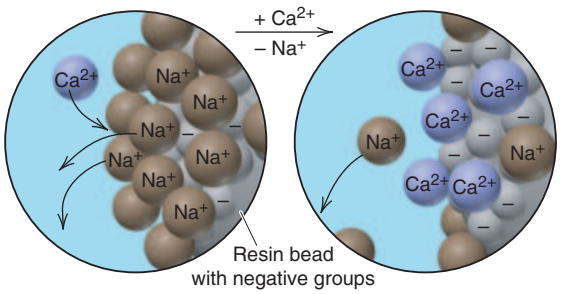

Figure B13.2 Ion exchange to remove hard-water cations.

ions for charge balance (Figure B13.2). The hard-water cations displace the Na^+ ions and bind to the anionic groups. When all resin sites are occupied, the resin is regenerated with concentrated Na^+ solution that exchanges Na^+ ions for bound Ca^{2+} and Mg^{2+}.

Membrane Processes and Reverse Osmosis

Membranes with 0.0001–0.01 μm pores can remove unwanted ions from water. Recall that solutions of different concentrations separated by a semipermeable membrane create osmotic pressure. In **reverse osmosis,** a pressure *greater* than the osmotic pressure is *applied* to the more concentrated solution to force water back through the membrane and filter out ions. In homes, toxic *heavy-metal ions,* such as Pb^{2+}, Cd^{2+}, and Hg^{2+}, are removed this way. On a large scale, reverse osmosis is used for **desalination,** which can convert seawater (40,000 ppm of ions) to drinking water (400 ppm) (Figure B13.3).

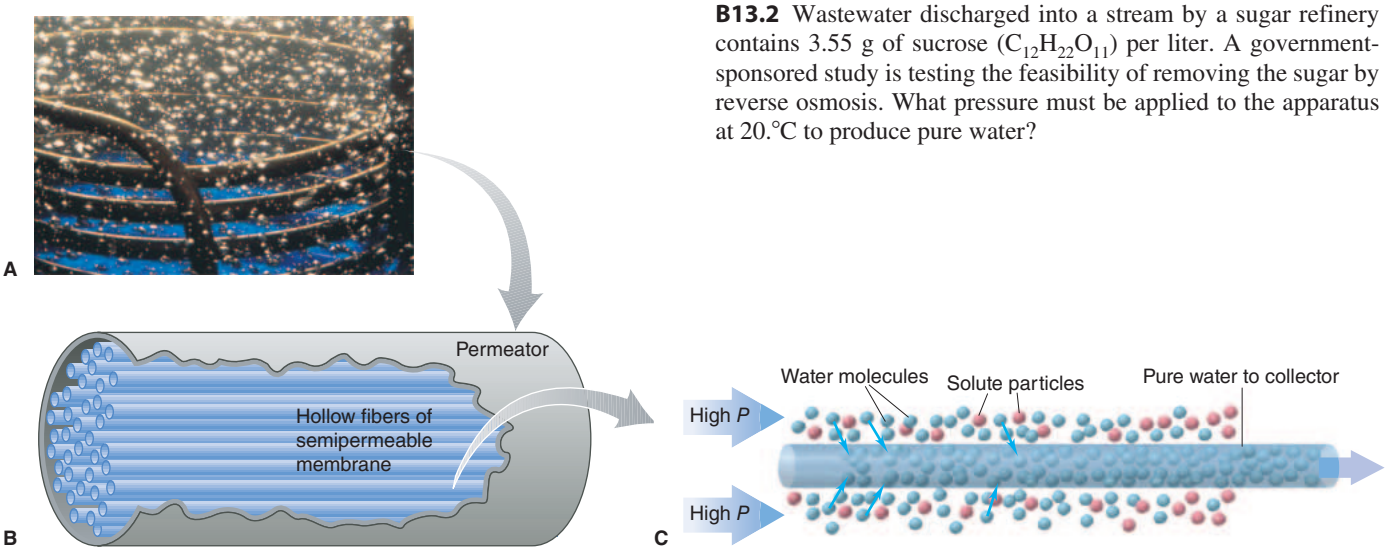

Figure B13.3 **Reverse osmosis to remove ions. A,** Part of a reverse-osmosis permeator. **B,** Each permeator contains a bundle of hollow fibers of semipermeable membrane. **C,** Pumping seawater at high pressure removes ions and purer water enters the fibers and is collected.

Wastewater Treatment

Wastewater, used domestic or industrial water, is treated in several ways before being returned to a natural source:

- In *primary* treatment, the water enters a settling basin to remove particles.
- In *biological* treatment, bacteria metabolize organic compounds and are then removed by settling.
- In *advanced* treatment, a process is tailored to remove a specific pollutant. For example, ammonia, which causes excessive growth of plants and algae, is removed in two steps:

1. *Nitrification*. Certain bacteria oxidize ammonia (electron donor) with O_2 (electron acceptor) to form nitrate ion:

$$NH_4^+ + 2O_2 \longrightarrow NO_3^- + 2H^+ + H_2O$$

2. *Denitrification*. Other bacteria oxidize an added compound like methanol (CH_3OH) using the NO_3^-:

$$5CH_3OH + 6NO_3^- \longrightarrow 3N_2 + 5CO_2 + 7H_2O + 6OH^-$$

Thus, the process converts NH_3 in wastewater to N_2, which is released to the atmosphere.

Problems

B13.1 Briefly answer each of the following:
(a) Why is cake alum [$Al_2(SO_4)_3$] added during water purification?
(b) Why is water that contains large amounts of Ca^{2+} and Mg^{2+} difficult to use for cleaning?
(c) What is the meaning of "reverse" in reverse osmosis?
(d) Why might a water treatment plant use ozone as a disinfectant instead of chlorine?
(e) How does passing a saturated NaCl solution through a "spent" ion-exchange resin regenerate the resin?

B13.2 Wastewater discharged into a stream by a sugar refinery contains 3.55 g of sucrose ($C_{12}H_{22}O_{11}$) per liter. A government-sponsored study is testing the feasibility of removing the sugar by reverse osmosis. What pressure must be applied to the apparatus at 20.°C to produce pure water?

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The quantitative meaning of solubility (§13.1)
2. The major types of intermolecular forces in solution and their relative strengths (§13.1)
3. How the like-dissolves-like rule depends on intermolecular forces (§13.1)
4. Why gases have relatively low solubilities in water (§13.1)
5. General characteristics of solutions formed by various combinations of gases, liquids, and solids (§13.1)
6. How intermolecular forces stabilize the structures of proteins, the cell membrane, and DNA (§13.2)
7. The enthalpy components of a solution cycle and their effect on ΔH_{soln} (§13.3)
8. The dependence of ΔH_{hydr} on ionic charge density and the factors that determine whether ionic solution processes are exothermic or endothermic (§13.3)
9. The meaning of entropy and how the balance between the change in enthalpy and the change in entropy governs the solution process (§13.3)
10. The distinctions among saturated, unsaturated, and supersaturated solutions, and the equilibrium nature of a saturated solution (§13.4)
11. The relation between temperature and the solubility of solids (§13.4)
12. Why the solubility of gases in water decreases with a rise in temperature (§13.4)
13. The effect of gas pressure on solubility and its quantitative expression as Henry's law (§13.4)
14. The meaning of molarity, molality, mole fraction, and parts by mass or by volume of a solution, and how to convert among them (§13.5)
15. The distinction between electrolytes and nonelectrolytes in solution (§13.6)
16. The four colligative properties and their dependence on number of dissolved particles (§13.6)
17. Ideal solutions and the importance of Raoult's law (§13.6)
18. How the phase diagram of a solution differs from that of the pure solvent (§13.6)
19. Why the vapor over a solution of volatile nonelectrolyte is richer in the more volatile component (§13.6)
20. Why electrolyte solutions are not ideal and the meanings of the van't Hoff factor and ionic atmosphere (§13.6)
21. How particle size distinguishes suspensions, colloids, and solutions (§13.7)
22. How colloidal behavior is demonstrated by the Tyndall effect and Brownian motion (§13.7)

Master These Skills

1. Predicting relative solubilities from intermolecular forces (SP 13.1)
2. Calculating the heat of solution for an ionic compound (SP 13.2)
3. Using Henry's law to calculate the solubility of a gas (SP 13.3)
4. Expressing concentration in terms of molality, parts by mass, parts by volume, and mole fraction (SPs 13.4, 13.5)
5. Interconverting among the various terms for expressing concentration (SP 13.6)
6. Using Raoult's law to calculate the vapor pressure lowering of a solution (SP 13.7)
7. Determining boiling point elevation and freezing point depression of a solution (SP 13.8)
8. Using a colligative property to calculate the molar mass of a solute (SP 13.9)
9. Calculating the composition of vapor over a solution of volatile nonelectrolyte (§13.6)
10. Calculating the van't Hoff factor (i) from the magnitude of a colligative property (§13.6)
11. Using a solution depiction to determine colligative properties (SP 13.10)

Key Equations and Relationships

Page numbers appear in parentheses.

13.1 Dividing the general heat of solution into component enthalpies (528):

$$\Delta H_{soln} = \Delta H_{solute} + \Delta H_{solvent} + \Delta H_{mix}$$

13.2 Dividing the heat of solution of an ionic compound in water into component enthalpies (530):

$$\Delta H_{soln} = \Delta H_{lattice} + \Delta H_{hydr\ of\ the\ ions}$$

13.3 Relating gas solubility to its partial pressure (Henry's law) (535):

$$S_{gas} = k_H \times P_{gas}$$

13.4 Defining concentration in terms of molarity (537):

$$\text{Molarity } (M) = \frac{\text{amount (mol) of solute}}{\text{volume (L) of solution}}$$

13.5 Defining concentration in terms of molality (537):

$$\text{Molality } (m) = \frac{\text{amount (mol) of solute}}{\text{mass (kg) of solvent}}$$

13.6 Defining concentration in terms of mass percent (538):

$$\text{Mass percent } [\%\ (w/w)] = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100$$

13.7 Defining concentration in terms of volume percent (538):

$$\text{Volume percent } [\%\ (v/v)] = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100$$

13.8 Defining concentration in terms of mole fraction (538):

$$\text{Mole fraction } (X) = \frac{\text{amount (mol) of solute}}{\text{amount (mol) of solute} + \text{amount (mol) of solvent}}$$

13.9 Expressing the relationship between the vapor pressure of solvent above a solution and its mole fraction in the solution (Raoult's law) (542):

$$P_{solvent} = X_{solvent} \times P^{\circ}_{solvent}$$

13.10 Calculating the vapor pressure lowering due to solute (542):

$$\Delta P = X_{solute} \times P^{\circ}_{solvent}$$

13.11 Calculating the boiling point elevation of a solution (544):

$$\Delta T_b = K_b m$$

13.12 Calculating the freezing point depression of a solution (545):

$$\Delta T_f = K_f m$$

13.13 Calculating the osmotic pressure of a solution (546):

$$\Pi = \frac{n_{solute}}{V_{soln}} RT = MRT$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

13.1A (a) 1,4-Butanediol is more soluble in water because it can form more H bonds.
(b) Chloroform is more soluble in water because of dipole-dipole forces.

13.1B (a) Chloroform dissolves more chloromethane due to similar dipole-dipole forces.
(b) Hexane dissolves more pentanol due to dispersion forces.

13.2A From Equation 13.2, we have

$$\Delta H_{soln}\ \text{of}\ KNO_3 = \Delta H_{lattice}\ \text{of}\ KNO_3 + (\Delta H_{hydr}\ \text{of}\ K^+ + \Delta H_{hydr}\ \text{of}\ NO_3^-)$$

$$34.89\ \text{kJ/mol} = 685\ \text{kJ/mol} + (\Delta H_{hydr}\ \text{of}\ K^+ + \Delta H_{hydr}\ \text{of}\ NO_3^-)$$

$$\Delta H_{hydr}\ \text{of}\ K^+ + \Delta H_{hydr}\ \text{of}\ NO_3^- = 34.89\ \text{kJ/mol} - 685\ \text{kJ/mol} = -650.\ \text{kJ/mol}$$

13.2B From Equation 13.2, we have

$$\Delta H_{soln}\ \text{of NaCN} = \Delta H_{lattice}\ \text{of NaCN} + (\Delta H_{hydr}\ \text{of}\ Na^+ + \Delta H_{hydr}\ \text{of}\ CN^-)$$

$$1.21\ \text{kJ/mol} = 766\ \text{kJ/mol} - 410\ \text{kJ/mol} + \Delta H_{hydr}\ \text{of}\ CN^-$$

$$\Delta H_{hydr}\ \text{of}\ CN^- = 1.21\ \text{kJ/mol} - 766\ \text{kJ/mol} + 410.\ \text{kJ/mol} = -355\ \text{kJ/mol}$$

13.3A $S_{N_2} = (7\times10^{-4}\ \text{mol/L·atm})(0.78\ \text{atm}) = 5\times10^{-4}\ \text{mol/L}$

13.3B In a mixture of gases, the volume percent of each gas times the total pressure equals its partial pressure (Dalton's law, Section 5.4). From Equation 13.3, we have

$$S_{gas} = k_H \times P_{gas} = (2.5\times10^{-2}\ \text{mol/L·atm})(0.40 \times 1.2\ \text{atm}) = 1.2\times10^{-2}\ \text{mol/L}$$

13.4A

$$\text{Mass (g) of glucose} = 563\ \text{g ethanol} \times \frac{1\ \text{kg}}{10^3\ \text{g}} \times \frac{2.40\times10^{-2}\ \text{mol glucose}}{1\ \text{kg ethanol}} \times \frac{180.16\ \text{g glucose}}{1\ \text{mol glucose}} = 2.43\ \text{g glucose}$$

13.4B Convert mass (g) of I_2 to amount (mol) and amount (mol) of $(CH_3CH_2)_2O$ to mass (kg). Then divide moles of I_2 by kg of $(CH_3CH_2)_2O$.

$$\text{Amount (mol) of } I_2 = 15.20\ \text{g } I_2 \times \frac{1\ \text{mol } I_2}{253.8\ \text{g } I_2} = 5.989\times10^{-2}\ \text{mol } I_2$$

$$\text{Mass (kg) of } (CH_3CH_2)_2O = 1.33\ \text{mol } (CH_3CH_2)_2O \times \frac{74.12\ \text{g } (CH_3CH_2)_2O}{1\ \text{mol } (CH_3CH_2)_2O} \times \frac{1\ \text{kg}}{10^3\ \text{g}} = 9.86\times10^{-2}\ \text{kg } (CH_3CH_2)_2O$$

$$\text{Molality } (m) = \frac{5.989\times10^{-2}\ \text{mol}}{9.86\times10^{-2}\ \text{kg}} = 0.607\ m$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

13.5A $$\text{Mass \% } C_3H_7OH = \frac{35.0\text{ g}}{35.0\text{ g} + 150.\text{ g}} \times 100 = 18.9 \text{ mass \%}$$

$$\text{Mass \% } C_2H_5OH = 100.0 - 18.9 = 81.1 \text{ mass \%}$$

$$X_{C_3H_7OH} = \frac{35.0\text{ g } C_3H_7OH \times \frac{1\text{ mol } C_3H_7OH}{60.09\text{ g } C_3H_7OH}}{\left(35.0\text{ g } C_3H_7OH \times \frac{1\text{ mol } C_3H_7OH}{60.09\text{ g } C_3H_7OH}\right) + \left(150.\text{ g } C_2H_5OH \times \frac{1\text{ mol } C_2H_5OH}{46.07\text{ g } C_2H_5OH}\right)} = 0.152$$

$$X_{C_2H_5OH} = 1.000 - 0.152 = 0.848$$

13.5B Total mass (g) = 1.87 g + 27.4 g + 4.10 g = 33.4 g

$$\text{Mass \% } C_2H_5OH = \frac{1.87\text{ g}}{33.4\text{ g}} \times 100 = 5.60\%$$

Mass % C_8H_{18} = 82.0%

Mass % C_7H_{16} = 12.3%

$$\text{Amount (mol) of } C_2H_5OH = 1.87\text{ g } C_2H_5OH \times \frac{1\text{ mol } C_2H_5OH}{46.07\text{ g } C_2H_5OH} = 0.0406\text{ mol } C_2H_5OH$$

Amount (mol) of C_8H_{18} = 0.240 mol C_8H_{18}

Amount (mol) of C_7H_{16} = 0.0409 mol C_7H_{16}

Total amount (mol) = 0.0406 mol + 0.240 mol + 0.0409 mol = 0.322 mol

$$\text{Mole \% } C_2H_5OH = \frac{0.0406\text{ mol}}{0.322\text{ mol}} \times 100 = 12.6\%$$

Mole % C_8H_{18} = 74.5%

Mole % C_7H_{16} = 12.7%

(Slight differences from 100% are due to rounding.)

13.6A $$\text{Mass \% HCl} = \frac{\text{mass of HCl}}{\text{mass of soln}} \times 100 = \frac{\frac{11.8\text{ mol HCl}}{1\text{ L soln}} \times \frac{36.46\text{ g HCl}}{1\text{ mol HCl}}}{\frac{1.190\text{ g}}{1\text{ mL soln}} \times \frac{10^3\text{ mL}}{1\text{ L}}} \times 100 = 36.2 \text{ mass \% HCl}$$

$$\text{Mass (kg) of soln} = 1\text{ L soln} \times \frac{1.190 \times 10^{-3}\text{ kg soln}}{1 \times 10^{-3}\text{ L soln}} = 1.190\text{ kg soln}$$

$$\text{Mass (kg) of HCl} = 11.8\text{ mol HCl} \times \frac{36.46\text{ g HCl}}{1\text{ mol HCl}} \times \frac{1\text{ kg}}{10^3\text{ g}} = 0.430\text{ kg HCl}$$

$$\text{Molality of HCl} = \frac{\text{mol HCl}}{\text{kg water}} = \frac{\text{mol HCl}}{\text{kg soln} - \text{kg HCl}} = \frac{11.8\text{ mol HCl}}{0.760\text{ kg } H_2O} = 15.5\ m \text{ HCl}$$

$$X_{HCl} = \frac{\text{mol HCl}}{\text{mol HCl} + \text{mol } H_2O} = \frac{11.8\text{ mol}}{11.8\text{ mol} + \left(760\text{ g } H_2O \times \frac{1\text{ mol}}{18.02\text{ g } H_2O}\right)} = 0.219$$

13.6B $$\text{Molality } (m) = \frac{\text{amount (mol) } CaBr_2}{\text{mass (kg) } H_2O} = \frac{52.1\text{ g } CaBr_2 \times \frac{1\text{ mol } CaBr_2}{199.88\text{ } CaBr_2}}{(100.0\text{ g} - 52.1\text{ g}) H_2O \times \frac{1\text{ kg}}{10^3\text{ g}}} = 5.44\ m$$

$$\text{Molarity } (M) = \frac{\text{amount (mol) } CaBr_2}{\text{L soln}} = \frac{1.70\text{ g}}{\text{mL}} \times \frac{10^3\text{ mL}}{1\text{ L}} \times 0.521 \times \frac{1\text{ mol } CaBr_2}{199.88\text{ g } CaBr_2} = 4.43\ M$$

$$\text{Mole \%} = \frac{\text{amount (mol) } CaBr_2}{\text{amount (mol) } CaBr_2 + \text{amount (mol) } H_2O} \times 100 = \frac{0.261\text{ mol } CaBr_2}{0.261\text{ mol } CaBr_2 + 2.66\text{ mol } H_2O} \times 100 = 8.94\%$$

13.7A $$\Delta P = X_{\text{aspirin}} \times P^\circ_{\text{methanol}} = \frac{\frac{2.00\text{ g}}{180.15\text{ g/mol}}}{\frac{2.00\text{ g}}{180.15\text{ g/mol}} + \frac{50.0\text{ g}}{32.04\text{ g/mol}}} \times 101\text{ torr} = 0.713\text{ torr}$$

13.7B Find mole fraction of menthol, apply Equation 13.10, and convert kPa to torr:

$$X_{\text{menthol}} = \frac{\text{amount (mol) of menthol}}{\text{amount (mol) of menthol + amount (mol) of ethanol}}$$

$$= \frac{6.49\text{ g menthol} \times \dfrac{1\text{ mol menthol}}{156.26\text{ g menthol}}}{6.49\text{ g menthol} \times \dfrac{1\text{ mol menthol}}{156.26\text{ g menthol}} + 25.0\text{ g ethanol} \times \dfrac{1\text{ mol ethanol}}{46.07\text{ g ethanol}}}$$

$$= 0.0710$$

$$\Delta P\text{ (kPa)} = X_{\text{menthol}} \times P^{\circ}_{\text{ethanol}} = 0.0710 \times 6.87\text{ kPa} = 0.488\text{ kPa}$$

$$\Delta P\text{ (torr)} = \Delta P\text{ (kPa)} \times \frac{760\text{ torr}}{101.325\text{ kPa}} = 3.66\text{ torr}$$

13.8A Find molality and then apply Equations 13.11 and 13.12:

$$\text{Molality } (m) = \frac{\text{amount (mol) } P_4}{\text{mass (kg) } CS_2} = \frac{8.44\text{ g } P_4 \times \dfrac{1\text{ mol } P_4}{123.88\text{ g } P_4}}{60.0\text{ g } CS_2 \times \dfrac{1\text{ kg}}{10^3\text{ g}}}$$

$$= 1.14\ m$$

$$\Delta T_b = K_b m = 2.34^{\circ}\text{C}/m \times 1.14\ m = 2.67^{\circ}\text{C};$$

$$T_{b(\text{solution})} = T_{b(\text{solvent})} + \Delta T_b = 46.2^{\circ}\text{C} + 2.67^{\circ}\text{C} = 48.9^{\circ}\text{C}$$

$$\Delta T_f = K_f m = 3.83^{\circ}\text{C}/m \times 1.14\ m = 4.37^{\circ}\text{C};$$

$$T_{f(\text{solution})} = T_{f(\text{solvent})} - \Delta T_f = -111.5^{\circ}\text{C} - 4.37^{\circ}\text{C} = -115.9^{\circ}\text{C}$$

13.8B Molality of $C_2H_6O_2$ $= \dfrac{(32^{\circ}\text{F} - 0.00^{\circ}\text{F})\left(\dfrac{5^{\circ}\text{C}}{9^{\circ}\text{F}}\right)}{1.86^{\circ}\text{C}/m} = 9.56\ m$

13.9A Find the molarity with Equation 13.13, use V to find the amount (mol), and then use mass to find the molar mass:

$$\text{Molarity } (M) = \frac{\Pi}{RT} = \frac{8.98\text{ torr} \times \dfrac{1\text{ atm}}{760\text{ torr}}}{\left(0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}}\right)(273.15\text{ K} + 27.0)}$$

$$= 4.79\times10^{-4}\text{ mol/L}$$

$$\text{Amount (mol)} = M \times V = 4.79\times10^{-4}\text{ mol/L} \times 0.0120\text{ L}$$

$$= 5.75\times10^{-6}\text{ mol}$$

$$\mathcal{M} = \frac{0.200\text{ g}}{5.75\times10^{-6}\text{ mol}} = 3.48\times10^{4}\text{ g/mol}$$

13.9B $\Pi = MRT$

$$= (0.30\text{ mol/L})\left(0.0821\ \frac{\text{atm·L}}{\text{mol·K}}\right)(37^{\circ}\text{C} + 273.15)$$

$$= 7.6\text{ atm}$$

13.10A (a) Scene B has separate ions in a $3K^+/1PO_4^{3-}$ ratio.

(b) $\text{Molality } (m) = \dfrac{\text{amount (mol) of } K_3PO_4}{\text{mass (kg) of } H_2O}$

$$= \frac{31.2\text{ g } K_3PO_4 \times \dfrac{1\text{ mol } K_3PO_4}{212.27\text{ g } K_3PO_4}}{85.0\text{ g } H_2O \times \dfrac{1\text{ kg}}{10^3\text{ g}}} = 1.73\ m$$

With $i = 4$, $\Delta T_b = iK_b m = 4 \times 0.512^{\circ}\text{C}/m \times 1.73\ m = 3.54^{\circ}\text{C}$;

$T_{b(\text{solution})} = T_{b(\text{solvent})} + \Delta T_b = 100.00^{\circ}\text{C} + 3.54^{\circ}\text{C} = 103.54^{\circ}\text{C}$

13.10B (a) Mass of 0.100 m solution

$$= 1\text{ kg water} + 0.100\text{ mol } MgCl_2$$

$$= 1000.\text{ g} + 9.52\text{ g} = 1009.52\text{ g}$$

$$\text{Volume of solution} = 1009.52\text{ g} \times \frac{1\text{ mL}}{1.006\text{ g}} = 1003\text{ mL}$$

$$\text{Molarity} = \frac{9.52\text{ g } MgCl_2}{1003\text{ mL soln}} \times \frac{1\text{ mol}}{95.21\text{ g } MgCl_2} \times \frac{10^3\text{ mL}}{1\text{ L}}$$

$$= 9.97\times10^{-2}\ M$$

Osmotic pressure (Π)

$$= i(MRT)$$

$$= 3(9.97\times10^{-2}\text{ mol/L})\left(0.0821\ \frac{\text{atm·L}}{\text{mol·K}}\right)(293\text{ K})$$

$$= 7.19\text{ atm}$$

(b) Scene C, because it has more particles per unit volume.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Types of Solutions: Intermolecular Forces and Solubility

(Sample Problem 13.1)

Concept Review Questions

13.1 Describe how properties of seawater illustrate the two characteristics that define mixtures.

13.2 What types of intermolecular forces give rise to hydration shells in an aqueous solution of sodium chloride?

13.3 Acetic acid is miscible with water. Would you expect carboxylic acids with general formula $CH_3(CH_2)_nCOOH$ to become more or less water soluble as n increases? Explain.

13.4 Which would you expect to be more effective as a soap, sodium acetate or sodium stearate? Explain.

13.5 Hexane and methanol are miscible as gases but only slightly soluble in each other as liquids. Explain.

13.6 Hydrogen chloride (HCl) gas is much more soluble than propane gas (C_3H_8) in water, even though HCl has a lower boiling point. Explain.

Skill-Building Exercises (grouped in similar pairs)

13.7 Which gives the more concentrated solution, (a) KNO_3 in H_2O or (b) KNO_3 in carbon tetrachloride (CCl_4)? Explain.

13.8 Which gives the more concentrated solution, stearic acid [$CH_3(CH_2)_{16}COOH$] in (a) H_2O or (b) CCl_4? Explain.

13.9 What is the strongest type of intermolecular force between solute and solvent in each solution?

(a) $CsCl(s)$ in $H_2O(l)$ (b) $CH_3\overset{\overset{O}{\|}}{C}CH_3(l)$ in $H_2O(l)$
(c) $CH_3OH(l)$ in $CCl_4(l)$

13.10 What is the strongest type of intermolecular force between solute and solvent in each solution?

(a) $Cu(s)$ in $Ag(s)$ (b) $CH_3Cl(g)$ in $CH_3OCH_3(g)$
(c) $CH_3CH_3(g)$ in $CH_3CH_2CH_2NH_2(l)$

13.11 What is the strongest type of intermolecular force between solute and solvent in each solution?

(a) $CH_3OCH_3(g)$ in $H_2O(l)$ (b) $Ne(g)$ in $H_2O(l)$
(c) $N_2(g)$ in $C_4H_{10}(g)$

13.12 What is the strongest type of intermolecular force between solute and solvent in each solution?

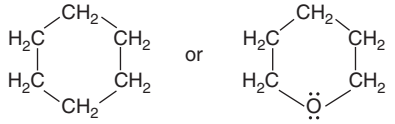
(a) $C_6H_{14}(l)$ in $C_8H_{18}(l)$ (b) $H_2C{=}O(g)$ in $CH_3OH(l)$
(c) $Br_2(l)$ in $CCl_4(l)$

13.13 Which member of each pair is more soluble in diethyl ether? Why?

(a) $NaCl(s)$ or $HCl(g)$ (b) $H_2O(l)$ or $CH_3\overset{\overset{O}{\|}}{C}H(l)$
(c) $MgBr_2(s)$ or $CH_3CH_2MgBr(s)$

13.14 Which member of each pair is more soluble in water? Why?

(a) $CH_3CH_2OCH_2CH_3(l)$ or $CH_3CH_2OCH_3(g)$
(b) $CH_2Cl_2(l)$ or $CCl_4(l)$
(c)

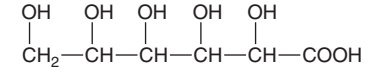


cyclohexane tetrahydropyran

Problems in Context

13.15 A dictionary definition of *homogeneous* is "uniform in composition throughout." River water is a mixture of dissolved compounds, such as calcium bicarbonate, and suspended soil particles. Is river water homogeneous? Explain.

13.16 Gluconic acid is a derivative of glucose used in cleaners and in the dairy and brewing industries. Caproic acid is a carboxylic acid used in the flavoring industry. Although both are six-carbon acids *(see structures below)*, gluconic acid is soluble in water and nearly insoluble in hexane, whereas caproic acid has the opposite solubility behavior. Explain.



gluconic acid

caproic acid

Intermolecular Forces and Biological Macromolecules

Concept Review Questions

13.17 Name three intermolecular forces that stabilize the shape of a soluble, globular protein, and explain how they act.

13.18 Name three intermolecular forces that stabilize the structure of DNA, and explain how they act.

13.19 How can relatively weak H bonds hold the double helix together yet allow DNA to function?

13.20 Is sodium propanoate (the sodium salt of propanoic acid) as effective a soap as sodium stearate (the sodium salt of stearic acid)? Explain.

13.21 What intermolecular forces stabilize a lipid bilayer?

13.22 In what way do proteins embedded in a membrane differ structurally from soluble proteins?

13.23 Histones are proteins that control gene function by attaching through salt links to exterior regions of DNA. Name an amino acid whose side chain is often found on the exterior of histones.

Why Substances Dissolve: Understanding the Solution Process

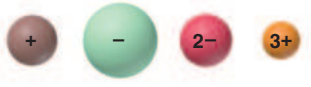
(Sample Problem 13.2)

Concept Review Questions

13.24 What is the relationship between solvation and hydration?

13.25 For a general solvent, which enthalpy terms in the thermochemical solution cycle are combined to obtain $\Delta H_{solvation}$?

13.26 (a) What is the charge density of an ion, and what two properties of an ion affect it?
(b) Arrange the following in order of increasing charge density:



(c) How do the two properties in part (a) affect the ionic heat of hydration, ΔH_{hydr}?

13.27 For ΔH_{soln} to be very small, what quantities must be nearly equal in magnitude? Will their signs be the same or opposite?

13.28 Water is added to a flask containing solid NH_4Cl. As the salt dissolves, the solution becomes colder.
(a) Is the dissolving of NH_4Cl exothermic or endothermic?
(b) Is the magnitude of $\Delta H_{lattice}$ of NH_4Cl larger or smaller than the combined ΔH_{hydr} of the ions? Explain.
(c) Given the answer to (a), why does NH_4Cl dissolve in water?

13.29 An ionic compound has a highly negative ΔH_{soln} in water. Would you expect it to be very soluble or nearly insoluble in water? Explain in terms of enthalpy and entropy changes.

Skill-Building Exercises (grouped in similar pairs)

13.30 Sketch an enthalpy diagram for the process of dissolving $KCl(s)$ in H_2O (endothermic).

13.31 Sketch an enthalpy diagram for the process of dissolving $NaI(s)$ in H_2O (exothermic).

13.32 Which ion in each pair has greater charge density? Explain.
(a) Na^+ or Cs^+ (b) Sr^{2+} or Rb^+ (c) Na^+ or Cl^-
(d) O^{2-} or F^- (e) OH^- or SH^- (f) Mg^{2+} or Ba^{2+}
(g) Mg^{2+} or Na^+ (h) NO_3^- or CO_3^{2-}

13.33 Which ion has the lower ratio of charge to volume? Explain.
(a) Br^- or I^- (b) Sc^{3+} or Ca^{2+} (c) Br^- or K^+
(d) S^{2-} or Cl^- (e) Sc^{3+} or Al^{3+} (f) SO_4^{2-} or ClO_4^-
(g) Fe^{3+} or Fe^{2+} (h) Ca^{2+} or K^+

13.34 Which ion of each pair in Problem 13.32 has the *larger* ΔH_{hydr}?

13.35 Which ion of each pair in Problem 13.33 has the *smaller* ΔH_{hydr}?

13.36 (a) Use the following data to calculate the combined heat of hydration for the ions in potassium bromate ($KBrO_3$):

$$\Delta H_{lattice} = 745 \text{ kJ/mol} \qquad \Delta H_{soln} = 41.1 \text{ kJ/mol}$$

(b) Which ion contributes more to the answer for part (a)? Why?

13.37 (a) Use the following data to calculate the combined heat of hydration for the ions in sodium acetate ($NaC_2H_3O_2$):

$$\Delta H_{lattice} = 763 \text{ kJ/mol} \qquad \Delta H_{soln} = 17.3 \text{ kJ/mol}$$

(b) Which ion contributes more to the answer for part (a)? Why?

13.38 State whether the entropy of the system increases or decreases in each of the following processes:
(a) Gasoline burns in a car engine.
(b) Gold is extracted and purified from its ore.
(c) Ethanol (CH_3CH_2OH) dissolves in 1-propanol ($CH_3CH_2CH_2OH$).

13.39 State whether the entropy of the system increases or decreases in each of the following processes:
(a) Pure gases are mixed to prepare an anesthetic.
(b) Electronic-grade silicon is prepared from sand.
(c) Dry ice (solid CO_2) sublimes.

Problems in Context

13.40 Besides its use in making black-and-white film, silver nitrate ($AgNO_3$) is used similarly in forensic science. The NaCl left behind in the sweat of a fingerprint is treated with $AgNO_3$ solution to form AgCl. This precipitate is developed to show the black-and-white fingerprint pattern. Given that $\Delta H_{lattice} = 822$ kJ/mol and $\Delta H_{hydr} = -799$ kJ/mol for $AgNO_3$, calculate its ΔH_{soln}.

Solubility as an Equilibrium Process

(Sample Problem 13.3)

Concept Review Questions

13.41 You are given a bottle of solid X and three aqueous solutions of X—one saturated, one unsaturated, and one supersaturated. How would you determine which solution is which?

13.42 Potassium permanganate ($KMnO_4$) has a solubility of 6.4 g/100 g of H_2O at 20°C and a curve of solubility vs. temperature that slopes upward to the right. How would you prepare a supersaturated solution of $KMnO_4$?

13.43 Why does the solubility of any gas in water decrease with rising temperature?

Skill-Building Exercises (grouped in similar pairs)

13.44 For a saturated aqueous solution of each of the following at 20°C and 1 atm, will the solubility increase, decrease, or stay the same when the indicated change occurs?
(a) $O_2(g)$, increase P (b) $N_2(g)$, increase V

13.45 For a saturated aqueous solution of each of the following at 20°C and 1 atm, will the solubility increase, decrease, or stay the same when the indicated change occurs?
(a) He(g), decrease T (b) RbI(s), increase P

13.46 The Henry's law constant (k_H) for O_2 in water at 20°C is 1.28×10^{-3} mol/L·atm. (a) How many grams of O_2 will dissolve in 2.50 L of H_2O that is in contact with pure O_2 at 1.00 atm? (b) How many grams of O_2 will dissolve in 2.50 L of H_2O that is in contact with air, where the partial pressure of O_2 is 0.209 atm?

13.47 Argon makes up 0.93% by volume of air. Calculate its solubility (mol/L) in water at 20°C and 1.0 atm. The Henry's law constant for Ar under these conditions is 1.5×10^{-3} mol/L·atm.

Problems in Context

13.48 Caffeine is about 10 times as soluble in hot water as in cold water. A chemist puts a hot-water extract of caffeine into an ice bath, and some caffeine crystallizes. Is the remaining solution saturated, unsaturated, or supersaturated?

13.49 The partial pressure of CO_2 gas above the liquid in a bottle of champagne at 20°C is 5.5 atm. What is the solubility of CO_2 in champagne? Assume Henry's law constant is the same for champagne as for water: at 20°C, $k_H = 3.7\times10^{-2}$ mol/L·atm.

13.50 Respiratory problems are treated with devices that deliver air with a higher partial pressure of O_2 than normal air. Why?

Concentration Terms

(Sample Problems 13.4 to 13.6)

Concept Review Questions

13.51 Explain the difference between molarity and molality. Under what circumstances would molality be a more accurate measure of the concentration of a prepared solution than molarity? Why?

13.52 Which way of expressing concentration includes (a) volume of solution; (b) mass of solution; (c) mass of solvent?

13.53 A solute has a solubility in water of 21 g/kg solvent. Is this value the same as 21 g/kg solution? Explain.

13.54 You want to convert among molarity, molality, and mole fraction of a solution. You know the masses of solute and solvent and the volume of solution. Is this enough information to carry out all the conversions? Explain.

13.55 When a solution is heated, which ways of expressing concentration change in value? Which remain unchanged? Explain.

Skill-Building Exercises (grouped in similar pairs)

13.56 Calculate the molarity of each aqueous solution:
(a) 32.3 g of table sugar ($C_{12}H_{22}O_{11}$) in 100. mL of solution
(b) 5.80 g of $LiNO_3$ in 505 mL of solution

13.57 Calculate the molarity of each aqueous solution:
(a) 0.82 g of ethanol (C_2H_5OH) in 10.5 mL of solution
(b) 1.27 g of gaseous NH_3 in 33.5 mL of solution

13.58 Calculate the molarity of each aqueous solution:
(a) 78.0 mL of 0.240 *M* NaOH diluted to 0.250 L with water
(b) 38.5 mL of 1.2 *M* HNO_3 diluted to 0.130 L with water

13.59 Calculate the molarity of each aqueous solution:
(a) 25.5 mL of 6.25 *M* HCl diluted to 0.500 L with water
(b) 8.25 mL of 2.00×10^{-2} *M* KI diluted to 12.0 mL with water

13.60 How would you prepare the following aqueous solutions?
(a) 365 mL of 8.55×10^{-2} *M* KH_2PO_4 from solid KH_2PO_4
(b) 465 mL of 0.335 *M* NaOH from 1.25 *M* NaOH

13.61 How would you prepare the following aqueous solutions?
(a) 2.5 L of 0.65 *M* NaCl from solid NaCl
(b) 15.5 L of 0.3 *M* urea [$(NH_2)_2C{=}O$] from 2.1 *M* urea

13.62 How would you prepare the following aqueous solutions?
(a) 1.40 L of 0.288 *M* KBr from solid KBr
(b) 255 mL of 0.0856 *M* $LiNO_3$ from 0.264 *M* $LiNO_3$

13.63 How would you prepare the following aqueous solutions?
(a) 57.5 mL of 1.53×10^{-3} *M* $Cr(NO_3)_3$ from solid $Cr(NO_3)_3$
(b) 5.8×10^3 m^3 of 1.45 *M* NH_4NO_3 from 2.50 *M* NH_4NO_3

13.64 Calculate the molality of the following:
(a) A solution containing 85.4 g of glycine (NH_2CH_2COOH) dissolved in 1.270 kg of H_2O
(b) A solution containing 8.59 g of glycerol ($C_3H_8O_3$) in 77.0 g of ethanol (C_2H_5OH)

13.65 Calculate the molality of the following:
(a) A solution containing 174 g of HCl in 757 g of H_2O
(b) A solution containing 16.5 g of naphthalene ($C_{10}H_8$) in 53.3 g of benzene (C_6H_6)

13.66 What is the molality of a solution consisting of 44.0 mL of benzene (C_6H_6; $d = 0.877$ g/mL) in 167 mL of hexane (C_6H_{14}; $d = 0.660$ g/mL)?

13.67 What is the molality of a solution consisting of 2.66 mL of carbon tetrachloride (CCl_4; $d = 1.59$ g/mL) in 76.5 mL of methylene chloride (CH_2Cl_2; $d = 1.33$ g/mL)?

13.68 How would you prepare the following aqueous solutions?
(a) 3.10×10^2 g of 0.125 *m* ethylene glycol ($C_2H_6O_2$) from ethylene glycol and water
(b) 1.20 kg of 2.20 mass % HNO_3 from 52.0 mass % HNO_3

13.69 How would you prepare the following aqueous solutions?
(a) 1.50 kg of 0.0355 *m* ethanol (C_2H_5OH) from ethanol and water
(b) 445 g of 13.0 mass % HCl from 34.1 mass % HCl

13.70 A solution contains 0.35 mol of isopropanol (C_3H_7OH) dissolved in 0.85 mol of water. (a) What is the mole fraction of isopropanol? (b) The mass percent? (c) The molality?

13.71 A solution contains 0.100 mol of NaCl dissolved in 8.60 mol of water. (a) What is the mole fraction of NaCl? (b) The mass percent? (c) The molality?

13.72 What mass of cesium bromide must be added to 0.500 L of water ($d = 1.00$ g/mL) to produce a 0.400 *m* solution? What are the mole fraction and the mass percent of CsBr?

13.73 What are the mole fraction and the mass percent of a solution made by dissolving 0.30 g of KI in 0.400 L of water ($d = 1.00$ g/mL)?

13.74 Calculate the molality, molarity, and mole fraction of NH_3 in ordinary household ammonia, which is an 8.00 mass % aqueous solution ($d = 0.9651$ g/mL).

13.75 Calculate the molality, molarity, and mole fraction of $FeCl_3$ in a 28.8 mass % aqueous solution ($d = 1.280$ g/mL).

Problems in Context

13.76 Wastewater from a cement factory contains 0.25 g of Ca^{2+} ion and 0.056 g of Mg^{2+} ion per 100.0 L of solution. The solution density is 1.001 g/mL. Calculate the Ca^{2+} and Mg^{2+} concentrations in ppm (by mass).

13.77 An automobile antifreeze mixture is made by mixing equal volumes of ethylene glycol ($d = 1.114$ g/mL; $\mathcal{M} = 62.07$ g/mol) and water ($d = 1.00$ g/mL) at 20°C. The density of the mixture is 1.070 g/mL. Express the concentration of ethylene glycol as:
(a) Volume percent (b) Mass percent (c) Molarity
(d) Molality (e) Mole fraction

Colligative Properties of Solutions

(Sample Problems 13.7 to 13.10)

Concept Review Questions

13.78 The chemical formula of a solute does *not* affect the extent of the solution's colligative properties. What characteristic of a solute *does* affect these properties? Name a physical property of a solution that *is* affected by the chemical formula of the solute.

13.79 What is a nonvolatile nonelectrolyte? Why is using this type of solute the simplest way to demonstrate colligative properties?

13.80 In what sense is a strong electrolyte "strong"? What property of the substance makes it a strong electrolyte?

13.81 Express Raoult's law in words. Is Raoult's law valid for a solution of a volatile solute? Explain.

13.82 What are the most important differences between the phase diagram of a pure solvent and the phase diagram of a solution of that solvent?

13.83 Is the composition of the vapor at the top of a fractionating column different from the composition at the bottom? Explain.

13.84 Is the boiling point of 0.01 *m* KF(*aq*) higher or lower than that of 0.01 *m* glucose(*aq*)? Explain.

13.85 Which aqueous solution has a boiling point closer to its predicted value, 0.050 *m* NaF or 0.50 *m* KCl? Explain.

13.86 Which aqueous solution has a freezing point closer to its predicted value, 0.01 *m* NaBr or 0.01 *m* $MgCl_2$? Explain.

13.87 The freezing point depression constants of the solvents cyclohexane and naphthalene are 20.1°C/*m* and 6.94°C/*m*, respectively. Which solvent would give a more accurate result if you are using freezing point depression to determine the molar mass of a substance that is soluble in either one? Why?

Skill-Building Exercises (grouped in similar pairs)

13.88 Classify the following substances as strong electrolytes, weak electrolytes, or nonelectrolytes:
(a) Hydrogen chloride (HCl) (b) Potassium nitrate (KNO_3)
(c) Glucose ($C_6H_{12}O_6$) (d) Ammonia (NH_3)

13.89 Classify the following substances as strong electrolytes, weak electrolytes, or nonelectrolytes:
(a) Sodium permanganate ($NaMnO_4$)
(b) Acetic acid (CH_3COOH)
(c) Methanol (CH_3OH)
(d) Calcium acetate [$Ca(C_2H_3O_2)_2$]

13.90 How many moles of solute particles are present in 1 L of each of the following aqueous solutions?
(a) 0.3 *M* KBr (b) 0.065 *M* HNO_3
(c) 10^{-4} *M* $KHSO_4$ (d) 0.06 *M* ethanol (C_2H_5OH)

13.91 How many moles of solute particles are present in 1 mL of each of the following aqueous solutions?
(a) 0.02 *M* $CuSO_4$ (b) 0.004 *M* $Ba(OH)_2$
(c) 0.08 *M* pyridine (C_5H_5N) (d) 0.05 *M* $(NH_4)_2CO_3$

13.92 Which solution has the lower freezing point?
(a) 11.0 g of CH_3OH in 100. g of H_2O *or*
22.0 g of CH_3CH_2OH in 200. g of H_2O
(b) 20.0 g of H_2O in 1.00 kg of CH_3OH *or*
20.0 g of CH_3CH_2OH in 1.00 kg of CH_3OH

13.93 Which solution has the higher boiling point?
(a) 38.0 g of $C_3H_8O_3$ in 250. g of ethanol *or*
38.0 g of $C_2H_6O_2$ in 250. g of ethanol
(b) 15 g of $C_2H_6O_2$ in 0.50 kg of H_2O *or*
15 g of NaCl in 0.50 kg of H_2O

13.94 Rank the following aqueous solutions in order of increasing (a) osmotic pressure; (b) boiling point; (c) freezing point; (d) vapor pressure at 50°C:
(I) 0.100 *m* $NaNO_3$
(II) 0.100 *m* glucose
(III) 0.100 *m* $CaCl_2$

13.95 Rank the following aqueous solutions in order of decreasing (a) osmotic pressure; (b) boiling point; (c) freezing point; (d) vapor pressure at 298 K:
(I) 0.04 *m* urea [$(NH_2)_2C{=}O$]
(II) 0.01 *m* $AgNO_3$
(III) 0.03 *m* $CuSO_4$

13.96 Calculate the vapor pressure of a solution of 34.0 g of glycerol ($C_3H_8O_3$) in 500.0 g of water at 25°C. The vapor pressure of water at 25°C is 23.76 torr. (Assume ideal behavior.)

13.97 Calculate the vapor pressure of a solution of 0.39 mol of cholesterol in 5.4 mol of toluene at 32°C. Pure toluene has a vapor pressure of 41 torr at 32°C. (Assume ideal behavior.)

13.98 What is the freezing point of 0.251 *m* urea in water?

13.99 What is the boiling point of 0.200 *m* lactose in water?

13.100 The boiling point of ethanol (C_2H_5OH) is 78.5°C. What is the boiling point of a solution of 6.4 g of vanillin ($\mathcal{M}$ = 152.14 g/mol) in 50.0 g of ethanol (K_b of ethanol = 1.22°C/*m*)?

13.101 The freezing point of benzene is 5.5°C. What is the freezing point of a solution of 5.00 g of naphthalene ($C_{10}H_8$) in 444 g of benzene (K_f of benzene = 4.90°C/*m*)?

13.102 What is the minimum mass of ethylene glycol ($C_2H_6O_2$) that must be dissolved in 14.5 kg of water to prevent the solution from freezing at −12.0°F? (Assume ideal behavior.)

13.103 What is the minimum mass of glycerol ($C_3H_8O_3$) that must be dissolved in 11.0 mg of water to prevent the solution from freezing at −15°C? (Assume ideal behavior.)

13.104 A small protein has a molar mass of 1.50×10^4 g/mol. What is the osmotic pressure exerted at 24.0°C by 25.0 mL of an aqueous solution that contains 37.5 mg of the protein?

13.105 A 125-mL sample of an aqueous solution of the protein ovalbumin from chicken egg white contains 1.31 g of the dissolved protein and has an osmotic pressure of 4.32 torr at 25°C. What is the molar mass of ovalbumin?

13.106 Assuming ideal behavior, find the freezing point of a solution made by dissolving 13.2 g of ammonium phosphate in 45.0 g of water.

13.107 Assuming ideal behavior, find the boiling point of a solution made by dissolving 32.8 g of calcium nitrate in 108 g of water.

13.108 Calculate the molality and van't Hoff factor (*i*) for the following aqueous solutions:
(a) 1.00 mass % NaCl, freezing point = −0.593°C
(b) 0.500 mass % CH_3COOH, freezing point = −0.159°C

13.109 Calculate the molality and van't Hoff factor (*i*) for the following aqueous solutions:
(a) 0.500 mass % KCl, freezing point = −0.234°C
(b) 1.00 mass % H_2SO_4, freezing point = −0.423°C

Problems in Context

13.110 In a study designed to prepare new gasoline-resistant coatings, a polymer chemist dissolves 6.053 g of poly(vinyl alcohol) in enough water to make 100.0 mL of solution. At 25°C, the osmotic pressure of this solution is 0.272 atm. What is the molar mass of the polymer sample?

13.111 The U.S. Food and Drug Administration lists dichloromethane (CH_2Cl_2) and carbon tetrachloride (CCl_4) among the many cancer-causing chlorinated organic compounds. What are the partial pressures of these substances in the vapor above a solution of 1.60 mol of CH_2Cl_2 and 1.10 mol of CCl_4 at 23.5°C? The vapor pressures of pure CH_2Cl_2 and CCl_4 at 23.5°C are 352 torr and 118 torr, respectively. (Assume ideal behavior.)

The Structure and Properties of Colloids

Concept Review Questions

13.112 Is the fluid inside a bacterial cell considered a solution, a colloid, or both? Explain.

13.113 What type of colloid is each of the following?
(a) Milk (b) Fog (c) Shaving cream

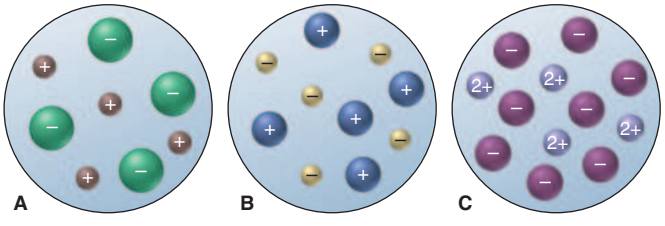
13.114 What is Brownian motion, and what causes it?

13.115 In a movie theater, you can see the beam of projected light. What phenomenon does this exemplify? Why does it occur?

13.116 Why don't soap micelles coagulate and form large globules? Is soap more effective in freshwater or in seawater? Why?

Comprehensive Problems

13.117 The three aqueous ionic solutions below have total volumes of 25. mL for A, 50. mL for B, and 100. mL for C. If each sphere represents 0.010 mol of ions, calculate: (a) the total molarity of ions for each solution; (b) the highest molarity of solute; (c) the lowest molality of solute (assuming the solution densities are equal); (d) the highest osmotic pressure (assuming ideal behavior).



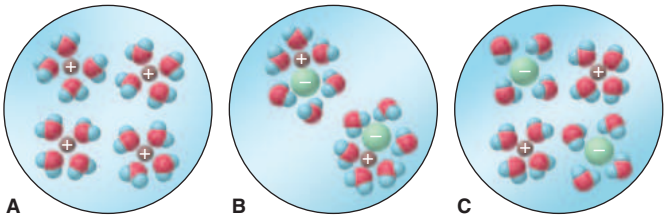
13.118 An aqueous solution is 10.% glucose by mass (d = 1.039 g/mL at 20°C). Calculate its freezing point, boiling point at 1 atm, and osmotic pressure.

13.119 Because zinc has nearly the same atomic radius as copper (d = 8.95 g/cm^3), zinc atoms substitute for some copper atoms in the many types of brass. Calculate the density of the brass with (a) 10.0 atom % Zn and (b) 38.0 atom % Zn.

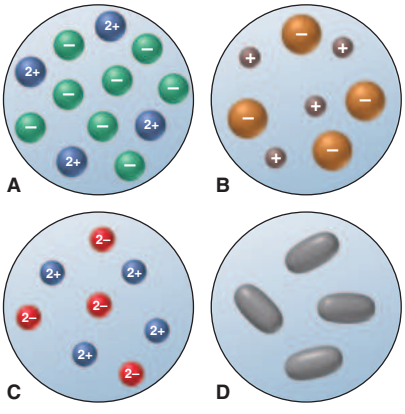
13.120 Gold occurs in seawater at an average concentration of 1.1×10^{-2} ppb. How many liters of seawater must be processed to recover 1 troy ounce of gold, assuming 81.5% efficiency (d of seawater = 1.025 g/mL; 1 troy ounce = 31.1 g)?

13.121 Use atomic properties to explain why xenon is 11 times as soluble as helium in water at 0°C on a mole basis.

13.122 Which of the following best represents a molecular-scale view of an ionic compound in aqueous solution? Explain.



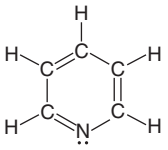
13.123 Four 0.50 m aqueous solutions are depicted below. Assume that the solutions behave ideally.
(a) Which has the highest boiling point?
(b) Which has the lowest freezing point?
(c) Can you determine which one has the highest osmotic pressure? Explain.



13.124 Thermal pollution from industrial wastewater causes the temperature of river or lake water to increase, which can affect fish survival as the concentration of dissolved O_2 decreases. Use the following data to find the molarity of O_2 at each temperature (assume the solution density is the same as water):

Temperature (°C)	Solubility of O_2 (mg/kg H_2O)	Density of H_2O (g/mL)
0.0	14.5	0.99987
20.0	9.07	0.99823
40.0	6.44	0.99224

13.125 Pyridine *(right)* is an essential portion of many biologically active compounds, such as nicotine and vitamin B_6. Like ammonia, it has a nitrogen with a lone pair, which makes it act as a weak base. Because it is miscible in a wide range of solvents, from water to benzene, pyridine is one of the most important bases and solvents in organic syntheses. Account for its solubility behavior in terms of intermolecular forces.

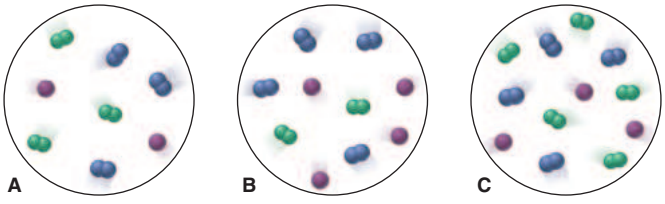


13.126 A chemist is studying small organic compounds for their potential use as an antifreeze. When 0.243 g of a compound is dissolved in 25.0 mL of water, the freezing point of the solution is −0.201°C.
(a) Calculate the molar mass of the compound (d of water = 1.00 g/mL).
(b) Analysis shows that the compound is 53.31 mass % C and 11.18 mass % H, the remainder being O. Calculate the empirical and molecular formulas of the compound.
(c) Draw a Lewis structure for a compound with this formula that forms H bonds and another for one that does not.

13.127 Air in a smoky bar contains 4.0×10^{-6} mol/L of CO. What mass of CO is inhaled by a bartender who respires at a rate of 11 L/min during an 8.0-h shift?

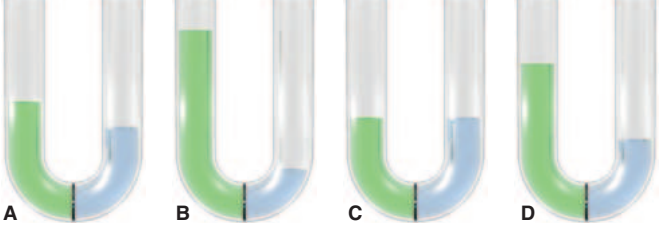
13.128 Is 50% by mass of methanol dissolved in ethanol different from 50% by mass of ethanol dissolved in methanol? Explain.

13.129 Three gaseous mixtures of N_2 *(blue)*, Cl_2 *(green)*, and Ne *(purple)* are depicted below. (a) Which has the smallest mole fraction of N_2? (b) Which have the same mole fraction of Ne? (c) Rank all three in order of increasing mole fraction of Cl_2.



13.130 A water treatment plant needs to attain a fluoride concentration of 4.50×10^{-5} M. (a) What mass of NaF must be added to 5000. L of water in a blending tank? (b) What mass per day of fluoride is ingested by a person who drinks 2.0 L of this water?

13.131 Four U tubes each have distilled water in the right arm, a solution in the left arm, and a semipermeable membrane between arms. (a) If the solute is KCl, which solution is most concentrated? (b) If each solute is different but all the solutions have the same molarity, which contains the smallest number of dissolved ions?



13.132 β-Pinene ($C_{10}H_{16}$) and α-terpineol ($C_{10}H_{18}O$) are used in cosmetics to provide a "fresh pine" scent. At 367 K, the pure sub-

stances have vapor pressures of 100.3 torr and 9.8 torr, respectively. What is the composition of the vapor (in terms of mole fractions) above a solution containing equal masses of these compounds at 367 K? (Assume ideal behavior.)

13.133 A solution of 1.50 g of solute dissolved in 25.0 mL of H_2O at 25°C has a boiling point of 100.45°C. (a) What is the molar mass of the solute if it is a nonvolatile nonelectrolyte and the solution behaves ideally (d of H_2O at 25°C = 0.997 g/mL)? (b) Conductivity measurements show that the solute is ionic with general formula AB_2 or A_2B. What is the molar mass if the solution behaves ideally? (c) Analysis indicates an empirical formula of CaN_2O_6. Explain the difference between the actual formula mass and that calculated from the boiling point elevation. (d) Find the van't Hoff factor (i) for this solution.

13.134 A pharmaceutical preparation made with ethanol (C_2H_5OH) is contaminated with methanol (CH_3OH). A sample of vapor above the liquid mixture contains a 97/1 mass ratio of C_2H_5OH to CH_3OH. What is the mass ratio of these alcohols in the liquid? At the temperature of the liquid, the vapor pressures of C_2H_5OH and CH_3OH are 60.5 torr and 126.0 torr, respectively.

13.135 Water treatment plants commonly use chlorination to destroy bacteria. A byproduct is chloroform ($CHCl_3$), a suspected carcinogen, produced when HOCl, formed by reaction of Cl_2 and water, reacts with dissolved organic matter. The United States, Canada, and the World Health Organization have set a limit of 100. ppb of $CHCl_3$ in drinking water. Convert this concentration into molarity, molality, mole fraction, and mass percent.

13.136 A saturated Na_2CO_3 solution is prepared, and a small excess of solid is present (white pile in beaker). A seed crystal of $Na_2{}^{14}CO_3$ (^{14}C is a radioactive isotope of ^{12}C) is added (small red piece), and the radioactivity is measured over time. (a) Would you expect radioactivity in the solution? Explain. (b) Would you expect radioactivity in all the solid or just in the seed crystal? Explain.

13.137 A biochemical engineer isolates a bacterial gene fragment and dissolves a 10.0-mg sample in enough water to make 30.0 mL of solution. The osmotic pressure of the solution is 0.340 torr at 25°C. (a) What is the molar mass of the gene fragment? (b) If the solution density is 0.997 g/mL, how large is the freezing point depression for this solution (K_f of water = 1.86°C/m)?

13.138 A river is contaminated with 0.65 mg/L of dichloroethylene ($C_2H_2Cl_2$). What is the concentration (in ng/L) of dichloroethylene at 21°C in the air breathed by a person swimming in the river (k_H for $C_2H_2Cl_2$ in water is 0.033 mol/L·atm)?

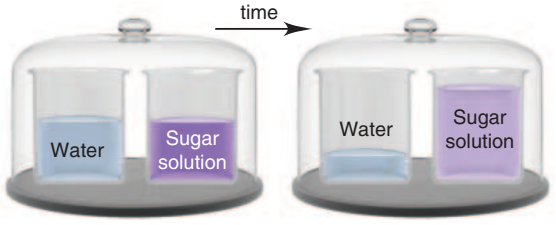
13.139 At an air-water interface, fatty acids such as oleic acid lie in a one-molecule-thick layer *(monolayer),* with the heads in the water and the tails perpendicular in the air. When 2.50 mg of oleic acid is placed on a water surface, it forms a circular monolayer 38.6 cm in diameter. Find the surface area (in cm^2) occupied by one molecule ($\mathcal{M}$ of oleic acid = 283 g/mol).

13.140 A simple device used for estimating the concentration of total dissolved solids in an aqueous solution works by measuring the electrical conductivity of the solution. The method assumes that equal concentrations of different solids give approximately the same conductivity, and that the conductivity is proportional to concentration. The table below gives some actual electrical conductivities (in arbitrary units) for solutions of selected solids at the indicated concentrations (in ppm by mass):

	Conductivity		
Sample	**0 ppm**	**5.00×10^3 ppm**	**10.00×10^3 ppm**
$CaCl_2$	0.0	8.0	16.0
K_2CO_3	0.0	7.0	14.0
Na_2SO_4	0.0	6.0	11.0
Seawater (dil)	0.0	8.0	15.0
Sucrose ($C_{12}H_{22}O_{11}$)	0.0	0.0	0.0
Urea [$(NH_2)_2C{=}O$]	0.0	0.0	0.0

(a) How reliable are these measurements for estimating concentrations of dissolved solids? (b) For what types of substances might this method have a large error? Why? (c) Based on this method, an aqueous $CaCl_2$ solution has a conductivity of 14.0 units. Calculate its mole fraction and molality.

13.141 Two beakers are placed in a closed container *(left)*. One beaker contains water, the other a concentrated aqueous sugar solution. With time, the solution volume increases and the water volume decreases *(right)*. Explain on the molecular level.



13.142 The release of volatile organic compounds into the atmosphere is regulated to limit ozone formation. In a laboratory simulation, 5% of the ethanol in a liquid detergent is released. Thus, a "down-the-drain" factor of 0.05 is used to estimate ethanol emissions from the detergent. The k_H values for ethanol and 2-butoxyethanol ($C_4H_9OCH_2CH_2OH$) are 5×10^{-6} atm·m^3/mol and 1.6×10^{-6} atm·m^3/mol, respectively. (a) Estimate a "down-the-drain" factor for 2-butoxyethanol in the detergent. (b) What is the k_H for ethanol in units of L·atm/mol? (c) Is this value consistent with a value given as 0.64 Pa·m^3/mol?

13.143 Although other solvents are available, dichloromethane (CH_2Cl_2) is still often used to "decaffeinate" drinks because the solubility of caffeine in CH_2Cl_2 is 8.35 times that in water.
(a) A 100.0-mL sample of cola containing 10.0 mg of caffeine is extracted with 60.0 mL of CH_2Cl_2. What mass of caffeine remains in the aqueous phase?
(b) A second identical cola sample is extracted with two successive 30.0-mL portions of CH_2Cl_2. What mass of caffeine remains in the aqueous phase after each extraction?
(c) Which approach extracts more caffeine?

13.144 How do you prepare 250. g of 0.150 m aqueous $NaHCO_3$?

13.145 Tartaric acid occurs in crystalline residues found in wine vats. It is used in baking powders and as an additive in foods. It

contains 32.3% by mass carbon and 3.97% by mass hydrogen; the balance is oxygen. When 0.981 g of tartaric acid is dissolved in 11.23 g of water, the solution freezes at −1.26°C. Find the empirical and molecular formulas of tartaric acid.

13.146 Methanol (CH_3OH) and ethanol (C_2H_5OH) are miscible because the major intermolecular force for each is H bonding. In some methanol-ethanol solutions, the mole fraction of methanol is higher, but the mass percent of ethanol is higher. What is the range of mole fraction of methanol for these solutions?

13.147 A solution of 5.0 g of benzoic acid (C_6H_5COOH) in 100.0 g of carbon tetrachloride has a boiling point of 77.5°C.
(a) Calculate the molar mass of benzoic acid in the solution.
(b) Suggest a reason for the difference between the molar mass based on the formula and that found in part (a).

13.148 Derive a general equation that expresses the relationship between the molarity and the molality of a solution. Why are the numerical values of these two terms approximately equal for very dilute aqueous solutions?

13.149 A florist prepares a solution of nitrogen-phosphorus fertilizer by dissolving 5.66 g of NH_4NO_3 and 4.42 g of $(NH_4)_3PO_4$ in enough water to make 20.0 L of solution. What are the molarities of NH_4^+ and of PO_4^{3-} in the solution?

13.150 Suppose coal-fired power plants used water in scrubbers to remove SO_2 from smokestack gases (see Chemical Connections, p. 273). (a) If the partial pressure of SO_2 in the stack gases is 2.0×10^{-3} atm, what is the solubility of SO_2 in the scrubber liquid (k_H for SO_2 in water is 1.23 mol/L·atm at 200.°C)? (b) From your answer to part (a), why are basic solutions, such as limewater slurries [$Ca(OH)_2$], used in scrubbers?

13.151 Urea is a white crystalline solid used as a fertilizer, in the pharmaceutical industry, and in the manufacture of certain polymer resins. Analysis of urea reveals that, by mass, it is 20.1% carbon, 6.7% hydrogen, 46.5% nitrogen, and the balance oxygen.
(a) Find the empirical formula of urea.
(b) A 5.0 g/L solution of urea in water has an osmotic pressure of 2.04 atm, measured at 25°C. What is the molar mass and molecular formula of urea?

13.152 The total concentration of dissolved particles in blood is 0.30 *M*. An intravenous (IV) solution must be isotonic with blood, which means it must have the same concentration.
(a) To relieve dehydration, a patient is given 100. mL/h of IV glucose ($C_6H_{12}O_6$) for 2.5 h. What mass (g) of glucose did she receive? (b) If isotonic saline (NaCl) is used, what is the molarity of the solution? (c) If the patient is given 150. mL/h of IV saline for 1.5 h, how many grams of NaCl did she receive?

13.153 Deviations from Raoult's law lead to the formation of *azeotropes,* constant boiling mixtures that cannot be separated by distillation, making industrial separations difficult. For components A and B, there is a positive deviation if the A-B attraction is less than A-A and B-B attractions (A and B reject each other), and a negative deviation if the A-B attraction is greater than A-A and B-B attractions. If the A-B attraction is nearly equal to the A-A and B-B attractions, the solution obeys Raoult's law. Explain whether the behavior of each pair will be nearly ideal, have a positive deviation, or a negative deviation:
(a) Benzene (C_6H_6) and methanol
(b) Water and ethyl acetate
(c) Hexane and heptane
(d) Methanol and water
(e) Water and hydrochloric acid

13.154 Acrylic acid ($CH_2{=}CHCOOH$) is a monomer used to make superabsorbent polymers and various compounds for paint and adhesive production. At 1 atm, it boils at 141.5°C but is prone to polymerization. Its vapor pressure at 25°C is 4.1 mbar. What pressure (in mmHg) is needed to distill the pure acid at 65°C?

13.155 To effectively stop polymerization, certain inhibitors require the presence of a small amount of O_2. At equilibrium with 1 atm of air, the concentration of O_2 dissolved in the monomer acrylic acid ($CH_2{=}CHCOOH$) is 1.64×10^{-3} *M*. (a) What is k_H (mol/L·atm) for O_2 in acrylic acid? (b) If 0.005 atm of O_2 is sufficient to stop polymerization, what is the molarity of O_2? (c) What is the mole fraction? (d) What is the concentration in ppm? (Pure acrylic acid is 14.6 *M*; P_{O_2} in air is 0.2095 atm.)

13.156 Volatile organic solvents have been implicated in adverse health effects in industrial workers. Greener methods are phasing these solvents out. Rank the solvents in Table 13.6 (p. 544) in terms of increasing volatility.

13.157 At ordinary temperatures, water is a poor solvent for organic substances. But at high pressure and above 200°C, water develops many properties of organic solvents. Find the minimum pressure needed to maintain water as a liquid at 200.°C (ΔH_{vap} = 40.7 kJ/mol at 100°C and 1.00 atm; assume that this value remains constant with temperature).

13.158 In ice-cream making, the ingredients are kept below 0.0°C in an ice-salt bath. (a) Assuming that NaCl dissolves completely and forms an ideal solution, what mass of it is needed to lower the melting point of 5.5 kg of ice to −5.0°C? (b) Given the same assumptions as in part (a), what mass of $CaCl_2$ is needed?

13.159 Perfluorocarbons (PFCs), hydrocarbons with all H atoms replaced by F atoms, have very weak cohesive forces. One interesting consequence of this property is that a live mouse can breathe while submerged in O_2-saturated PFCs.
(a) At 298 K, perfluorohexane (C_6F_{14}, $\mathcal{M}$ = 338 g/mol and d = 1.674 g/mL) in equilibrium with 101,325 Pa of O_2 has a mole fraction of O_2 of 4.28×10^{-3}. What is k_H in mol/L·atm?
(b) According to one source, k_H for O_2 in water at 25°C is 756.7 L·atm/mol. What is the solubility of O_2 in water at 25°C in ppm? (c) Rank the k_H values in descending order for O_2 in water, ethanol, C_6F_{14}, and C_6H_{14}. Explain your ranking.

13.160 The solubility of N_2 in blood is a serious problem for divers breathing compressed air (78% N_2 by volume) at depths greater than 50 ft.
(a) What is the molarity of N_2 in blood at 1.00 atm?
(b) What is the molarity of N_2 in blood at a depth of 50. ft?
(c) Find the volume (in mL) of N_2, measured at 25°C and 1.00 atm, released per liter of blood when a diver at a depth of 50. ft rises to the surface (k_H for N_2 in water at 25°C is 7.0×10^{-4} mol/L·atm and at 37°C is 6.2×10^{-4} mol/L·atm; assume d of water is 1.00 g/mL).

13.161 Figure 12.11 (p. 466) shows the phase changes of pure water. Consider how the diagram would change if air were present at 1 atm and dissolved in the water.
(a) Would the three phases of water still attain equilibrium at some temperature? Explain.
(b) In principle, would that temperature be higher, lower, or the same as the triple point for pure water? Explain.

(c) Would ice sublime at a few degrees below the freezing point under this pressure? Explain.
(d) Would the liquid have the same vapor pressure as that shown in Figure 12.7 (p. 464) at 100°C? At 120°C?

13.162 KNO_3, $KClO_3$, KCl, and NaCl are recrystallized as follows:
Step 1. A saturated aqueous solution of the compound is prepared at 50°C.
Step 2. The mixture is filtered to remove undissolved compound.
Step 3. The filtrate is cooled to 0°C.
Step 4. The crystals that form are filtered, dried, and weighed.
(a) Which compound has the highest percent recovery and which the lowest (see Figure 13.19, p. 534)?
(b) Starting with 100. g of each compound, how many grams of each can be recovered?

13.163 Eighty proof whiskey is 40% ethanol (C_2H_5OH) by volume. A man has 7.0 L of blood and drinks 28 mL of the whiskey, of which 22% of the ethanol goes into his blood.
(a) What concentration (in g/mL) of ethanol is in his blood (d of ethanol = 0.789 g/mL)?
(b) What volume (in mL) of whiskey would raise his blood alcohol level to 8.0×10^{-4} g/mL, the level at which a person is considered intoxicated?

13.164 Soft drinks are canned under 4 atm of CO_2 and release CO_2 when opened.
(a) How many moles of CO_2 are dissolved in a 355-mL can of soda before it is opened?
(b) After it has gone flat?
(c) What volume (in L) would the released CO_2 occupy at 1.00 atm and 25°C (k_H for CO_2 at 25°C is 3.3×10^{-2} mol/L·atm; P_{CO_2} in air is 4×10^{-4} atm)?

13.165 Gaseous O_2 in equilibrium with O_2 dissolved in water at 283 K is depicted at right. (a) Which scene below represents the system at 298 K? (b) Which scene represents the system when the pressure of O_2 is increased by half?

Recurring patterns appear throughout nature, helping us make sense of the diversity in the world around us. Astronomical patterns allow us to predict phases of the Moon, eclipses, and comet appearances; physical patterns we observe in animals and plants give rise to systems of biological classification; and patterns within our bodies, such as a heartbeat *(photo)* or a diurnal change in a hormone, allow us to monitor health and disease. As you'll see in the upcoming discussions, patterns also appear in the atomic, chemical, and physical properties of the elements, which help us make sense of their behavior.

IN THIS CHAPTER . . . *We apply general ideas of bonding, structure, and reactivity (from Chapters 7–12) to the main-group elements and see how their behavior correlates with their position in the periodic table.*

- We begin with hydrogen, the simplest element, considering its position in the table and examining the three types of hydrides.
- We then survey Period 2 as an example of the general changes in chemical and physical properties from left to right *across* the periodic table.
- We go on to discuss each of the eight families of main-group elements by exploring vertical trends in physical and chemical properties. In the process, we highlight some of the most important elements—boron, carbon, silicon, nitrogen, phosphorus, oxygen, sulfur, and the halogens.

14.1 HYDROGEN, THE SIMPLEST ATOM

A hydrogen atom consists of a nucleus with a single positive charge, surrounded by a single electron. Perhaps because of this simple structure, hydrogen may be the most important element of all. In the Sun, hydrogen (H) nuclei combine to form helium (He) nuclei in a process that provides nearly all Earth's energy. About 90% of all the atoms in the universe are H atoms, so it is the most abundant element by far. On Earth, only tiny amounts of the free, diatomic element occur naturally, but hydrogen is abundant in combination with oxygen in water. With its simple structure and low molar mass, nonpolar H_2 is a colorless, odorless gas with extremely weak dispersion forces that result in very low melting (−259°C) and boiling points (−253°C).

Where Hydrogen Fits in the Periodic Table

Hydrogen has no perfectly suitable position in the periodic table (Figure 14.1). Depending on the property, hydrogen may fit better in Group 1A(1), 4A(14), or 7A(17):

- *Like the Group 1A(1) elements,* hydrogen has an outer electron configuration of ns^1 and most commonly a +1 oxidation state. However, unlike the alkali metals, hydrogen *shares* its single valence electron with nonmetals rather than transferring it to them. Moreover, hydrogen has a much higher ionization energy (IE = 1311 kJ/mol) and electronegativity (EN = 2.1) than the alkali metals. By comparison, lithium has an IE of only 520 kJ/mol and an EN of 1.0, the highest of the alkali metals.

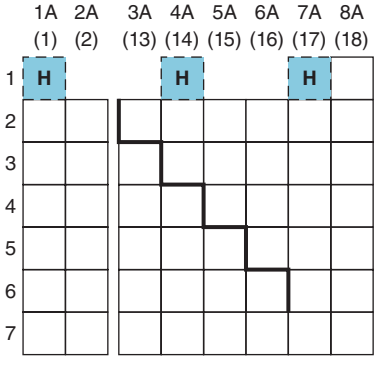

Figure 14.1 **Where does hydrogen belong?**

- *Like the Group 4A(14) elements,* hydrogen's valence level is half-filled, but with only one electron, and it has similar ionization energy, electron affinity, electronegativity, and bond energies.
- *Like the Group 7A(17) elements,* hydrogen occurs as diatomic molecules and fills its outer level either by electron sharing or by gaining one electron from a metal to form a 1− ion (hydride, H^-). However, while the monatomic halide ions (X^-) are common and stable, H^- is rare and reactive. Moreover, hydrogen has a lower electronegativity (EN = 2.1) than any of the halogens (ENs range from 4.0 to 2.2) and lacks their three valence electron pairs.

Hydrogen's unique behavior arises from its tiny size. It has a high IE because its electron is very close to the nucleus, with no inner electrons to shield it from the positive charge. And it has a low EN (for a nonmetal) because it has only one proton to attract bonding electrons. In this chapter, H will be discussed as part of either Group 1A(1) or 7A(17) depending on the property being considered.

Highlights of Hydrogen Chemistry

In Chapters 12 and 13, we discussed the vital importance of H bonding, and in Chapter 22, we'll look at hydrogen's many uses in industry. Elemental hydrogen is very reactive and combines with nearly every other element. It forms three types of hydrides—ionic, covalent, and metallic.

Ionic (Saltlike) Hydrides With very reactive metals, such as those in Group 1A(1) and the larger members of Group 2A(2) (Ca, Sr, and Ba), hydrogen forms *saltlike hydrides*—white, crystalline solids composed of the metal cation and the hydride ion:

$$2Li(s) + H_2(g) \longrightarrow 2LiH(s)$$
$$Ca(s) + H_2(g) \longrightarrow CaH_2(s)$$

In water, H^- is a strong base that pulls H^+ from surrounding H_2O molecules to form H_2 and OH^-:

$$NaH(s) + H_2O(l) \longrightarrow Na^+(aq) + OH^-(aq) + H_2(g)$$

The hydride ion is also a powerful reducing agent; for example, it reduces Ti(IV) to the free metal:

$$TiCl_4(l) + 4LiH(s) \longrightarrow Ti(s) + 4LiCl(s) + 2H_2(g)$$

Covalent (Molecular) Hydrides Hydrogen reacts with nonmetals to form many *covalent hydrides,* such as CH_4, PH_3, H_2S, and HCl. Most are gases, but many hydrides of boron and carbon are liquids or solids that consist of much larger molecules. In most covalent hydrides, hydrogen has an oxidation number of +1 because the other nonmetal has a higher electronegativity.

Conditions for preparing the covalent hydrides depend on the reactivity of the other nonmetal. For example, with stable, triple-bonded N_2, hydrogen reacts at high temperatures (~400°C) and pressures (~250 atm), and the reaction needs a catalyst to proceed at any practical speed:

$$N_2(g) + 3H_2(g) \xrightarrow{\text{catalyst}} 2NH_3(g) \quad \Delta H^\circ_{rxn} = -91.8 \text{ kJ}$$

Industrial facilities throughout the world use this reaction to produce millions of tons of ammonia each year for fertilizers, explosives, and synthetic fibers. On the other hand, hydrogen combines rapidly with reactive, single-bonded F_2, even at extremely low temperatures (−196°C):

$$F_2(g) + H_2(g) \longrightarrow 2HF(g) \quad \Delta H^\circ_{rxn} = -546 \text{ kJ}$$

Metallic (Interstitial) Hydrides Many transition elements form *metallic (interstitial) hydrides,* in which H_2 molecules (and H atoms) occupy the holes in the metal's crystal structure (Figure 14.2). Thus, such hydrides are *not* compounds but gas-solid solutions. Also, unlike ionic and covalent hydrides, interstitial hydrides, such as $TiH_{1.7}$, typically lack one stoichiometric formula because the metal can incorporate variable amounts

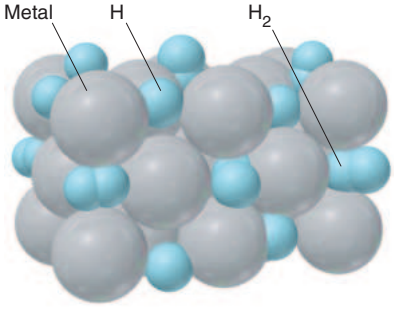

Figure 14.2 A metallic (interstitial) hydride.

of hydrogen, depending on the pressure and temperature. Metallic hydrides cannot serve as "storage containers" for hydrogen fuel in cars; the metals that store the most hydrogen are expensive and heavy and release hydrogen only at very high temperatures. But other systems, including carbon nanotubes, are being studied for this role.

14.2 TRENDS ACROSS THE PERIODIC TABLE: THE PERIOD 2 ELEMENTS

Table 14.1 on pages 572–573 presents the main horizontal trends in atomic properties and the physical and chemical properties that emerge from them for the Period 2 elements, lithium through neon. In general, *these trends apply to the other periods as well*. Note the following points:

- Electrons fill the one *ns* and the three *np* orbitals according to Pauli's exclusion principle and Hund's rule.
- As a result of increasing nuclear charge and the addition of electrons to orbitals of the same energy level (same *n* value), atomic size generally decreases, whereas first ionization energy and electronegativity generally increase (see bar graphs).
- Metallic character decreases with increasing nuclear charge as elements change from metals to metalloids to nonmetals.
- Reactivity is highest at the left and right ends of the period, except for the inert noble gas, because members of Groups 1A(1) and 7A(17) are only one electron away from attaining a filled outer level.
- Bonding between atoms of an element changes from metallic, to covalent in networks, to covalent in individual molecules, to none (noble gases exist as separate atoms). As expected, physical properties, such as melting point, change abruptly at the network/molecule boundary, which occurs between carbon (solid) and nitrogen (gas).
- Bonding between each element and an active nonmetal changes from ionic, to polar covalent, to covalent. Bonding between each element and an active metal changes from metallic to polar covalent to ionic (see Figure 9.2, p. 360).
- The acid-base behavior of the common element oxide in water changes from basic to amphoteric to acidic as the bond between the element and oxygen changes from ionic to covalent (see the similar trend for the Period 3 elements in Figure 8.24, p. 346).
- Reducing strength decreases through the metals, and oxidizing strength increases through the nonmetals. In Period 2, oxidation numbers (O.N.s) equal the A-group number for Li and Be and the A-group number minus 8 for O and F. Boron has several O.N.s, Ne has none, and C and N show all possible O.N.s for their groups.

The Anomalous Behavior of Period 2 Members One point that is not shown in Table 14.1 is the *anomalous (unrepresentative) behavior specific for the Period 2 elements within their groups*. This behavior arises from the relatively *small size* and *small number of orbitals* in the outer energy level of these elements.

1. *Anomalous properties of lithium.* In Group 1A(1), Li is the only member that forms a simple oxide and nitride, Li_2O and Li_3N, on reaction with O_2 and N_2 in air and the only member that forms molecular compounds with organic halides:

$$2Li(s) + CH_3CH_2Cl(g) \longrightarrow CH_3CH_2Li(s) + LiCl(s)$$

Because of its small size, Li^+ has a relatively high charge density. Therefore, it can deform nearby electron clouds to a much greater extent than the other 1A ions can, which increases orbital overlap and gives many lithium salts significant covalent character. Thus, LiCl, LiBr, and LiI are much more soluble in polar organic solvents, such as ethanol and acetone, than are the halides of Na and K, because the lithium halide bond polarity interacts with these solvents through dipole-dipole forces. The small, highly positive Li^+ makes Li salts much less soluble in water than those of Na and K.

Table 14.1 Trends in Atomic, Physical, and Chemical Properties of the Period 2 Elements

Group: Element/At. No.:	1A(1) Lithium (Li) $Z = 3$	2A(2) Beryllium (Be) $Z = 4$	3A(13) Boron (B) $Z = 5$	4A(14) Carbon (C) $Z = 6$

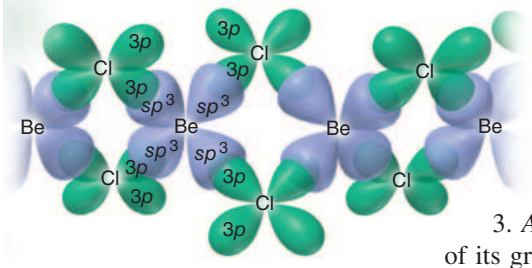
A *Gaseous $BeCl_2$ has only $4e^-$ around Be.*



B *Solid $BeCl_2$ has an octet around Be.*

Figure 14.3 **Overcoming electron deficiency in beryllium chloride.**

2. *Anomalous properties of beryllium.* Because of the extremely high charge density of Be^{2+}, the discrete ion does not exist, and *all Be compounds exhibit covalent bonding*. With only two valence electrons, Be does not attain an octet in its simple gaseous compounds (Section 10.1), but this electron deficiency is overcome as the gas condenses.

Consider beryllium chloride ($BeCl_2$). At temperatures greater than 900°C, it consists of linear molecules in which two *sp* hybrid orbitals hold four electrons around the central Be (Figure 14.3A). As it cools, the molecules bond together, solidifying in long chains with each Cl bridging two Be atoms. Each Be is sp^3 hybridized and has attained an octet (Figure 14.3B).

3. *Anomalous properties of other Period 2 elements.* Boron is the only member of its group to form complex families of compounds with metals and with hydrogen (boranes). Carbon shows extremely unusual behavior: it bonds to itself (and a small number of other elements) so extensively and diversely that it gives rise to countless organic compounds. Triple-bonded, unreactive, gaseous nitrogen is very different from its reactive, solid family members. Oxygen, the only gas in its group, is much more reactive than sulfur and the other members. Fluorine is so electronegative that it reacts violently with water, and it is the only member that forms a weak hydrohalic acid, HF.

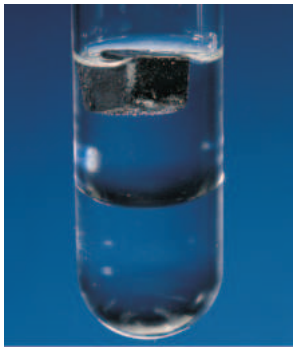
14.3 GROUP 1A(1): THE ALKALI METALS

The first group of elements in the periodic table is named for the alkaline (basic) nature of their oxides and for the basic solutions the elements form in water. Group 1A(1) provides the best example of regular trends with no significant exceptions. All the elements in the group—lithium (Li), sodium (Na), potassium (K), rubidium (Rb), cesium (Cs), and rare, radioactive francium (Fr)*—are very reactive metals. The Family Portrait of Group 1A(1) is the first in a series that provides an overview of each of the main groups, summarizing key atomic, physical, and chemical properties.

Why the Alkali Metals Are Unusual Physically

Alkali metals have some properties that are unique for metals:

- They are unusually soft and can be easily cut with a knife. Na has the consistency of cold butter and K can be squeezed like clay.
- Alkali metals have lower melting and boiling points than any other group of metals. Li is the only member that melts above 100°C, and Cs melts only a few degrees above room temperature.
- They have lower densities than most metals. Li floats on lightweight mineral oil *(see photo)*.



Lithium floating in oil floating on water.

The unusual physical behavior of these metals can be traced to the largest atomic size in their respective periods and to the ns^1 valence electron configuration. Because the single valence electron is relatively far from the nucleus, only weak attractions exist in the solid between the delocalized electrons and the metal-ion cores. Such weak metallic bonding means that the alkali metal crystal structure can be easily deformed or broken down, which results in a soft consistency and low melting point. The low densities of the alkali metals result from their having the lowest molar masses and largest atomic radii (and, thus, volumes) in their periods.

*Francium is so rare (estimates indicate only 15 g of the element in the top kilometer of Earth's crust) that its properties are largely unknown. Therefore, we will mention it only occasionally in the discussion.

Group 1A(1): The Alkali Metals

KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

KEY
Atomic No.
Symbol
Atomic mass
Valence e^- configuration
(Common oxidation states)

3 **Li** 6.941 $2s^1$ (+1)	11 **Na** 22.99 $3s^1$ (+1)	19 **K** 39.10 $4s^1$ (+1)	
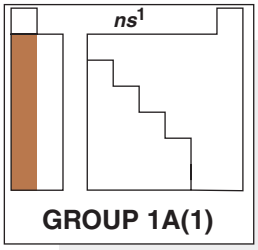
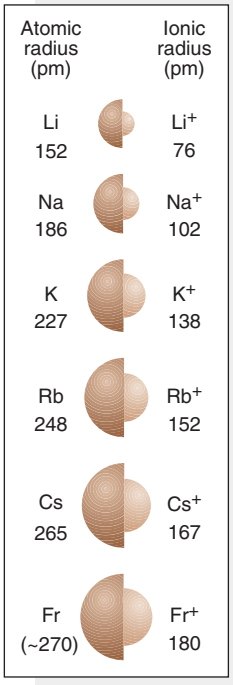
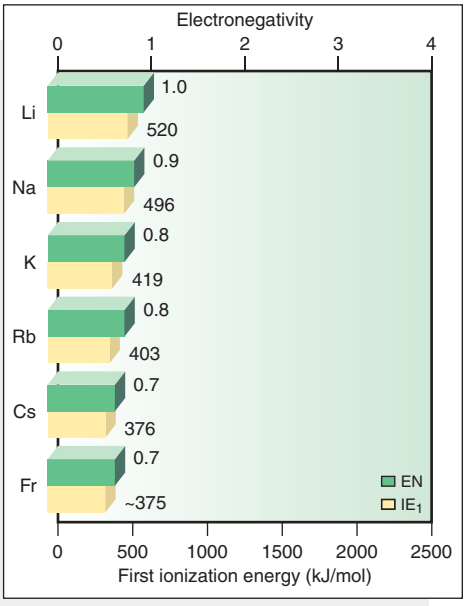
37 **Rb** 85.47 $5s^1$ (+1)	
55 **Cs** 132.9 $6s^1$ (+1)	
87 **Fr** (223) $7s^1$ (+1)	No sample available





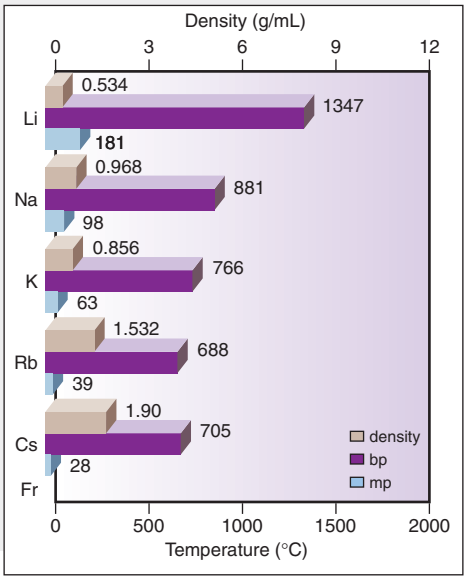
Atomic Properties

Group electron configuration is ns^1. All members have the +1 oxidation state and form an E^+ ion. Atoms have the largest size and lowest IE and EN in their periods. Down the group, atomic and ionic size increase, while IE and EN decrease.



Physical Properties

Metallic bonding is relatively weak because there is only one valence electron. Therefore, these metals are soft with relatively low melting and boiling points. These values decrease down the group because larger atom cores attract delocalized electrons less strongly. Large atomic size and low atomic mass result in low density; thus, density generally increases down the group because mass increases more than size.



Reactions

1. The alkali metals reduce H in H_2O from the +1 to the 0 oxidation state (E represents any element in the group):

$$2E(s) + 2H_2O(l) \longrightarrow 2E^+(aq) + 2OH^-(aq) + H_2(g)$$

The reaction becomes more vigorous down the group.

2. The alkali metals reduce oxygen, but the product depends on the metal. Li forms the oxide, Li_2O; Na forms the peroxide (O.N. of O = −1), Na_2O_2; K, Rb, and Cs form the superoxide (O.N. of O = $-\frac{1}{2}$), EO_2:

$$4Li(s) + O_2(g) \longrightarrow 2Li_2O(s)$$
$$2Na(s) + O_2(g) \longrightarrow Na_2O_2(s)$$
$$K(s) + O_2(g) \longrightarrow KO_2(s)$$

In emergency breathing units, KO_2 reacts with H_2O and CO_2 in exhaled air to release O_2 (Section 22.4).

3. The alkali metals reduce hydrogen to form ionic (saltlike) hydrides:

$$2E(s) + H_2(g) \longrightarrow 2EH(s)$$

NaH is an industrial base and reducing agent that is used to prepare other reducing agents, such as $NaBH_4$.

4. The alkali metals reduce halogens to form ionic halides:

$$2E(s) + X_2 \longrightarrow 2EX(s) \qquad (X = F, Cl, Br, I)$$

Why the Alkali Metals Are So Reactive

The alkali metals are extremely reactive elements. They are *powerful reducing agents,* always occurring in nature as 1+ cations rather than as free metals. Some examples of their reactivity follow:

- The alkali metals (E)* reduce halogens to form ionic solids in highly exothermic reactions:

$$2E(s) + X_2 \longrightarrow 2EX(s) \qquad (X = F, Cl, Br, I)$$

- They reduce hydrogen in water, reacting vigorously (Rb and Cs explosively) to form H_2 and a metal hydroxide solution *(see photo):*

$$2E(s) + 2H_2O(l) \longrightarrow 2E^+(aq) + 2OH^-(aq) + H_2(g)$$

- They reduce molecular hydrogen to form ionic hydrides:

$$2E(s) + H_2(g) \longrightarrow 2EH(s)$$

- They reduce O_2 in air, and thus tarnish rapidly. Because of this reactivity, Na and K are usually kept under mineral oil (an unreactive liquid) in the laboratory, and Rb and Cs are handled with gloves under an inert argon atmosphere.

Potassium reacting with water.

The ns^1 configuration, which is the basis for their physical properties, is also the basis of their reactivity, as shown in the steps for the reaction between an alkali metal and a nonmetal:

1. *Atomization: the solid metal separates into gaseous atoms.* The weak metallic bonding leads to *low values for* ΔH_{atom} (the heat needed to convert the solid into individual gaseous atoms), which decrease down the group:

$$E(s) \longrightarrow E(g) \qquad \Delta H_{atom}\ (Li > Na > K > Rb > Cs)$$

2. *Ionization: the metal atom transfers its outer electron to the nonmetal.* Alkali metals have *low ionization energies* (the lowest in their periods) and form *cations with small radii* since a great decrease in size occurs when the outer electron is lost: the volume of the Li^+ is about 13% the volume of Li! Thus, Group 1A(1) ions are small spheres with considerable charge density.

3. *Lattice formation: the resulting cations and anions attract each other to form an ionic solid.* Group 1A(1) salts have *high lattice energies,* which easily overcome the endothermic atomization and ionization steps, because the small cations lie close to the anions. For a given anion, the trend in lattice energy is the inverse of the trend in cation size: *as cation radius increases, lattice energy decreases*. The Group 1A(1) and 2A(2) chlorides exemplify this steady decrease in lattice energy (Figure 14.4).

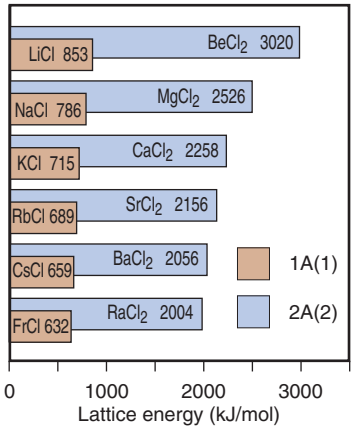


Figure 14.4 Lattice energies of the Group 1A(1) and 2A(2) chlorides.

Despite these strong ionic attractions in the solid, *nearly all Group 1A(1) salts are water soluble.* The attraction between the ions and water molecules creates a highly exothermic heat of hydration (ΔH_{hydr}), and a large increase in entropy occurs when ions in the organized crystal become dispersed and hydrated in solution; together, these factors outweigh the high lattice energy.

The magnitude of the hydration energy *decreases* as ionic size increases:

$$E^+(g) \longrightarrow E^+(aq) \qquad \Delta H = -\Delta H_{hydr}\ (Li^+ > Na^+ > K^+ > Rb^+ > Cs^+)$$

Interestingly, the *smaller* ions form larger *hydrated ions*. This size trend is key to the function of nerves, kidneys, and cell membranes because the *sizes* of $Na^+(aq)$ and $K^+(aq)$, the most common cations in cell fluids, influence their movement in and out of cells.

14.4 GROUP 2A(2): THE ALKALINE EARTH METALS

The Group 2A(2) elements are called *alkaline earth metals* because their oxides give basic (alkaline) solutions and melt at such high temperatures that they remained as solids ("earths") in the alchemists' fires. The group is a fascinating collection of elements:

*Throughout the chapter, we use E to represent any element in a group other than in Group 7A(17), for which the halogens are represented as X.

rare beryllium (Be), common magnesium (Mg) and calcium (Ca), less familiar strontium (Sr) and barium (Ba), and radioactive radium (Ra). The Group 2A(2) Family Portrait *(next page)* presents an overview of these elements.

How the Alkaline Earth and Alkali Metals Compare Physically

In general terms, the elements in Groups 1A(1) and 2A(2) behave as close cousins physically, with differences due to the change in outer electron configuration from ns^1 to ns^2. Two electrons from each 2A atom and one more proton in the nucleus strengthen metallic bonding. The following changes result:

- Melting and boiling points are much higher for 2A elements; in fact, they melt at around the same temperatures as the 1A elements boil.
- Compared to many transition metals, the alkaline earths are soft and lightweight, but they are harder and denser than the alkali metals.

How the Alkaline Earth and Alkali Metals Compare Chemically

The second valence electron in an alkaline earth metal lies in the same sublevel as the first and thus it is not shielded very well from the additional nuclear charge, so Z_{eff} is greater. As a result, Group 2A(2) elements have smaller atomic radii and higher ionization energies than Group 1A(1) elements. Despite the higher IEs, *all the alkaline earths (except Be) occur as 2+ cations in ionic compounds*. (As we said, Be behaves anomolously because so much energy is needed to remove two electrons from this tiny atom that it never forms discrete Be^{2+} ions, and so its bonds are polar covalent.)

Some important chemical properties of Group 2A(2) elements are

1. *Reducing strength.* Like the alkali metals, the alkaline earth metals are *strong reducing agents:*

- Each reduces O_2 in air to form the oxide (Ba also forms the peroxide, BaO_2).
- Except for Be and Mg, which form adherent oxide coatings, each reduces H_2O at room temperature to form H_2.
- Except for Be, each reduces the halogens, N_2, and H_2 to form ionic compounds.

2. *Basicity of oxides.* The oxides are strongly basic (except for amphoteric BeO) and react with acidic oxides to form salts, such as sulfites and carbonates; for example,

$$SrO(s) + CO_2(g) \longrightarrow SrCO_3(s)$$

Natural carbonates, such as limestone and marble, are major structural materials and the commercial sources for most 2A compounds. Calcium carbonate is heated to obtain calcium oxide (lime); this important industrial compound has essential roles in steelmaking, water treatment, and smokestack scrubbing and is used to make glass, whiten paper, and neutralize acidic soil.

3. *Lattice energies and solubilities.* The 2A elements are reactive because the high lattice energies of their compounds more than compensate for the large total IE required to form 2+ cations (Section 9.2). Because the cations are smaller and doubly charged, their charge densities and lattice energies are much higher than salts of Group 1A(1) (see Figure 14.4). This property also leads to lower solubility of 2A salts in water. Higher charge density increases heat of hydration, but it increases lattice energy even more. Thus, unlike the corresponding 1A compounds, most 2A fluorides, carbonates, phosphates, and sulfates have very low solubility. Nevertheless, the ion-dipole attractions between 2+ ions and water molecules are so strong that many slightly soluble 2A salts crystallize as hydrates; two examples are Epsom salt, $MgSO_4 \cdot 7H_2O$, used as a soak for inflammations, and gypsum, $CaSO_4 \cdot 2H_2O$, used as the bonding material between the paper sheets in wallboard and as the cement in surgical casts.

Diagonal Relationships: Lithium and Magnesium

One of the clearest ways to see how atomic properties influence chemical behavior is in three **diagonal relationships,** similarities between a Period 2 element and one diagonally down and to the right in Period 3.

Group 2A(2): The Alkaline Earth Metals

KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

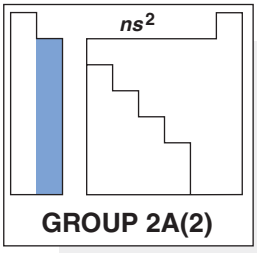
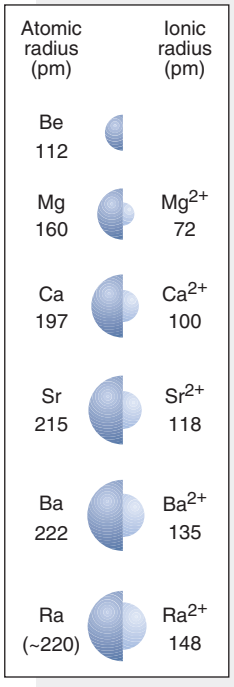
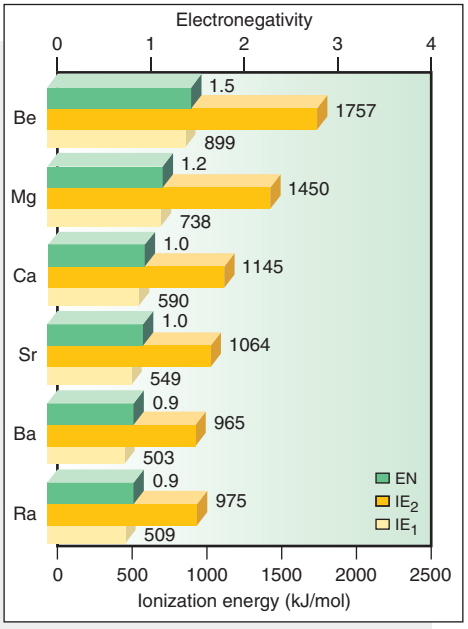
20 **Ca** 40.08 $4s^2$ (+2)	
38 **Sr** 87.62 $5s^2$ (+2)	
56 **Ba** 137.3 $6s^2$ (+2)	
88 **Ra** (226) $7s^2$ (+2)	No sample available





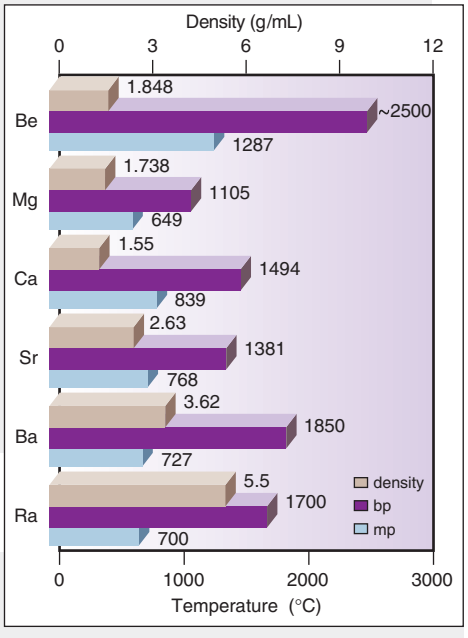
Atomic Properties

Group electron configuration is ns^2 (filled ns sublevel). All members have the +2 oxidation state and, except for Be, form compounds with an E^{2+} ion. Atomic and ionic sizes increase down the group but are smaller than for the corresponding 1A(1) elements. IE and EN decrease down the group but are higher than for the corresponding 1A(1) elements.



Physical Properties

Metallic bonding involves two valence electrons. These metals are still relatively soft but are much harder than the 1A(1) metals. Melting and boiling points generally decrease and densities generally increase down the group. These values are much higher than for 1A(1) elements, and the trend is not as regular.



Reactions

1. The metals reduce O_2 to form the oxides:

$$2E(s) + O_2(g) \longrightarrow 2EO(s)$$

Ba also forms the peroxide, BaO_2.

2. The larger metals reduce water to form hydrogen gas:

$$E(s) + 2H_2O(l) \longrightarrow E^{2+}(aq) + 2OH^-(aq) + H_2(g) \quad (E = Ca, Sr, Ba)$$

Be and Mg form an oxide coating that allows only slight reaction.

3. The metals reduce halogens to form ionic halides:

$$E(s) + X_2 \longrightarrow EX_2(s) \quad [X = F \text{ (not with Be)}, Cl, Br, I]$$

4. Most of the elements reduce hydrogen to form ionic hydrides:

$$E(s) + H_2(g) \longrightarrow EH_2(s) \quad (E = \text{all except Be})$$

5. The elements reduce nitrogen to form ionic nitrides:

$$3E(s) + N_2(g) \longrightarrow E_3N_2(s)$$

6. Except for amphoteric BeO, the element oxides are basic:

$$EO(s) + H_2O(l) \longrightarrow E^{2+}(aq) + 2OH^-(aq)$$

$Ca(OH)_2$ is a component of cement and mortar.

7. All carbonates undergo thermal decomposition to the oxide:

$$ECO_3(s) \xrightarrow{\Delta} EO(s) + CO_2(g)$$

This reaction is used to produce CaO (lime) in huge amounts from naturally occurring limestone.

The first of these occurs between Li and Mg, which have similar atomic and ionic sizes (Figure 14.5). Note that *one period down increases atomic (or ionic) size and one group to the right decreases it*. The Li radius is 152 pm and that of Mg is 160 pm; the Li^+ radius is 76 pm and that of Mg^{2+} is 72 pm. From similar atomic properties emerge similar chemical properties. Both elements form nitrides with N_2, hydroxides and carbonates that decompose easily with heat, organic compounds with a polar covalent metal-carbon bond, and salts with similar solubilities. We'll discuss the relationships between Be and Al and between B and Si in upcoming sections.

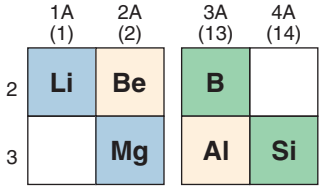


Figure 14.5 Three diagonal relationships in the periodic table.

14.5 GROUP 3A(13): THE BORON FAMILY

The third family of main-group elements contains both familiar and unusual members, which engage in some exotic bonding and have strange physical properties. Boron (B) heads the family, but, as we said, its properties are not representative. Metallic aluminum (Al) has properties more typical of the group, but its great abundance and importance contrast with the rareness of gallium (Ga), indium (In), thallium (Tl), and the recently synthesized element 113. The atomic, physical, and chemical properties of these elements are summarized in the Group 3A(13) Family Portrait *(next page)*.

How the Transition Elements Influence This Group's Properties

If you look only at the main groups, Group 3A(13), the first of the *p* block, seems to be just one group away from Group 2A(2). In Period 4 and higher, however, a gap of 10 transition elements (*d* block) separates these groups (see Figure 8.11, p. 334). And an additional 14 inner transition elements (*f* block) appear in Periods 6 and 7. Thus, the heavier 3A members have nuclei with many more protons, but since *d* and *f* electrons penetrate very little (Section 8.1), the outer (*s* and *p*) electrons of Ga, In, and Tl are poorly shielded from this much higher positive charge. As a result, *these elements have greater Z_{eff} than the two lighter members,* and this stronger nuclear pull explains why Ga, In, and Tl have smaller atomic radii and larger ionization energies and electronegativities than expected. This effect influences later groups, too.

Physical properties are influenced by the type of bonding. Boron is a network covalent metalloid—black, hard, and very high melting. The other group members are metals—shiny and relatively soft and low melting. Aluminum's low density and three valence electrons make it an exceptional conductor: for a given mass, aluminum conducts a current twice as effectively as copper. Gallium's metallic bonding gives it the largest liquid temperature range of any element: it melts at skin temperature *(see photo in the Family Portrait, p. 580)* but does not boil until 2403°C. The bonding is too weak to keep the Ga atoms fixed when the solid is warmed, but strong enough to keep them from escaping the molten metal until it is very hot.

Features That First Appear in This Group's Chemical Properties

Looking down Group 3A(13), we see a wide range of chemical behavior. Boron, the anomalous member from Period 2, is the only metalloid. It is much less reactive at room temperature than the other members and forms covalent bonds exclusively. Although aluminum acts like a metal physically, its halides exist in the gas phase as covalent *dimers*—molecules formed by joining two identical smaller molecules (Figure 14.6)—and its oxide is amphoteric rather than basic. Most of the other 3A compounds are ionic. However, because the 3A cations are smaller and triply charged, they polarize an anion more effectively than do 2A cations, so their compounds are more covalent.

The redox behavior of this group exhibits three features that appear first in Group 3A(13), but in Groups 4A(14) to 6A(16) as well:

1. *Presence of multiple oxidation states.* Larger members of these groups also have an important oxidation state *two lower than the A-group number.* The lower state

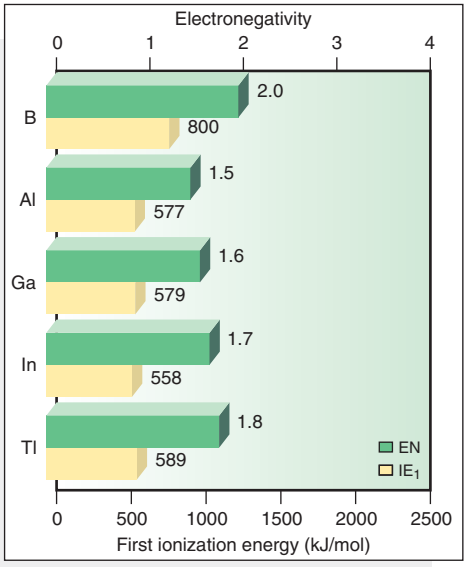
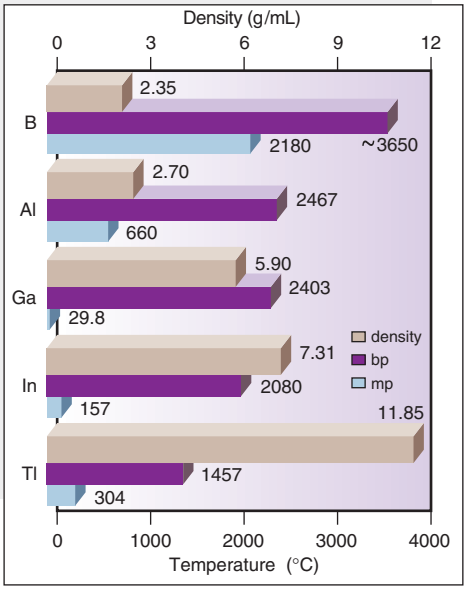
Atomic Properties

Group electron configuration is ns^2np^1. All except Tl commonly display the +3 oxidation state. The +1 state becomes more common down the group. Atomic size is smaller and EN is higher than for 2A(2) elements; IE is lower, however, because it is easier to remove an electron from the higher energy *p* sublevel. Atomic size, IE, and EN do not change as expected down the group because there are intervening transition and inner transition elements.



Physical Properties

Bonding changes from network covalent in B to metallic in the rest of the group. Thus, B has a much higher melting point than the others, but there is no overall trend. Boiling points decrease down the group. Densities increase down the group.



Reactions

1. The elements react sluggishly, if at all, with water:

$$2Ga(s) + 6H_2O(hot) \longrightarrow 2Ga^{3+}(aq) + 6OH^-(aq) + 3H_2(g)$$
$$2Tl(s) + 2H_2O(steam) \longrightarrow 2Tl^+(aq) + 2OH^-(aq) + H_2(g)$$

Al becomes covered with a layer of Al_2O_3 that prevents further reaction.

2. When strongly heated in pure O_2, all members form oxides:

$$4E(s) + 3O_2(g) \xrightarrow{\Delta} 2E_2O_3(s) \qquad (E = B, Al, Ga, In)$$
$$4Tl(s) + O_2(g) \xrightarrow{\Delta} 2Tl_2O(s)$$

Oxide acidity decreases down the group: B_2O_3 (weakly acidic) > Al_2O_3 > Ga_2O_3 > In_2O_3 > Tl_2O (strongly basic), and the +1 oxide is more basic than the +3 oxide.

3. All members reduce halogens (X_2):

$$2E(s) + 3X_2 \longrightarrow 2EX_3 \qquad (E = B, Al, Ga, In)$$
$$2Tl(s) + X_2 \longrightarrow 2TlX(s)$$

The BX_3 compounds are volatile and covalent. Trihalides of Al, Ga, and In are (mostly) ionic solids.

occurs when the atoms lose their *np* electrons only, not their two *ns* electrons. This fact is often called the *inert-pair effect* (Section 8.4).

2. *Increasing stability of the lower oxidation state.* For these groups, *the lower state becomes more stable going down the group*. In Group 3A(13), for instance, all members exhibit the +3 state, but the +1 state first appears with some compounds of gallium and becomes the only important state of thallium.

3. *Increasing metallic behavior and basicity of oxides*. In general, *oxides of the element in the lower oxidation state are more basic.* Thus, for example, in Group 3A(13), In_2O is more basic than In_2O_3. The reason is that *an element acts more like a metal in its lower state*. In this example, the lower charge of In^+ does not polarize the O^{2-} ion as much as the higher charge of In^{3+} does, so the In-to-O bonding is more ionic and the O^{2-} ion is more available to act as a base.

Highlights of Boron Chemistry

Like the other Period 2 elements, the chemical behavior of boron is strikingly different from that of the other members of its group. *All boron compounds are covalent,* and unlike the other Group 3A(13) members, boron forms network covalent compounds or large molecules with metals, H, O, N, and C. The unifying feature of many boron compounds is the element's *electron deficiency.* Boron adopts two strategies to fill its outer level: accepting a bonding pair from an electron-rich atom and forming bridge bonds with an electron-poor atom.

Accepting a Bonding Pair from an Electron-Rich Atom In gaseous boron trihalides (BX_3), the B atom is electron deficient, with only six electrons around it (Section 10.1). To attain an octet, the B atom accepts a lone pair *(blue)* from an electron-rich atom and forms a covalent bond:

$$BF_3(g) + :NH_3(g) \longrightarrow F_3B{-}NH_3(g)$$

(Reactions in which one reactant accepts an electron pair from another to form a covalent bond are very common and are known as *Lewis acid-base reactions.* We'll discuss them in Chapters 18 and 23 and see examples of them throughout the rest of the text.)

Similarly, B has only six electrons in boric acid, $B(OH)_3$ (sometimes written as H_3BO_3). In water, the acid itself does not release a proton. Rather, it accepts an electron pair from the O in H_2O, forming a fourth bond and releasing an H^+ ion:

$$B(OH)_3(s) + H_2O(l) \rightleftharpoons B(OH)_4^-(aq) + H^+(aq)$$

Boron's outer shell is filled in the wide variety of borate salts, such as the mineral borax (sodium borate), $Na_2[B_4O_5(OH)_4]\cdot 8H_2O$, used for decades as a household cleaning agent. Strong heating of boric acid (or borate salts) drives off water molecules and gives molten boron oxide:

$$2B(OH)_3(s) \xrightarrow{\Delta} B_2O_3(l) + 3H_2O(g)$$

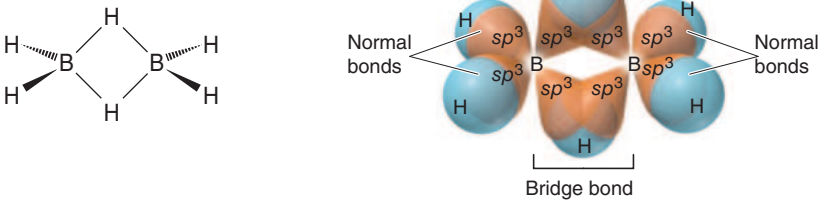
When mixed with silica (SiO_2), this molten oxide forms borosilicate glass. Its high transparency and small change in size when heated or cooled make borosilicate glass useful in cookware and in lab glassware *(see photo)*.

Labware made of borosilicate glass.

Forming a Bridge Bond with an Electron-Poor Atom In elemental boron and its many hydrides (boranes), there is no electron-rich atom to supply boron with electrons. In these substances, boron attains an octet through some unusual bonding. In diborane (B_2H_6) and many larger boranes, for example, two types of B—H bonds exist. The first type is a normal electron-pair bond. The valence bond picture in Figure 14.7 *(next page)* shows an sp^3 orbital of B overlapping a 1*s* orbital of H in each of the four terminal B—H bonds, using two of the three electrons in the valence level of each B atom.

The other type of bond is a hydride **bridge bond** (or three-center, two-electron bond), in which *each B—H—B grouping is held together by only two electrons.* Two sp^3 orbitals, one from *each* B, overlap an H 1*s* orbital between them. Two electrons move through this extended bonding orbital—one from one of the B atoms and the

Figure 14.7 The two types of covalent bonding in diborane.



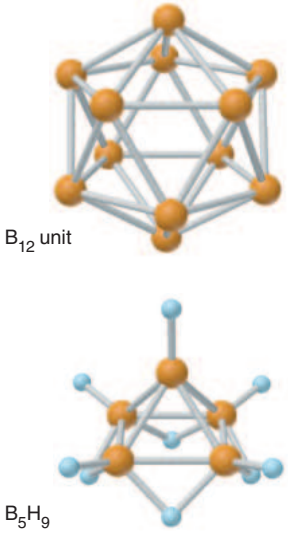


Figure 14.8 The boron icosahedron and one of the boranes.

other from the H atom—and join the two B atoms via the H-atom bridge. Notice that *each B atom is surrounded by eight electrons:* four from the two normal B—H bonds and four from the two B—H—B bridge bonds with a tetrahedral arrangement around each B atom. In many boranes and in elemental boron (Figure 14.8), one B atom bridges two others in a three-center, two-electron B—B—B bond.

Diagonal Relationships: Beryllium and Aluminum

Beryllium in Group 2A(2) and aluminum in Group 3A(13) are another pair of diagonally related elements. Both form oxoanions in strong base: beryllate, $Be(OH)_4^{2-}$, and aluminate, $Al(OH)_4^-$. Both have bridge bonds in their hydrides and chlorides. Both form oxide coatings impervious to reaction with water (which explains aluminum's great use as a structural metal), and both oxides are amphoteric, extremely hard, and high melting. Although the atomic and ionic sizes of these elements differ, the small, highly charged Be^{2+} and Al^{3+} ions polarize nearby electron clouds strongly. Therefore, some Al compounds and all Be compounds have significant covalent character.

14.6 GROUP 4A(14): THE CARBON FAMILY

The whole range of behavior occurs in Group 4A(14): nonmetallic carbon (C) leads off, followed by the metalloids silicon (Si) and germanium (Ge), then metallic tin (Sn) and lead (Pb), and ending with recently synthesized flerovium (Fl). Information about the compounds of C and of Si fills libraries: organic chemistry, most polymer chemistry, and biochemistry are based on carbon, whereas geochemistry and some essential polymer and electronic technologies are based on silicon. The Group 4A(14) Family Portrait summarizes atomic, physical, and chemical properties.

How Type of Bonding Affects Physical Properties

The elements of Group 4A(14) and their neighbors in Groups 3A(13) and 5A(15) illustrate how some physical properties depend on the type of bonding in an element (Table 14.2). Within Group 4A, the large decrease in melting point between the

Table 14.2 Bond Type and the Melting Process in Groups 3A(13) to 5A(15)

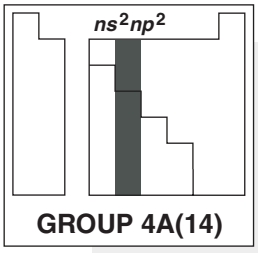
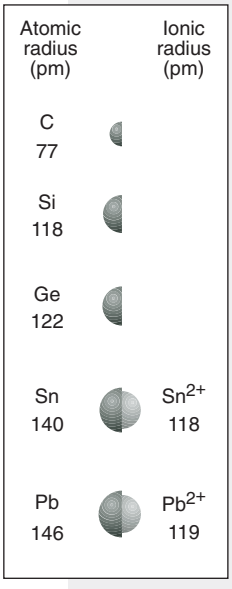
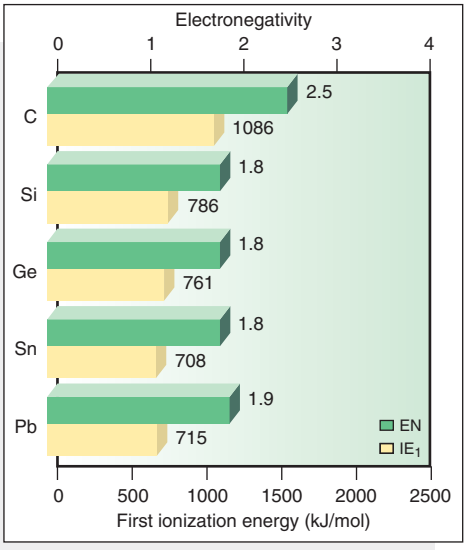
114 Fl (289) $7s^27p^2$	Observed in experiments at Dubna, Russia, in 1998





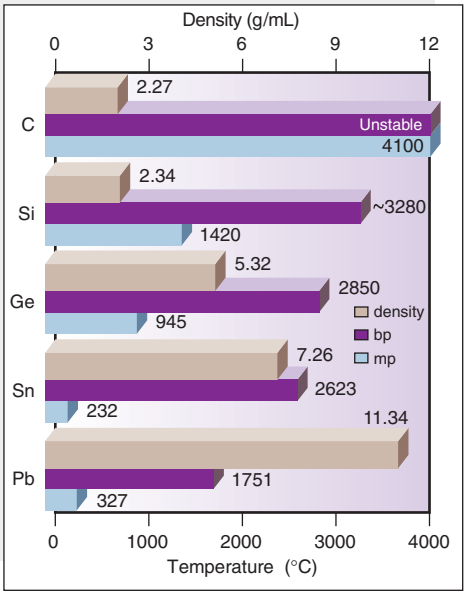
Atomic Properties

Group electron configuration is ns^2np^2. Down the group, the number of oxidation states decreases, and the lower (+2) state becomes more common. Down the group, size increases. Because transition and inner transition elements intervene, IE and EN do not decrease smoothly.



Physical Properties

Trends in properties, such as decreasing hardness and melting point, are due to changes in types of bonding within the solid: covalent network in C, Si, and Ge; metallic in Sn and Pb *(see text)*. Down the group, density increases because of several factors, including differences in crystal packing.



Reactions

1. The elements are oxidized by halogens:

$$E(s) + 2X_2 \longrightarrow EX_4 \quad (E = C, Si, Ge)$$

The +2 halides are more stable for tin and lead, SnX_2 and PbX_2.

2. The elements are oxidized by O_2:

$$E(s) + O_2(g) \longrightarrow EO_2 \quad (E = C, Si, Ge, Sn)$$

Pb forms the +2 oxide, PbO. Oxides become more basic down the group. The reaction of CO_2 and H_2O provides the weak acidity of natural unpolluted waters:

$$CO_2(g) + H_2O(l) \rightleftharpoons [H_2CO_3(aq)] \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$

3. Hydrocarbons react with O_2 to form CO_2 and H_2O. The reaction for methane is adapted to yield heat or electricity:

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$$

4. Silica is reduced to form elemental silicon:

$$SiO_2(s) + 2C(s) \longrightarrow Si(s) + 2CO(g)$$

This crude silicon is made ultrapure through zone refining for use in the manufacture of computer chips.

network covalent solids C and Si is due to longer, weaker bonds in the Si structure; the large decrease between Ge and Sn is due to the change from covalent network to metallic bonding. Similarly, considering horizontal trends, the large increases in melting point and ΔH_{fus} across a period between Al and Si and between Ga and Ge reflect the change from metallic to covalent network bonding. Note the abrupt rises in the values for these properties from metallic Al, Ga, and Sn to the network covalent metalloids Si, Ge, and Sb, and note the abrupt drops from the covalent networks of C and Si to the individual molecules of N and P in Group 5A.

Allotropism: Different Forms of an Element Striking variations in physical properties often appear among **allotropes,** different crystalline or molecular forms of a substance. One allotrope is usually more stable than another at a particular pressure and temperature. Group 4A(14) provides the first important examples of allotropism, in the forms of carbon and tin.

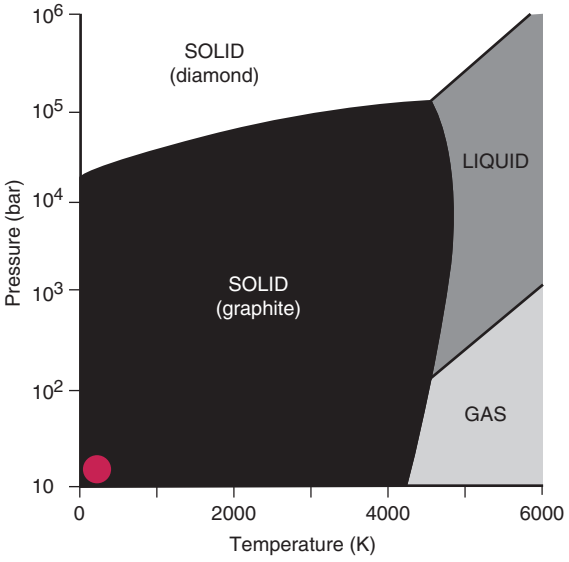


Figure 14.9 Phase diagram of carbon.

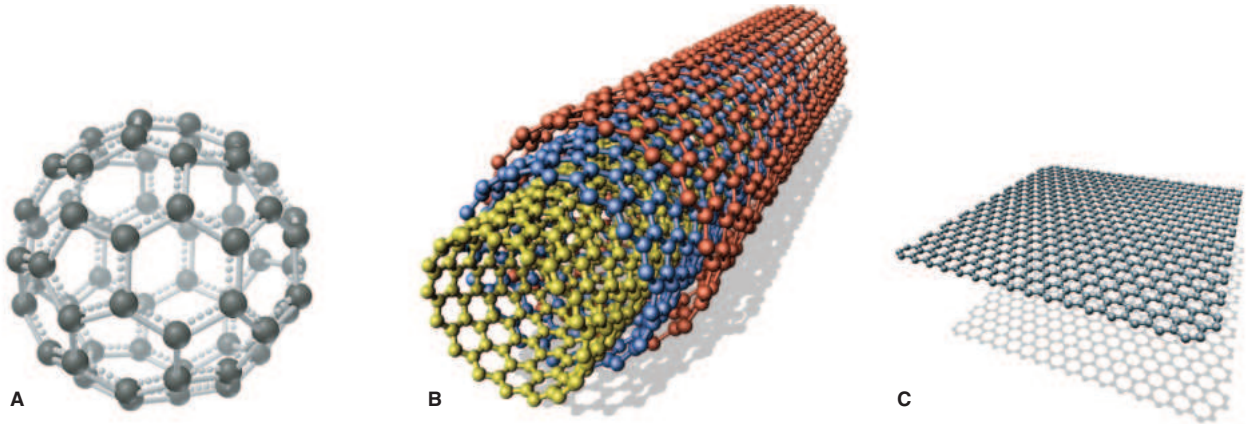
1. *Allotropes and other structures of carbon.* It is difficult to imagine two substances made entirely of the same atom that are more different than graphite and diamond. Graphite is a black electrical conductor that is soft and "greasy," whereas diamond is a colorless electrical insulator that is extremely hard. Graphite is the standard state of carbon, the more stable form at ordinary temperature and pressure (Figure 14.9, *red dot*). Fortunately for jewelry owners, diamond changes to graphite at a negligible rate under normal conditions.

In the mid-1980s, a new allotrope was discovered. Mass spectra of soot showed a soccer ball–shaped molecule of formula C_{60} (Figure 14.10A). The molecule has also been found in geological samples formed by meteorite impacts, even the one that occurred around the time the dinosaurs became extinct. The molecule was dubbed *buckminsterfullerene* (and called a "buckyball") after the architect-engineer R. Buckminster Fuller, who designed structures with similar shapes. Excitement rose in 1990, when scientists learned how to prepare enough C_{60} to study its behavior and applications. Since then, metal atoms have been incorporated in the balls and many different groups (fluorine, hydroxyl groups, sugars, etc.) have been attached, resulting in compounds with a range of useful properties.

In 1991, scientists passed an electric discharge through graphite rods and obtained extremely thin (~1 nm in diameter) graphite-like tubes with fullerene ends called *nanotubes* (Figure 14.10B; the model shows concentric nanotubes, colored differently, without the fullerene ends). Rigid and, on a mass basis, stronger than steel along their long axis, they also conduct electricity along this axis because of the delocalized electrons. With applications in nanoscale electronics, energy storage, catalysis,

Figure 14.10 Models of buckminsterfullerene (A), a carbon nanotube (B), and graphene (C).



polymers, and medicine, nanotube chemistry is a major area of materials research. Then, in 2010, the Nobel Prize in physics was awarded for studies of a new form of carbon called *graphene*, which exists as extended sheets only one atom thick but has remarkable conductivity and strength (Figure 14.10C).

2. *Allotropes of tin.* Tin has two allotropes. White β-tin is stable at room temperature and above, whereas gray α-tin is the more stable form below 13°C (56°F). When white tin is kept for long periods at a low temperature, some converts to microcrystals of gray tin. The random formation and growth of these regions of gray tin, which has a different crystal structure, weaken the metal and make it crumble. In the unheated cathedrals of medieval northern Europe, tin pipes of magnificent organs were sometimes destroyed by the "tin disease" caused by this allotropic transition.

How Bonding Changes in This Group's Compounds

The Group 4A(14) elements display a wide range of chemical behavior, from the covalent compounds of carbon to the ionic compounds of lead, and the features we saw first in Group 3A(13) appear here as well.

1. *Multiple oxidation states.* All the members have at least two important states (+4 and +2), and carbon has three (+4, +2, and −4).

2. *Increasing stability of lower oxidation state.* Compounds with Si in the +4 state are much more stable than those with Si in the +2 state, whereas compounds with Pb in the +2 state are more stable than those with Pb in the +4 state.

3. *Increasing metallic behavior, ionic bonding, and oxide basicity.* Carbon's intermediate EN of 2.5 ensures that it always bonds covalently, but the larger members form bonds with increasing ionic character. With nonmetals, Si and Ge form strong polar covalent bonds, such as the Si—O bond, one of the strongest Period 3 bonds (BE = 368 kJ/mol) and responsible for the stability of Earth's solid surface. Although individual ions of Sn or Pb rarely exist, their bonding with a nonmetal has considerable ionic character. And the bonding becomes more ionic in the lower state. Thus, $SnCl_2$ and $PbCl_2$ are white, high-melting, water-soluble crystals—typical properties of a salt (Figure 14.11)—whereas $SnCl_4$ is a volatile, nonpolar liquid, and $PbCl_4$ is a thermally unstable oil. Similarly, SnO and PbO are more basic than SnO_2 and PbO_2: because the +2 metals are less able to polarize the oxide ion, the E-to-O bonding is more ionic.

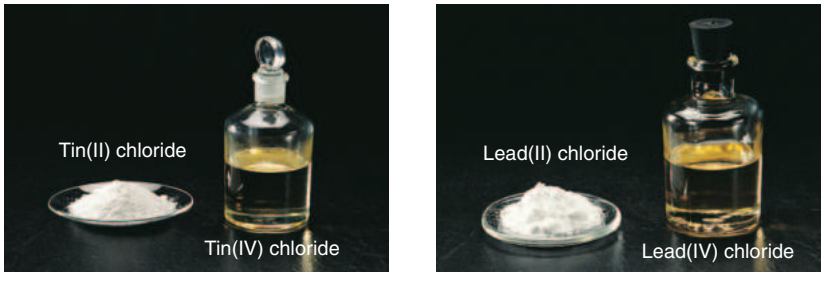


Figure 14.11 Saltlike +2 chlorides and oily +4 chlorides show the greater metallic character of tin and lead in their lower oxidation state.

Highlights of Carbon Chemistry

Like the other Period 2 elements, carbon is an anomaly in its group; indeed, it may be an anomaly in the entire periodic table. Carbon forms bonds with the smaller Group 1A(1) and 2A(2) metals, many transition metals, the halogens, and many other metalloids and nonmetals. In addition to the three common oxidation states, carbon exhibits all the others possible for its group, from +4 through −4.

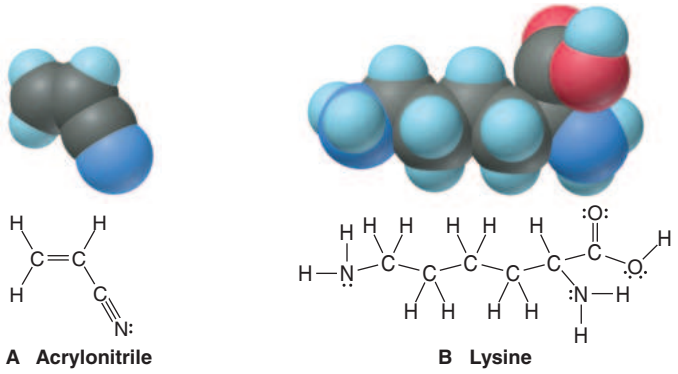

Figure 14.12 **Two of the several million known organic compounds of carbon.** **A,** Acrylonitrile, a precursor of acrylic fibers. **B,** Lysine, one of about 20 amino acids that occur in proteins.

Organic Compounds Two major properties of carbon give rise to the enormous field of organic chemistry.

1. Carbon has the ability to bond to itself—a process known as *catenation.* As a result of its small size and its capacity for four bonds, carbon can form chains, branches, and rings that lead to myriad structures. Add a lot of H, some O and N, a bit of S, P, halogens, and a few metals, and you have the whole organic world! Figure 14.12 shows two of the several million organic compounds known.

Halogenated organic compounds have major polymer applications, such as poly (vinyl chloride) in plumbing and Teflon in cookware. Some are very long-lived in the environment. PCBs, previously used in electrical equipment, are now banned because they are carcinogenic (Figure 14.13). And Freons, used as cleaners of electronic parts and coolants in air conditioners, are responsible for a severe reduction in Earth's protective ozone layer (Chapter 16).

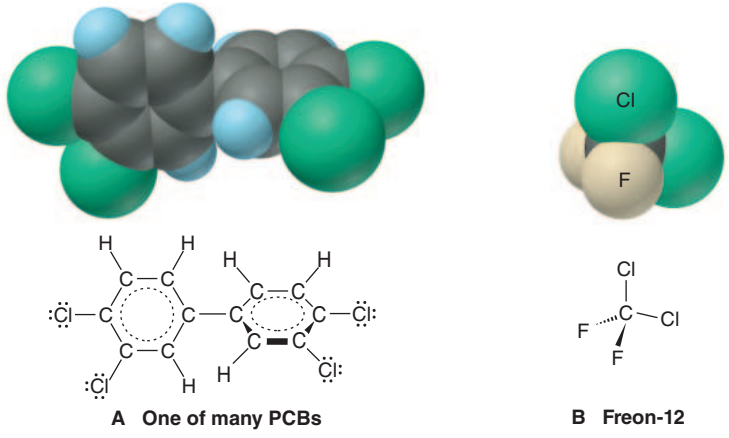

Figure 14.13 **Two important halogenated organic compounds.** **A,** A typical PCB (one of the polychlorinated biphenyls). **B,** Freon-12 (CCl_2F_2), a chlorofluorocarbon.

2. Carbon has the ability to form multiple bonds. Multiple bonds are common in carbon structures because the C—C bond is short enough for side-to-side overlap of two half-filled 2*p* orbitals to form π bonds. (In Chapter 15, we discuss how the properties of carbon give rise to the diverse structures and reactivities of organic compounds.)

Because the other 4A members are larger, E—E bonds become longer and weaker, so catenation and multiple bonding are much less important down the group.

Inorganic Compounds In contrast to its organic compounds, carbon's inorganic compounds are simple.

1. *Carbonates.* Metal carbonates are the main mineral form. Marble, limestone, chalk, coral, and several other types are found in enormous deposits throughout the world. Many of these compounds are remnants of fossilized marine organisms. Carbonates are essential to many industries, and they occur in several common antacids because they react with the HCl in stomach acid:

$$CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + CO_2(g) + H_2O(l)$$

Identical net ionic reactions with sulfuric and nitric acids protect lakes bounded by limestone deposits from the harmful effects of acid rain.

2. *Oxides.* Unlike the other 4A members, which form only solid network covalent or ionic oxides, carbon forms two common gaseous oxides, CO_2 and CO.

- Carbon dioxide is essential to all life: it is the primary source of carbon in plants, through photosynthesis, and in animals who eat the plants. Its aqueous solution is the cause of mild acidity in natural waters. However, its atmospheric buildup from deforestation and excessive use of fossil fuels is severely affecting the global climate through warming (Section 6.5).
- Carbon monoxide forms when carbon or its compounds burn in an inadequate supply of O_2:

$$2C(s) + O_2(g) \longrightarrow 2CO(g)$$

It is a key component of syngas fuels (see Chemical Connections, Chapter 6, p. 273) and is widely used in the production of methanol, formaldehyde, and other major industrial compounds. CO binds strongly to many transition metals. When inhaled in cigarette smoke or polluted air, it enters the blood and binds strongly to the Fe(II) in hemoglobin, preventing the normal binding of O_2, and to other iron-containing proteins. The cyanide ion (CN^-) is *isoelectronic* with CO:

$$[:C{\equiv}N:]^- \quad \text{same electronic structure as} \quad :C{\equiv}O:$$

Cyanide binds to many of the same iron-containing proteins and is also toxic.

Highlights of Silicon Chemistry

To a great extent, the chemistry of silicon is the chemistry of the *silicon-oxygen bond*. Just as carbon forms unending C—C chains, the —Si—O— grouping repeats itself endlessly in a wide variety of **silicates,** the most important minerals on the planet, and in **silicones,** synthetic polymers that have many applications:

1. *Silicate minerals*. From common sand and clay to semiprecious amethyst and carnelian, silicate minerals are the dominant form of matter in the nonliving world. Oxygen, the most abundant element on Earth, and silicon, the next most abundant, account for four of every five atoms on the surface of the planet!

The silicate building unit is the *orthosilicate grouping,* —SiO_4—, a tetrahedral arrangement of four O atoms around the central Si. Several minerals contain SiO_4^{4-} ions or small groups of them linked together. The gemstone zircon ($ZrSiO_4$) contains one unit; hemimorphite [$Zn_4(OH)_2Si_2O_7 \cdot H_2O$] contains two units linked through an oxygen corner of each one; and beryl ($Be_3Al_2Si_6O_{18}$), the major source of beryllium, contains six units joined into a cyclic ion (Figure 14.14).

In extended structures, one of the O atoms links the next Si—O group to form chains, a second one forms crosslinks to neighboring chains to form sheets, and the

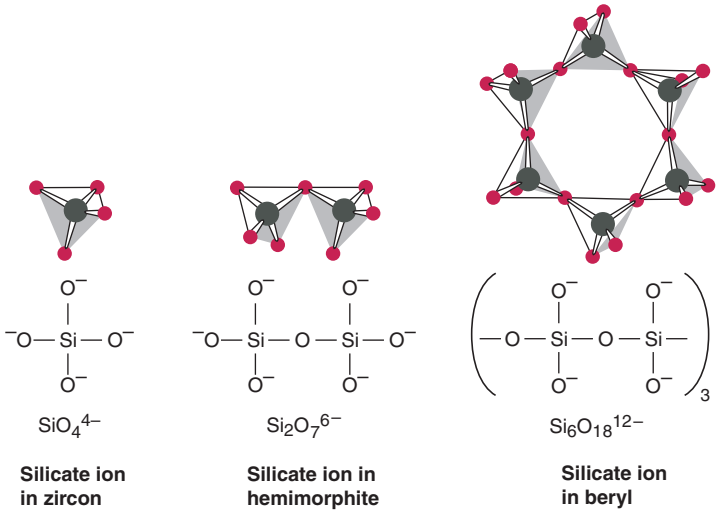

Figure 14.14 Structures of the silicate anions in some minerals.

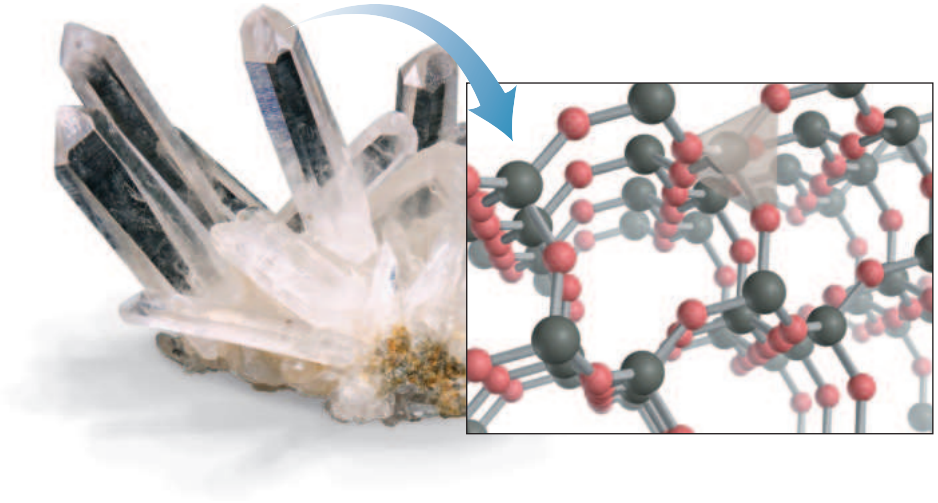

Figure 14.15 Quartz is a three-dimensional framework silicate.

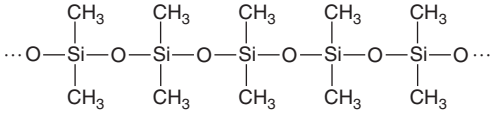
third forms more crosslinks to create three-dimensional frameworks. Chains of silicate groups compose the asbestos minerals, sheets give rise to talc and mica, and frameworks occur in feldspar and quartz (Figure 14.15).

2. *Silicone polymers*. Unlike the naturally occurring silicates, silicone polymers are manufactured substances that consist of alternating Si and O atoms with two organic groups also bonded to each Si atom in a very long Si—O chain, as in *poly(dimethyl siloxane):*



Silicones have properties of both plastics and minerals. The organic groups give them the flexibility and weak intermolecular forces between chains that are characteristic of a plastic, while the O—Si—O backbone confers the thermal stability and nonflammability of a mineral. Structural categories similar to those of the silicates can be created by adding various reactants to form silicone chains, sheets, and frameworks. Chains are oily liquids used as lubricants and as components of car polish and makeup. Sheets are components of gaskets, space suits, and contact lenses. Frameworks have uses as laminates on circuit boards, in nonstick cookware, and in artificial skin and bone.

Diagonal Relationships: Boron and Silicon

Our final diagonal relationship occurs between the semiconducting metalloids boron and silicon. Both B and Si and their mineral oxoanions—borates and silicates—occur in extended covalent networks. Both boric acid [$B(OH)_3$] and silicic acid [$Si(OH)_4$] are weakly acidic solids that occur as layers held together by widespread H bonding. Their hydrides—the compact boranes and the extended silanes—are both flammable, low-melting compounds that act as reducing agents.

14.7 GROUP 5A(15): THE NITROGEN FAMILY

The first two elements of Group 5A(15), gaseous nonmetallic nitrogen (N) and solid nonmetallic phosphorus (P), play major roles in both nature and industry. Below these nonmetals are two metalloids, arsenic (As) and antimony (Sb), followed by the metal bismuth (Bi), and the recently synthesized element 115. The Group 5A(15) Family Portrait provides an overview.

Group 5A(15): The Nitrogen Family

KEY ATOMIC PROPERTIES, PHYSICAL PROPERTIES, AND REACTIONS

KEY

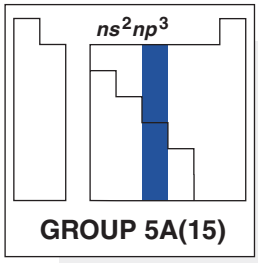
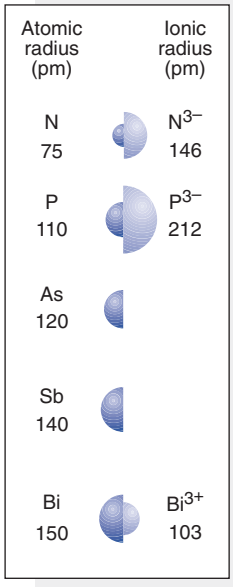
Valence e^- configuration
(Common oxidation states)

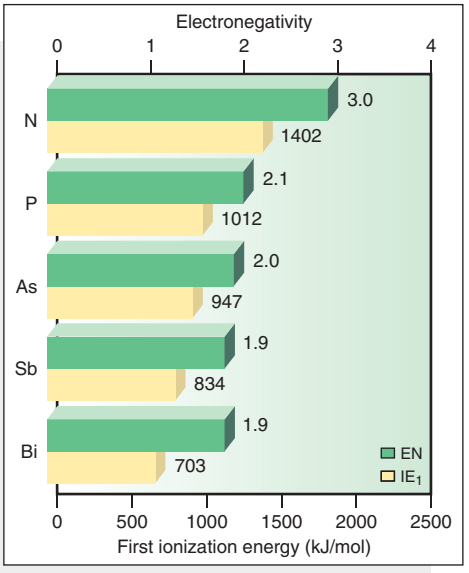
7 **N** 14.01 $2s^22p^3$ (**−3, +5,** +4, +3, +2, +1)	
15 **P** 30.97 $3s^23p^3$ (−3, **+5,** +3)	
33 **As** 74.92 $4s^24p^3$ (−3, +5, **+3**)	
51 **Sb** 121.8 $5s^25p^3$ (−3, +5, **+3**)	
83 **Bi** 209.0 $6s^26p^3$ (**+3**)	
115 (288) $7s^27p^3$	Observed in experiments at Dubna, Russia, in 2003





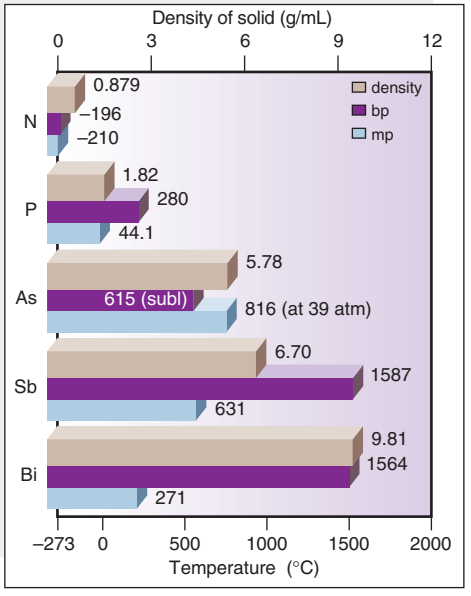
Atomic Properties

Group electron configuration is ns^2np^3. The *np* sublevel is half-filled, with each *p* orbital containing one electron (parallel spin). The number of oxidation states decreases down the group, and the lower (+3) state becomes more common. Atomic properties follow generally expected trends. The large (~50%) increase in size from N to P correlates with the much lower IE and EN of P.



Physical Properties

Physical properties reflect the change from individual molecules (N, P) to network covalent solid (As, Sb) to metal (Bi). Thus, melting points increase and then decrease. Large atomic size and low atomic mass result in low density. Because mass increases more than size down the group, the density of the elements as solids increases. The dramatic increase in density from P to As is due to the intervening transition elements.



Reactions

1. Nitrogen is "fixed" industrially in the Haber process:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

Further reactions convert NH_3 to NO, NO_2, and HNO_3 *(see text)*. Hydrides of some other group members are formed from reaction in water (or with H_3O^+) of a metal phosphide, arsenide, and so forth:

$$Ca_3P_2(s) + 6H_2O(l) \longrightarrow 2PH_3(g) + 3Ca(OH)_2(aq)$$

2. Halides are formed by direct combination of the elements:

$$2E(s) + 3X_2 \longrightarrow 2EX_3 \qquad (E = \text{all except N})$$

$$EX_3 + X_2 \longrightarrow EX_5 \qquad (E = \text{all except N and Bi with X = F and Cl, but no } BiCl_5;\ E = P \text{ for X = Br})$$

3. Oxoacids are formed from the halides in a reaction with water that is common to many nonmetal halides:

$$EX_3 + 3H_2O(l) \longrightarrow H_3EO_3(aq) + 3HX(aq) \qquad (E = \text{all except N})$$

$$EX_5 + 4H_2O(l) \longrightarrow H_3EO_4(aq) + 5HX(aq) \qquad (E = \text{all except N and Bi})$$

Note that the oxidation number of E does *not* change.

The Wide Range of Physical Behavior

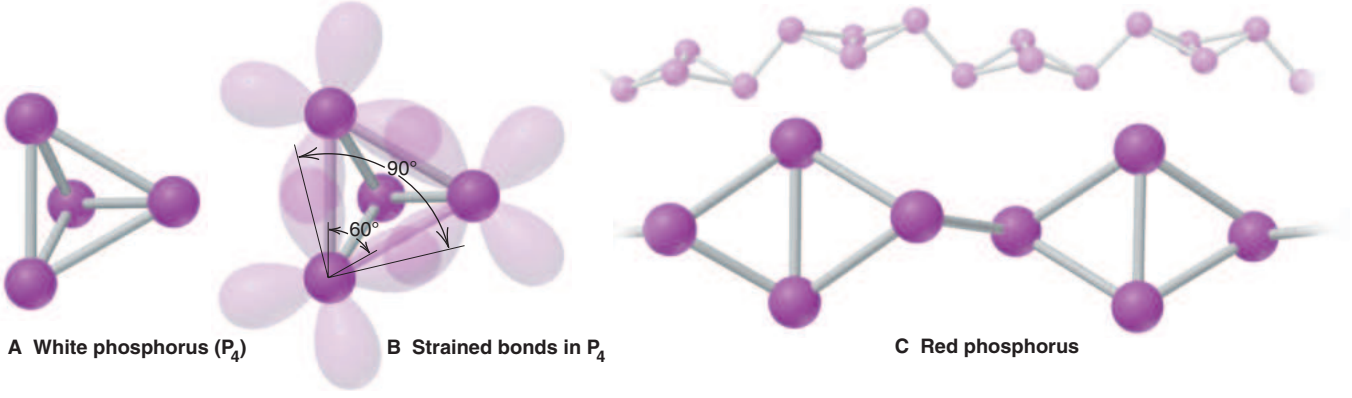
Group 5A(15) displays the widest range of physical behavior we've seen so far because of large changes in bonding and intermolecular forces:

- *Nitrogen* is a gas consisting of N_2 molecules with such weak intermolecular forces that the element *boils* more than 200°C below room temperature.
- *Phosphorus* exists most commonly as tetrahedral P_4 molecules in the solid phase. Because P is heavier and more polarizable than N, it has stronger dispersion forces and melts about 25°C above room temperature.
- *Arsenic* consists of extended sheets. Each As atom bonds to three others in the sheet, and each sheet exhibits dispersion forces with adjacent sheets, which gives As the highest melting point in the group.
- *Antimony* has a similar covalent network, also resulting in a high melting point.
- *Bismuth* has metallic bonding and thus a lower melting point than As and Sb.

Two Allotropes of Phosphorus Phosphorus has several allotropes, which have very different properties. Two major ones are white and red phosphorus:

- *White phosphorus* consists of tetrahedral molecules (Figure 14.16A). It is a low-melting, whitish, waxy solid that is soluble in nonpolar solvents, such as CS_2. Each P atom uses its half-filled 3*p* orbitals to bond to the other three; with a small 60° bond angle, and thus weak P—P bonds, it is highly reactive (Figure 14.16B).
- *Red phosphorus* is formed by heating the white form in the absence of air. One of the P—P bonds in each tetrahedron breaks, and those 3*p* orbitals overlap with others to form chains of P_4 units (Figure 14.16C). The chains make the red allotrope much less reactive, high melting, and insoluble.

Figure 14.16 Two allotropes of phosphorus.



A White phosphorus (P_4) B Strained bonds in P_4 C Red phosphorus

Patterns in Chemical Behavior

Many of the patterns we saw in Group 4A(14) appear here in the change from nonmetallic N to metallic Bi. The great majority of Group 5A(15) compounds have *covalent bonds*. Whereas N can form no more than four bonds, the next three members can form more by expanding their valence levels and using empty *d* orbitals.

1. *Formation of ions.* For a 5A element to form an ion with a noble gas electron configuration, it must *gain* three electrons, the last two in endothermic steps. Nevertheless, the enormous lattice energy released when such highly charged anions attract cations drives their formation. However, the 3− anion of N occurs only in compounds with active metals, such as Li_3N and Mg_3N_2 (and that of P may occur in Na_3P). Metallic Bi mostly bonds covalently but exists as a cation in a few compounds, such as BiF_3 and $Bi(NO_3)_3 \cdot 5H_2O$, through *loss* of its three valence *p* electrons.

2. *Oxidation states and basicity of oxides.* As in Groups 3A and 4A, the lower oxidation state becomes more prominent down the group: N exhibits every state possible

for a 5A element, from +5 to −3; only the +5 and +3 states are common for P, As, and Sb; and +3 is the only common state of Bi. The oxides change from acidic to amphoteric to basic, reflecting the increase in the metallic character of the elements. In addition, the lower oxide of an element is more basic than the higher oxide, reflecting the greater ionic character of its E-to-O bonding.

3. *Formation of hydrides.* All the Group 5A(15) elements form gaseous hydrides of formula EH_3. Except for NH_3, these are extremely reactive and poisonous and are synthesized by reaction of a metal phosphide, arsenide, and so forth, which acts as a strong base in water or aqueous acid. For example,

$$Ca_3As_2(s) + 6H_2O(l) \longrightarrow 2AsH_3(g) + 3Ca(OH)_2(aq)$$

Ammonia is made industrially by direct combination of the elements at high pressure and moderately high temperature:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

Nitrogen forms a second hydride, hydrazine, N_2H_4. Like NH_3, hydrazine is a weak base; it is used to make antituberculin drugs, plant growth regulators, and fungicides.

Molecular properties of the Group 5A(15) hydrides reveal some interesting bonding and structural patterns:

- Despite its much lower molar mass, NH_3 melts and boils at higher temperatures than the other 5A hydrides, as a result of its H *bonding*.
- Bond angles decrease from 107.3° for NH_3 to around 90° for the other hydrides, which suggests that the larger atoms use unhybridized *p* orbitals.
- E—H bond lengths increase down the group, so bond strength and thermal stability decrease: AsH_3 decomposes at 250°C, SbH_3 at 20°C, and BiH_3 at −45°C.

We'll see these features—H bonding for the smallest member, change in bond angles, change in bond energies—in the hydrides of Group 6A(16) as well.

4. *Types and properties of halides.* The Group 5A(15) elements all form trihalides (EX_3). All except nitrogen form pentafluorides (EF_5), but only a few other pentahalides (PCl_5, PBr_5, $AsCl_5$, and $SbCl_5$) are known. Nitrogen cannot form pentahalides because it cannot expand its valence level. Most trihalides are prepared by direct combination:

$$P_4(s) + 6Cl_2(g) \longrightarrow 4PCl_3(l)$$

The pentahalides form with excess halogen:

$$PCl_3(l) + Cl_2(g) \longrightarrow PCl_5(s)$$

As with the hydrides, thermal stability of the halides decreases as the E—X bond becomes longer; we see this trend easiest if we change the halogen. Among the nitrogen halides, for example, NF_3 is a stable, rather unreactive gas. NCl_3 is explosive and reacts rapidly with water. (The chemist who first prepared it lost three fingers and an eye!) NBr_3 can only be made below −87°C. NI_3 has never been prepared, but an ammoniated product ($NI_3 \cdot NH_3$) explodes at the slightest touch. Other Group 5A members show less drastic trends, but stability decreases as the halogen gets larger.

5. *Reaction of halides in water.* In a reaction pattern *typical of many nonmetal halides,* each 5A halide reacts with water to yield the hydrogen halide and the oxoacid, in which E has the *same* O.N. as in the original halide. For example, PX_5 (O.N. of P = +5) produces phosphoric acid (O.N. of P = +5) and HX:

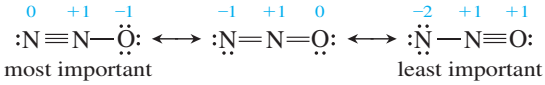
$$PCl_5(s) + 4H_2O(l) \longrightarrow H_3PO_4(l) + 5HCl(g)$$

Highlights of Nitrogen Chemistry

The most striking highlight of nitrogen chemistry is the inertness of N_2. Even with four-fifths of the atmosphere N_2 and the other fifth nearly all O_2, it takes the searing temperature of lightning to form significant amounts of nitrogen oxides. Although N_2 is inert at moderate temperatures, it reacts at high temperatures with H_2, Li, Group 2A(2), B, Al, C, Si, Ge, and many transition elements. In fact, nearly every element forms bonds to N. Here we focus on the oxides and the oxoacids and their salts.

Nitrogen Oxides Nitrogen is remarkable for having six stable oxides, each with a *positive* enthalpy of formation because of the great strength of the N≡N bond (BE = 945 kJ/mol). Their structures and some properties are shown in Table 14.3. Unlike the hydrides and halides of nitrogen, the oxides are planar. Nitrogen displays all its positive oxidation states in these compounds, and in N_2O and N_2O_3, the two N atoms have different states. Let's highlight the three most important:

1. *Dinitrogen monoxide* (N_2O; also called *nitrous oxide*) is the dental anesthetic "laughing gas" and the propellant in canned whipped cream. It is a linear molecule with an electronic structure described by three resonance forms (note formal charges):



2. *Nitrogen monoxide* (NO; also called *nitric oxide*) is an odd-electron molecule with biochemical functions ranging from neurotransmission to control of blood flow. In Section 11.3, we used MO theory to explain its bonding. The commercial preparation of NO occurs as a first step in the production of nitric acid:

$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$$

Nitrogen monoxide is also produced whenever air is heated to high temperatures, as in a car engine or by lightning during a thunderstorm:

$$N_2(g) + O_2(g) \xrightarrow{\text{high } T} 2NO(g)$$

Heating converts NO to two other oxides:

$$3NO(g) \xrightarrow{\Delta} N_2O(g) + NO_2(g)$$

Table 14.3 Structures and Properties of the Nitrogen Oxides

Formula	Name	Space-filling Model	Lewis Structure	Oxidation State of N	ΔH_f° (kJ/mol) at 298 K	Comment
N_2O	Dinitrogen monoxide (nitrous oxide)		:N≡N—Ö:	+1 (0, +2)	82.0	Colorless gas; used as dental anesthetic ("laughing gas") and aerosol propellant
NO	Nitrogen monoxide (nitric oxide)		:N=Ö:	+2	90.3	Colorless, paramagnetic gas; biochemical messenger; air pollutant
N_2O_3	Dinitrogen trioxide			+3 (+2, +4)	83.7	Reddish brown gas (reversibly dissociates to NO and NO_2)
NO_2	Nitrogen dioxide			+4	33.2	Orange-brown, paramagnetic gas formed during HNO_3 manufacture; poisonous air pollutant
N_2O_4	Dinitrogen tetroxide			+4	9.16	Colorless to yellow liquid (reversibly dissociates to NO_2)
N_2O_5	Dinitrogen pentoxide			+5	11.3	Colorless, volatile solid consisting of NO_2^+ and NO_3^-; gas consists of N_2O_5 molecules

This type of redox reaction is called a **disproportionation,** in which *one substance acts as both the oxidizing and reducing agents*. In the process, an atom with an intermediate oxidation state in the reactant occurs in both lower and higher states in the products: the oxidation state of N in NO (+2) is intermediate between that in N_2O (+1) and that in NO_2 (+4).

3. *Nitrogen dioxide* (NO_2), a brown poisonous gas, forms to a small extent when NO reacts with additional oxygen:

$$2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$$

Like NO, NO_2 is an odd-electron molecule with the electron more localized on the N atom. Thus, NO_2 dimerizes reversibly to *dinitrogen tetroxide:*

$$O_2N\cdot(g) + \cdot NO_2(g) \rightleftharpoons O_2N{-}NO_2(g) \quad \text{(or } N_2O_4\text{)}$$

Thunderstorms form NO and NO_2 and carry them down to the soil, where they act as natural fertilizers. In urban traffic, however, their formation leads to *photochemical smog (see photo)* in a series of reactions also involving sunlight, ozone (O_3), unburned gasoline, and various other species.

Photochemical smog over Los Angeles, California.

Nitrogen Oxoacids and Oxoanions There are two common oxoacids of nitrogen (Figure 14.17):

1. *Nitric acid* (HNO_3) is produced in the *Ostwald process;* we have already seen the first two steps—the oxidations of NH_3 to NO and of NO to NO_2. The final step is a disproportionation, as the oxidation numbers show:

$$\overset{+4}{3NO_2}(g) + H_2O(l) \longrightarrow \overset{+5}{2HNO_3}(aq) + \overset{+2}{NO}(g)$$

The NO is recycled to make more NO_2.

In nitric acid, as in all oxoacids, *the acidic H is attached to one of the O atoms.* When the proton is lost, the trigonal planar nitrate ion is formed (Figure 14.17A). In the laboratory, nitric acid is used as a strong oxidizing acid. The products of its reactions with metals vary with the metal's reactivity and the acid's concentration. In the following examples, notice that *the NO_3^- ion is the oxidizing agent.* Nitrate ion that is not reduced is a spectator ion and does not appear in the net ionic equations.

- With an active metal, such as Al, and dilute nitric acid, N is reduced from the +5 state all the way to the −3 state in the ammonium ion, NH_4^+:

$$8Al(s) + 30HNO_3(aq;\, 1\ M) \longrightarrow 8Al(NO_3)_3(aq) + 3NH_4NO_3(aq) + 9H_2O(l)$$
$$8Al(s) + 30H^+(aq) + 3NO_3^-(aq) \longrightarrow 8Al^{3+}(aq) + 3NH_4^+(aq) + 9H_2O(l)$$

- With a less reactive metal, such as Cu, and more concentrated acid, N is reduced to the +2 state in NO:

$$3Cu(s) + 8HNO_3(aq;\, 3 \text{ to } 6\ M) \longrightarrow 3Cu(NO_3)_2(aq) + 4H_2O(l) + 2NO(g)$$
$$3Cu(s) + 8H^+(aq) + 2NO_3^-(aq) \longrightarrow 3Cu^{2+}(aq) + 4H_2O(l) + 2NO(g)$$

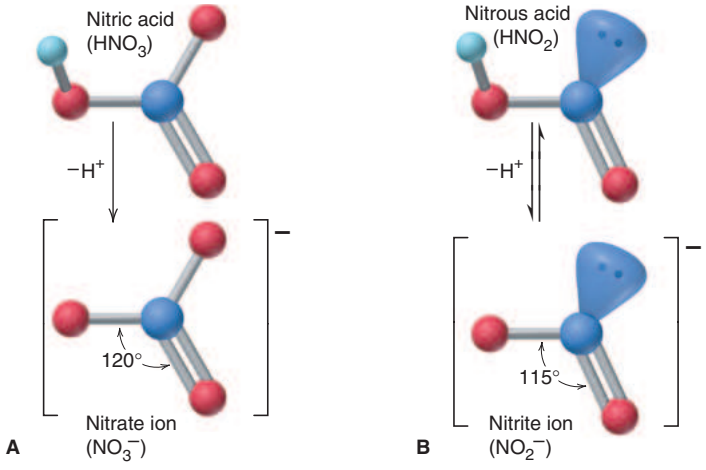


Figure 14.17 The structures of nitric and nitrous acids and their oxoanions.

- With still more concentrated acid, N is reduced only to the +4 state in NO_2:

$$Cu(s) + 4HNO_3(aq;\ 12\ M) \longrightarrow Cu(NO_3)_2(aq) + 2H_2O(l) + 2NO_2(g)$$
$$Cu(s) + 4H^+(aq) + 2NO_3^-(aq) \longrightarrow Cu^{2+}(aq) + 2H_2O(l) + 2NO_2(g)$$

Nitrates form when HNO_3 reacts with metals or with their hydroxides, oxides, or carbonates. *All nitrates are soluble in water.*

2. *Nitrous acid* (HNO_2) is a much weaker acid that forms when metal nitrites are treated with a strong acid:

$$NaNO_2(aq) + HCl(aq) \longrightarrow HNO_2(aq) + NaCl(aq)$$

This acid forms the planar nitrite ion (Figure 14.17B) in which nitrogen's lone pair reduces the ideal 120° bond angle to 115°.

These two acids reveal a *general pattern in relative acid strength among oxoacids: the more O atoms bonded to the central nonmetal, the stronger the acid.* The O atoms pull electron density from the N atom, which in turn pulls electron density from the O of the O—H bond, facilitating the release of the H^+ ion. The O atoms also stabilize the resulting oxoanion by delocalizing its negative charge. The same pattern occurs in the oxoacids of sulfur and the halogens; we'll discuss the pattern quantitatively in Chapter 18.

Highlights of Phosphorus Chemistry

Like nitrogen, phosphorus forms important oxides (although not as many) and oxoacids. Here we focus on these compounds as well as on some other important phosphorus compounds.

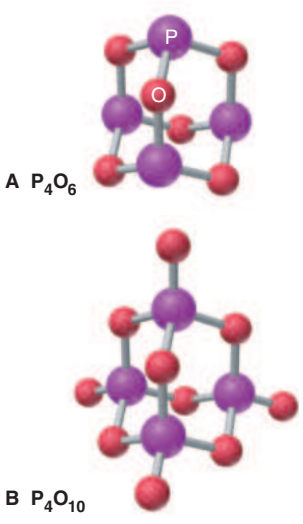

Figure 14.18 Important oxides of phosphorus.

Phosphorus Oxides Phosphorus forms two important oxides.

1. *Tetraphosphorus hexoxide* (P_4O_6) has P in its +3 oxidation state. It forms when P_4 reacts with limited oxygen:

$$P_4(s) + 3O_2(g) \longrightarrow P_4O_6(s)$$

P_4O_6 has the same tetrahedral orientation of the P atoms in P_4, with an O atom between each pair of P atoms (Figure 14.18A).

2. *Tetraphosphorus decoxide* (P_4O_{10}) has P in the +5 oxidation state. Commonly known as "phosphorus pentoxide" from the empirical formula (P_2O_5), it forms when P_4 burns in excess O_2:

$$P_4(s) + 5O_2(g) \longrightarrow P_4O_{10}(s)$$

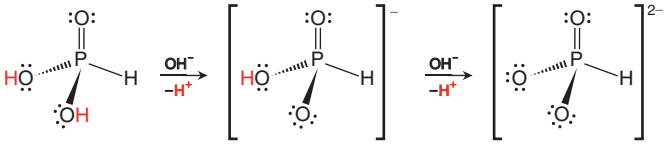
Its structure is that of P_4O_6 with another O atom bonded to each of the four corner P atoms (Figure 14.18B). P_4O_{10} is a powerful drying agent.

Phosphorus Oxoacids and Oxoanions The two common phosphorus oxoacids are phosphorous acid (note the different spelling) and phosphoric acid.

1. *Phosphorous acid* (H_3PO_3) is formed when P_4O_6 reacts with water:

$$P_4O_6(s) + 6H_2O(l) \longrightarrow 4H_3PO_3(l)$$

The formula H_3PO_3 is misleading because the acid has only two acidic H atoms; the third is bonded to the central P and does not dissociate. Phosphorous acid is a weak acid in water but reacts completely in two steps with excess strong base:



Salts of phosphorous acid contain the phosphite ion, HPO_3^{2-}.

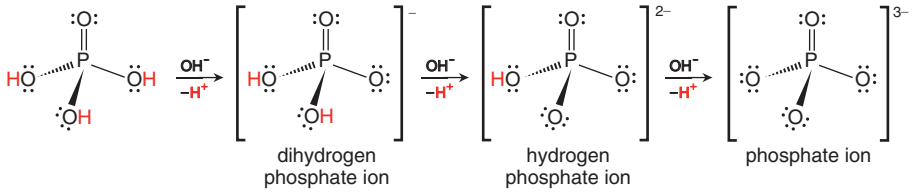
2. *Phosphoric acid* (H_3PO_4), one of the "top-10" most important compounds in manufacturing, is formed in a vigorous exothermic reaction of P_4O_{10} with water:

$$P_4O_{10}(s) + 6H_2O(l) \longrightarrow 4H_3PO_4(l)$$

The presence of many H bonds makes pure H_3PO_4 syrupy, more than 75 times as viscous as water. The laboratory-grade concentrated acid is an 85% by mass aqueous solution. H_3PO_4 is a weak triprotic acid; in water, it loses one proton:

$$H_3PO_4(l) + H_2O(l) \rightleftharpoons H_2PO_4^-(aq) + H_3O^+(aq)$$

In excess strong base, however, the three protons dissociate completely in three steps to give the three phosphate oxoanions:



Phosphoric acid has a central role in fertilizer production and is also added to soft drinks for tartness. The various phosphate salts also have numerous essential applications. Na_3PO_4 is a paint stripper and grease remover. K_3PO_4 is used to stabilize latex for synthetic rubber, and K_2HPO_4 is a radiator corrosion inhibitor. Ammonium phosphates are used as fertilizers and as flame retardants on curtains, and calcium phosphates are used in baking powders and toothpastes, as mineral supplements in livestock feed, and as fertilizers.

Polyphosphates When they are heated, hydrogen phosphates lose water and form P—O—P linkages in compounds called *polyphosphates.* A reaction in which an H_2O molecule is lost for every pair of groups that join is called a **dehydration-condensation;** this type of reaction occurs frequently in the formation of polyoxoanion chains and other polymeric structures, both synthetic and natural. For example, sodium diphosphate, $Na_4P_2O_7$, is prepared by heating sodium hydrogen phosphate:

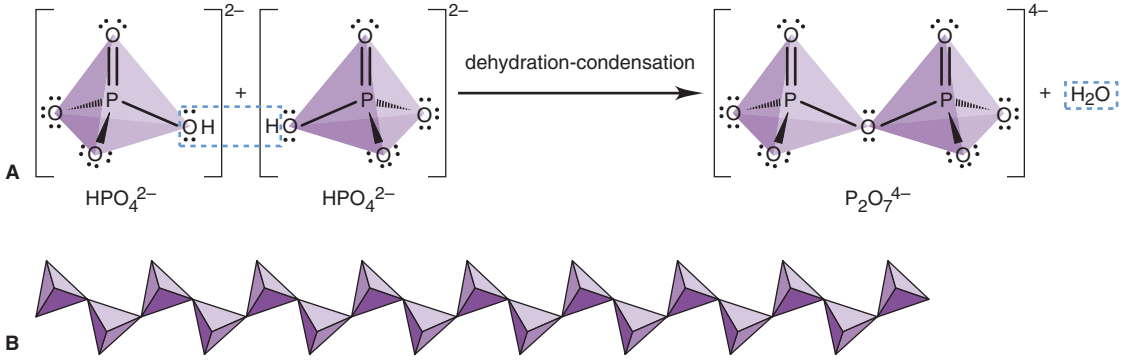
$$2Na_2HPO_4(s) \xrightarrow{\Delta} Na_4P_2O_7(s) + H_2O(g)$$

The diphosphate ion, $P_2O_7^{4-}$, the smallest of the polyphosphates, consists of two PO_4 units linked through a common oxygen corner (Figure 14.19A). Its reaction with water, the reverse of the previous reaction, generates heat:

$$P_2O_7^{4-}(aq) + H_2O(l) \longrightarrow 2HPO_4^-(aq) + heat$$

A similar process is put to vital use by organisms, when a third PO_4 unit linked to diphosphate creates the triphosphate grouping, part of the all-important high-energy biomolecule adenosine triphosphate (ATP). In Chapters 20 and 21, we discuss the central role of ATP in biological energy production. Extended polyphosphate chains consist of many tetrahedral PO_4 units (Figure 14.19B) and are structurally similar to silicate chains.

Figure 14.19 **The diphosphate ion and polyphosphates.**



Phosphorus Compounds with Sulfur and Nitrogen Phosphorus forms many sulfides and nitrides. P_4S_3 is used in "strike anywhere" match heads, and P_4S_{10} is used in the manufacture of organophosphorus pesticides, such as malathion. Compounds of

phosphorus and nitrogen called *polyphosphazenes* have properties similar to those of silicones. The $—(R_2)P{=}N—$ unit is isoelectronic with the silicone unit, $—(R_2)Si—N—$. Sheets, films, fibers, and foams of polyphosphazene are water repellent, flame resistant, solvent resistant, and flexible at low temperatures—perfect for the gaskets and O-rings in spacecraft and polar vehicles.

14.8 GROUP 6A(16): THE OXYGEN FAMILY

The first two members—gaseous nonmetallic oxygen (O) and solid nonmetallic sulfur (S)—are among the most important elements in industry, the environment, and living things. Two metalloids, selenium (Se) and tellurium (Te), appear next, followed by the radioactive metal polonium (Po), and recently synthesized livermorium (Lv). The Group 6A(16) Family Portrait displays the features of these elements.

How the Oxygen and Nitrogen Families Compare Physically

Group 6A(16) resembles Group 5A(15) in many respects, so let's look at some common themes. The pattern of physical properties we saw in Group 5A appears again:

- *Oxygen,* like nitrogen, occurs as a low-boiling diatomic gas.
- *Sulfur,* like phosphorus, occurs as a polyatomic molecular solid.
- *Selenium,* like arsenic, commonly occurs as a gray metalloid.
- *Tellurium,* like antimony, is slightly more metallic but still displays network covalent bonding.
- *Polonium,* like bismuth, has a metallic crystal structure.

As in Group 5A, electrical conductivities increase steadily down Group 6A as bonding changes from nonmetal molecules (insulators) to metalloid networks (semiconductors) to a metallic solid (conductor).

Allotropism in the Oxygen Family Allotropism is even more common in Group 6A(16) than in Group 5A(15).

1. *Oxygen.* Oxygen has two allotropes: life-giving dioxygen (O_2), and poisonous triatomic ozone (O_3). Dioxygen is colorless, odorless, paramagnetic, and thermally stable. In contrast, ozone is bluish, has a pungent odor, is diamagnetic, and decomposes in heat and especially in ultraviolet (UV) light:

$$2O_3(g) \xrightarrow{UV} 3O_2(g)$$

This ability to absorb high-energy photons makes stratospheric ozone vital to life. A thinning of the ozone layer, observed above the North Pole and especially the South Pole, means that more UV light is reaching Earth's surface, with potentially hazardous effects. (We'll discuss the chemical causes of ozone depletion in Chapter 16.)

2. *Sulfur.* Sulfur is the allotrope "champion" of the periodic table, with more than 10 forms. The S atom's ability to bond to other S atoms (catenate) creates rings and chains, many with S—S bond lengths that range from 180 pm to 260 pm and bond angles from 90° to 180°. The most stable allotrope is orthorhombic α-S_8, which consists of a crown-shaped ring of eight atoms called *cyclo-*S_8 (Figure 14.20); all other S allotropes eventually revert to this one.

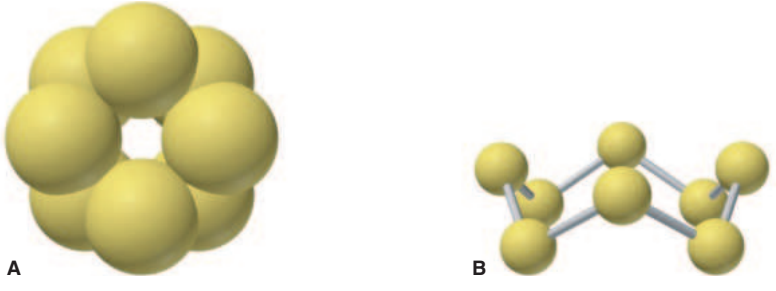


Figure 14.20 **The cyclo-S_8 molecule.** **A,** Top view of a space-filling model. **B,** Side view of a ball-and-stick model; note the crownlike shape.

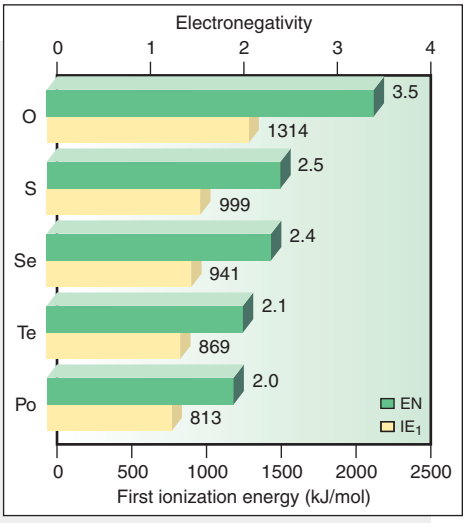
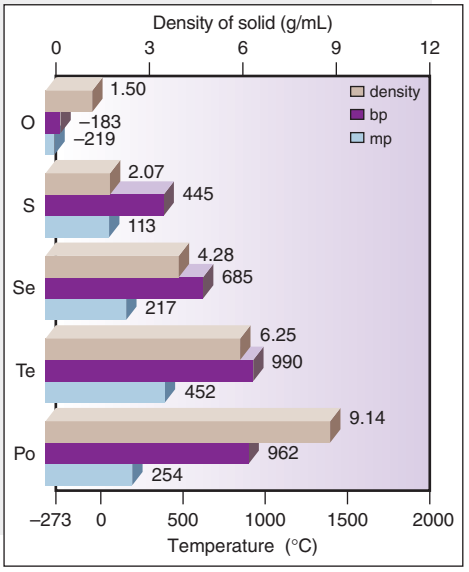
Atomic Properties

Group electron configuration is ns^2np^4. As in Groups 3A(13) and 5A(15), a lower (+4) oxidation state becomes more common down the group. Down the group, atomic and ionic sizes increase, and IE and EN decrease.



Physical Properties

Melting points increase through Te, which has covalent bonding, and then decrease for Po, which has metallic bonding. Densities of the elements as solids increase steadily.



Reactions

1. Halides are formed by direct combination:

$$E(s) + X_2(g) \longrightarrow \text{various halides}$$

(E = S, Se, Te; X = F, Cl)

2. The other elements in the group are oxidized by O_2:

$$E(s) + O_2(g) \longrightarrow EO_2 \quad (E = S, Se, Te, Po)$$

SO_2 is oxidized further, and the product is used in the final step of H_2SO_4 manufacture *(see text)*:

$$2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$$

3. The thiosulfate ion is formed when an alkali metal sulfite reacts with sulfur, as in the preparation of "hypo," photographers' developing solution:

$$S_8(s) + 8Na_2SO_3(s) \longrightarrow 8Na_2S_2O_3(aq)$$

3. *Selenium.* Selenium also has several allotropes, some consisting of crown-shaped Se_8 molecules. Gray Se is composed of layers of helical chains. When molten glass, cadmium sulfide, and gray Se are mixed and heated in the absence of air, a ruby-red glass forms, which is still used in traffic lights. The ability of gray Se to conduct an electric current when illuminated is applied in photocopying. A film of amorphous Se is deposited on an aluminum drum and electrostatically charged. Exposure to a document produces an "image" of low and high positive charges corresponding to the document's bright and dark areas. Negatively charged black, dry ink (toner) particles are attracted to the regions of high charge more than to those of low charge. This pattern of black particles is transferred electrostatically to paper, and the particles are fused to the paper's surface by heat or solvent. Excess toner is removed from the Se film, the charges are "erased" by exposure to light, and the film is ready for the next page.

How the Oxygen and Nitrogen Families Compare Chemically

Trends in Group 6A(16) chemical behavior are also similar to those in Group 5A(15). O and S occur as anions much more often than do N and P, but like N and P, they also bond covalently with almost every other nonmetal. Covalent bonds appear in the compounds of Se and Te (as in those of As and Sb), and Po behaves like a metal (as does Bi) in some saltlike compounds. In contrast to N, O has few common oxidation states, but the earlier pattern returns with the other Group 6A members: the +6, +4, and −2 states occur most often, with the lower positive (+4) state becoming more common in Te and Po [as the lower positive (+3) state does in Sb and Bi].

The range in atomic properties is wider in this group than in Group 5A(15) because of oxygen's high EN (3.5) and great oxidizing strength, second only to that of fluorine. But the other members of Group 6A(16) behave very little like oxygen: they are much less electronegative, form anions much less often (S^{2-} occurs with active metals), and their hydrides exhibit no H bonding.

Types and Properties of Hydrides Oxygen forms two hydrides, water and hydrogen peroxide (H_2O_2). Both have relatively high boiling points and viscosities due to hydrogen bonding. In peroxides, O is in the −1 oxidation state, midway between that in O_2 (zero) and that in oxides (−2); thus, H_2O_2 readily disproportionates:

$$H_2O_2(l) \longrightarrow H_2O(l) + \tfrac{1}{2}O_2(g)$$

Though its most familiar use is in hair bleach and disinfectants, much more H_2O_2 is used to bleach paper, textiles, and leather and in sewage treatment to oxidize bacteria.

The other 6A elements form foul-smelling, poisonous, gaseous hydrides (H_2E) on treatment with acid of the metal sulfide, selenide, and so forth. For example,

$$FeSe(s) + 2HCl(aq) \longrightarrow H_2Se(g) + FeCl_2(aq)$$

Hydrogen sulfide also forms naturally in swamps from the breakdown of organic matter. It is as toxic as HCN, and even worse, it anesthetizes your olfactory nerves, so that as its concentration increases, you smell it less! And the other hydrides are about 100 times *more* toxic.

In their bonding and thermal stability, these Group 6A hydrides have several features in common with those of Group 5A:

- Only water and H_2O_2 can form H bonds, so they melt and boil much higher than the other H_2E compounds (see Figure 12.15, p. 471).
- Bond angles drop from the nearly tetrahedral 104.5° for H_2O to around 90° for the larger 6A hydrides, suggesting that the central atom uses unhybridized *p* orbitals.
- E—H bond length increases, so bond energy decreases, down the group. Thus, H_2Te decomposes above 0°C, and H_2Po can be made only in extreme cold because thermal energy from radioactive Po decomposes it. Another result of longer (weaker) bonds is that the 6A hydrides are acids in water, and their acidity increases from H_2S to H_2Po.

Types and Properties of Halides Except for O, the Group 6A elements form a wide range of halides, whose structure and reactivity patterns depend on the *sizes of the central atom and the surrounding halogens:*

- Sulfur forms many fluorides, a few chlorides, one bromide, but no stable iodides.
- As the central atom becomes larger, the halides become more stable. Thus, tetrachlorides and tetrabromides of Se, Te, and Po are known, as are tetraiodides of Te and Po. Hexafluorides are known only for S, Se, and Te.

The inverse relationship between bond length and bond strength that we've seen previously does not account for this pattern. Rather, it is based on the effect of electron repulsions due to crowding of lone pairs and halogen (X) atoms around the central Group 6A atom. With S, the larger X atoms would be too crowded, which explains why sulfur iodides do not occur. With increasing size of E, and therefore increasing length of E—X bonds, however, lone pairs and X atoms do not crowd each other as much, so a greater number of stable halides form.

Highlights of Oxygen Chemistry: Range of Oxide Properties

Oxygen is the most abundant element on Earth's surface, occurring both as the free element and in innumerable oxides, silicates, carbonates, and phosphates, as well as in water. Virtually all free O_2 has been formed for billions of years by photosynthetic algae and multicellular plants in an overall equation that only looks simple:

$$n\mathrm{H_2O}(l) + n\mathrm{CO_2}(g) \xrightarrow{\text{light}} n\mathrm{O_2}(g) + (\mathrm{CH_2O})_n \text{ (carbohydrates)}$$

The reverse process occurs during combustion and respiration. Through these O_2-forming and O_2-utilizing processes, the 1.5×10^9 km^3 of water on Earth is, on average, used and remade every 2 million years!

Every element (except He, Ne, and Ar) forms at least one oxide, many by direct combination. A spectrum of properties characterizes these compounds. Some oxides are gases that condense at very low temperatures, such as CO (bp = −192°C); others are solids that melt at extremely high temperatures, such as BeO (mp = 2530°C). Oxides cover the full range of conductivity: insulators (MgO), semiconductors (NiO), conductors (ReO_3), and superconductors ($YBa_2Cu_3O_7$). They may be thermally stable (CaO) or unstable (HgO), as well as chemically reactive (Li_2O) or inert (Fe_2O_3).

Another useful way to classify element oxides is by their acid-base properties. The oxides of Group 6A(16) exhibit expected trends in acidity, with SO_3 [the higher (+6) oxide] the most acidic and PoO_2 [the lower (+4) oxide] the most basic.

Highlights of Sulfur Chemistry

Like phosphorus, sulfur forms two common oxides and two oxoacids, one of which is essential to many industries. There are also several important metal sulfides.

Sulfur Oxides Sulfur forms two important oxides.

1. *Sulfur dioxide* (SO_2) has S in its +4 oxidation state. It is a colorless, choking gas that forms when S, H_2S, or a metal sulfide burns in air:

$$2\mathrm{H_2S}(g) + 3\mathrm{O_2}(g) \longrightarrow 2\mathrm{H_2O}(g) + 2\mathrm{SO_2}(g)$$
$$4\mathrm{FeS_2}(s) + 11\mathrm{O_2}(g) \longrightarrow 2\mathrm{Fe_2O_3}(s) + 8\mathrm{SO_2}(g)$$

2. *Sulfur trioxide* (SO_3), which has S in the +6 oxidation state, is produced when SO_2 reacts in O_2. A catalyst (Chapter 16) must be used to speed up this very slow reaction. For the production of sulfuric acid, a vanadium(V) oxide catalyst is used:

$$\mathrm{SO_2}(g) + \tfrac{1}{2}\mathrm{O_2}(g) \xrightarrow{\mathrm{V_2O_5/K_2O\ catalyst}} \mathrm{SO_3}(g)$$

Sulfur Oxoacids Sulfur forms two important oxoacids.

1. *Sulfurous acid* (H_2SO_3), formed when SO_2 dissolves in water, exists in equilibrium with hydrated SO_2 rather than as stable H_2SO_3 molecules:

$$\mathrm{SO_2}(aq) + \mathrm{H_2O}(l) \rightleftharpoons [\mathrm{H_2SO_3}(aq)] \rightleftharpoons \mathrm{H^+}(aq) + \mathrm{HSO_3^-}(aq)$$

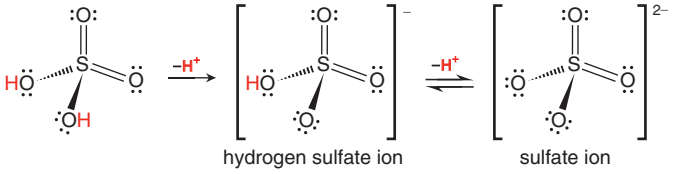
Sulfurous acid is weak and has two acidic protons, forming the hydrogen sulfite (bisulfite, HSO_3^-) and sulfite (SO_3^{2-}) ions with strong base. Because the S in SO_3^{2-} is in the +4 state and is easily oxidized to the +6 state, sulfites are good reducing agents and preserve foods and wine by eliminating undesirable products of air oxidation.

2. *Sulfuric acid* (H_2SO_4) is produced when SO_2 is oxidized catalytically to SO_3, which is then absorbed into concentrated H_2SO_4 and treated with H_2O:

$$SO_3 \text{ (in concentrated } H_2SO_4) + H_2O(l) \longrightarrow H_2SO_4(l)$$

With more than 60 million tons produced each year in the United States alone, H_2SO_4 ranks first among all industrial chemicals; it is vital to fertilizer production, metal, pigment, and textile processing, and soap and detergent manufacturing. (The production of H_2SO_4 will be discussed in detail in Chapter 22.)

Concentrated laboratory-grade sulfuric acid is a viscous, colorless liquid that is 98% H_2SO_4 by mass. Like other strong acids, H_2SO_4 dissociates completely in water, forming the hydrogen sulfate (or bisulfate) ion, a much weaker acid:



Most common hydrogen sulfates and sulfates are water soluble, but those of the larger Group 2A(2) members (Ca^{2+}, Sr^{2+}, Ba^{2+}, and Ra^{2+}), Ag^+, and Pb^{2+} are not.

Concentrated sulfuric acid is an excellent dehydrating agent. Its loosely held proton transfers to water in a highly exothermic formation of hydronium (H_3O^+) ions. This process can occur even when the reacting substance contains no free water. For example, H_2SO_4 dehydrates wood, natural fibers, and many other organic substances, such as table sugar $(CH_2O)_n$, by removing the components of water from the molecular structure, leaving behind a carbonaceous mass (Figure 14.21).

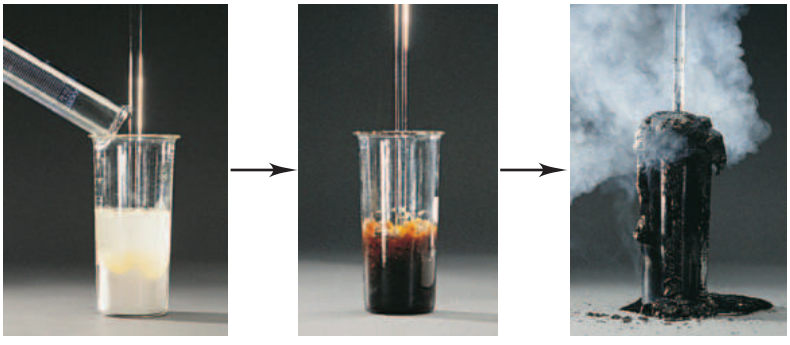


Figure 14.21 **The dehydration of sugar by sulfuric acid.**

Industrial sources produce the sulfur oxides that lead to acid rain.

Sulfuric acid is one of the components of acid rain. Enormous amounts of SO_2 are emitted by coal-burning power plants, petroleum refineries, and metal-ore smelters *(see photo)*. In contact with H_2O, the SO_2 and its oxidation product SO_3 form H_2SO_3 and H_2SO_4 in the atmosphere, which then fall in rain, snow, and dust on animals, plants, buildings, and lakes (see Chemical Connections, Chapter 19, p. 858).

Metal Sulfides Many metals combine directly with S to form *metal sulfides.* Sulfide ores are mined for the extraction of many metals, including copper, zinc, lead, and silver. Aside from the sulfides of Groups 1A(1) and 2A(2), most metal sulfides do not have discrete S^{2-} ions. Several transition metals, such as chromium, iron, and nickel, form covalent, alloy-like, nonstoichiometric compounds with S, such as $Cr_{0.88}S$ and $Fe_{0.86}S$. Some important minerals contain S_2^{2-} ions; an example is iron pyrite, or "fool's gold" (FeS_2). We discuss the metallurgy of ores in Chapter 22.

14.9 GROUP 7A(17): THE HALOGENS

The halogens, the last elements of great reactivity, begin with fluorine (F), the strongest electron "grabber" of all. Chlorine (Cl, the most important industrially), bromine (Br), and iodine (I) also form compounds with most elements, and even rare, radioactive astatine (At) is reactive; little is known of the newly synthesized element 117. The key features of Group 7A(17) are presented in the Family Portrait *(next page)*.

Physical Behavior of the Halogens

As expected from the increase in molar mass, the halogens display regular trends in their physical properties: melting and boiling points and heats of fusion and vaporization *increase* down Group 7A(17). The halogens exist as diatomic molecules that interact through dispersion forces, which *increase* in strength as the atoms become larger and, thus, more easily polarized. Even their color darkens with molar mass: F_2 is a very pale yellow gas, Cl_2 a yellow-green gas, Br_2 a brown-orange liquid, and I_2 a purple-black solid.

Why the Halogens Are So Reactive

The Group 7A(17) elements react with most metals and nonmetals to form many ionic and covalent compounds: metal and nonmetal halides, halogen oxides, and oxoacids. The main reason for halogen reactivity is the same as for alkali metal reactivity—an electron configuration one electron away from that of a noble gas. Whereas a 1A metal atom must lose one electron to attain a filled outer level, *a 7A nonmetal atom must gain one electron to fill its outer level.* It accomplishes this filling in either of two ways:

1. Gaining an electron from a metal atom, thus forming a negative ion as the metal forms a positive one.
2. Sharing an electron pair with a nonmetal atom, thus forming a covalent bond.

Electronegativity and Bond Properties The halogens display the largest range in electronegativity of any group, but all are electronegative enough to behave as nonmetals. Down the group, reactivity reflects the decrease in electronegativity: F_2 is the most reactive and I_2 the least. The exceptional reactivity of elemental F_2 is also related to the weakness of the F—F bond. Although bond energy generally decreases as atomic size increases down the group (Figure 14.22), F_2 deviates from this trend. The short F—F bond is weaker than expected because lone pairs on each small F atom repel those on the other. As a result of these factors, F_2 reacts with every element (except He, Ne, and Ar), in many cases, explosively.

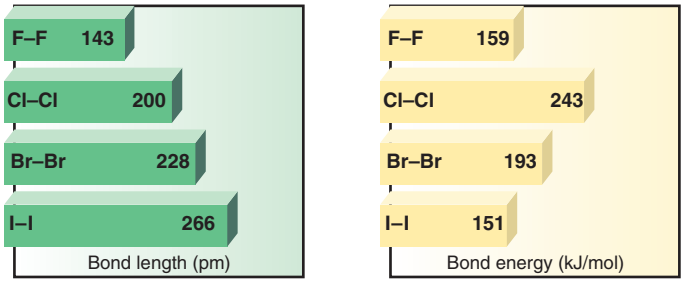

Figure 14.22 Bond energies and bond lengths of the halogens.

Redox Behavior The halogens act as *oxidizing agents* in the majority of their reactions, and halogens higher in the group can oxidize halide ions lower down:

$$F_2(g) + 2X^-(aq) \longrightarrow 2F^-(aq) + X_2(aq) \quad (X = Cl, Br, I)$$

Thus, the oxidizing ability of X_2 increases *up* the group: the higher the EN, the more strongly each X atom pulls electrons away. Similarly, the reducing ability of X^-

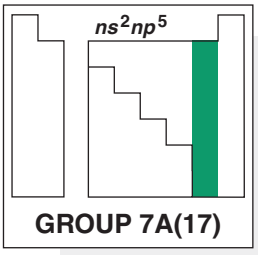
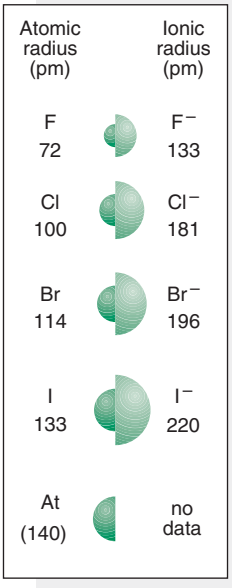
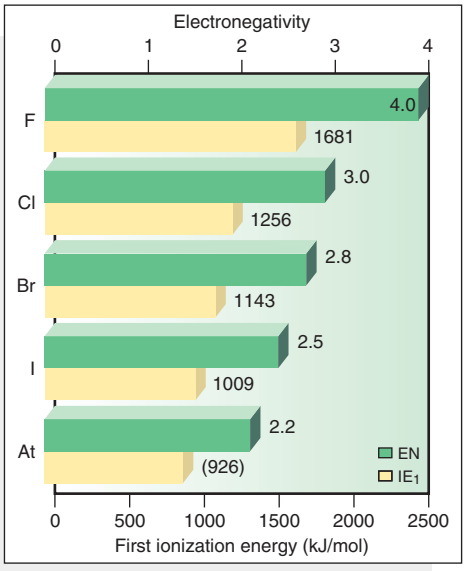
117 (294) $7s^2 7p^5$	Observed in experiments at Dubna, Russia, in 2010





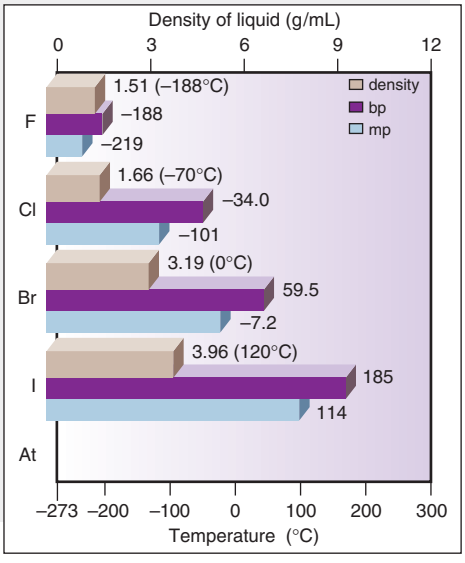
Atomic Properties

Group electron configuration is ns^2np^5; elements lack one electron to complete their outer level. The −1 oxidation state is the most common for all members. Except for F, the halogens exhibit all odd-numbered states (+7 through −1). Down the group, atomic and ionic sizes increase steadily, as IE and EN decrease.



Physical Properties

Down the group, melting and boiling points increase smoothly as a result of stronger dispersion forces between larger molecules. The densities of the elements as liquids (at the given T) increase steadily with molar mass.



Reactions

1. The halogens (X_2) oxidize many metals and nonmetals. The reaction with hydrogen, although not used commercially for HX production (except for high-purity HCl), is characteristic of these strong oxidizing agents:

$$X_2 + H_2(g) \longrightarrow 2HX(g)$$

2. The halogens undergo disproportionation in water:

$$X_2 + H_2O(l) \rightleftharpoons HX(aq) + HXO(aq) \qquad (X = Cl, Br, I)$$

In aqueous base, the reaction goes to completion to form hypohalites and, at higher temperatures, halates, for example:

$$3Cl_2(g) + 6OH^-(aq) \xrightarrow{\Delta} ClO_3^-(aq) + 5Cl^-(aq) + 3H_2O(l)$$

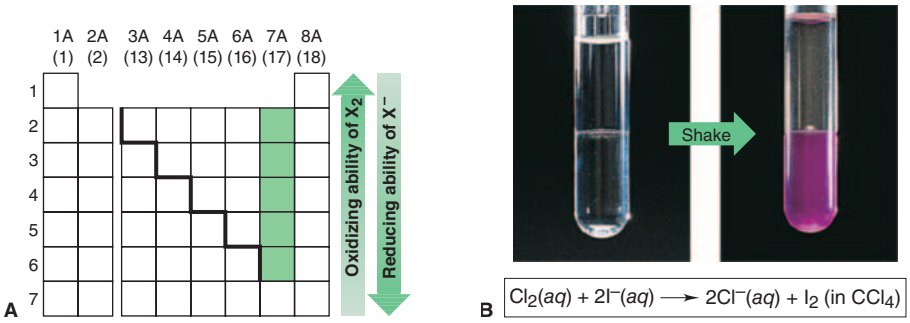


Figure 14.23 The relative oxidizing ability of the halogens.

increases *down* the group: the larger the ion, the more easily it gives up its electron (Figure 14.23A). Aqueous Cl_2 added to a solution of I^- (Figure 14.23B, *top layer*) oxidizes the I^- to I_2, which dissolves in the CCl_4 solvent *(bottom layer)* to give a purple solution.

The halogens undergo some important aqueous redox chemistry. Fluorine is such a powerful oxidizing agent that it reacts vigorously with water, oxidizing the O to produce O_2, some O_3, and HFO (hypofluorous acid). The other halogens undergo disproportionations (note the oxidation numbers):

$$\overset{0}{X_2} + H_2O(l) \rightleftharpoons \overset{-1}{HX}(aq) + \overset{+1}{HXO}(aq) \qquad (X = Cl, Br, I)$$

At equilibrium, very little product is present unless excess OH^- ion is added, which reacts with the HX and HXO and drives the reaction to completion:

$$X_2 + 2OH^-(aq) \longrightarrow X^-(aq) + XO^-(aq) + H_2O(l)$$

When X is Cl, the product mixture acts as a bleach: household bleach is a dilute solution of sodium hypochlorite (NaClO). Heating causes XO^- to disproportionate further, creating oxoanions with X in a higher oxidation state:

$$\overset{+1}{3XO^-}(aq) \xrightarrow{\Delta} \overset{-1}{2X^-}(aq) + \overset{+5}{XO_3^-}(aq)$$

Highlights of Halogen Chemistry

Now, let's examine the compounds the halogens form with hydrogen and with each other, as well as their oxides, oxoanions, and oxoacids.

The Hydrogen Halides The halogens form gaseous hydrogen halides (HX) through direct combination with H_2 or through the action of a concentrated acid on the metal halide (a nonoxidizing acid is used for HBr and HI):

$$CaF_2(s) + H_2SO_4(l) \longrightarrow CaSO_4(s) + 2HF(g)$$

$$3NaBr(s) + H_3PO_4(l) \longrightarrow Na_3PO_4(s) + 3HBr(g)$$

Commercially, most HCl is formed as a byproduct in the chlorination of hydrocarbons for plastics production:

$$CH_2{=}CH_2(g) + Cl_2(g) \longrightarrow ClCH_2CH_2Cl(l) \xrightarrow{500°C} \underset{\text{vinyl chloride}}{CH_2{=}CHCl}(g) + HCl(g)$$

In this case, the vinyl chloride reacts in a separate process to form poly(vinyl chloride), or PVC, a polymer used extensively in plumbing and for other piping needs.

In water, gaseous HX molecules form a *hydrohalic acid*. Only HF, with its relatively short, strong bond, forms a weak acid:

$$HF(g) + H_2O(l) \rightleftharpoons H_3O^+(aq) + F^-(aq)$$

HF has many uses, including the synthesis of cryolite (Na_3AlF_6) for aluminum production (Chapter 22), of fluorocarbons for refrigeration, and of NaF for water fluoridation. HF is also used in nuclear fuel processing and for glass etching.

The other hydrohalic acids dissociate completely to form the stoichiometric amount of H_3O^+ ions:

$$HBr(g) + H_2O(l) \longrightarrow H_3O^+(aq) + Br^-(aq)$$

(We saw reactions similar to these in Chapter 4. They involve *transfer* of a proton from acid to H_2O and are classified as *Brønsted-Lowry acid-base reactions*. In Chapter 18, we discuss them thoroughly and examine the relation between bond length and acidity of the larger HX molecules.)

HCl, a common laboratory reagent, is used in the "pickling" of steel to remove adhering oxides and in the production of syrups, rayon, and plastic. HCl(*aq*) occurs naturally in the stomach fluids of mammals.

Interhalogen Compounds: The "Halogen Halides" Halogens react exothermically with one another to form many **interhalogen compounds.** The simplest are diatomic molecules, such as ClF and BrCl. Every binary combination of the four common halogens is known. The more electronegative halogen is in the −1 oxidation state, and the less electronegative is in the +1 state. Interhalogens of general formula XY_n ($n = 3, 5, 7$) form through a variety of reactions, including direct reaction of the elements. In every case, the central atom has the lower *electronegativity* and a positive oxidation state.

Some interhalogens are used commercially as powerful *fluorinating agents,* which react with metals, nonmetals, and oxides—even wood and asbestos:

$$Sn(s) + ClF_3(l) \longrightarrow SnF_2(s) + ClF(g)$$
$$P_4(s) + 5ClF_3(l) \longrightarrow 4PF_3(g) + 3ClF(g) + Cl_2(g)$$
$$2B_2O_3(s) + 4BrF_3(l) \longrightarrow 4BF_3(g) + 2Br_2(l) + 3O_2(g)$$

Their reactions with water are nearly explosive and yield HF and the *oxoacid with the central halogen in the same oxidation state,* for example:

$$3H_2O(l) + \overset{+5}{BrF_5}(l) \longrightarrow 5HF(g) + \overset{+5}{HBrO_3}(aq)$$

The Oddness and Evenness of Oxidation States *Almost all stable molecules have paired electrons,* either as bonding or lone pairs. Therefore, *when bonds form or break, two electrons are involved, so the oxidation state changes by 2.* For this reason, odd-numbered groups exhibit odd-numbered oxidation states and even-numbered groups exhibit even-numbered states.

1. *Odd-numbered oxidation states.* Consider the interhalogens. Four general formulas are XY, XY_3, XY_5, and XY_7; examples are shown in Figure 14.24. With Y in the −1 state, X must be in the +1, +3, +5, and +7 state, respectively. The −1 state arises when Y fills its valence level; the +7 state arises when the central halogen (X) is completely oxidized, that is, when all seven valence electrons have shifted away from it to the more electronegative Y atoms around it.

Let's examine the iodine fluorides to see why the oxidation states jump by two units. When I_2 reacts with F_2, IF forms (note the oxidation number of I):

$$I_2 + F_2 \longrightarrow \overset{+1}{2IF}$$

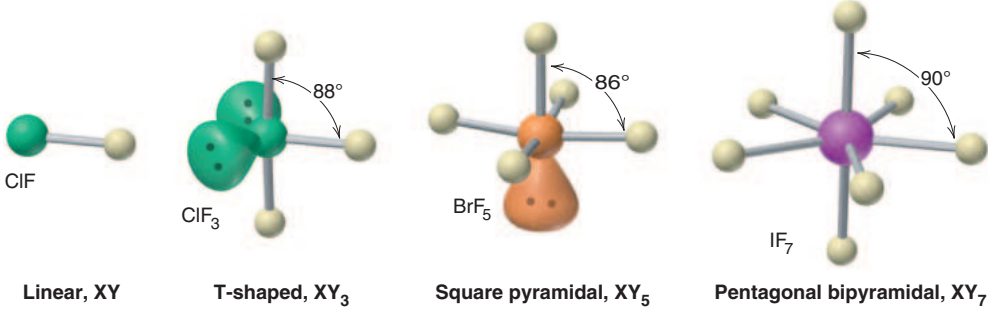

Figure 14.24 Molecular shapes of the main types of interhalogen compounds.

In IF_3, I uses *two* more valence electrons to form *two* more bonds:

$$\overset{+1}{IF} + F_2 \longrightarrow \overset{+3}{IF_3}$$

Otherwise, an unstable lone-electron species containing two fluorines would form. With more fluorine, another jump of two units occurs and the pentafluoride forms:

$$\overset{+3}{IF_3} + F_2 \longrightarrow \overset{+5}{IF_5}$$

With still more fluorine, the heptafluoride forms:

$$\overset{+5}{IF_5} + F_2 \longrightarrow \overset{+7}{IF_7}$$

2. *Even-numbered oxidation states.* An element in an even-numbered group, such as sulfur in Group 6A(16), shows the same tendency to have paired electrons in its compounds. Elemental sulfur (oxidation number, O.N. = 0) gains or shares two electrons to complete its shell (O.N. = −2). It uses two electrons to react with fluorine, for example, to form SF_2 (O.N. = +2), two more electrons to form SF_4 (O.N. = +4), and two more to form SF_6 (O.N. = +6).

Thus, an element with one even state typically has all even states, and an element with one odd state typically has all odd states. To reiterate the main point, *successive oxidation states differ by two units because stable molecules have electrons in pairs around their atoms.*

Halogen Oxides, Oxoacids, and Oxoanions The Group 7A(17) elements form many oxides that are *powerful oxidizing agents and acids in water.* Dichlorine monoxide (Cl_2O) and especially chlorine dioxide (ClO_2) are used to bleach paper (Figure 14.25). ClO_2 is unstable to heat and shock, so it is prepared on site, and more than 100,000 tons are used annually:

$$2NaClO_3(s) + SO_2(g) + H_2SO_4(aq) \longrightarrow 2ClO_2(g) + 2NaHSO_4(aq)$$

The dioxide has an unpaired electron and Cl in the unusual +4 oxidation state.

Chlorine is in its highest (+7) oxidation state in dichlorine heptoxide, Cl_2O_7, which is a symmetrical molecule formed when two $HClO_4$ (HO—ClO_3) molecules undergo a dehydration-condensation reaction:

$$O_3Cl—O\boxed{H + HO}—ClO_3 \longrightarrow O_3Cl—O—ClO_3(l) + H_2O(l)$$

The halogen oxoacids and oxoanions are produced by reaction of the halogens and their oxides with water. Most of the oxoacids are stable only in solution. Table 14.4 *(on the next page)* shows ball-and-stick models of the acids in which each atom has its lowest formal charge; note the formulas, which emphasize that the H is bonded to O. The hypohalites (XO^-), halites (XO_2^-), and halates (XO_3^-) are oxidizing agents formed by aqueous disproportionation reactions [see the Group 7A(17) Family Portrait, reaction 2]. You may have heated solid alkali chlorates in the laboratory to form small amounts of O_2:

$$2MClO_3(s) \xrightarrow{\Delta} 2MCl(s) + 3O_2(g)$$

Potassium chlorate is the oxidizer in "safety" matches.

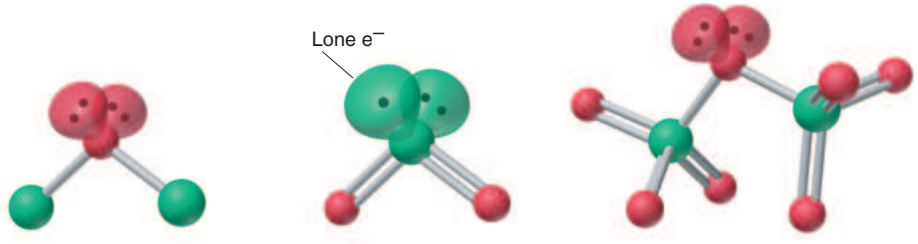

Figure 14.25 Chlorine oxides. Structures show each central Cl atom with its lowest formal charge.

Table 14.4 The Known Halogen Oxoacids*

Central Atom	Hypohalous Acid (HOX)	Halous Acid (HOXO)	Halic Acid ($HOXO_2$)	Perhalic Acid ($HOXO_3$)
				Fluorine	HOF	—	—	—
Chlorine	HOCl	HOClO	$HOClO_2$	$HOClO_3$
Bromine	HOBr	HOBrO	$HOBrO_2$	$HOBrO_3$
Iodine	HOI	—	$HOIO_2$	$HOIO_3$, $(HO)_5IO$
Oxoanion	Hypohalite	Halite	Halate	Perhalate

*Lone pairs are shown only on the halogen atom, and each atom has its lowest formal charge.

Several perhalates (XO_4^-) are also strong oxidizing agents. Thousands of tons of perchlorates are made each year for use in explosives and fireworks. Ammonium perchlorate, prepared from sodium perchlorate, was the oxidizing agent for the aluminum powder in the solid-fuel booster rockets of space shuttles; each launch used more than 700 tons of NH_4ClO_4:

$$10Al(s) + 6NH_4ClO_4(s) \longrightarrow 4Al_2O_3(s) + 12H_2O(g) + 3N_2(g) + 2AlCl_3(g)$$

The relative strengths of the halogen oxoacids depend on two factors:

1. *Electronegativity of the halogen.* Among oxoacids with the halogen in the same oxidation state, such as the halic acids, HXO_3 (or $HOXO_2$), acid strength decreases as the halogen's EN decreases:

$$HOClO_2 > HOBrO_2 > HOIO_2$$

The more electronegative the halogen, the more electron density it removes from the O—H bond, and the more easily the proton is lost.

2. *Oxidation state of the halogen.* Among oxoacids of a given halogen, such as chlorine, acid strength decreases as the oxidation state of the halogen decreases:

$$HOClO_3 > HOClO_2 > HOClO > HOCl$$

The higher the oxidation state (number of attached O atoms) of the halogen, the more electron density it pulls from the O—H bond. We consider these trends quantitatively in Chapter 18.

14.10 GROUP 8A(18): THE NOBLE GASES

The last main group consists of individual atoms too "noble" to interact much with others. The Group 8A(18) elements display regular trends in physical properties and very low, if any, reactivity. The group consists of the following elements: helium (He), the second most abundant element in the universe; neon (Ne); argon (Ar); krypton (Kr), xenon (Xe), and radioactive radon (Rn), the only members for which compounds have been well studied; and the recently synthesized element 118. The noble gases make up about 1% by volume of the atmosphere, primarily due to the abundance of Ar. The Group 8A(18) Family Portrait presents an overview of these elements.

Group 8A(18): The Noble Gases

KEY ATOMIC AND PHYSICAL PROPERTIES

KEY
Atomic No.
Symbol
Atomic mass
Valence e⁻ configuration
(Common oxidation states)

2 **He** 4.003 $1s^2$ **(none)**	
10 **Ne** 20.18 $2s^22p^6$ **(none)**	
18 **Ar** 39.95 $3s^23p^6$ **(none)**	
36 **Kr** 83.80 $4s^24p^6$ **(+2)**	
54 **Xe** 131.3 $5s^25p^6$ **(+8, +6, +4, +2)**	
86 **Rn** (222) $6s^26p^6$ **(+2)**	Mass spectral peak 118 (294) $7s^27p^6$	Observed in experiments at Dubna, Russia, in 2002 and 2005

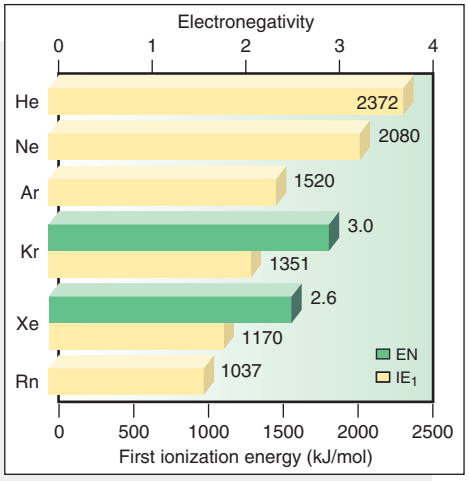
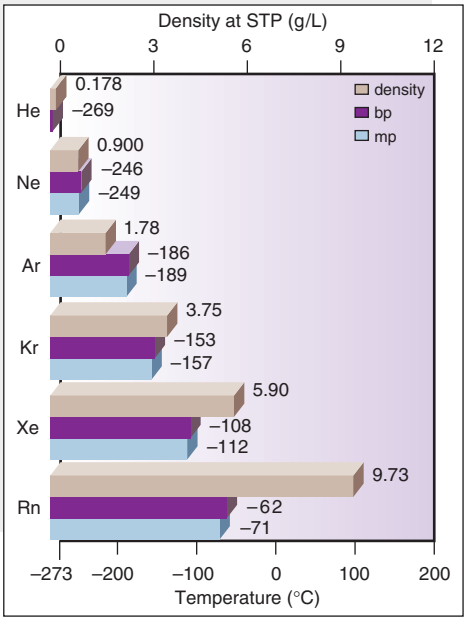
Atomic Properties

Group electron configuration is $1s^2$ for He and ns^2np^6 for the others. The valence shell is filled. Only Kr, Xe, and Rn are known to form compounds. The more reactive Xe exhibits all even oxidation states (+2 to +8). This group contains the smallest atoms with the highest IEs in their periods. Down the group, atomic size increases and IE decreases steadily. (EN values are given only for Kr and Xe.)



Physical Properties

Melting and boiling points of these gaseous elements are extremely low but increase down the group because of stronger dispersion forces. Note the extremely small liquid ranges. Densities (at STP) increase steadily, as expected.



How the Noble Gases and Alkali Metals Contrast Physically

Lying at the far right side of the periodic table, the Group 8A(18) elements come as close to behaving as ideal gases as any other substances. Like the alkali metals at the other end of the periodic table, the noble gases display regular trends in physical properties. However, whereas melting and boiling points and heats of fusion and vaporization *decrease* down Group 1A(1), these properties *increase* down Group 8A(18). The reason for these opposite trends is the different bonding interactions in the elements. The alkali metals consist of atoms held together by metallic bonding, which *decreases* in strength as the atoms become larger. The noble gases, on the other hand, exist as individual atoms that interact through dispersion forces, which *increase* in strength as the atoms become larger and more easily polarized. Nevertheless, these dispersion forces are so weak that only at very low temperatures do the elements condense and solidify. For example, even argon, which makes up almost 1% of the atmosphere, melts at −189°C, and it boils only about three degrees higher.

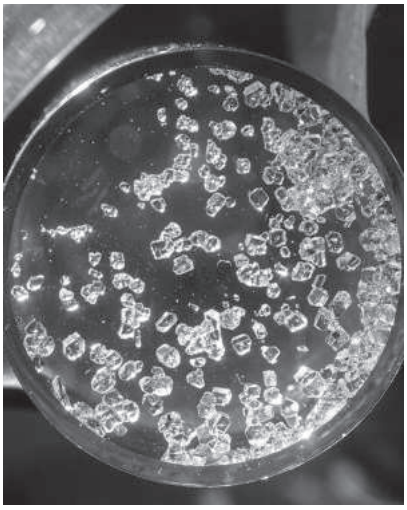


Figure 14.26 Crystals of xenon tetrafluoride (XeF_4).

How Noble Gases Can Form Compounds

Following their discovery in the late 19th century, these elements were considered, and even formerly named, the "inert" gases. Early 20th century atomic theory and, more important, all experiments supported this idea. Then, in 1962, all this changed when the first noble gas compound was prepared. How, with filled outer levels and extremely high ionization energies, *can* noble gases react?

The discovery of noble gas reactivity is a classic example of clear thinking in the face of an unexpected event. At the time, a young inorganic chemist named Neil Bartlett was studying platinum fluorides, known to be strong oxidizing agents. When he accidentally exposed PtF_6 to air, its deep-red color lightened slightly, and analysis showed that the PtF_6 had oxidized O_2 to form the ionic compound $[O_2]^+[PtF_6]^-$. Knowing that the ionization energy of the oxygen molecule ($O_2 \longrightarrow O_2^+ + e^-$; IE = 1175 kJ/mol) is very close to IE_1 of xenon (1170 kJ/mol), Bartlett reasoned that PtF_6 might be able to oxidize xenon. Shortly thereafter, he prepared $XePtF_6$, an orange-yellow solid. Within a few months, the white crystalline XeF_2 and XeF_4 (Figure 14.26) were also prepared. In addition to its +2 and +4 oxidation states, Xe has the +6 state in several compounds, such as XeF_6, and the +8 state in the unstable oxide, XeO_4. A few compounds of Kr and Rn have also been made.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) numbers appear in parentheses.

Understand These Concepts

Note: Many characteristic reactions appear in the "Reactions" section of each group's Family Portrait.

1. How hydrogen is similar to, yet different from, alkali metals and halogens; the differences between ionic, covalent, and metallic hydrides (§14.1)
2. Key horizontal trends in atomic properties, types of bonding, oxide acid-base properties, and redox behavior as the elements change from metals to nonmetals (§14.2)
3. How small atomic size and limited number of valence orbitals account for the anomalous behavior of the Period 2 member of each group (§14.2)
4. How the ns^1 configuration accounts for the physical and chemical properties of the alkali metals (§14.3)
5. How the ns^2 configuration accounts for the key differences between Groups 1A(1) and 2A(2) (§14.4)
6. The basis of the three important diagonal relationships (Li/Mg, Be/Al, B/Si) (§14.4–14.6)
7. How the presence of inner $(n - 1)d$ electrons affects properties in Group 3A(13) (§14.5)
8. Patterns among larger members of Groups 3A(13) to 6A(16): two common oxidation states (inert-pair effect), lower state more important down the group, and more basic lower oxide (§14.5–14.8)
9. How boron attains an octet of electrons (§14.5)
10. The effect of bonding on the physical behavior of Groups 4A(14) to 6A(16) (§14.6–14.8)
11. Allotropism in carbon, phosphorus, and sulfur (§14.6–14.8)
12. How atomic properties lead to catenation and multiple bonds in organic compounds (§14.6)
13. Structures and properties of the silicates and silicones (§14.6)

14. Patterns of behavior among hydrides and halides of Groups 5A(15) and 6A(16) (§14.7, 14.8)
15. The meaning of disproportionation (§14.7)
16. Structure and chemistry of the nitrogen oxides and oxoacids (§14.7)
17. Structure and chemistry of the phosphorus oxides and oxoacids (§14.7)
18. Dehydration-condensation reactions and polyphosphate structures (§14.7)
19. Structure and chemistry of the sulfur oxides and oxoacids (§14.8)
20. How the ns^2np^5 configuration accounts for halogen reactivity with metals (§14.9)
21. Why the oxidation states of an element change by two units (§14.9)
22. Structure and chemistry of the halogen oxides and oxoacids (§14.9)
23. How the ns^2np^6 configuration accounts for the relative inertness of the noble gases (§14.10)

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Hydrogen, the Simplest Atom

Concept Review Questions

14.1 Hydrogen has only one proton, but its IE_1 is much greater than that of lithium, which has three protons. Explain.

14.2 Sketch a periodic table, and label the areas containing elements that give rise to the three types of hydrides.

Skill-Building Exercises (grouped in similar pairs)

14.3 Draw Lewis structures for the following compounds, and predict which member of each pair will form hydrogen bonds:
(a) NF_3 or NH_3 (b) CH_3OCH_3 or CH_3CH_2OH

14.4 Draw Lewis structures for the following compounds, and predict which member of each pair will form hydrogen bonds:
(a) NH_3 or AsH_3 (b) CH_4 or H_2O

14.5 Complete and balance the following equations:
(a) An active metal reacting with acid,

$$Al(s) + HCl(aq) \longrightarrow$$

(b) A saltlike (alkali metal) hydride reacting with water,

$$LiH(s) + H_2O(l) \longrightarrow$$

14.6 Complete and balance the following equations:
(a) A saltlike (alkaline earth metal) hydride reacting with water,

$$CaH_2(s) + H_2O(l) \longrightarrow$$

(b) Reduction of a metal halide by hydrogen to form a metal,

$$PdCl_2(aq) + H_2(g) \longrightarrow$$

Problems in Context

14.7 Compounds such as $NaBH_4$, $Al(BH_4)_3$, and $LiAlH_4$ are complex hydrides used as reducing agents in many syntheses.
(a) Give the oxidation state of each element in these compounds.
(b) Write a Lewis structure for the polyatomic anion in $NaBH_4$, and predict its shape.

14.8 Unlike the F^- ion, which has an ionic radius close to 133 pm in all alkali metal fluorides, the ionic radius of H^- varies from 137 pm in LiH to 152 pm in CsH. Suggest an explanation for the large variability in the size of H^- but not F^-.

Trends Across the Periodic Table: The Period 2 Elements

Concept Review Questions

14.9 How does the maximum oxidation number vary across a period in the main groups? Is the pattern in Period 2 different?

14.10 What correlation, if any, exists for the Period 2 elements between group number and the number of covalent bonds the element typically forms? How is the correlation different for elements in Periods 3 to 6?

14.11 Each of the chemically active Period 2 elements forms stable compounds in which it has bonds to fluorine.
(a) What are the names and formulas of these compounds?
(b) Does ΔEN increase or decrease left to right across the period?
(c) Does percent ionic character increase or decrease left to right?
(d) Draw Lewis structures for these compounds.

14.12 Period 6 is unusual in several ways.
(a) It is the longest period in the table. How many elements belong to Period 6? How many metals?
(b) It contains no metalloids. Where is the metal/nonmetal boundary in Period 6?

14.13 An element forms an oxide, E_2O_3, and a fluoride, EF_3.
(a) Of which two groups might E be a member?
(b) How does the group to which E belongs affect the properties of the oxide and the fluoride?

14.14 Fluorine lies between oxygen and neon in Period 2. Whereas atomic sizes and ionization energies of these three elements change smoothly, their electronegativities display a dramatic change. What is this change, and how do their electron configurations explain it?

Group 1A(1): The Alkali Metals

Concept Review Questions

14.15 Lithium salts are often much less soluble in water than the corresponding salts of other alkali metals. For example, at 18°C, the concentration of a saturated LiF solution is 1.0×10^{-2} *M*, whereas that of a saturated KF solution is 1.6 *M*. How would you explain this behavior?

14.16 The alkali metals play virtually the same general chemical role in all their reactions. (a) What is this role? (b) How is it based on atomic properties? (c) Using sodium, write two balanced equations that illustrate this role.

14.17 How do atomic properties account for the low densities of the Group 1A(1) elements?

Skill-Building Exercises (grouped in similar pairs)

14.18 Each of the following properties shows a regular trend in Group 1A(1). Predict whether each increases or decreases *down* the group: (a) density; (b) ionic size; (c) E—E bond energy; (d) IE_1; (e) magnitude of ΔH_{hydr} of E^+ ion.

14.19 Each of the following properties shows a regular trend in Group 1A(1). Predict whether each increases or decreases *up* the group: (a) melting point; (b) E—E bond length; (c) hardness; (d) molar volume; (e) lattice energy of EBr.

14.20 Write a balanced equation for the formation from its elements of sodium peroxide, an industrial bleach.

14.21 Write a balanced equation for the formation of rubidium bromide through a reaction of a strong acid and a strong base.

Problems in Context

14.22 Although the alkali metal halides can be prepared directly from the elements, the far less expensive industrial route is treatment of the carbonate or hydroxide with aqueous hydrohalic acid (HX) followed by recrystallization. Balance the reaction between potassium carbonate and aqueous hydriodic acid.

14.23 Lithium forms several useful organolithium compounds. Calculate the mass percent of Li in the following:
(a) Lithium stearate ($C_{17}H_{35}COOLi$), a water-resistant grease used in cars because it does not harden at cold temperatures
(b) Butyllithium (LiC_4H_9), a reagent in organic syntheses

Group 2A(2): The Alkaline Earth Metals

Concept Review Questions

14.24 How do Groups 1A(1) and 2A(2) compare with respect to reaction of the metals with water?

14.25 Alkaline earth metals are involved in two key diagonal relationships in the periodic table.
(a) Give the two pairs of elements in these diagonal relationships.
(b) For each pair, cite two similarities that demonstrate the relationship.
(c) Why are the members of each pair so similar in behavior?

14.26 The melting points of alkaline earth metals are many times higher than those of the alkali metals. Explain this difference on the basis of atomic properties. Name three other physical properties for which Group 2A(2) metals have higher values than the corresponding 1A(1) metals.

Skill-Building Exercises (grouped in similar pairs)

14.27 Write a balanced equation for each reaction:
(a) "Slaking" of lime (treatment with water)
(b) Combustion of calcium in air

14.28 Write a balanced equation for each reaction:
(a) Thermal decomposition of witherite (barium carbonate)
(b) Neutralization of stomach acid (HCl) by milk of magnesia (magnesium hydroxide)

Problems in Context

14.29 Lime (CaO) is one of the most abundantly produced chemicals in the world. Write balanced equations for these reactions:
(a) The preparation of lime from natural sources
(b) The use of slaked lime to remove SO_2 from flue gases
(c) The reaction of lime with arsenic acid (H_3AsO_4) to manufacture the insecticide calcium arsenate
(d) The regeneration of NaOH in the paper industry by reaction of lime with aqueous sodium carbonate

14.30 In some reactions, Be behaves like a typical alkaline earth metal; in others, it does not. Complete and balance the following:
(a) $BeO(s) + H_2O(l) \longrightarrow$
(b) $BeCl_2(l) + Cl^-(l;$ from molten NaCl$) \longrightarrow$
In which reaction does Be behave like the other Group 2A(2) members?

Group 3A(13): The Boron Family

Concept Review Questions

14.31 How do the transition metals in Period 4 affect the pattern of ionization energies in Group 3A(13)? How does this pattern compare with that in Group 3B(3)?

14.32 How do the acidities of aqueous solutions of Tl_2O and Tl_2O_3 compare with each other? Explain.

14.33 Despite the expected decrease in atomic size, there is an unexpected drop in the first ionization energy between Groups 2A(2) and 3A(13) in Periods 2 through 4. Explain this pattern in terms of electron configurations and orbital energies.

14.34 Many compounds of Group 3A(13) elements have chemical behavior that reflects an electron deficiency.
(a) What is the meaning of *electron deficiency?*
(b) Give two reactions that illustrate this behavior.

14.35 Boron's chemistry is not typical of its group.
(a) Cite three ways in which boron and its compounds differ significantly from the other 3A(13) members and their compounds.
(b) What is the reason for these differences?

Skill-Building Exercises (grouped in similar pairs)

14.36 Rank the following oxides in order of increasing aqueous *acidity:* Ga_2O_3, Al_2O_3, In_2O_3.

14.37 Rank the following hydroxides in order of increasing aqueous *basicity:* $Al(OH)_3$, $B(OH)_3$, $In(OH)_3$.

14.38 Thallium forms the compound TlI_3. What is the apparent oxidation state of Tl in this compound? Given that the anion is I_3^-, what is the actual oxidation state of Tl? Draw the shape of the anion, giving its VSEPR class and bond angles. Propose a reason why the compound does not exist as $(Tl^{3+})(I^-)_3$.

14.39 Very stable dihalides of the Group 3A(13) metals are known. What is the apparent oxidation state of Ga in $GaCl_2$? Given that $GaCl_2$ consists of a Ga^+ cation and a $GaCl_4^-$ anion, what are the actual oxidation states of Ga? Draw the shape of the anion, giving its VSEPR class and bond angles.

Problems in Context

14.40 Give the name and symbol or formula of a Group 3A(13) element or compound that fits each description or use:
(a) Component of heat-resistant (Pyrex-type) glass
(b) Largest temperature range for liquid state of an element
(c) Elemental substance with three-center, two-electron bonds
(d) Metal protected from oxidation by adherent oxide coat
(e) Toxic metal that lies between two other toxic metals

14.41 Indium (In) reacts with HCl to form a diamagnetic solid with the formula $InCl_2$. (a) Write condensed electron configurations for In, In^+, In^{2+}, and In^{3+}. (b) Which of these species is (are) diamagnetic and which paramagnetic? (c) What is the apparent oxidation state of In in $InCl_2$? (d) Given your answers to parts (b) and (c), explain how $InCl_2$ can be diamagnetic.

14.42 Use VSEPR theory to draw structures, with ideal bond angles, for boric acid and the anion it forms when it reacts with water.

14.43 Boron nitride (BN) has a structure similar to graphite, but is a white insulator rather than a black conductor. It is synthesized by heating diboron trioxide with ammonia at about 1000°C.
(a) Write a balanced equation for the formation of BN; water also forms.
(b) Calculate ΔH°_{rxn} for the production of BN (ΔH°_f of BN is −254 kJ/mol).
(c) Boron is obtained from the mineral borax, $Na_2B_4O_7 \cdot 10H_2O$. How much borax is needed to produce 1.0 kg of BN, assuming 72% yield?

Group 4A(14): The Carbon Family

Concept Review Questions

14.44 How does the basicity of SnO_2 in water compare with that of CO_2? Explain.

14.45 Nearly every compound of silicon has the element in the +4 oxidation state. In contrast, most compounds of lead have the element in the +2 state.
(a) What general observation do these facts illustrate?
(b) Explain in terms of atomic and molecular properties.
(c) Give an analogous example from Group 3A(13).

14.46 The sum of IE_1 through IE_4 for Group 4A(14) elements shows a decrease from C to Si, a slight increase from Si to Ge, a decrease from Ge to Sn, and an increase from Sn to Pb.
(a) What is the expected trend for IEs down a group?
(b) Suggest a reason for the deviations in Group 4A(14).
(c) Which group might show even greater deviations?

14.47 Give explanations for the large drops in melting point from C to Si and from Ge to Sn.

14.48 What is an allotrope? Name two Group 4A(14) elements that exhibit allotropism, and identify two of their allotropes.

14.49 Even though EN values vary relatively little down Group 4A(14), the elements change from nonmetal to metal. Explain.

14.50 How do atomic properties account for the enormous number of carbon compounds? Why don't other Group 4A(14) elements behave similarly?

Skill-Building Exercises (grouped in similar pairs)

14.51 Draw a Lewis structure for each species:
(a) The cyclic silicate ion $Si_4O_{12}^{8-}$
(b) A cyclic hydrocarbon with formula C_4H_8

14.52 Draw a Lewis structure for each species:
(a) The cyclic silicate ion $Si_6O_{18}^{12-}$
(b) A cyclic hydrocarbon with formula C_6H_{12}

Problems in Context

14.53 Zeolite A, $Na_{12}[(AlO_2)_{12}(SiO_2)_{12}] \cdot 27H_2O$, is used to soften water by replacing Ca^{2+} and Mg^{2+} with Na^+. Hard water from a certain source is 4.5×10^{-3} *M* Ca^{2+} and 9.2×10^{-4} *M* Mg^{2+}, and a pipe delivers 25,000 L of this hard water per day. What mass (in kg) of zeolite A is needed to soften a week's supply of the water? (Assume zeolite A loses its capacity to exchange ions when 85 mol % of its Na^+ has been lost.)

14.54 Give the name and symbol or formula of a Group 4A(14) element or compound that fits each description or use:
(a) Hardest known natural substance
(b) Medicinal antacid
(c) Atmospheric gas implicated in the greenhouse effect
(d) Gas that binds to Fe(II) in blood
(e) Element used in the manufacture of computer chips

14.55 One similarity between B and Si is the explosive combustion of their hydrides in air. Write balanced equations for the combustion of B_2H_6 and of Si_4H_{10}.

Group 5A(15): The Nitrogen Family

Concept Review Questions

14.56 Which Group 5A(15) elements form trihalides? Pentahalides? Explain.

14.57 As you move down Group 5A(15), the melting points of the elements increase and then decrease. Explain.

14.58 (a) What is the range of oxidation states shown by the elements of Group 5A(15) as you move down the group? (b) How does this range illustrate the general rule for the range of oxidation states in groups on the right side of the periodic table?

14.59 Bismuth(V) compounds are such powerful oxidizing agents that they have not been prepared in pure form. How is this fact consistent with the location of Bi in the periodic table?

14.60 Rank the following oxides in order of increasing acidity in water: Sb_2O_3, Bi_2O_3, P_4O_{10}, Sb_2O_5.

Skill-Building Exercises (grouped in similar pairs)

14.61 Assuming acid strength relates directly to electronegativity of the central atom, rank H_3PO_4, HNO_3, and H_3AsO_4 in order of *increasing* acid strength.

14.62 Assuming acid strength relates directly to number of O atoms bonded to the central atom, rank $H_2N_2O_2$ [or $(HON)_2$]; HNO_3 (or $HONO_2$); and HNO_2 (or HONO) in order of *decreasing* acid strength.

14.63 Complete and balance the following:
(a) $As(s)$ + excess $O_2(g)$ ⟶
(b) $Bi(s)$ + excess $F_2(g)$ ⟶
(c) $Ca_3As_2(s) + H_2O(l)$ ⟶

14.64 Complete and balance the following:
(a) Excess $Sb(s) + Br_2(l)$ ⟶
(b) $HNO_3(aq) + MgCO_3(s)$ ⟶
(c) $K_2HPO_4(s) \xrightarrow{\Delta}$

14.65 Complete and balance the following:
(a) $N_2(g) + Al(s) \xrightarrow{\Delta}$ (b) $PF_5(g) + H_2O(l)$ ⟶

14.66 Complete and balance the following:
(a) $AsCl_3(l) + H_2O(l)$ ⟶ (b) $Sb_2O_3(s) + NaOH(aq)$ ⟶

14.67 Based on the relative sizes of F and Cl, predict the structure of PF_2Cl_3.

14.68 Use the VSEPR model to predict the structure of the cyclic ion $P_3O_9^{3-}$.

Problems in Context

14.69 The pentafluorides of the larger members of Group 5A(15) have been prepared, but N can have only eight electrons. A claim has been made that, at low temperatures, a compound with the empirical formula NF_5 forms. Draw a possible Lewis structure for this compound. (*Hint:* NF_5 is ionic.)

14.70 Give the name and symbol or formula of a Group 5A(15) element or compound that fits each description or use:
(a) Hydride that exhibits hydrogen bonding
(b) Compound used in "strike-anywhere" match heads
(c) Oxide used as a laboratory drying agent
(d) Odd-electron molecule (two examples)
(e) Compound used as an additive in soft drinks

14.71 In addition to those in Table 14.3, other less stable nitrogen oxides exist. Draw a Lewis structure for each of the following:
(a) N_2O_2, a dimer of nitrogen monoxide with an N—N bond
(b) N_2O_2, a dimer of nitrogen monoxide with no N—N bond
(c) N_2O_3 with no N—N bond
(d) NO^+ and NO_3^-, products of the ionization of liquid N_2O_4

14.72 Nitrous oxide (N_2O), the "laughing gas" used as an anesthetic by dentists, is made by thermal decomposition of solid NH_4NO_3. Write a balanced equation for this reaction. What are the oxidation states of N in NH_4NO_3 and in N_2O?

14.73 Write balanced equations for the thermal decomposition of potassium nitrate (O_2 is also formed in both cases): (a) at low temperature to the nitrite; (b) at high temperature to the metal oxide and nitrogen.

Group 6A(16): The Oxygen Family

Concept Review Questions

14.74 Rank the following in order of increasing electrical conductivity, and explain your ranking: Po, S, Se.

14.75 The oxygen and nitrogen families have some obvious similarities and differences.
(a) State two general physical similarities between Group 5A(15) and 6A(16) elements.
(b) State two general chemical similarities between Group 5A(15) and 6A(16) elements.
(c) State two chemical similarities between P and S.
(d) State two physical similarities between N and O.
(e) State two chemical differences between N and O.

14.76 A molecular property of the Group 6A(16) hydrides changes abruptly down the group. This change has been explained in terms of a change in orbital hybridization.
(a) Between what periods does the change occur?
(b) What is the change in the molecular property?
(c) What is the change in hybridization?
(d) What other group displays a similar change?

Skill-Building Exercises (grouped in similar pairs)

14.77 Complete and balance the following:
(a) $NaHSO_4(aq) + NaOH(aq)$ ⟶
(b) $S_8(s)$ + excess $F_2(g)$ ⟶
(c) $FeS(s) + HCl(aq)$ ⟶
(d) $Te(s) + I_2(s)$ ⟶

14.78 Complete and balance the following:
(a) $H_2S(g) + O_2(g)$ ⟶
(b) $SO_3(g) + H_2O(l)$ ⟶
(c) $SF_4(g) + H_2O(l)$ ⟶
(d) $Al_2Se_3(s) + H_2O(l)$ ⟶

14.79 Is each oxide basic, acidic, or amphoteric in water: (a) SeO_2; (b) N_2O_3; (c) K_2O; (d) BeO; (e) BaO?

14.80 Is each oxide basic, acidic, or amphoteric in water: (a) MgO; (b) N_2O_5; (c) CaO; (d) CO_2; (e) TeO_2?

14.81 Rank the following hydrides in order of *increasing* acid strength: H_2S, H_2O, H_2Te.

14.82 Rank the following species in order of *decreasing* acid strength: H_2SO_4, H_2SO_3, HSO_3^-.

Problems in Context

14.83 Selenium tetrafluoride reacts with more fluorine to form selenium hexafluoride.
(a) Draw Lewis structures for both selenium fluorides and predict any deviations from ideal bond angles.
(b) Describe the change in orbital hybridization of the central Se during the reaction.

14.84 Give the name and symbol or formula of a Group 6A(16) element or compound that fits each description or use:
(a) Unstable allotrope of oxygen
(b) Oxide having sulfur with the same O.N. as in sulfuric acid
(c) Air pollutant produced by burning sulfur-containing coal
(d) Powerful dehydrating agent
(e) Compound used in solution in the photographic process

14.85 Give the oxidation state of sulfur in (a) S_8; (b) SF_4; (c) SF_6; (d) H_2S; (e) FeS_2; (f) H_2SO_4; (g) $Na_2S_2O_3 \cdot 5H_2O$.

14.86 Disulfur decafluoride is intermediate in reactivity between SF_4 and SF_6. It disproportionates at 150°C to these monosulfur fluorides. Write a balanced equation for this reaction, and give the oxidation state of S in each compound.

Group 7A(17): The Halogens

Concept Review Questions

14.87 (a) Give the physical state and color of each halogen at STP.
(b) Explain the change in physical state down Group 7A(17) in terms of molecular properties.

14.88 (a) What are the common oxidation states of the halogens? (b) Give an explanation based on electron configuration for the range and values of the oxidation states of chlorine. (c) Why is fluorine an exception to the pattern of oxidation states found for the other group members?

14.89 How many electrons does a halogen atom need to complete its octet? Give examples of the ways a Cl atom can do so.

14.90 Select the stronger bond in each pair:
(a) Cl—Cl or Br—Br (b) Br—Br or I—I
(c) F—F or Cl—Cl. Why doesn't the F—F bond strength follow the group trend?

14.91 In addition to interhalogen compounds, many interhalogen ions exist. Would you expect interhalogen ions with a 1+ or a 1− charge to have an even or odd number of atoms? Explain.

14.92 (a) A halogen (X_2) disproportionates in base in several steps to X^- and XO_3^-. Write the overall equation for the disproportionation of Br_2 in excess OH^- to Br^- and BrO_3^-.
(b) Write a balanced equation for the reaction of ClF_5 with aqueous base (*Hint:* Add base to the reaction of BrF_5 on p. 604).

Skill-Building Exercises (grouped in similar pairs)

14.93 Complete and balance the following equations. If no reaction occurs, write NR:
(a) $Rb(s) + Br_2(l) \longrightarrow$ (b) $I_2(s) + H_2O(l) \longrightarrow$
(c) $Br_2(l) + I^-(aq) \longrightarrow$ (d) $CaF_2(s) + H_2SO_4(l) \longrightarrow$

14.94 Complete and balance the following equations. If no reaction occurs, write NR:
(a) $H_3PO_4(l) + NaI(s) \longrightarrow$ (b) $Cl_2(g) + I^-(aq) \longrightarrow$
(c) $Br_2(l) + Cl^-(aq) \longrightarrow$ (d) $ClF(g) + F_2(g) \longrightarrow$

14.95 Rank the following acids in order of *increasing* acid strength: HClO, $HClO_2$, HBrO, HIO.

14.96 Rank the following acids in order of *decreasing* acid strength: $HBrO_3$, $HBrO_4$, HIO_3, $HClO_4$.

Problems in Context

14.97 Give the name and symbol or formula of a Group 7A(17) element or compound that fits each description or use:
(a) Used in etching glass
(b) Compound used in household bleach
(c) Weakest hydrohalic acid
(d) Element that is a liquid at room temperature
(e) Organic chloride used to make PVC

14.98 An industrial chemist treats solid NaCl with concentrated H_2SO_4 and obtains gaseous HCl and $NaHSO_4$. When she substitutes solid NaI for NaCl, gaseous H_2S, solid I_2, and S_8 are obtained but no HI. (a) What type of reaction did the H_2SO_4 undergo with NaI? (b) Why does NaI, but not NaCl, cause this type of reaction? (c) To produce HI(*g*) by the reaction of NaI with an acid, how does the acid have to differ from sulfuric acid?

14.99 Rank the halogens Cl_2, Br_2, and I_2 in order of increasing oxidizing strength based on their products with metallic Re: $ReCl_6$, $ReBr_5$, ReI_4. Explain your ranking.

Group 8A(18): The Noble Gases

14.100 Which noble gas is the most abundant in the universe? In Earth's atmosphere?

14.101 What oxidation states does Xe show in its compounds?

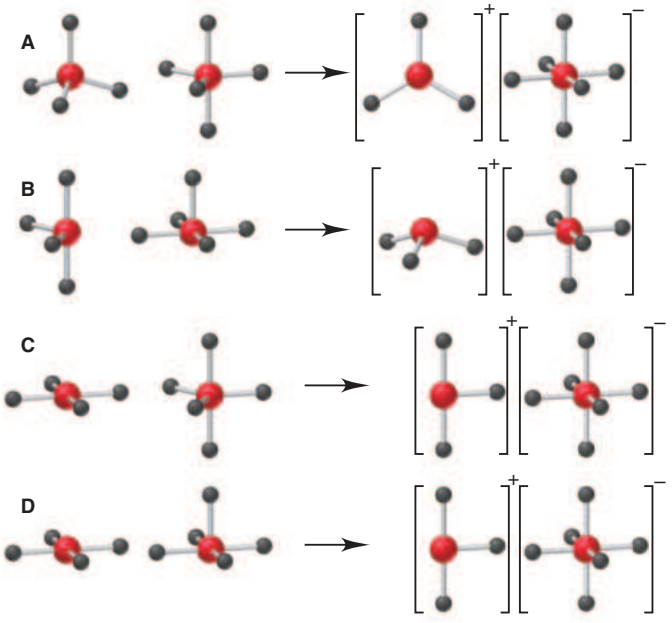
14.102 Why do the noble gases have such low boiling points?

14.103 Explain why Xe, and to a limited extent Kr, form compounds, whereas He, Ne, and Ar do not.

14.104 (a) Why do stable xenon fluorides have an even number of F atoms? (b) Why do the ionic species XeF_3^+ and XeF_7^- have odd numbers of F atoms? (c) Predict the shape of XeF_3^+.

Comprehensive Problems

14.105 Xenon tetrafluoride reacts with antimony pentafluoride to form the ionic complex $[XeF_3]^+[SbF_6]^-$. (a) Which depiction shows the molecular shapes of the reactants and product? (b) How, if at all, does the hybridization of xenon change in the reaction?



14.106 Given the following information,

$$H^+(g) + H_2O(g) \longrightarrow H_3O^+(g) \qquad \Delta H = -720 \text{ kJ}$$
$$H^+(g) + H_2O(l) \longrightarrow H_3O^+(aq) \qquad \Delta H = -1090 \text{ kJ}$$
$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H = 40.7 \text{ kJ}$$

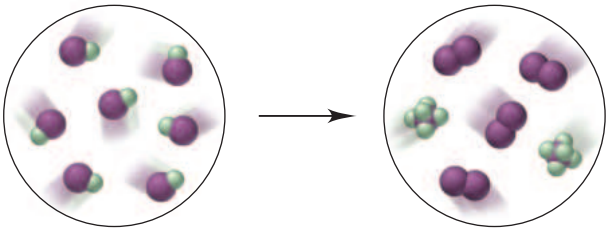
calculate the heat of solution of the hydronium ion:

$$H_3O^+(g) \xrightarrow{H_2O} H_3O^+(aq)$$

14.107 The electronic transition in Na from $3p^1$ to $3s^1$ gives rise to a bright yellow-orange emission at 589.2 nm. What is the energy of this transition?

14.108 Unlike other Group 2A(2) metals, beryllium reacts like aluminum and zinc with concentrated aqueous base to release hydrogen gas and form oxoanions of formula $M(OH)_4^{n-}$. Write equations for the reactions of these three metals with NaOH.

14.109 The interhalogen IF undergoes the reaction depicted below (I is purple and F is green):



(a) Write the balanced equation. (b) Name the interhalogen product. (c) What type of reaction is shown? (d) If each molecule of IF represents 2.50×10^{-3} mol, what mass of each product forms?

14.110 The main reason alkali metal dihalides (MX_2) do *not* form is the high IE_2 of the metal. (a) Why is IE_2 so high for alkali metals? (b) The IE_2 for Cs is 2255 kJ/mol, low enough for CsF_2 to form exothermically ($\Delta H_f^\circ = -125$ kJ/mol). This compound cannot be synthesized, however, because CsF forms with a much greater release of heat ($\Delta H_f^\circ = -530$ kJ/mol). Thus, the breakdown of CsF_2 to CsF happens readily. Write the equation for this breakdown, and calculate the enthalpy of reaction per mole of CsF.

14.111 Semiconductors made from elements in Groups 3A(13) and 5A(15) are typically prepared by direct reaction of the elements at high temperature. An engineer treats 32.5 g of molten gallium with 20.4 L of white phosphorus vapor at 515 K and 195 kPa. If purification losses are 7.2% by mass, how many grams of gallium phosphide will be prepared?

14.112 Two substances with empirical formula HNO are hyponitrous acid ($\mathcal{M} = 62.04$ g/mol) and nitroxyl ($\mathcal{M} = 31.02$ g/mol).
(a) What is the molecular formula of each species?
(b) For each species, draw the Lewis structure having the lowest formal charges. (*Hint:* Hyponitrous acid has an N═N bond.)
(c) Predict the shape around the N atoms of each species.
(d) When hyponitrous acid loses two protons, it forms the hyponitrite ion. Draw *cis* and *trans* forms of this ion.

14.113 The species CO, CN^-, and C_2^{2-} are isoelectronic.
(a) Draw their Lewis structures.
(b) Draw their MO diagrams (assume 2*s*-2*p* mixing, as in N_2), and give the bond order and electron configuration for each.

14.114 The Ostwald process is a series of three reactions used for the industrial production of nitric acid from ammonia.
(a) Write a series of balanced equations for the Ostwald process.
(b) If NO is *not* recycled, how many moles of NH_3 are consumed per mole of HNO_3 produced?
(c) In a typical industrial unit, the process is very efficient, with a 96% yield for the first step. Assuming 100% yields for the subsequent steps, what volume of concentrated aqueous nitric acid (60.% by mass; $d = 1.37$ g/mL) can be prepared for each cubic meter of a gas mixture that is 90.% air and 10.% NH_3 by volume at the industrial conditions of 5.0 atm and 850.°C?

14.115 All common plant fertilizers contain nitrogen compounds. Determine the mass % of N in (a) ammonia; (b) ammonium nitrate; (c) ammonium hydrogen phosphate.

14.116 Producer gas is a fuel formed by passing air over red-hot coke (amorphous carbon). What mass of a producer gas that consists of 25% CO, 5.0% CO_2, and 70.% N_2 by mass can be formed from 1.75 metric tons of coke, assuming an 87% yield?

14.117 Gaseous F_2 reacts with water to form HF and O_2. In NaOH solution, F_2 forms F^-, water, and oxygen difluoride (OF_2), a highly toxic gas and powerful oxidizing agent. The OF_2 reacts with excess OH^-, forming O_2, water, and F^-.
(a) For each reaction, write a balanced equation, give the oxidation state of O in all compounds, and identify the oxidizing and reducing agents.
(b) Draw a Lewis structure for OF_2, and predict its shape.

14.118 What is a disproportionation reaction, and which of the following fit the description?
(a) $I_2(s) + KI(aq) \longrightarrow KI_3(aq)$
(b) $2ClO_2(g) + H_2O(l) \longrightarrow HClO_3(aq) + HClO_2(aq)$
(c) $Cl_2(g) + 2NaOH(aq) \longrightarrow NaCl(aq) + NaClO(aq) + H_2O(l)$
(d) $NH_4NO_2(s) \longrightarrow N_2(g) + 2H_2O(g)$
(e) $3MnO_4^{2-}(aq) + 2H_2O(l) \longrightarrow 2MnO_4^-(aq) + MnO_2(s) + 4OH^-(aq)$
(f) $3AuCl(s) \longrightarrow AuCl_3(s) + 2Au(s)$

14.119 Explain the following observations:
(a) In reactions with Cl_2, phosphorus forms PCl_5 in addition to the expected PCl_3, but nitrogen forms only NCl_3.
(b) Carbon tetrachloride is unreactive toward water, but silicon tetrachloride reacts rapidly and completely. (To give what?)
(c) The sulfur-oxygen bond in SO_4^{2-} is shorter than expected for an S—O single bond.
(d) Chlorine forms ClF_3 and ClF_5, but ClF_4 is unknown.

14.120 Which group(s) of the periodic table is (are) described by each of the following general statements?
(a) The elements form compounds of VSEPR class AX_3E.
(b) The free elements are strong oxidizing agents and form monatomic ions and oxoanions.
(c) The atoms form compounds by combining with two other atoms that donate one electron each.
(d) The free elements are strong reducing agents, show only one nonzero oxidation state, and form mainly ionic compounds.
(e) The elements can form stable compounds with only three bonds, but as a central atom, they can accept a pair of electrons from a fourth atom without expanding their valence shell.
(f) Only larger members of the group are chemically active.

14.121 Diiodine pentoxide (I_2O_5) was discovered by Joseph Gay-Lussac in 1813, but its structure was unknown until 1970! Like Cl_2O_7, it can be prepared by the dehydration-condensation of the corresponding oxoacid.
(a) Name the precursor oxoacid, write a reaction for formation of the oxide, and draw a likely Lewis structure.
(b) Data show that the bonds to the terminal O are shorter than the bonds to the bridging O. Why?
(c) I_2O_5 is one of the few chemicals that can oxidize CO rapidly and completely; elemental iodine forms in the process. Write a balanced equation for this reaction.

14.122 Bromine monofluoride (BrF) disproportionates to bromine gas and bromine tri- and pentafluorides. Use the following to find ΔH_{rxn}° for the decomposition of BrF to its elements:

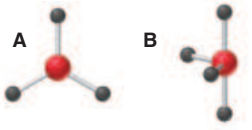
$$3BrF(g) \longrightarrow Br_2(g) + BrF_3(l) \quad \Delta H_{rxn} = -125.3 \text{ kJ}$$
$$5BrF(g) \longrightarrow 2Br_2(g) + BrF_5(l) \quad \Delta H_{rxn} = -166.1 \text{ kJ}$$
$$BrF_3(l) + F_2(g) \longrightarrow BrF_5(l) \quad \Delta H_{rxn} = -158.0 \text{ kJ}$$

14.123 White phosphorus is prepared by heating phosphate rock [principally $Ca_3(PO_4)_2$] with sand and coke:

$$Ca_3(PO_4)_2(s) + SiO_2(s) + C(s) \longrightarrow CaSiO_3(s) + CO(g) + P_4(g) \text{ [unbalanced]}$$

How many kilograms of phosphate rock are needed to produce 315 mol of P_4, assuming that the conversion is 90.% efficient?

14.124 Element E forms an oxide of general structure A and a chloride of general structure B, shown at right. For the anion EF_5^-, what is (a) the molecular shape; (b) the hybridization of E; (c) the O.N. of E?



14.125 From its formula, one might expect CO to be quite polar, but its dipole moment is actually low (0.11 D).
(a) Draw the Lewis structure for CO.
(b) Calculate the formal charges.
(c) Based on your answers to parts (a) and (b), explain why the dipole moment is so low.

14.126 When an alkaline earth carbonate is heated, it releases CO_2, leaving the metal oxide. The temperature at which each Group 2A(2) carbonate yields a CO_2 partial pressure of 1 atm is

Carbonate	Temperature (°C)
$MgCO_3$	542
$CaCO_3$	882
$SrCO_3$	1155
$BaCO_3$	1360

(a) Suggest a reason for this trend.
(b) Mixtures of $CaCO_3$ and MgO are used to absorb dissolved silicates from boiler water. How would you prepare a mixture of $CaCO_3$ and MgO from dolomite, which contains $CaCO_3$ and $MgCO_3$?

14.127 The bond angles in the nitrite ion, nitrogen dioxide, and the nitronium ion (NO_2^+) are 115°, 134°, and 180°, respectively. Explain these values using Lewis structures and VSEPR theory.

14.128 A common method for producing a gaseous hydride is to treat a salt containing the anion of the volatile hydride with a strong acid.
(a) Write an equation for each of the following examples: (1) the production of HF from CaF_2; (2) the production of HCl from NaCl; (3) the production of H_2S from FeS.
(b) In some cases, even as weak an acid as water can be used for this preparation if the anion of the salt has a sufficiently strong attraction for protons. An example is the production of PH_3 from Ca_3P_2 and water. Write the equation for this reaction.
(c) By analogy, predict the products and write the equation for the reaction of Al_4C_3 with water.

14.129 Chlorine trifluoride was formerly used in the production of uranium hexafluoride for the U.S. nuclear industry:

$$U(s) + 3ClF_3(l) \longrightarrow UF_6(l) + 3ClF(g)$$

How many grams of UF_6 can form from 1.00 metric ton of uranium ore that is 1.55% by mass uranium and 12.75 L of chlorine trifluoride ($d = 1.88$ g/mL)?

14.130 Chlorine is used to make bleach solutions containing 5.25% NaClO (by mass). Assuming 100% yield in the reaction producing NaClO from Cl_2, how many liters of $Cl_2(g)$ at STP will be needed to make 1000. L of bleach solution ($d = 1.07$ g/mL)?

14.131 The triatomic molecular ion H_3^+ was first detected and characterized by J. J. Thomson using mass spectrometry. Use the bond energy of H_2 (432 kJ/mol) and the proton affinity of H_2 ($H_2 + H^+ \longrightarrow H_3^+$; $\Delta H = -337$ kJ/mol) to calculate the enthalpy of reaction for $H + H + H^+ \longrightarrow H_3^+$.

14.132 An atomic hydrogen torch is used for cutting and welding thick sheets of metal. When H_2 passes through an electric arc, the molecules decompose into atoms, which react with O_2. Temperatures over 5000°C are reached, which can melt all metals. Write equations for the breakdown of H_2 to H atoms and for the subsequent overall reaction of the H atoms with oxygen. Use Appendix B to find the standard enthalpy of each reaction per mole of product.

14.133 Which of the following oxygen ions are paramagnetic: O^+, O^-, O^{2-}, O^{2+}?

14.134 Copper(II) hydrogen arsenite ($CuHAsO_3$) is a green pigment once used in wallpaper. In damp conditions, mold metabolizes this compound to trimethylarsine [$(CH_3)_3As$], a highly toxic gas.
(a) Calculate the mass percent of As in each compound.
(b) How much $CuHAsO_3$ must react to reach a toxic level in a room that measures 12.35 m × 7.52 m × 2.98 m (arsenic is toxic at 0.50 mg/m^3)?

14.135 Hydrogen peroxide can act as either an oxidizing agent or a reducing agent.
(a) When H_2O_2 is treated with aqueous KI, I_2 forms. In which role is H_2O_2 acting? What oxygen-containing product is formed?
(b) When H_2O_2 is treated with aqueous $KMnO_4$, the purple color of MnO_4^- disappears and a gas forms. In which role is H_2O_2 acting? What is the oxygen-containing product formed?

Aside from the air and the water in the sugar solution, everything in the photo *(opposite)*—hummingbird, plants, sugar, and plastic feeder—consists of organic compounds. And so does nearly everything you put into or on your body—food, medicine, cosmetics, and clothing. Organic fuels warm our homes, cook our meals, and power our vehicles. Major industries are devoted to producing organic compounds, including plastics, pharmaceuticals, and insecticides.

What *is* an organic compound? According to the dictionary, it is "a compound of carbon," but that definition is too general because carbonates, cyanides, carbides, cyanates, and so forth, also contain carbon but are classified as inorganic. Here is a more specific definition: all **organic compounds** contain carbon, nearly always bonded to other carbons and hydrogen, and often to other elements.

In the early 19th century, organic compounds were usually obtained from living things, so they were thought to possess a spiritual "vital force," which made them impossible to synthesize and fundamentally different from inorganic compounds. But, in 1828, Friedrich Wöhler destroyed this notion when he obtained urea by heating ammonium cyanate. Today, we know that *the same chemical principles govern organic and inorganic systems* because the behavior of a compound—no matter how amazing—can be explained by understanding the properties of its elements.

IN THIS CHAPTER . . . *We see that the structures and reactivities of organic molecules emerge naturally from the properties of their component atoms.*

- We begin by reviewing the atomic properties of carbon and seeing how they lead to the complex structures and reactivity of organic molecules.
- We focus on drawing and naming hydrocarbons as a prelude to naming other types of organic compounds.
- We classify the main types of organic reactions in terms of bond order and apply them to the functional groups that characterize families of organic compounds.
- We examine the giant organic molecules of commerce and life—synthetic and natural polymers.

15.1 THE SPECIAL NATURE OF CARBON AND THE CHARACTERISTICS OF ORGANIC MOLECULES

Although there is nothing mystical about organic molecules, their indispensable role in biology and industry leads us to wonder if carbon is somehow special. Of course, each element has specific properties, but the atomic properties of carbon do give it bonding capabilities beyond those of any element, and this exceptional behavior leads to the two characteristics of organic molecules—structural complexity and chemical diversity.

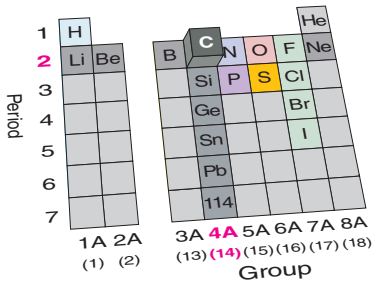

Figure 15.1 The position of carbon in the periodic table.

The Structural Complexity of Organic Molecules

Most organic molecules have more complex structures than most inorganic molecules. A quick review of carbon's atomic properties and bonding behavior shows why.

1. *Electron configuration, electronegativity, and bonding.* Carbon forms covalent, rather than ionic, bonds in all its elemental forms and compounds. This bonding behavior is the result of carbon's electron configuration and electronegativity:

- Carbon's ground-state electron configuration of [He] $2s^2 2p^2$—four electrons more than He and four fewer than Ne—means that the formation of carbon ions is energetically impossible under ordinary conditions. The loss of four e^- to form the C^{4+} cation requires the sum of IE_1 through IE_4; the gain of four e^- to form the C^{4-} anion requires the sum of EA_1 through EA_4, the last three steps of which are endothermic.
- Lying at the center of Period 2, carbon has an electronegativity (EN = 2.5) that is midway between that of the most metallic element (Li, EN = 1.0) and the most nonmetallic active element (F, EN = 4.0) (Figure 15.1).

2. *Catenation, bond properties, and molecular shape.* The *number* and *strength* of carbon's bonds lead to its property of **catenation,** the ability to bond to itself repeatedly, which results in a multitude of chemically and thermally stable chain, ring, and branched compounds:

- Through the process of orbital hybridization (Section 11.1), carbon forms four bonds in virtually all its compounds, and they point in as many as four different directions.
- The small size of carbon allows close approach to another atom and thus greater orbital overlap, so carbon forms relatively short, strong bonds.
- The C—C bond is short enough to allow side-to-side overlap of half-filled, unhybridized *p* orbitals and the formation of multiple bonds. These restrict rotation of attached groups (see Figure 11.13, p. 439), leading to additional structures.

3. *Molecular stability.* Although silicon and several other elements catenate also, none forms chains as stable as those of carbon. Atomic and bonding properties explain why C chains are so stable and, therefore, so common:

- *Atomic size and bond strength.* As atomic size increases down Group 4A(14), bonds between identical atoms become longer and weaker. Thus, a C—C bond (347 kJ/mol) is much stronger than an Si—Si bond (226 kJ/mol).
- *Relative enthalpies of reaction.* A C—C bond (347 kJ/mol), a C—O bond (358 kJ/mol), and a C—Cl bond (339 kJ/mol) have nearly the same energy, so relatively little heat is released when a C chain reacts and one bond replaces the other. In contrast, an Si—O bond (368 kJ/mol) or an Si—Cl bond (381 kJ/mol) is much stronger than an Si—Si bond (226 kJ/mol), so the large quantity of heat released when an Si chain reacts favors reactivity.
- *Orbitals available for reaction.* Unlike C, Si has low-energy *d* orbitals that can be attacked (occupied) by the lone pairs of incoming reactants. Thus, for example, ethane (CH_3—CH_3) is stable in water and reacts in air only when sparked, whereas disilane (SiH_3—SiH_3) breaks down in water and ignites spontaneously in air.

The Chemical Diversity of Organic Molecules

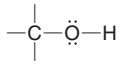
In addition to their complex structures, organic compounds are remarkable for their sheer number and diverse chemical behavior. Several million organic compounds are known, and thousands more are discovered or synthesized each year. This diversity is also founded on atomic behavior and is due to three interrelated factors—bonding to heteroatoms, variations in reactivity, and the occurrence of functional groups.

1. *Bonding to heteroatoms.* Many organic compounds contain **heteroatoms,** atoms other than C or H. The most common heteroatoms are N and O, but S, P, and the halogens often occur, and organic compounds with other elements are known as well. Figure 15.2 shows that 23 different molecular structures are possible from various arrangements of four C atoms singly bonded to each other, just one O atom (either singly or doubly bonded), and the necessary number of H atoms.

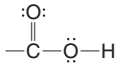
2. *Electron density and reactivity.* Most reactions start—that is, a new bond begins to form—*when a region of high electron density on one molecule meets a region of low electron density on another.* These regions may be due to the properties of a multiple bond or a carbon-heteroatom bond. Consider the reactivities of four bonds commonly found in organic molecules:

- *The C—C bond.* When C is singly bonded to another C, as occurs in portions of nearly every organic molecule, the EN values are equal and the bond is nonpolar. Therefore, in most cases, *C—C bonds are unreactive.*
- *The C—H bond.* This bond, which also occurs in nearly every organic molecule, is short (109 pm) and, with EN values of H (2.1) and C (2.5), very nearly nonpolar. Thus, *C—H bonds are largely unreactive*.
- *The C—O bond.* This bond, which occurs in many types of organic molecules, is highly polar ($\Delta EN = 1.0$), with the O end electron rich and the C end electron poor. As a result of this imbalance in electron density, *the C—O bond is reactive* (easy to break), and, given appropriate conditions, a reaction will occur there.
- *Bonds to other heteroatoms.* Even when a carbon-heteroatom bond has a small ΔEN, such as that for C—Br ($\Delta EN = 0.3$), or none at all, as for C—S ($\Delta EN = 0$), the heteroatoms are generally large, so their bonds to carbon are long, weak, and thus *reactive.*

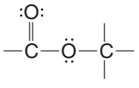
3. *Importance of functional groups.* The central feature of most organic molecules is the **functional group,** a specific combination of bonded atoms that reacts in a *characteristic* way, no matter what molecule it occurs in. In nearly every case, *the reaction of an organic compound takes place at the functional group.* (In fact, as you'll see in Section 15.3, we often write a general symbol for the remainder of the molecule because it stays the same while the functional group reacts.) Functional groups vary from carbon-carbon multiple bonds to several combinations of carbon-heteroatom bonds, and each has its own pattern of reactivity. A particular bond may be a functional group itself or *part* of one or more functional groups. For example, the C—O bond occurs in four functional groups. We will discuss the reactivity of three of these groups in this chapter:



alcohol group



carboxylic acid group



ester group

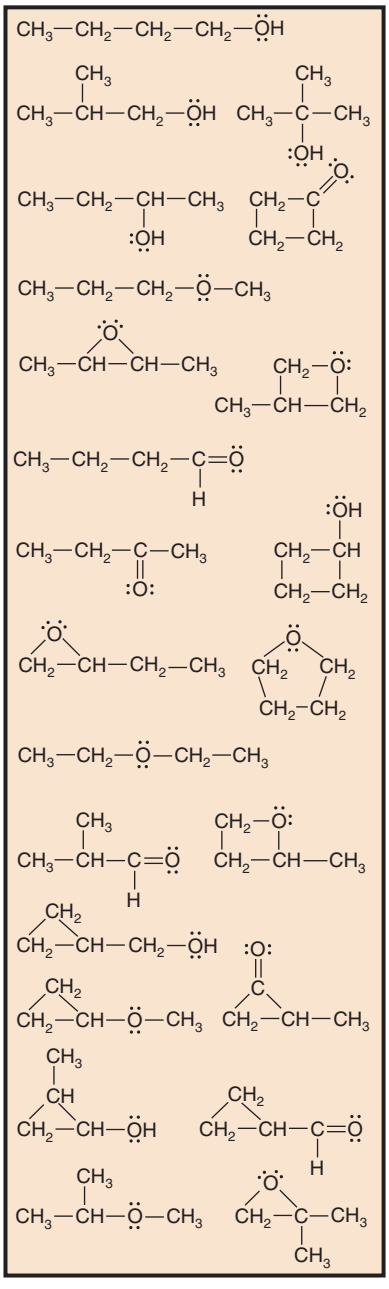


Figure 15.2 **Heteroatoms and different bonding arrangements lead to great chemical diversity.**

Summary of Section 15.1

- Carbon's small size, intermediate electronegativity, four valence electrons, and ability to form multiple bonds result in the structural complexity of organic compounds.
- These factors lead to carbon's ability to catenate, which creates chains, branches, and rings of C atoms. Small size and absence of *d* orbitals in the valence level lead to strong, chemically resistant bonds that point in as many as four directions from each C.
- Carbon's ability to bond to many other elements, especially O and N, creates polar, reactive bonds, which leads to the chemical diversity of organic compounds.
- Most organic compounds contain functional groups, specific combinations of bonded atoms that react in characteristic ways.

15.2 THE STRUCTURES AND CLASSES OF HYDROCARBONS

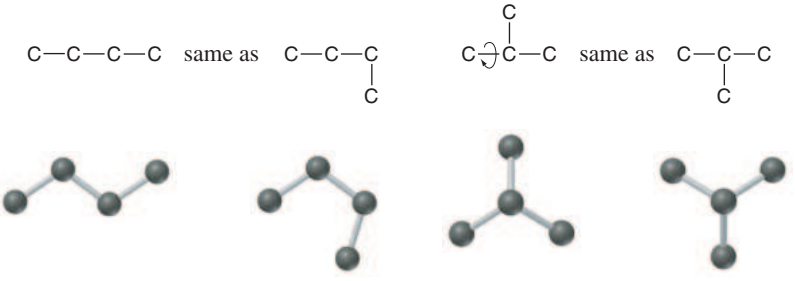
Let's make an anatomical analogy between an organic molecule and an animal. The carbon-carbon bonds form the skeleton: the longest continual chain is the backbone, and any branches are the limbs. Covering the skeleton is a skin of hydrogen atoms, with functional groups protruding at specific locations, like chemical hands ready to grab an incoming reactant. In this section, we "dissect" one group of compounds down to their skeletons and see how to draw and name them.

Hydrocarbons, the simplest type of organic compound, contain only H and C atoms. Some common fuels, such as natural gas and gasoline, are hydrocarbon mixtures. Some hydrocarbons, such as ethylene, acetylene, and benzene, are important *feedstocks,* precursor reactants used to make other compounds.

Carbon Skeletons and Hydrogen Skins

We'll begin by examining the possible bonding arrangements of C atoms only (leaving off the H atoms for now) in simple skeletons without multiple bonds or rings. To distinguish different skeletons, focus on the *arrangement* of C atoms (that is, the successive linkages of one to another) and keep in mind that *groups joined by a single (sigma) bond are relatively free to rotate* (Section 11.2).

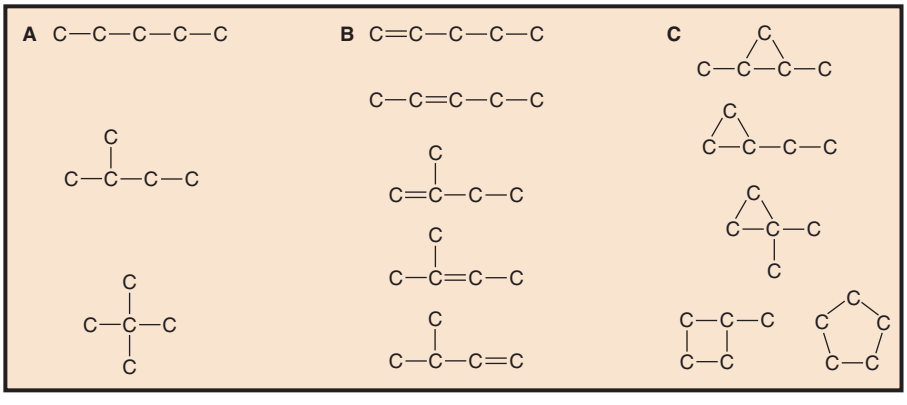
Number of C Atoms and Number of Arrangements One, two, or three C atoms can be arranged in only one way. Whether you draw three C atoms in a line or with a bend, the arrangement is the same. Four C atoms, however, have two possible arrangements—a four-C chain or a three-C chain with a one-C branch at the central C:



When we show the chains with bends due to the tetrahedral C (as in the ball-and-stick models above), the different arrangements are especially clear. Notice that if the branch is added to either end of the three-C chain, it is simply a bend in a four-C chain, *not* a different arrangement. Similarly, if the branch points down instead of up, it represents the same arrangement because single-bonded groups rotate.

As the total number of C atoms increases, the number of different arrangements increases as well. Five C atoms joined by single bonds have 3 possible arrangements (Figure 15.3A); 6 C atoms can be arranged in 5 ways, 7 C atoms in 9 ways, 10 C atoms in 75 ways, and 20 C atoms in more than 300,000 ways! If we include multiple bonds and rings, the number of arrangements increases further. For example,

Figure 15.3 Some five-carbon skeletons.



including just one C═C bond in the five-C skeletons creates 5 more arrangements (Figure 15.3B), and including one ring creates 5 more (Figure 15.3C).

Drawing Hydrocarbons When determining the number of different skeletons for a given number of C atoms, remember that

- Each C atom can form four single bonds, two single and one double bond, or one single and one triple bond.
- A straight chain or a bent chain of C atoms represent the same skeleton.
- For a single-bonded arrangement, a branch pointing down is the same as one pointing up.
- A double bond *restricts rotation,* so different groups joined by a double bond can lead to different arrangements.

If we put a hydrogen "skin" on a carbon skeleton, we obtain a hydrocarbon. Figure 15.4 shows that a skeleton has the correct number of H atoms when each C has four bonds. Sample Problem 15.1 provides practice drawing hydrocarbons.

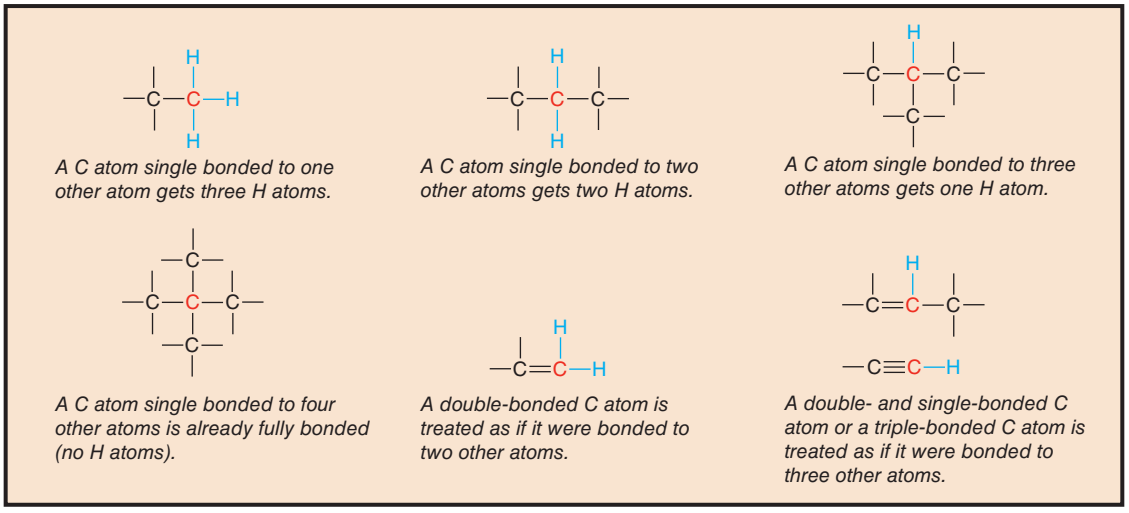


Figure 15.4 Adding the H-atom skin to the C-atom skeleton.

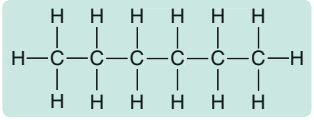
SAMPLE PROBLEM 15.1 Drawing Hydrocarbons

Problem Draw structures that have different atom arrangements for hydrocarbons with:
(a) Six C atoms, no multiple bonds, and no rings
(b) Four C atoms, one double bond, and no rings
(c) Four C atoms, no multiple bonds, and one ring

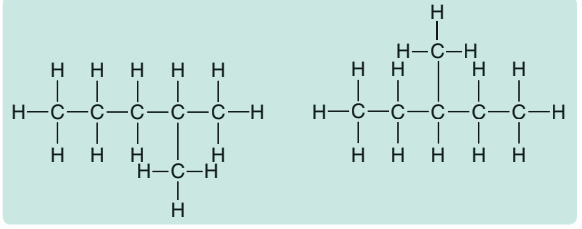
Plan In each case, we draw the longest carbon chain first and then work down to smaller chains with branches at different points along them. The process typically involves trial and error. Then, we add H atoms to give each C a total of four bonds.

Solution **(a)** Compounds with six C atoms:

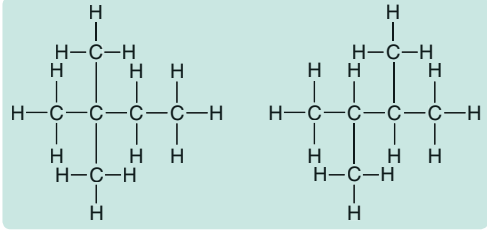
6-C chain:



5-C chains:



4-C chains:



(b) Compounds with four C atoms and one double bond:

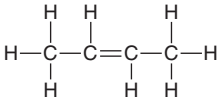
4-C chains:  3-C chain: 
(c) Compounds with four C atoms and one ring:

4-C ring:  3-C ring: 
Check Be sure each skeleton has the correct number of C atoms, multiple bonds, and/or rings, and no arrangements are repeated or omitted; remember a double bond counts as two bonds.

Comment Avoid some *common mistakes:*

In (a): 
In (b): C—C—C=C is the same skeleton as C=C—C—C

The double bond restricts rotation, so, in addition to the *cis* form shown on the left of the 4-C chains in the solution for part (b), another possibility is the *trans* form:



(We discuss *cis* and *trans* forms fully later in this section.)

Also, avoid drawing too many bonds to one C, as here: 
In (c): there are too many bonds to one C in 
FOLLOW-UP PROBLEMS

Brief Solutions to ***all*** *Follow-up Problems appear at the end of the chapter.*

15.1A Draw all hydrocarbons that have different atom arrangements with **(a)** seven C atoms, no multiple bonds, and no rings (nine arrangements); **(b)** five C atoms, one triple bond, and no rings (three arrangements).

15.1B Draw all hydrocarbons that have different atom arrangements with **(a)** four C atoms, one ring, and one double bond (four arrangements); **(b)** four C atoms, no rings, and two double bonds (two arrangements).

SOME SIMILAR PROBLEMS 15.13–15.16

Hydrocarbons can be classified into four main groups. In the rest of this section, we discuss how to name them, as well as some structural features and physical properties of each group. Later, we'll discuss the chemical behavior of the hydrocarbons.

Alkanes: Hydrocarbons with Only Single Bonds

A hydrocarbon that contains only single bonds is an **alkane** (general formula $\mathbf{C_nH_{2n+2}}$, where n is a positive integer). For example, if $n = 5$, the formula is $C_5H_{[(2\times5)+2]}$, or C_5H_{12}. The alkanes comprise a **homologous series,** one in which each member

differs from the next by a —CH_2— (methylene) group. In an alkane, each C is sp^3 hybridized. Because each C is bonded to the *maximum number of other atoms* (C or H), alkanes are referred to as **saturated hydrocarbons.**

Naming Alkanes You learned the names of the 10 smallest straight-chain alkanes in Section 2.8. Here we discuss the rules for naming any alkane and, by extension, other organic compounds as well. The key point is that *each chain, branch, or ring has a name based on the* ***number*** *of C atoms.* The name of a compound has three portions:

PREFIX + ROOT + SUFFIX

- *Root:* The root tells the number of C atoms in the longest *continuous* chain in the molecule. The roots for the ten smallest alkanes are shown in Table 15.1. As you can see, there are special roots for compounds with chains of one to four C atoms; roots of longer chains are based on Greek numbers.
- *Suffix:* The suffix tells the *type of organic compound* that is being named; that is, it identifies the key functional group the molecule possesses. The suffix is placed *after* the root.
- *Prefix:* Each prefix identifies a *group attached to the main chain* and the number of the carbon to which it is attached. Prefixes identifying hydrocarbon branches are the same as root names (Table 15.1) but have *-yl* as their ending. Each prefix is placed *before* the root.

For example, in the name 2-methylbutane, *2-methyl-* is the prefix (a one-carbon branch is attached to C-2 of the main chain), *-but-* is the root (the main chain has four C atoms), and *-ane* is the suffix (the compound is an alkane).

To obtain the systematic name of a compound,

1. Name the longest chain (ROOT).
2. Add the compound type (SUFFIX).
3. Name any branches (PREFIX).

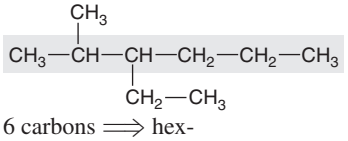
Table 15.2 presents the rules for naming any organic compound and applies them to an alkane component of gasoline. Other organic compounds are named with a variety of other prefixes and suffixes (see Table 15.5, p. 639). In addition to these *systematic* names, as you'll see, some *common* names are still in use.

Table 15.1 Numerical Roots for Carbon Chains and Branches

Roots	Number of C Atoms
meth-	1
eth-	2
prop-	3
but-	4
pent-	5
hex-	6
hept-	7
oct-	8
non-	9
dec-	10

Table 15.2 Rules for Naming an Organic Compound

1. Naming the longest chain (root)
   (a) Find the longest *continuous* chain of C atoms.
   (b) Select the root that corresponds to the number of C atoms in this chain.

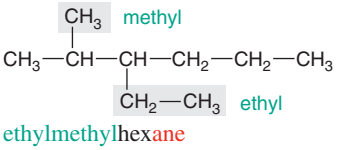


6 carbons ⟹ hex-

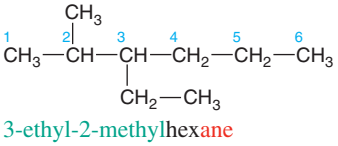
2. Naming the compound type (suffix)
   (a) For alkanes, add the suffix *-ane* to the chain root. (Other suffixes appear in Table 15.5 with their functional group and compound type.)
   (b) If the chain forms a ring, the name is preceded by *cyclo-*.

hex- + -ane ⟹ hexane

3. Naming the branches (prefixes) (If the compound has no branches, the name consists of the root and suffix.)
   (a) Each branch name consists of a subroot (number of C atoms) and the ending *-yl* to signify that it is not part of the main chain.
   (b) Branch names precede the chain name. When two or more branches are present, their names appear in *alphabetical* order.
   (c) To specify where a branch occurs along the chain, number the main-chain C atoms consecutively, starting at the end *closer* to the first branch, to achieve the *lowest* numbers for all the branches. Precede each branch name with the number of the main-chain C to which that branch is attached.



ethylmethylhexane



3-ethyl-2-methylhexane

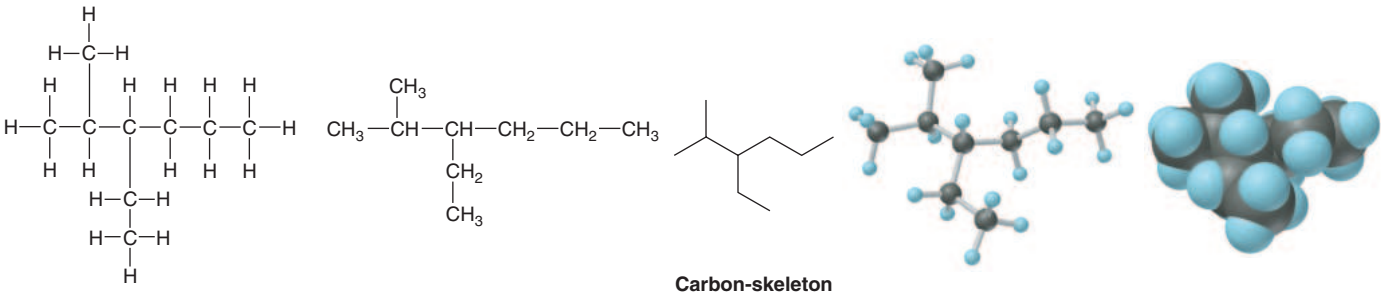


Figure 15.5 Ways of depicting the alkane 3-ethyl-2-methylhexane.

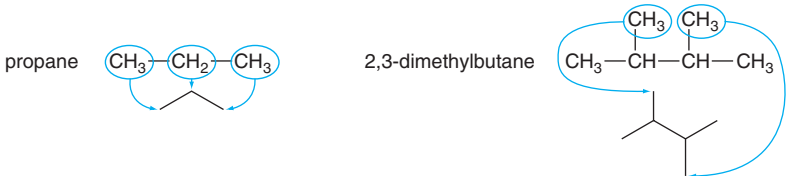
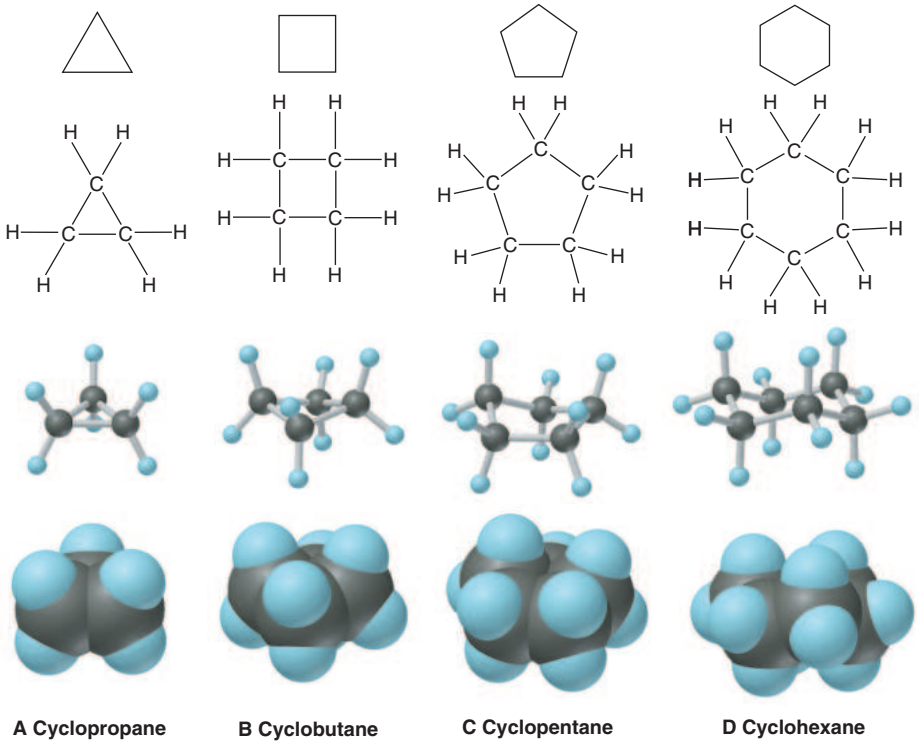
Depicting Alkanes with Formulas and Models Chemists have several ways to depict organic compounds. Expanded, condensed, and carbon-skeleton formulas are easy to draw; ball-and-stick and space-filling models show the actual shapes.

Figure 15.5 shows the formulas (and models) of the compound named in Table 15.2. The *expanded formula* is a Lewis structure, so it shows each atom and bond. One type of *condensed formula* groups each C atom with its H atoms. The *carbon-skeleton formula* shows only carbon-carbon bonds and appears as a zig-zag line, with one or more branches as needed. *Each end or bend of a line or branch represents a C atom attached to the number of H atoms that gives it four bonds:*



Cyclic Hydrocarbons A **cyclic hydrocarbon** contains one or more rings. When a straight-chain alkane (C_nH_{2n+2}) forms a ring, two H atoms are lost as the two ends of the chain form a C—C bond. Thus, *cycloalkanes* have the general formula C_nH_{2n}. Cyclic hydrocarbons are often drawn with carbon-skeleton formulas (Figure 15.6, *top row*). Except for three-carbon rings, *cycloalkanes are nonplanar,* as the ball-and-stick

Figure 15.6 Depicting cycloalkanes.

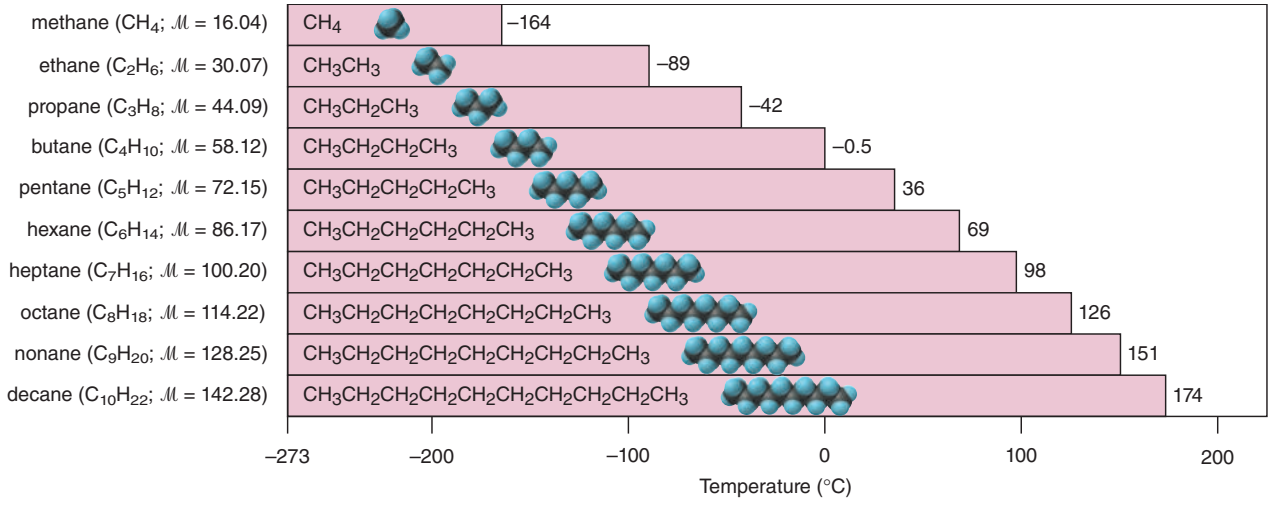


and space-filling models show. This structural feature arises from the tetrahedral shape around each C atom and the need to minimize electron repulsions between adjacent H atoms. The most stable form of cyclohexane is called the *chair conformation* (see the ball-and-stick model in Figure 15.6D).

Dispersion Forces and the Physical Properties of Alkanes

Because alkanes are nearly nonpolar, we would expect their physical properties and solubility behavior to be determined by dispersion forces (Section 12.3). A particularly clear example of this effect occurs among the unbranched alkanes (*n*-alkanes). Boiling points increase steadily with chain length (Figure 15.7): the longer the chain, the greater the intermolecular contact, the stronger the dispersion forces, and, thus, the higher the boiling point. Pentane (five C atoms) is the smallest *n*-alkane that exists as a liquid at room temperature.

Figure 15.7 **Formulas, molar masses (in g/mol), structures, and boiling points (at 1 atm pressure) of the first 10 unbranched alkanes.**



The solubility of alkanes, and of all hydrocarbons, is easy to predict from the like-dissolves-like rule (Section 13.1). Alkanes are miscible in each other and in other nonpolar solvents, such as benzene, but are nearly insoluble in water. The solubility of pentane in water, for example, is only 0.36 g/L at room temperature.

Constitutional Isomerism

Recall from Section 3.2 that two or more compounds that have the same molecular formula but different properties are called **isomers.** Those with *different arrangements of bonded atoms* are **constitutional** (or **structural**) **isomers;** alkanes with the same number of C atoms but different skeletons are examples. The smallest alkane to exhibit constitutional isomerism has four C atoms, C_4H_{10}; its two isomers are shown in the top of Table 15.3 *(next page).* The unbranched one is butane (common name, *n*-butane; *n*- stands for "normal," or having a straight chain), and the other is 2-methylpropane (common name, *iso*butane). Similarly, the bottom three isomers in the table have the formula C_5H_{12}. The unbranched isomer is pentane (common name, *n*-pentane); the one with a methyl branch at C-2 of a four-C chain is 2-methylbutane (common name, *iso*pentane). The third isomer has two methyl branches on C-2 of a three-C chain, so its name is 2,2-dimethylpropane (common name, *neo*pentane).

As expected, the physical properties of constitutional isomers depend on the strength of the dispersion forces (Table 15.3, *rightmost column*). The four-C compounds boil lower than the five-C compounds. Moreover, within each group, the more spherical member (isobutane or neopentane) boils lower than the more elongated one (*n*-butane or *n*-pentane). Recall that a spherical shape allows less intermolecular contact, and thus lower total dispersion forces, than does an elongated shape.

Table 15.3 The Constitutional Isomers of C_4H_{10} and C_5H_{12}

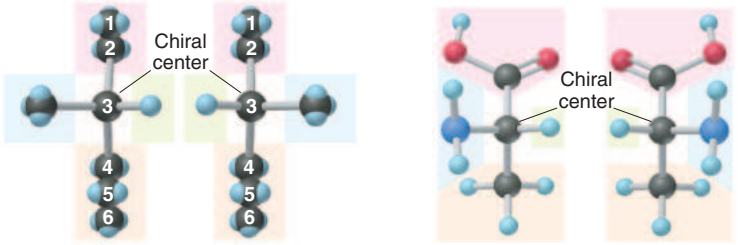
Systematic Name (Common Name)	Expanded Formula	Condensed and Skeleton Formulas	Space-Filling Model	Density (g/mL)	Boiling Point (°C)
Butane (*n*-butane)				0.579	−0.5
2-Methylpropane (isobutane)				0.549	−11.6
Pentane (*n*-pentane)				0.626	36.1
2-Methylbutane (isopentane)				0.620	27.8
2,2-Dimethylpropane (neopentane)				0.614	9.5

Figure 15.8 An analogy for optical isomers.

Chiral Molecules and Optical Isomerism

Another type of isomerism exhibited by some alkanes and many other organic (as well as some inorganic) compounds is called *stereoisomerism.* **Stereoisomers** are molecules with the same arrangement of atoms *but different orientations of groups in space. Optical isomerism* is one type of stereoisomerism: *when two objects are mirror images of each other and cannot be superimposed, they are* **optical isomers,** also called *enantiomers.* Your right hand is an optical isomer of your left. Look at your right hand in a mirror: the *image* is identical to your left hand (Figure 15.8). No matter how you twist your arms around, however, your hands cannot lie on top of each other with your palms facing in the same direction and be superimposed.

Asymmetry and Chirality Optical isomers are not superimposable because each is *asymmetric:* there is no plane of symmetry that divides the molecule (or your hand) into two identical parts. An asymmetric molecule is called **chiral** (Greek *cheir,* "hand"). Typically, an organic molecule *is chiral if it contains a carbon atom that is bonded to four* ***different*** *groups.* This C atom is called a *chiral center,* or an asymmetric carbon. In 3-methylhexane, for example, C-3 is a chiral center, because it is bonded to four different groups: H—, CH_3—, CH_3—CH_2—, and CH_3—CH_2—CH_2— (Figure 15.9A). Like your two hands, the two forms are mirror images: when two of the groups are superimposed, the other two are opposite each other. The central C atom in the amino acid alanine is also a chiral center (Figure 15.9B).



A Optical isomers of 3-methylhexane B Optical isomers of alanine

Figure 15.9 Two chiral molecules.

Properties of Optical Isomers Unlike constitutional isomers, which have different physical properties, optical isomers are identical in all but two respects:

1. In their physical properties, *optical isomers differ only in the direction that each isomer rotates the plane of polarized light.* A **polarimeter** is used to measure the angle that the plane is rotated (Figure 15.10). A beam of light consists of waves that oscillate in all planes. A polarizing filter blocks all waves except those in one plane, so the light emerging through the filter is *plane-polarized.* An optical isomer is **optically active** because it rotates the plane of this polarized light. (Liquid crystal displays incorporate polarizing filters and optically active compounds; see Figure 12.44, p. 497.) The *dextrorotatory* isomer (designated *d* or +) rotates the plane of light clockwise; the *levorotatory* isomer (designated *l* or −) is the mirror image of the *d* isomer and rotates the plane counterclockwise. An equimolar mixture of the two isomers (called a *racemic mixture*) does not rotate the plane of light because the dextrorotation cancels the levorotation. The *specific rotation* is a characteristic, measurable property of an optical isomer at a certain temperature, concentration, and wavelength of light.

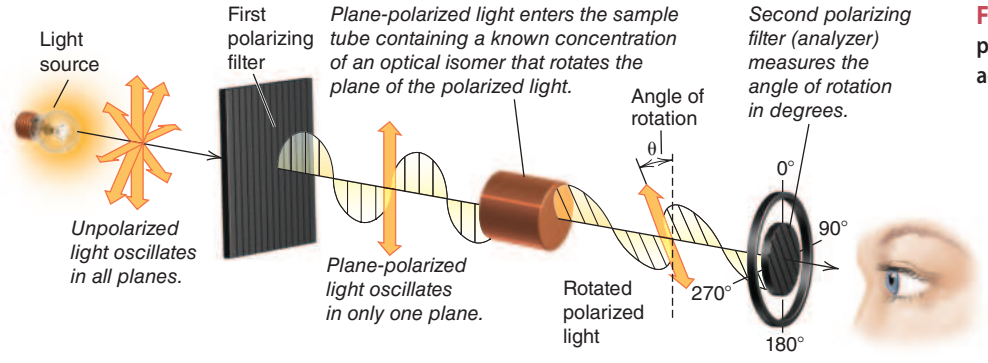


Figure 15.10 The rotation of plane-polarized light by an optically active substance.

2. In their chemical properties, *optical isomers differ only in a chiral (asymmetric) chemical environment,* one that distinguishes "right-handed" from "left-handed" molecules. As an analogy, your right hand fits well in your right glove but not in your left glove. Typically, one isomer of an optically active reactant is added to a mixture of optical isomers of another compound. The products of the reaction have different properties and can be separated.

The Role of Optical Isomerism in Organisms and Medicines Optical isomerism plays a vital role in living cells. Nearly all carbohydrates and amino acids are optically active, but only one of the isomers is biologically usable. For example, *d*-glucose is metabolized for energy, but *l*-glucose is not, and is excreted unused. Similarly, *l*-alanine is incorporated naturally into proteins, but *d*-alanine is not. An organism can utilize only one of a pair of optical isomers because of its enzymes (Section 16.7). Enzymes are proteins that speed virtually every reaction in a living cell by binding to the reactants and influencing bond breakage and formation. An enzyme distinguishes

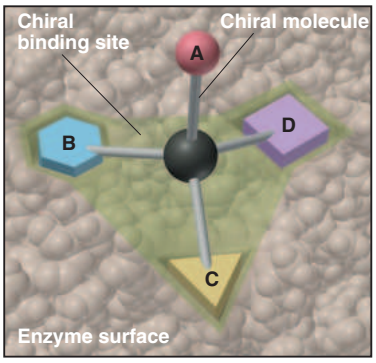

Figure 15.11 The binding site of an enzyme.

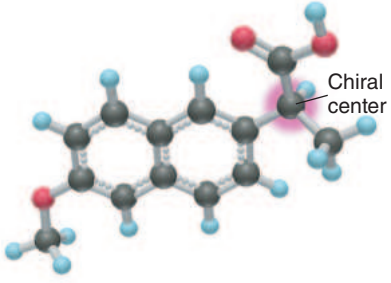

Naproxen

one optical isomer from another because its binding site is chiral (asymmetric) (Figure 15.11). The shape of one optical isomer fits at the binding site, but the mirror image shape of the other isomer does not fit, so it cannot bind.

Many drugs are chiral molecules. One optical isomer has certain biological activity, and the other has either a different type of activity or none at all. Naproxen *(see margin),* a pain reliever and anti-inflammatory agent, is an example: one isomer is active as an anti-arthritic agent, and the other is a potent liver toxin that must be removed from the mixture during manufacture. The notorious drug thalidomide is another example: one optical isomer is active against depression, whereas the other causes fetal mutations and deaths. Tragically, this drug was sold in the 1950s as the racemic mixture and caused limb malformations in many newborns whose mothers had it prescribed to relieve "morning sickness" during pregnancy.

Alkenes: Hydrocarbons with Double Bonds

A hydrocarbon that contains at least one C═C bond is called an **alkene.** With two H atoms removed to make the double bond, alkenes have the general formula $\mathbf{C_nH_{2n}}$**.** The double-bonded C atoms are sp^2 hybridized. Because their carbon atoms are bonded to fewer than the maximum of four atoms each, alkenes are considered **unsaturated hydrocarbons.**

Alkene names differ from those of alkanes in two respects:

1. The main chain (root) *must* contain both C atoms of the double bond, even if it is not the longest chain. The chain is numbered from the end *closer* to the C═C bond, and the position of the bond is indicated by the number of the *first* C atom in it.
2. The suffix for alkenes is -*ene*.

For example, there are three four-C alkenes (C_4H_8), two unbranched and one branched (see the solution for Sample Problem 15.1b). The branched isomer is 2-methylpropene; the unbranched isomer with the C═C bond between C-1 and C-2 is 1-butene; the unbranched isomer with the C═C bond between C-2 and C-3 is 2-butene. (As you'll see next, there are two different 2-butenes due to another type of stereoisomerism.)

There are two major structural differences between alkanes and alkenes.

- Alkanes have a *tetrahedral* geometry (bond angles of ~109.5°) around each C atom, whereas the double-bonded C atoms in alkenes are *trigonal planar* (~120°).
- The C—C bond *allows* rotation of bonded groups, so the atoms in an alkane continually change their relative positions; in contrast, the π bond of the alkene C═C bond *restricts* rotation, so the relative positions of the atoms attached to the double bond are fixed (see Section 11.2).

Restricted Rotation and Geometric *(Cis-Trans)* Isomerism

This rotational restriction of the π bond in the C═C bond leads to another type of stereoisomerism. **Geometric isomers** (also called ***cis-trans* isomers**) have different orientations of groups around a double bond (or similar structural feature). Table 15.4

Table 15.4 The Geometric Isomers of 2-Butene

Systematic Name	Condensed and Skeleton Formulas	Space-Filling Model	Density (g/mL)	Boiling Point (°C)
cis-2-Butene			0.621	3.7
trans-2-Butene			0.604	0.9

shows the two geometric isomers of 2-butene (see Comment, Sample Problem 15.1). One isomer, *cis*-2-butene, has the CH_3 groups on the *same* side of the C═C bond, whereas the other isomer, *trans*-2-butene, has them on *opposite* sides of the C═C bond. In general, the *cis* isomer has the *larger portions of the main chain* (in this case, two CH_3 groups) *on the same side* of the double bond, and the *trans* isomer has them on opposite sides. For a molecule to have geometric isomers, *each C atom in the C═C bond must also be bonded to two different groups.*

Like structural isomers, geometric isomers have different physical properties. Note in Table 15.4 that the two 2-butenes differ in molecular shape *and* physical properties. The *cis* isomer has a bend in the chain that the *trans* isomer lacks. In Chapters 10 and 12, you saw how such a difference affects molecular polarity and physical properties, which arise from differing strengths of intermolecular attractions.

Geometric Isomers and the Chemistry of Vision Differences in geometric isomers have profound effects in biological systems. For example, the first step in the sequence that allows us to see relies on the different shapes of two geometric isomers. *Retinal,* a 20-C compound consisting of a 15-C chain, including a ring, with five C═C bonds and five 1-C branches, is part of the molecule responsible for receiving light energy that is converted to electrical signals transmitted to the brain. There are two biologically occurring isomers of retinal:

- The all-*trans* isomer has a *trans* orientation around all five double bonds and is elongated.
- The 11-*cis* isomer has a *cis* orientation around the C═C bond between C-11 and C-12 and, thus, is bent.

Certain cells of the retina are densely packed with *rhodopsin,* a large molecule consisting of a protein covalently bonded to 11-*cis* retinal. The initial chemical event in vision occurs when rhodopsin absorbs a photon of visible light. The energy range of visible photons (165–293 kJ/mol) encompasses the energy needed to break a C═C π bond (about 250 kJ/mol). Within a few millionths of a second after rhodopsin absorbs a photon, the 11-*cis* π bond of retinal breaks, the intact σ bond between C-11 and C-12 rotates, and the π bond re-forms to produce all-*trans* retinal (Figure 15.12).

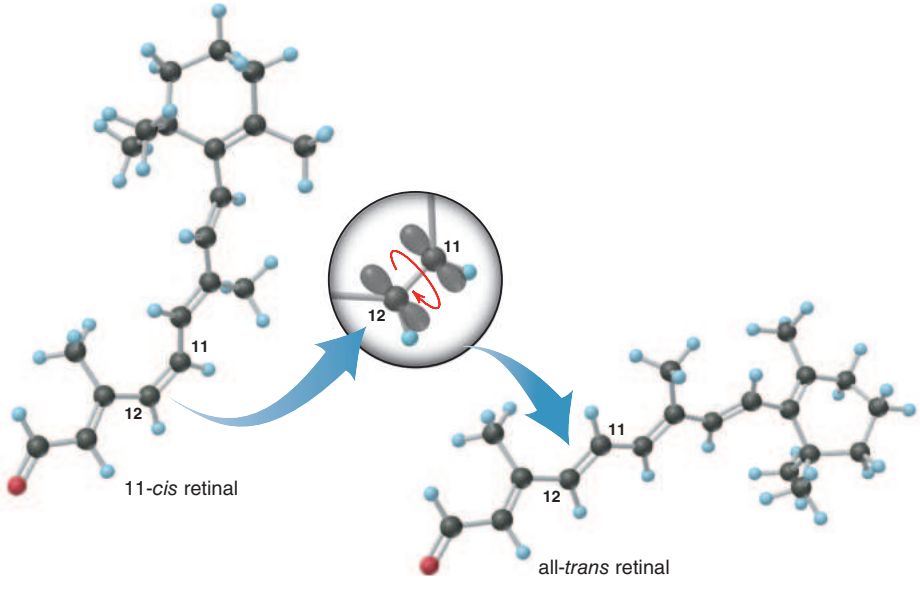

Figure 15.12 The initial chemical event in vision and the change in the shape of retinal.

This rapid, and quite sizeable, change in retinal's shape causes the attached protein to change its shape as well, triggering a flow of ions into the retina's cells and initiating electrical impulses, which the optic nerve conducts to the brain. Meanwhile, the free all-*trans* retinal diffuses away from the protein and is changed back to the *cis*

form, which then binds to the protein portion again. Because of the speed and efficiency with which light causes such a large structural change in retinal, evolutionary selection has made it the photon absorber in organisms as different as purple bacteria, mollusks, insects, and vertebrates.

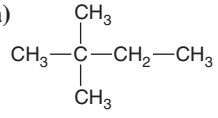
Alkynes: Hydrocarbons with Triple Bonds

Hydrocarbons that contain at least one C≡C bond are called **alkynes.** Because they have two H atoms fewer than alkenes, their general formula is $\mathbf{C_nH_{2n-2}}$. A carbon involved in a C≡C bond can bond to only one other atom, so the geometry around each C atom is linear (180°): each C is *sp* hybridized. Alkynes are named in the same way as alkenes, except that the suffix is *-yne*. Because of their localized π electrons, C=C and C≡C bonds are electron rich and act as functional groups. Thus, alkenes and alkynes are much more reactive than alkanes, as we'll discuss in Section 15.4.

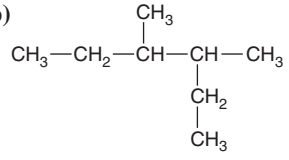
SAMPLE PROBLEM 15.2 Naming Alkanes, Alkenes, and Alkynes

Problem Give the systematic name for each of the following, identify the chiral center in part (d), and draw two geometric isomers for part (e):

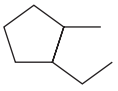
(a)



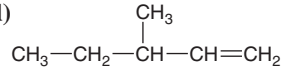
(b)



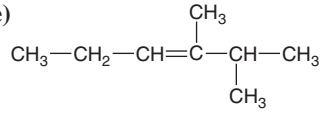
(c)



(d)



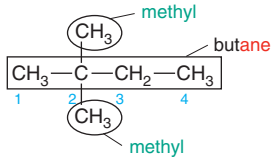
(e)



Plan For **(a)** to **(c),** we refer to Table 15.2, p. 623. We first name the longest chain (*root-*) and add the suffix *-ane* because there are only single bonds. Then we find the *lowest* branch numbers by counting C atoms from the end *closer* to a branch. Finally, we name each branch (*root-* + *-yl*) and put the names alphabetically before the root name. For **(c),** we add "cyclo" before the root. For **(d)** and **(e),** we number the longest chain that *includes* the multiple bond starting at the end closer to it. For **(d),** the chiral center is the C atom bonded to four different groups. In **(e),** the *cis* isomer has larger groups on the same side of the double bond, and the *trans* isomer has them on opposite sides.

Solution

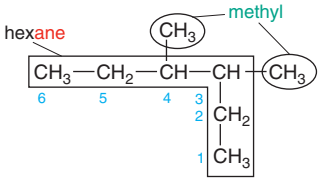
(a)



2,2-dimethylbutane

When a type of branch appears more than once, we group the branch numbers and indicate the number of branches with a prefix, as in 2,2-*di*methyl.

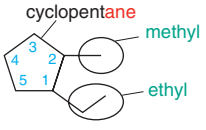
(b)



3,4-dimethylhexane

In this case, we can number the chain from either end because the branches are the same and are attached to the two central C atoms.

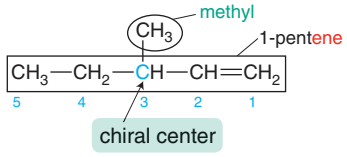
(c)



1-ethyl-2-methylcyclopentane

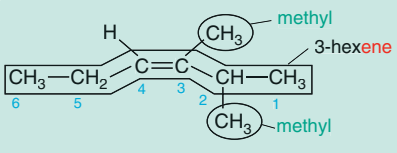
We number the ring C atoms so that a branch is attached to C-1.

(d)

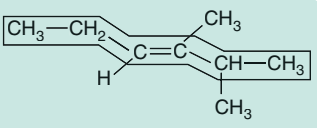


3-methyl-1-pentene

(e)



cis-2,3-dimethyl-3-hexene



trans-2,3-dimethyl-3-hexene

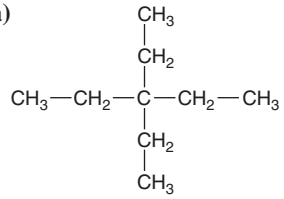
Check A good check (and excellent practice) is to reverse the process by drawing structures for the names to see if you come up with the structures given in the problem.

Comment **1.** In (b), C-3 and C-4 are chiral centers, as are C-1 and C-2 in (c). However, in (b) the molecule is not chiral: it has a plane of symmetry between C-3 and C-4, so each half of the molecule rotates light in opposite directions. **2.** Avoid these common mistakes: In (b), 2-ethyl-3-methylpentane is wrong: the longest chain is *hexane*. In (c), 1-methyl-2-ethylcyclopentane is wrong: the branch names should appear *alphabetically*.

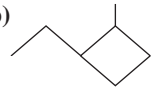
FOLLOW-UP PROBLEMS

15.2A Give the systematic name for each of the following, name the geometric isomer in (c), and identify the chiral centers in part (d):

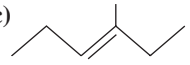
(a)



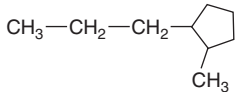
(b)



(c)



(d)



15.2B Draw condensed formulas for the following compounds: **(a)** 3-ethyl-3-methyloctane; **(b)** 1-ethyl-3-propylcyclohexane (also draw a carbon-skeleton formula for this compound); **(c)** 3,3-diethyl-1-hexyne; **(d)** *trans*-3-methyl-3-heptene.

SOME SIMILAR PROBLEMS 15.19–15.30

Aromatic Hydrocarbons: Cyclic Molecules with Delocalized π Electrons

Unlike the cycloalkanes, **aromatic hydrocarbons** are planar molecules, usually with one or more rings of six C atoms, and are often drawn with alternating single and double bonds. As you learned for benzene (Section 10.1), however, all the ring bonds are identical, with values of length and strength *between* those of a C—C and a C=C bond. To indicate this, benzene is also shown as a resonance hybrid, with a circle (or dashed circle) representing the delocalized character of the π electrons (Figure 15.13A). An orbital picture shows the two lobes of the delocalized π cloud above and below the hexagonal plane of the σ-bonded C atoms (Figure 15.13B).

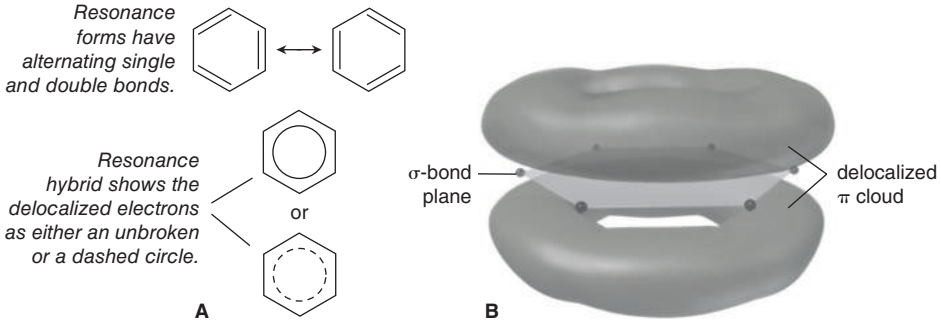


Figure 15.13 Representations of benzene.

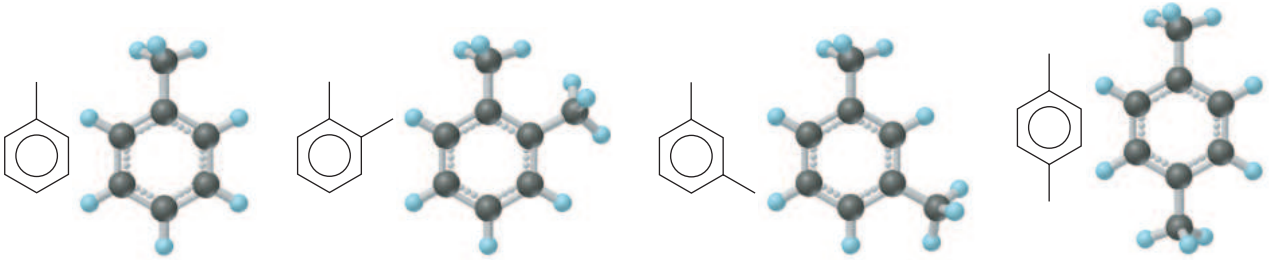
The systematic naming of aromatic compounds in which benzene is the parent is straightforward, because attached groups, or *substituents,* are named as prefixes. However, many common names are still in use. For example, benzene with one methyl group attached is systematically named *methylbenzene* but is better known by its common name, *toluene*. With only one substituent present in toluene, we do not number

the ring C atoms; when two or more groups are attached, however, we number in such a way that one of the groups is attached to ring C-1:



methylbenzene (toluene) bp = 110.6°C

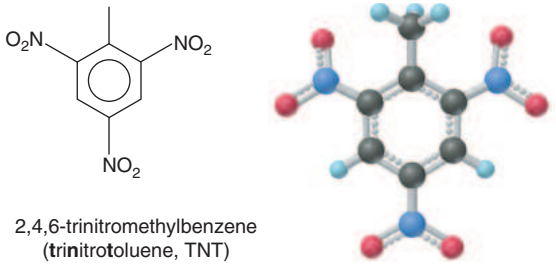
1,2-dimethylbenzene (*o*-xylene) bp = 144.4°C

1,3-dimethylbenzene (*m*-xylene) bp = 139.1°C

1,4-dimethylbenzene (*p*-xylene) bp = 138.3°C

In common names, the positions of two groups are indicated by *o*- (ortho) for groups on adjacent ring C atoms, *m*- (meta) for groups separated by one ring C atom, and *p*- (para) for groups on opposite ring C atoms. The dimethylbenzenes (commonly known as *xylenes*) are important solvents and feedstocks for polyester fibers and dyes. Benzene and many other aromatic hydrocarbons have been shown to have carcinogenic (cancer-causing) activity.

The number of isomers increases with more than two attached groups. For example, there are six isomers for a compound with one methyl and three nitro (—NO_2) groups attached to a benzene ring; the explosive TNT is one of the isomers:



2,4,6-trinitromethylbenzene (trinitrotoluene, TNT)

One of the most important methods for determining the structures of organic molecules is discussed in the upcoming Tools of the Laboratory essay.

Variations on a Theme: Catenated Inorganic Hydrides

In brief discussions throughout this chapter, called Variations on a Theme, we examine similarities between organic and inorganic compounds. Although no other element has as many different hydrides as carbon, catenated hydrides occur for several other elements, and many ring, chain, and cage structures are known.

- *Boranes.* One such group of inorganic compounds is the boron hydrides, or boranes (Section 14.5). Although their varied shapes rival those of the hydrocarbons, the weakness of their unusual bridge bonds renders most of them thermally and chemically unstable.
- *Silanes.* An obvious structural similarity exists between alkanes and the silicon hydrides, or silanes. Silanes even have an analogous general formula (Si_nH_{2n+2}). Branched silanes are known, but no cyclic or unsaturated (containing an Si═Si bond) compounds had been prepared until very recently. Unlike alkanes, silanes are unstable thermally and ignite spontaneously in air.
- *Polysulfanes.* Sulfur's ability to catenate is second only to carbon's, and many chains and rings occur among its allotropes (Section 14.8). A number of sulfur hydrides, or polysulfanes, are known. However, these molecules are unbranched chains with H atoms only at the ends (H—S_n—H). Like the silanes, the polysulfanes are oxidized easily and decompose readily, yielding sulfur's only stable hydride, H_2S, and its most stable allotrope, cyclo-S_8.

TOOLS OF THE LABORATORY

Nuclear Magnetic Resonance (NMR) Spectroscopy

In addition to mass spectrometry (Chapter 2) and infrared (IR) spectroscopy (Chapter 9), one of the most useful tools for analyzing organic and biochemical structures is **nuclear magnetic resonance (NMR) spectroscopy,** which measures the molecular environments of certain nuclei in a molecule.

Like electrons, several types of nuclei, such as ^{13}C, ^{19}F, ^{31}P, and ^{1}H, act as if they spin in either of two directions, each of which creates a tiny magnetic field. In this discussion, we focus primarily on ^{1}H-NMR spectroscopy, which measures changes in the nuclei of the most common isotope of hydrogen. Oriented randomly, the magnetic fields of all the ^{1}H nuclei in a sample of compound, when placed in a strong external magnetic field **(B_0),** become aligned either *with* the external field (parallel) or *against* it (antiparallel). Most nuclei adopt the parallel orientation, which is slightly lower in energy. The energy difference (ΔE) between the two energy states (spin states) lies in the radio-frequency (rf) region of the electromagnetic spectrum (Figure B15.1).

When an ^{1}H *(blue arrow)* in the lower energy (parallel) spin state absorbs a photon in the radio-frequency region with an energy equal to ΔE, it "flips," in a process called *resonance,* to the higher energy (antiparallel) spin state. The system then re-emits that energy, which is detected by the rf receiver of the ^{1}H-NMR spectrometer. The ΔE between the two states depends on the *actual* magnetic field felt by each ^{1}H nucleus, which is affected by the tiny magnetic fields of the *electrons* of atoms adjacent to that nucleus. Thus, the ΔE required for resonance of each ^{1}H nucleus depends on its specific molecular environment—the C atoms, electronegative atoms, multiple bonds, and aromatic rings around it. ^{1}H nuclei in different molecular environments produce different peaks in the ^{1}H-NMR spectrum.

An ^{1}H-NMR spectrum, which is unique for each compound, is a series of peaks that represents the resonance as a function of the changing magnetic field. The *chemical shift* of the ^{1}H nuclei in a given environment is where a peak appears. Chemical shifts are shown relative to that of an added standard, tetramethylsilane [$(CH_3)_4Si$, or TMS]. TMS has 12 ^{1}H nuclei bonded to four C atoms that are bonded to one Si atom in a tetrahedral arrangement, so all 12 are in identical environments and produce only one peak.

Figure B15.2 shows the ^{1}H-NMR spectrum of acetone. The six ^{1}H nuclei of acetone have identical environments: all six are bonded to two C atoms that are each bonded to the C atom in a C=O bond. So one peak is produced, but at a different position from the TMS peak. The spectrum of dimethoxymethane in Figure B15.3 shows *two* peaks in addition to the TMS peak since the ^{1}H nuclei have two different evironments. The taller peak is due to the six ^{1}H nuclei in the two CH_3 groups, and the shorter peak is due to the two ^{1}H nuclei in the CH_2 group. The area under each peak (given here in units of chart-paper spaces) is proportional to *the number of ^{1}H nuclei in a given environment*. Note that the area ratio is 20.3/6.8 ≈ 3/1, the same as the ratio of six nuclei in the CH_3 groups to two in the CH_2 group. Thus, by analyzing the chemical shifts and peak areas, the chemist learns the type and number of hydrogen atoms in the compound.

(continued)

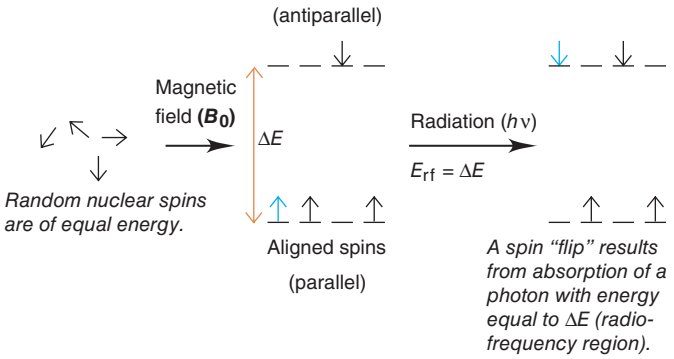


Figure B15.1 The basis of ^{1}H spin resonance.

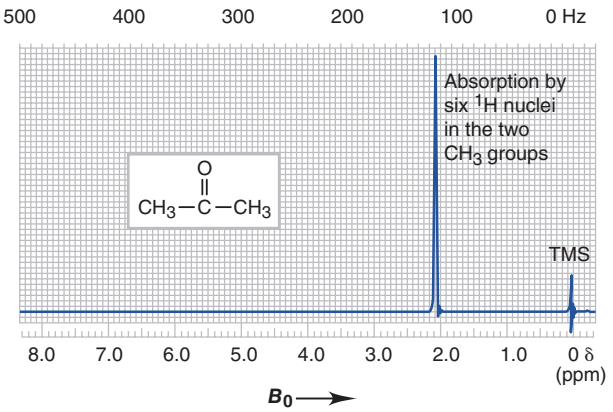

Figure B15.2 The ^{1}H-NMR spectrum of acetone.

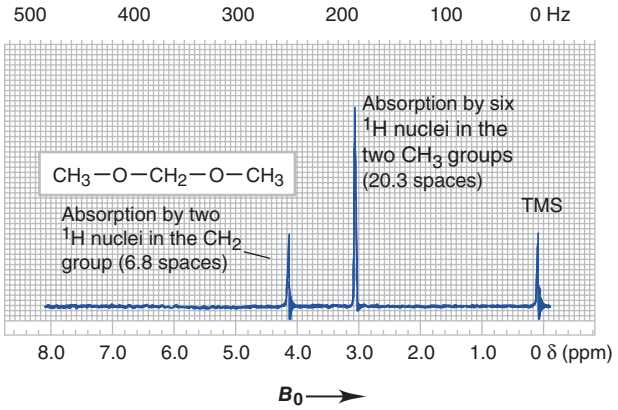

Figure B15.3 The ^{1}H-NMR spectrum of dimethoxymethane.

Nuclear Magnetic Resonance (NMR) Spectroscopy (continued)

NMR has many applications in biochemistry and medicine. Applying the principle to imaging of organs and other body parts is known as *computer-aided magnetic resonance imaging*, or *MRI*. For example, an MRI scan of the head (Figure B15.4) can reveal a brain tumor by mapping levels of metabolic activity in different regions of the brain.

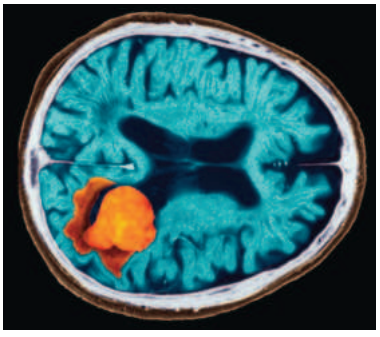

Figure B15.4 An MRI scan showing a brain tumor.

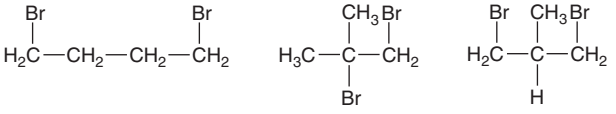
Problems

B15.1 How many peaks appear in the NMR spectrum of each isomer of C_4H_{10} and of C_5H_{12} shown in Table 15.3 (p. 626)?

B15.2 Radio-frequency radiation is used in NMR since ΔE, the energy difference between the two spin states of the ^1H nucleus, is very small. Calculate the ΔE (in J/mol) that corresponds to a frequency of 200. MHz.

B15.3 Consider three isomers of $C_4H_8Br_2$:



A **B** **C**

Which of these isomers is characterized by a ^1H-NMR spectrum that consists of two peaks with a 3/1 area ratio?

Summary of Section 15.2

- Hydrocarbons contain only C and H atoms, so their physical properties depend on the strength of their dispersion forces.
- Names of organic compounds have a root for the longest chain, a prefix for any attached group, and a suffix for the type of compound.
- Alkanes (C_nH_{2n+2}) have only single bonds. Cycloalkanes (C_nH_{2n}) have ring structures that are typically nonplanar. Alkenes (C_nH_{2n}) have at least one C═C bond. Alkynes (C_nH_{2n-2}) have at least one C≡C bond. Aromatic hydrocarbons have at least one planar ring with delocalized π electrons.
- Isomers are compounds with the same molecular formula but different properties.
- Constitutional (structural) isomers have different arrangements of atoms.
- Stereoisomers (optical and geometric) have the same arrangement of atoms, but their atoms are oriented differently in space. Optical isomers cannot be superimposed on each other because they are asymmetric, with four different groups bonded to the C that is the chiral center. They have identical physical and chemical properties except in their rotation of plane-polarized light, their reactivity with chiral reactants, and their biological activity. Geometric *(cis-trans)* isomers have groups oriented differently around a C═C bond, which restricts rotation.
- Light converts a *cis* isomer of retinal to the all-*trans* form, which initiates the process of vision.
- ^1H-NMR spectroscopy indicates the relative numbers of H atoms in the various environments within an organic molecule.
- Boron, silicon, and sulfur also form catenated hydrides, but these are unstable.

15.3 SOME IMPORTANT CLASSES OF ORGANIC REACTIONS

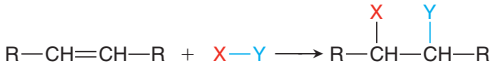
In Chapter 4, we classified chemical reactions based on the chemical process involved (precipitation, acid-base, or redox) and then briefly included a classification based on the number of reactants and products (combination, decomposition, or displacement). We take a similar approach here with organic reactions.

To depict reactions more generally, it's common practice to use R— to signify a nonreacting organic group attached to one of the atoms; you can usually picture R— as an **alkyl group,** a saturated hydrocarbon group with one bond available. Thus, R—CH_2—Br has an alkyl group attached to a CH_2 group bonded to a Br atom; R—CH=CH_2 is an alkene with an alkyl group attached to one of the carbons in the double bond; and so forth. (Often, when more than one R group is present, we write R, R′, R″, and so forth, to indicate that these groups may be different.)

Types of Organic Reactions

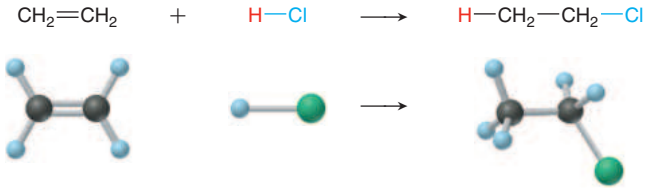
Three important organic reaction types are *addition, elimination,* and *substitution* reactions, which can be identified by comparing the *number of bonds to C* in reactants and products.

Addition Reactions An **addition reaction** occurs when an unsaturated reactant becomes a saturated product:



Note the C atoms are bonded to *more* atoms in the product than in the reactant.

The C=C and C≡C bonds and the C=O bond commonly undergo addition reactions. In each case, the π bond breaks, leaving the σ bond intact. In the product, the two C atoms (or C and O) form two additional σ bonds. Let's examine the standard enthalpy of reaction (ΔH°_{rxn}) for a typical addition reaction to see why these reactions occur. Consider the reaction between ethene (common name, ethylene) and HCl:

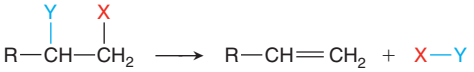


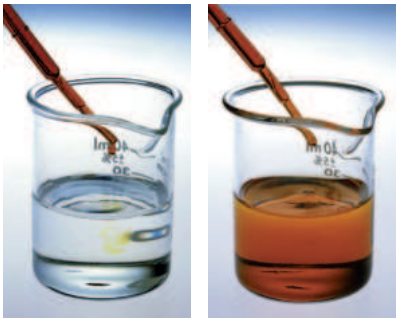
Reactants (bonds broken)		Product (bonds formed)	
1 C=C	614 kJ	1 C—C	−347 kJ
4 C—H	1652 kJ	5 C—H	−2065 kJ
1 H—Cl	427 kJ	1 C—Cl	−339 kJ
Total	2693 kJ	Total	−2751 kJ

$$\Delta H^\circ_{rxn} = \Sigma\Delta H^\circ_{\text{bonds broken}} + \Sigma\Delta H^\circ_{\text{bonds formed}} = 2693\text{ kJ} + (-2751\text{ kJ}) = -58\text{ kJ}$$

The reaction is exothermic. By looking at the *net* change in bonds, we see that the driving force for many additions is the formation of two σ bonds (in this case, C—H and C—Cl) from one σ bond (in this case, H—Cl) and one relatively weak π bond. An addition reaction is the basis of a color test for the presence of C=C bonds (Figure 15.14).

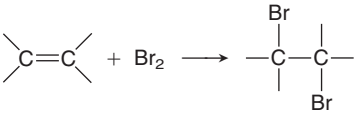
Elimination Reactions **Elimination reactions** are the opposite of addition reactions. They occur when a saturated reactant becomes an unsaturated product:





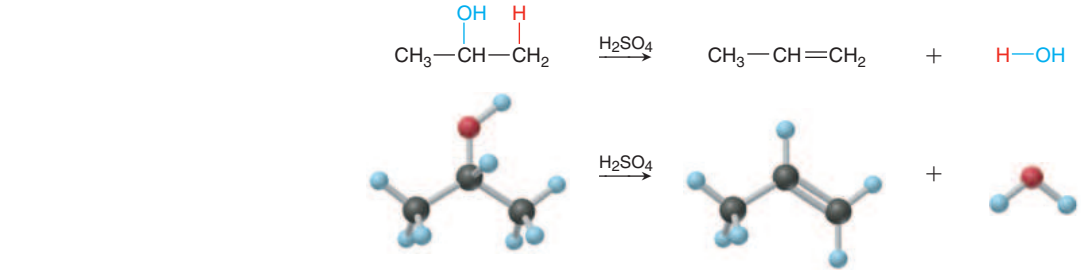
A **B**

Figure 15.14 A color test for C=C bonds. A, Br_2 (in pipet) reacts with a compound that has a C=C bond (in beaker), and its orange-brown color disappears:



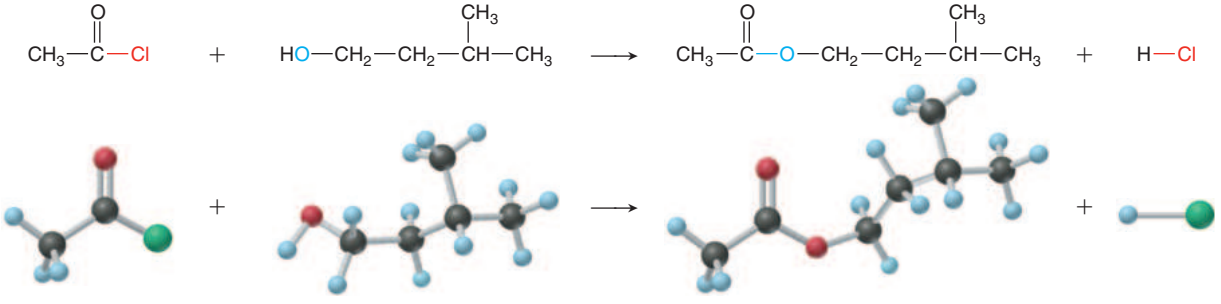
B, Here the compound in the beaker has no C=C bond, so the Br_2 does not react.

Note that the C atoms are bonded to *fewer* atoms in the product than in the reactant. A pair of halogen atoms, an H atom and a halogen atom, or an H atom and an —OH group are typically eliminated, but C atoms are not. Thus, the driving force for many elimination reactions is the formation of a small, stable molecule, such as HCl(*g*) or H_2O, which increases the entropy of the system (Section 13.3):



Substitution Reactions A **substitution reaction** occurs when an atom (or group) in one reactant substitutes for one attached to a carbon in the other reactant:

Note that the C atom is bonded to the *same number* of atoms in the product as in the reactant. The C atom may be saturated or unsaturated, and X and Y can be many different atoms, but generally *not* C. The main flavor ingredient in banana oil, for instance, forms through a substitution reaction; note that the O substitutes for the Cl:



SAMPLE PROBLEM 15.3 Recognizing the Type of Organic Reaction

Problem State whether each reaction is an addition, elimination, or substitution:

(a) $CH_3—CH_2—CH_2—Br \longrightarrow CH_3—CH{=}CH_2 + HBr$

(b) 
(c)

Plan We determine the type of reaction by looking for any change in the number of atoms bonded to C:

- More atoms bonded to C is an *addition.*
- Fewer atoms bonded to C is an *elimination.*
- Same number of atoms bonded to C is a *substitution.*

Solution **(a)** Elimination: two bonds in the reactant, C—H and C—Br, are absent in the product, so fewer atoms are bonded to C.

(b) Addition: two more C—H bonds have formed in the product, so more atoms are bonded to C.

(c) Substitution: the reactant C—Br bond becomes a C—O bond in the product, so the same number of atoms are bonded to C.

FOLLOW-UP PROBLEMS

15.3A State whether each reaction is an addition, elimination, or substitution:

(a) $CH_3—CH_2—Br + NaOH \longrightarrow CH_3—CH_2—OH + NaBr$

(b) 
(c) 
15.3B Write a balanced equation for each of the following:

(a) An addition reaction between 2-butene and Cl_2

(b) A substitution reaction between $CH_3—CH_2—CH_2—Br$ and OH^-

(c) The elimination of H_2O from $(CH_3)_3C—OH$

SOME SIMILAR PROBLEMS 15.40–15.43

The Redox Process in Organic Reactions

An important process in many organic reactions is *oxidation-reduction*. Even though a redox reaction always involves both an oxidation and a reduction, organic chemists typically *focus on the organic reactant only*. Instead of monitoring the change in oxidation numbers of the various C atoms, organic chemists usually note the movement of electron density around a C atom by counting the number of bonds to more electronegative atoms (usually O) or to less electronegative atoms (usually H). A more electronegative atom takes some electron density from the C, whereas a less electronegative atom gives some electron density to the C. Therefore,

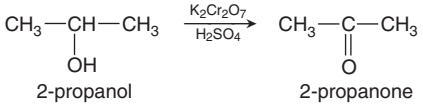
- When a C atom in the organic reactant forms more bonds to O or fewer bonds to H, thus losing some electron density, the reactant is oxidized, and the reaction is called an *oxidation*.
- When a C atom in the organic reactant forms fewer bonds to O or more bonds to H, thus gaining some electron density, the reactant is reduced, and the reaction is called a *reduction*.

The most dramatic redox reactions are combustion reactions. Virtually all organic compounds contain C and H atoms and burn in excess O_2 to form CO_2 and H_2O. For ethane, the reaction is

$$2CH_3—CH_3 + 7O_2 \longrightarrow 4CO_2 + 6H_2O$$

Obviously, when ethane is converted to CO_2 and H_2O, each of its C atoms has more bonds to O and fewer bonds to H. Thus, ethane is oxidized, and this reaction is referred to as an *oxidation,* even though O_2 is reduced as well.

Most oxidations do not involve a breakup of the entire molecule, however. When 2-propanol reacts with potassium dichromate in acidic solution (a common oxidizing agent in organic reactions), it forms 2-propanone (acetone):



Note that C-2 has one fewer bond to H and one more bond to O in 2-propanone than it does in 2-propanol. Thus, 2-propanol is oxidized, so this is an *oxidation.* Don't forget, however, that the dichromate ion is reduced at the same time:

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$

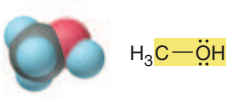
The reaction between H_2 and an alkene is both an addition and a *reduction:*

$$CH_2=CH_2 + H_2 \xrightarrow{Pd} CH_3—CH_3$$

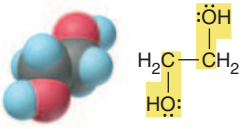
Note that each C has more bonds to H in ethane than it has in ethene, so the ethene is reduced. The H_2 is oxidized in the process, and the palladium shown over the arrow acts as a catalyst to speed up the reaction. (We discuss catalysts in Section 16.7.)

Summary of Section 15.3

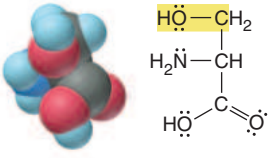
- In an addition reaction, a π bond breaks, and the two C atoms (or one C and one O) are bonded to more atoms in the product.
- In an elimination reaction, a π bond forms, with the two C atoms bonded to fewer atoms in the product.
- In a substitution reaction, one atom bonded to C is replaced by another, but the total number of atoms bonded to the C does not change.
- In an organic redox reaction, the organic reactant is oxidized if at least one of its C atoms forms more bonds to O atoms (or fewer bonds to H atoms), and it is reduced if a C atom forms more bonds to H (or fewer bonds to O).



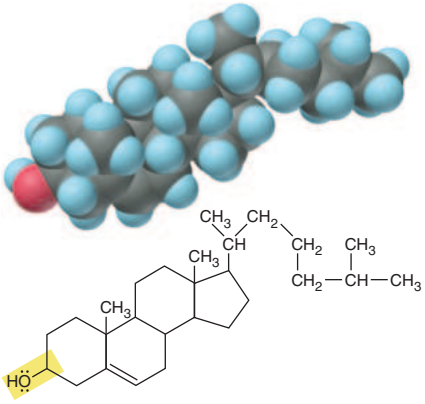
Methanol (methyl alcohol)
Byproduct in coal gasification; de-icing agent; gasoline substitute; precursor of organic compounds



1,2-Ethanediol (ethylene glycol)
Main component of auto antifreeze



Serine
Amino acid found in most proteins



Cholesterol
Major sterol in animals; essential for cell membranes; precursor of steroid hormones

Figure 15.15 Some molecules with the alcohol functional group.

15.4 PROPERTIES AND REACTIVITIES OF COMMON FUNCTIONAL GROUPS

A central organizing principle of organic reactions is that *the distribution of electron density in a functional group is a key to the reactivity of the compound.* The electron density can be high, as in the C═C and C≡C bonds, or it can be low at one end of a bond and high at the other, as in the C—Cl and C—O bonds. Such electron-rich or polar bonds enhance the opposite charge in a polar bond of the other reactant. As a result, the reactants attract each other and begin a sequence of bond-forming and bond-breaking steps that lead to a product. Thus, *the intermolecular forces that affect physical properties and solubility also affect reactivity.* Table 15.5 lists some of the important functional groups in organic compounds.

When we classify functional groups by bond order, they follow certain patterns of reactivity:

- Functional groups with only single bonds undergo elimination or substitution.
- Functional groups with double or triple bonds undergo addition.
- Functional groups with both single and double bonds undergo substitution.

In this section, we see how to name compounds that contain each functional group, examine some of their properties, and summarize their common reactions.

Functional Groups with Only Single Bonds

The most common functional groups with only single bonds are alcohols, haloalkanes, and amines.

Alcohols The **alcohol** functional group consists of a carbon bonded to an OH group, —C(—)—Ö—H, and the general formula of an alcohol is R—OH. Alcohols are named by dropping the final *-e* from the parent hydrocarbon name and adding the suffix *-ol*. Thus, the two-carbon alcohol is ethanol (ethan- + -ol). The common name is the hydrocarbon *root-* + *-yl,* followed by "alcohol"; thus, the common name of ethanol is ethyl alcohol. (This substance, obtained from fermented grain, has been consumed by people as an intoxicant in beverages since ancient times; today, it is recognized as the most abused drug in the world.) Alcohols are common organic reactants, and the functional group occurs in many biomolecules, including carbohydrates, sterols, and some amino acids. Figure 15.15 shows the names, structures, and uses of some important compounds that contain the alcohol group.

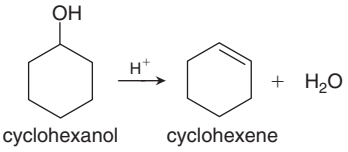
Table 15.5 Important Functional Groups in Organic Compounds

Functional Group	Compound Type	Prefix or Suffix of Name	Example		
			Lewis Structure	Ball-and-Stick Model	Systematic Name (Common Name)
	alkene	-ene			ethene (ethylene)
	alkyne	-yne			ethyne (acetylene)
	alcohol	-ol			methanol (methyl alcohol)
 (X = halogen)	haloalkane	halo-			chloromethane (methyl chloride)
	amine	-amine			ethanamine (ethylamine)
	aldehyde	-al			ethanal (acetaldehyde)
	ketone	-one			2-propanone (acetone)
	carboxylic acid	-oic acid			ethanoic acid (acetic acid)
	ester	-oate			methyl ethanoate (methyl acetate)
	amide	-amide			ethanamide (acetamide)
	nitrile	-nitrile			ethanenitrile (acetonitrile, methyl cyanide)

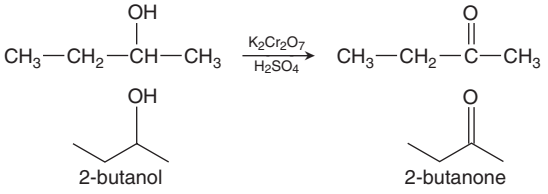
The physical properties of the smaller alcohols are similar to those of water. They have high melting and boiling points as a result of hydrogen bonding, and they dissolve polar molecules and some salts.

Alcohols undergo elimination and substitution reactions:

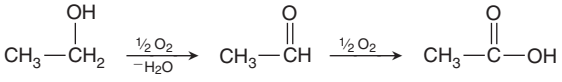
- *Elimination* of H and OH, called *dehydration,* requires acid and forms an alkene:



- *Elimination* of two H atoms is an *oxidation* that requires an inorganic oxidizing agent, such as potassium dichromate ($K_2Cr_2O_7$) in aqueous H_2SO_4. The product has a C═O group:



Alcohols with an OH group at the end of the chain (R—CH_2—OH) can be oxidized further to acids (but this step is *not* an elimination). Wine turns sour, for example, when the ethanol in contact with air is oxidized to acetic acid:



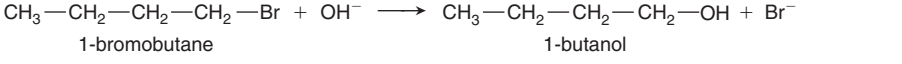
- *Substitution* yields products with other single-bonded functional groups. Reactions of hydrohalic acids with many alcohols give haloalkanes:

As you'll see below, *the C atom undergoing the change in a substitution is bonded to a more electronegative element,* which makes it partially positive and, thus, a target for a negatively charged or electron-rich group of an incoming reactant.

Haloalkanes A *halogen* atom (X) bonded to a carbon gives the **haloalkane** functional group,  , and compounds with the general formula R—X. Haloalkanes (common name, **alkyl halides**) are named by identifying the halogen with a prefix on the hydrocarbon name and numbering the C atom to which the halogen is attached, as in bromomethane, 2-chloropropane, or 1,3-diiodohexane.

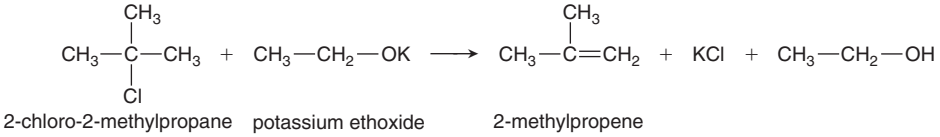
Like alcohols, haloalkanes undergo substitution and elimination reactions.

- Just as many alcohols undergo substitution to form alkyl halides when treated with halide ions in acid, many halides undergo substitution in base to form alcohols. For example, OH^- attacks the positive C end of the C—X bond and displaces X^-:



Substitutions by groups such as —CN, —SH, —OR, and —NH_2 allow chemists to convert alkyl halides to a host of other types of compounds.

- Just as addition of HX *to* an alkene produces haloalkanes, elimination of HX *from* a haloalkane by reaction with a strong base, such as potassium ethoxide, produces an alkene:



Haloalkanes have many important uses, but some, like the chlorofluorocarbons, cause serious environmental problems (Chapter 16, Chemical Connections, pp. 717–718). Also, some halogenated *aromatic* hydrocarbons (*aryl* halides) are carcinogenic in mammals, have severe neurological effects in humans, and, to make matters worse, are very stable in the environment. For example, the polychlorinated biphenyls (PCBs) (Figure 15.16), used as insulating fluids in electrical transformers, have accumulated for decades in rivers and lakes and have been incorporated into the food chain. PCBs in natural waters pose health risks and present an enormous cleanup problem.

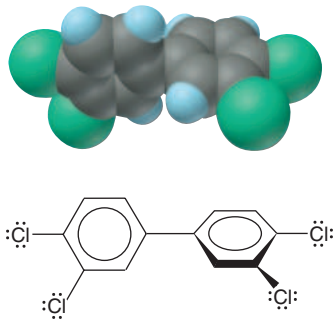


Figure 15.16 A tetrachlorobiphenyl, one of 209 polychlorinated biphenyls (PCBs).

Amines The **amine** functional group is —C—N—. Chemists classify amines as derivatives of ammonia, with R groups in place of one or more of the H atoms in NH_3. *Primary* (1°) amines are RNH_2, *secondary* (2°) amines are R_2NH, and *tertiary* (3°) amines are R_3N, where the R groups can be the same or different. Like ammonia, amines have trigonal pyramidal shapes and a lone pair of electrons on a partially negative N atom, which is the key to amine reactivity (Figure 15.17).

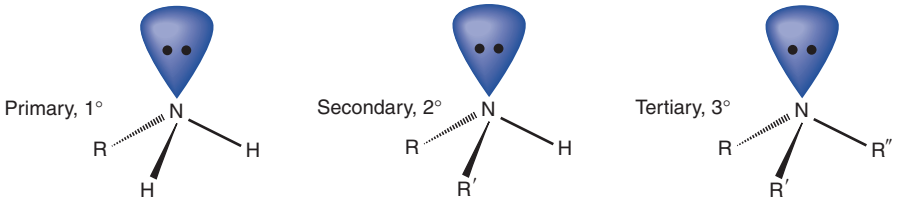

Figure 15.17 General structures of amines.

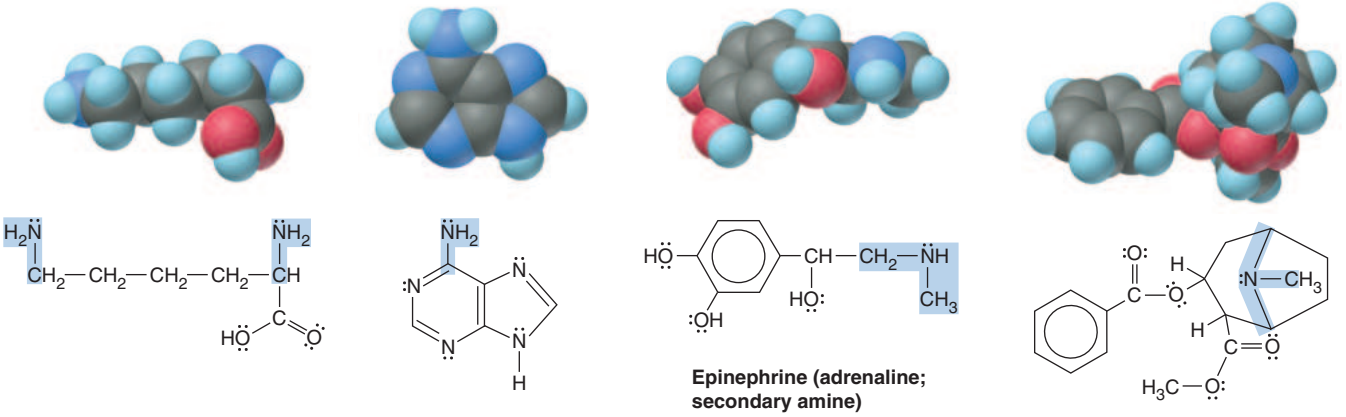
Systematic names drop the final *-e* of the alkane and add the suffix *-amine,* as in ethanamine. However, there is still wide usage of common names, in which the suffix *-amine* follows the name of the alkyl group; thus, methylamine has one methyl group attached to N, diethylamine has two ethyl groups attached, and so forth. Figure 15.18 shows that the amine functional group occurs in many biomolecules.

Figure 15.18 Some biomolecules with the amine functional group.



Lysine (primary amine)
Amino acid found in most proteins

Adenine (primary amine)
Component of nucleic acids

Epinephrine (adrenaline; secondary amine)
Neurotransmitter in brain; hormone released during stress

Cocaine (tertiary amine)
Brain stimulant; widely abused drug

Primary and secondary amines can form H bonds, so they have higher melting and boiling points than hydrocarbons and alkyl halides of similar molar mass. For example, dimethylamine ($\mathcal{M}$ = 45.09 g/mol) boils 45°C higher than ethyl fluoride ($\mathcal{M}$ = 48.06 g/mol). Trimethylamine has a greater molar mass than dimethylamine,

but it melts more than 20°C *lower* because it does not have an H atom attached to the N for H bonding.

Amines of low molar mass are fishy smelling, water soluble, and weakly basic because of the lone pair on N. The reaction with water proceeds only slightly to the right to reach equilibrium:

$$CH_3—\ddot{N}H_2 + H_2O \rightleftharpoons CH_3—\overset{+}{N}H_3 + OH^-$$

The lone pair is also the reason amines undergo substitution reactions: the lone pair attacks the partially positive C in an alkyl halide to displace X^- and form a larger amine:

$$2\ CH_3—CH_2—\ddot{N}H_2 + CH_3—CH_2—Cl \longrightarrow CH_3—CH_2—\ddot{N}H(—CH_2—CH_3) + CH_3—CH_2—\overset{+}{N}H_3Cl^-$$

ethylamine — chloroethane — diethylamine — ethylammonium chloride

(Two molecules of amine are needed: one attacks the chloroethane, and the other binds the released H^+ to prevent it from remaining on the diethylamine product.)

SAMPLE PROBLEM 15.4 Predicting the Reactions of Alcohols, Alkyl Halides, and Amines

Problem Determine the reaction type and the organic product(s) for each reaction:

(a) $CH_3—CH_2—CH_2—I + NaOH \longrightarrow$

(b) $CH_3—CH_2—Br + 2\ CH_3—CH_2—CH_2—NH_2 \longrightarrow$

(c) $CH_3—CH(OH)—CH_3 \xrightarrow[H_2SO_4]{Cr_2O_7^{2-}}$

Plan We first determine the functional group(s) of the organic reactant(s) and then examine any inorganic reactant(s) to decide on the reaction type, keeping in mind that, in general, these functional groups undergo substitution or elimination. **(a)** The reactant is an alkyl halide, so the OH^- of the inorganic base NaOH substitutes for I^-. **(b)** The reactants are an amine and an alkyl halide, so the N of the amine substitutes for the Br. **(c)** The organic reactant is an alcohol, the inorganic reactants form a strong oxidizing agent, and the alcohol group undergoes elimination to form a C=O.

Solution **(a)** Substitution: The product is $CH_3—CH_2—CH_2—OH + NaI$

(b) Substitution: The products are $CH_3—CH_2—CH_2—NH(—CH_2—CH_3) + CH_3—CH_2—CH_2—\overset{+}{N}H_3Br^-$

(c) Elimination (oxidation): The product is $CH_3—C(=O)—CH_3$

Check The only changes should be at the functional group.

FOLLOW-UP PROBLEMS

15.4A Determine the reaction type and the organic product(s) for each reaction:

(a) 
(b) $Br—CH_2—CH_2—CH_2—Br + NaCN \longrightarrow$

15.4B Fill in the blank in each reaction. (*Hint:* Examine any inorganic compounds and the organic product to determine the organic reactant.)

(a) ____ $+ CH_3—ONa \longrightarrow CH_3—CH=C(CH_3)—CH_3 + NaCl + CH_3—OH$

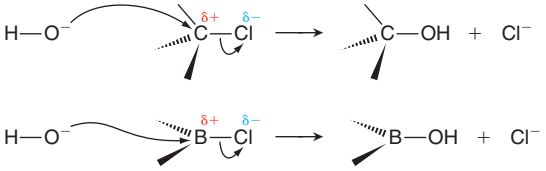
(b) ____ $\xrightarrow[H_2SO_4]{Cr_2O_7^{2-}} CH_3—CH_2—C(=O)—OH$

SOME SIMILAR PROBLEMS 15.65–15.74

Variations on a Theme: Inorganic Compounds with Single Bonds to O, X, or N

The —OH group occurs frequently in inorganic compounds. All oxoacids contain at least one —OH, usually bonded to a relatively electronegative nonmetal atom, which in most cases is bonded to other O atoms. Oxoacids are acidic in water because these additional O atoms pull electron density from the central nonmetal, which pulls electron density from the O—H bond, releasing an H^+ ion and stabilizing the oxoanion through resonance. Alcohols are *not* acidic in water because they lack the additional O atoms and the electronegative nonmetal.

Halides of nearly every nonmetal are known, and many undergo substitution reactions in base. As in the case of an alkyl halide, the process involves an attack on the partially positive central atom by OH^-:



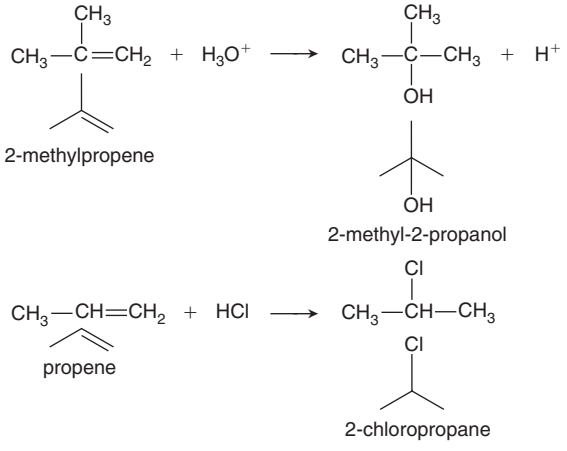
Thus, alkyl halides undergo the same general reaction as other nonmetal halides, such as BCl_3, SiF_4, and PCl_5.

The bonds between nitrogen and larger nonmetals, such as Si, P, and S, have significant double-bond character, which affects structure and reactivity. For example, $(SiH_3)_3N$, trisilylamine, the Si analog of trimethylamine, is trigonal planar, rather than trigonal pyramidal, because of the formation of a double bond between N and Si. Because the lone pair on N is delocalized in this π bond, trisilylamine is not basic.

Functional Groups with Double Bonds

The most important functional groups with double bonds are the C═C group of alkenes and the C═O group of aldehydes and ketones. Both appear in many organic and biological molecules. *Their most common reaction type is addition.*

Alkenes The C═C bond is the essential portion of the *alkene* functional group,  . Although they undergo elimination to alkynes, *alkenes typically undergo addition.* The electron-rich double bond is readily attracted to the partially positive H atoms of hydronium ions and hydrohalic acids, yielding alcohols and alkyl halides, respectively:



Comparing the Reactivities of Alkenes and Aromatic Compounds The *localized* unsaturation of alkenes is very different from the *delocalized* unsaturation of aromatic compounds. That is, despite the way we depict its resonance forms, benzene does *not* have double bonds and so, for example, it does not decolorize Br_2 (see Figure 15.14).

In general, aromatic rings are much *less* reactive than alkenes because of their delocalized π electrons. For example, let's compare the enthalpies of reaction for the

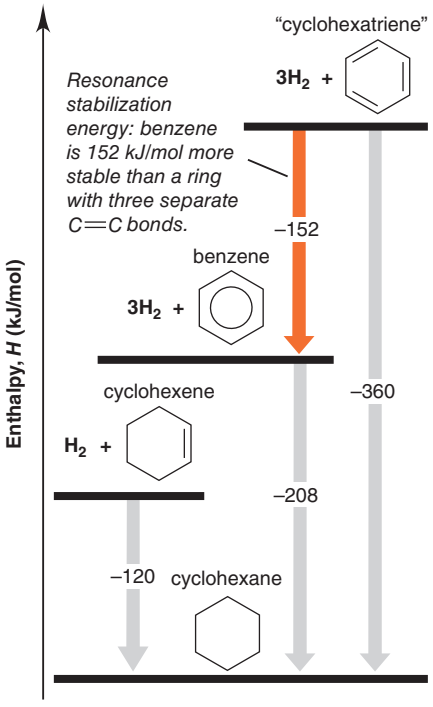


Figure 15.19 The stability of benzene.

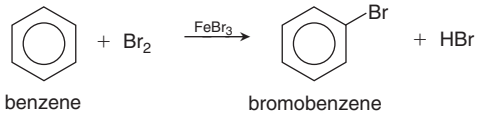
addition of H_2. Hydrogenation of cyclohexene, with one C=C bond, has a ΔH°_{rxn} of −120 kJ/mol. Then, for the imaginary molecule "cyclohexatriene," that is, the structure with three C=C bonds, the hypothetical ΔH°_{rxn} for hydrogenation would be three times as much, or −360 kJ/mol. Hydrogenation of benzene has a ΔH°_{rxn} of −208 kJ/mol. Thus, the ΔH°_{rxn} for hydrogenation of benzene is 152 kJ/mol *less* than that for "cyclohexatriene." This energy difference is attributed to the aromatic resonance stabilization of benzene (Figure 15.19).

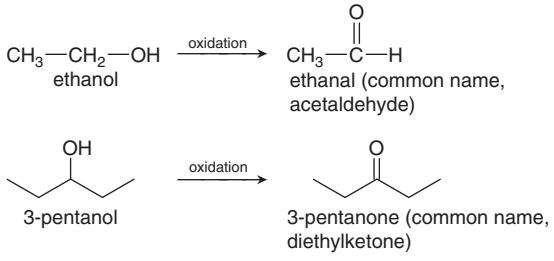
This extra energy needed to break up the delocalized π system means *addition* reactions with benzene occur rarely. But, benzene does undergo many *substitution* reactions in which the delocalization is retained when an H atom attached to a ring C is replaced by another group:

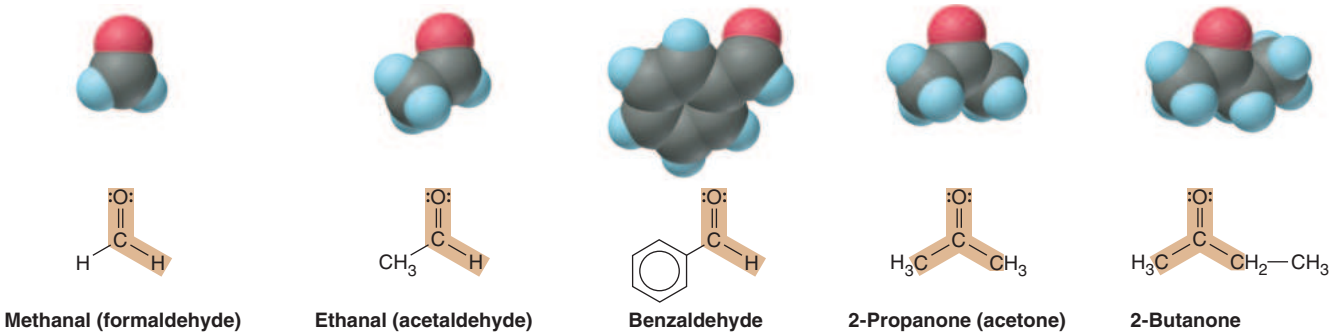


Aldehydes and Ketones The C=O bond, or **carbonyl group,** is one of the most chemically versatile.

- In the **aldehyde** functional group, the carbonyl C is bonded to H (and typically to another C), so it occurs *at the end of a chain,* R—C(=O:)—H. Aldehyde names drop the final *-e* from the alkane name and add *-al;* thus, the three-C aldehyde is propanal.
- In the **ketone** functional group, the carbonyl C is bonded to two other C atoms, —C—C(=O:)—C—, so it occurs *within the chain.* Ketones, R—C(=O)—R′, are named by numbering the carbonyl C, dropping the final *-e* from the alkane name, and adding *-one*. For example, the unbranched, five-C ketone with the carbonyl C as C-2 in the chain is named 2-pentanone. Figure 15.20 shows some common carbonyl compounds.

Aldehydes and ketones are formed by the oxidation of alcohols:





Methanal (formaldehyde)
Used to make resins in plywood, dishware, countertops; biological preservative

Ethanal (acetaldehyde)
Narcotic product of ethanol metabolism; used to make perfumes, flavors, plastics, other chemicals

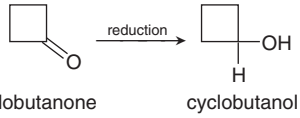
Benzaldehyde
Artificial almond flavoring

2-Propanone (acetone)
Solvent for fat, rubber, plastic, varnish, lacquer; chemical feedstock

2-Butanone (methyl ethyl ketone)
Important solvent

Figure 15.20 Some common aldehydes and ketones.

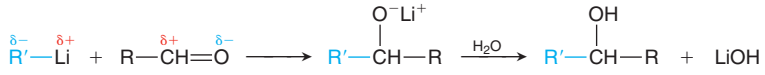
Conversely, as a result of their unsaturation, carbonyl compounds can undergo *addition* and be reduced to alcohols:



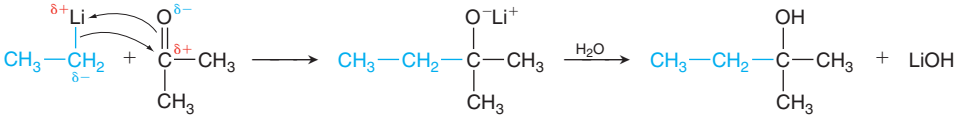
cyclobutanone cyclobutanol

Like the C═C bond, the C═O bond is *electron rich;* unlike the C═C bond, it is *highly polar* (ΔEN = 1.0). Figure 15.21 depicts this polarity with an orbital contour model (Figure 15.21A) and a charged resonance form (Figure 15.21B).

As a result of the bond polarity, addition often occurs with an electron-rich group bonding to the carbonyl C and an electron-poor group bonding to the carbonyl O. **Organometallic compounds,** which have a metal atom (usually Li or Mg) attached to an R group through a polar covalent bond, take part in this type of reaction. In a two-step sequence, they convert carbonyl compounds to alcohols with *different carbon skeletons:*



In the following example, the electron-rich C bonded to Li in ethyllithium, CH_3CH_2—Li, attacks the electron-poor carbonyl C of 2-propanone, adding its ethyl group; at the same time, the Li adds to the carbonyl O. Treating the mixture with water forms the C—OH group in the product, 2-methyl-2-butanol:



Note that the product skeleton combines the two reactant skeletons. The field of *organic synthesis* often employs organometallic compounds to create new compounds with different skeletons.

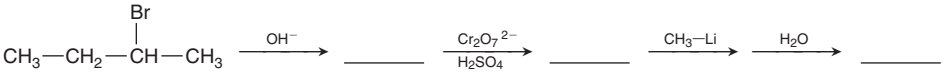
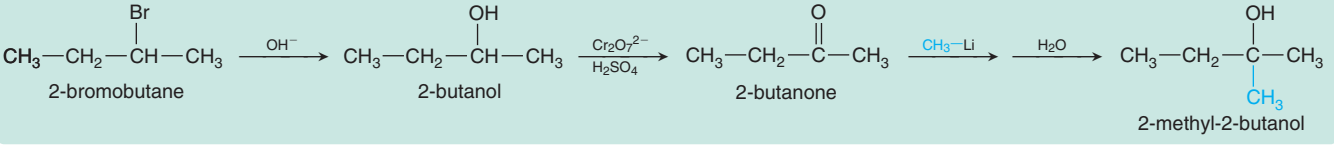
SAMPLE PROBLEM 15.5 Predicting the Steps in a Reaction Sequence

Problem Fill in the blanks in the following reaction sequence:



Plan For each step, we examine the functional group of the reactant and the reagent above the yield arrow to decide on the most likely product.

Solution The sequence starts with an alkyl halide reacting with OH^-. Substitution gives an alcohol. Oxidation of this alcohol with acidic dichromate gives a ketone. Finally, a two-step reaction of a ketone with CH_3—Li and then water forms an alcohol with a carbon skeleton that has the CH_3— group attached to the carbonyl C:



Check In this case, make sure that the first two reactions alter the functional group only and that the final steps change the C skeleton.

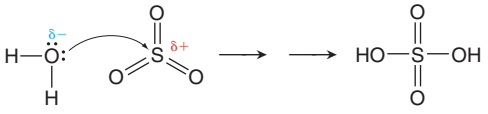
SOME SIMILAR PROBLEMS 15.65–15.74

Variations on a Theme: Inorganic Compounds with Double Bonds Homonuclear (same kind of atom) double bonds are rare for atoms other than C. However, we've seen many double bonds between O and other nonmetals, for example, in the oxides of S, N, and the halogens. Like carbonyl compounds, these substances undergo addition reactions. For example, the partially negative O of water attacks the partially positive S of SO_3 to form sulfuric acid:

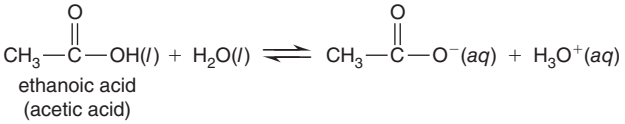


Functional Groups with Both Single and Double Bonds

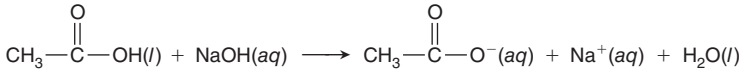
A family of three functional groups contains C double bonded to O (a carbonyl group) *and* single bonded to O or N. The parent of the family is the **carboxylic acid** group, —C(=O)—OH, also called the *carboxyl group* and written —COOH. *The most important reaction type of this family is substitution from one member to another.* Substitution for the —OH by the —OR of an alcohol gives the **ester** group, —C(=O)—O—R, and substitution for it by the —N— of an amine gives the **amide** group, —C(=O)—N—.

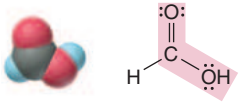
Carboxylic Acids Carboxylic acids, R—C(=O)—OH, are named by dropping the *-e* from the alkane name and adding *-oic acid;* however, many common names are used. For example, the four-C acid is butanoic acid (the carboxyl C is counted when choosing the root); its common name is butyric acid. Figure 15.22 shows some important carboxylic acids. The carboxyl C already has three bonds, so it forms only one other. In formic acid (methanoic acid), the carboxyl C is bonded to an H, but in all other carboxylic acids it is bonded to a chain or ring.

Carboxylic acids are weak acids in water:

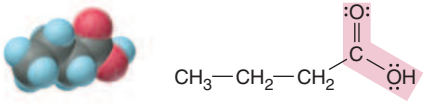


At equilibrium in a solution of typical concentration, more than 99% of the acid molecules are undissociated at any given moment. In strong base, however, a carboxylic acid reacts completely to form a salt and water:

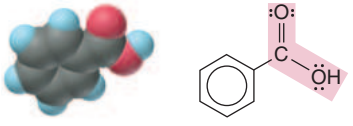




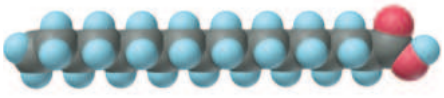
Methanoic acid (formic acid)
An irritating component of ant and bee stings

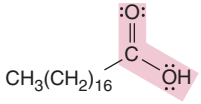


Butanoic acid (butyric acid)
Odor of rancid butter; suspected component of monkey sex attractant



Benzoic acid
Calorimetric standard; used in preserving food, dyeing fabric, curing tobacco





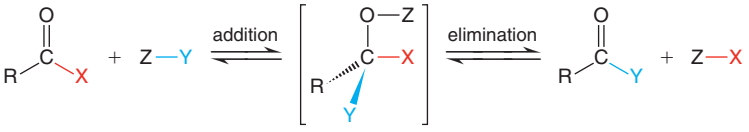
Octadecanoic acid (stearic acid)
Found in animal fats; used in making candles and soaps

Figure 15.22 Some molecules with the carboxylic acid functional group.

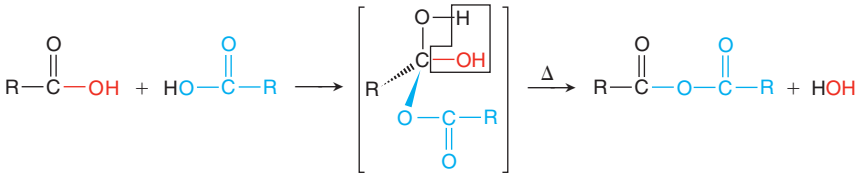
The anion of the salt is the *carboxylate ion,* named by dropping *-oic acid* and adding *-oate;* the sodium salt of butanoic acid, for instance, is sodium butanoate.

Carboxylic acids with long hydrocarbon chains are **fatty acids,** an essential group of compounds found in all cells. Animal fatty acids have saturated chains (see stearic acid, Figure 15.22, *bottom*), whereas many fatty acids from plants are unsaturated, usually with the C═C bonds in the *cis* configuration. The double bonds make them much easier to metabolize. Nearly all fatty acid skeletons have an even number of C atoms—16 and 18 carbons are very common—because cells use two-carbon units in synthesizing them. Fatty acid salts, usually with a cation from Group 1A(1) or 2A(2), are soaps (Section 13.2).

Substitution of carboxylic acids and other members of this family occurs through a two-step sequence: *addition plus elimination equals substitution.* Addition to the trigonal planar C atom gives an unstable tetrahedral intermediate, which immediately undergoes elimination to revert to a trigonal planar product (in this case, X is OH):

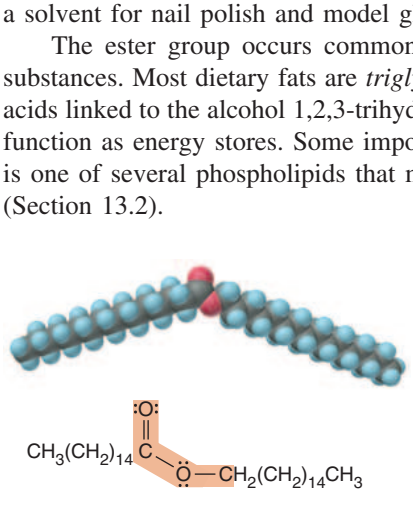


Strong heating of a carboxylic acid forms an **acid anhydride** through a type of substitution called a *dehydration-condensation reaction* (Section 14.7). Viewing this reaction as similar to the one above, but where X is OH, Z is H, and Y is the OOC—R group, we see the result is that two molecules condense into one with loss of a water molecule:

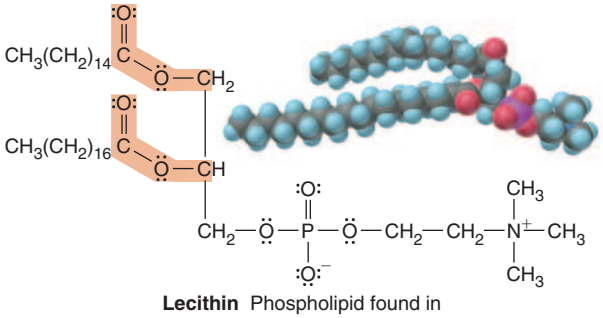


Esters An ester, R—C(=O)—O—R, is formed from an alcohol and a carboxylic acid. The first part of an ester name designates the alcohol portion and the second the acid portion (named in the same way as the carboxylate ion). For example, the ester formed between ethanol and ethanoic acid is ethyl ethanoate (common name, ethyl acetate), a solvent for nail polish and model glue.

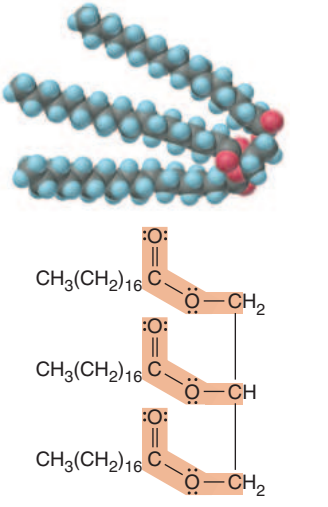
The ester group occurs commonly in **lipids,** a large group of fatty biological substances. Most dietary fats are *triglycerides,* esters that are composed of three fatty acids linked to the alcohol 1,2,3-trihydroxypropane (common name, glycerol) and that function as energy stores. Some important lipids are shown in Figure 15.23; lecithin is one of several phospholipids that make up the lipid bilayer in all cell membranes (Section 13.2).



Cetyl palmitate The most common lipid in whale blubber



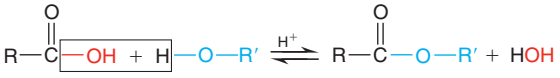
Lecithin Phospholipid found in all cell membranes



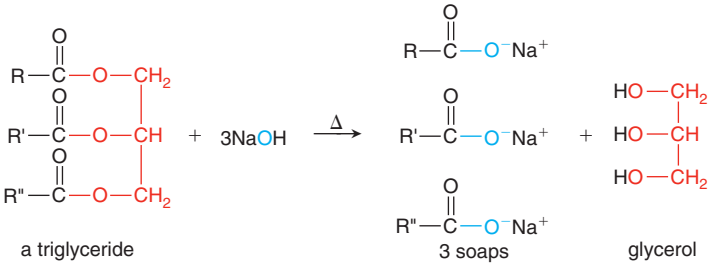
Tristearin Typical dietary fat used as an energy store in animals

Figure 15.23 **Some lipid molecules with the ester functional group.**

Esters, like acid anhydrides, form through a dehydration-condensation reaction; in this case, it is called an *esterification:*



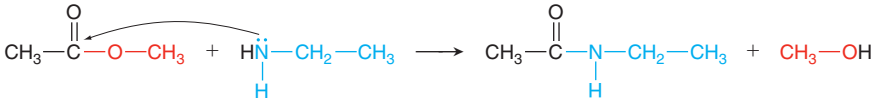
Note that the esterification reaction is reversible. The opposite of dehydration-condensation is **hydrolysis,** in which the O atom of water is attracted to the partially positive C atom of the ester, cleaving (lysing) the ester molecule into two parts. One part bonds to water's —OH, and the other part to water's other H. In the process of soap manufacture, or *saponification* (Latin *sapon,* "soap"), used since ancient times, the ester bonds in animal or vegetable fats are hydrolyzed with a strong base:



While carboxylic acids have pungent, vinegary, or cheesy odors, esters have pleasant odors. For example, ethyl butanoate has the scent of pineapple, and pentyl-pentanoate has the aroma of apples *(see photo).* Naturally occurring and synthetic esters are used to add fruity, floral, and herbal odors to foods, cosmetics, household deodorizers, and medicines.

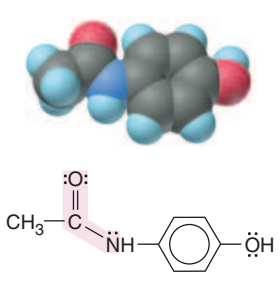
Carboxylic acids and esters have some familiar and distinctive odors.

Amides The product of a substitution between an amine (or NH_3) and an ester is an amide, R—C(=O)—N—. The partially negative N of the amine is attracted to the partially positive C of the ester, an alcohol (ROH) is lost, and an amide forms:

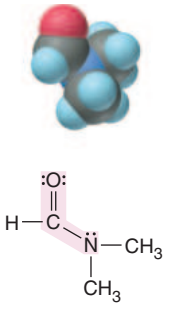


Amides are named by denoting the amine portion with italic *N-* and replacing *-oic acid* from the parent carboxylic acid with *-amide*. In the amide produced in the preceding reaction, the ethyl group comes from the amine, and the acid portion comes from ethanoic acid (acetic acid). Some amides are shown in Figure 15.24. The most important example of the amide group is the *peptide bond* (discussed in Sections 13.2 and 15.6), which links amino acids in a protein.

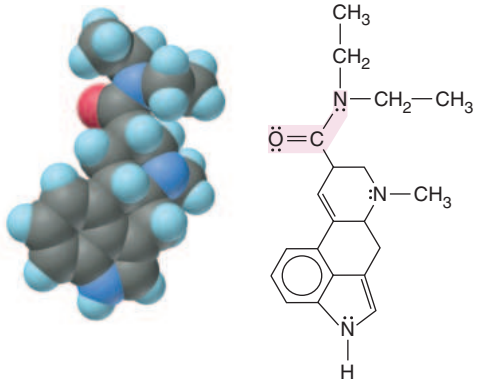
Figure 15.24 **Some molecules with the amide functional group.**



Acetaminophen
Active ingredient in nonaspirin pain relievers; used to make dyes and photographic chemicals

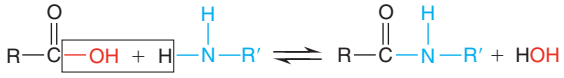


***N,N*-Dimethylmethanamide (dimethylformamide)**
Major organic solvent; used in production of synthetic fibers

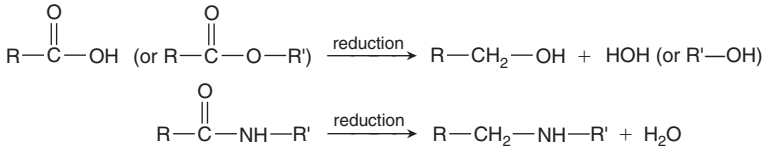


Lysergic acid diethylamide (LSD-25) A potent hallucinogen

An amide is hydrolyzed in hot water (or base) to a carboxylic acid (or carboxylate ion) and an amine. Thus, even though amides are not normally formed in the following way, they can be viewed as the result of a reversible dehydration-condensation:



Reduction Reactions Compounds in the carboxylic acid family also undergo reduction to form other functional groups. For example, certain inorganic *reducing agents* (such as lithium aluminum hydride, $LiAlH_4$, or sodium borohydride, $NaBH_4$) convert acids or esters to alcohols and convert amides to amines:



SAMPLE PROBLEM 15.6 Predicting Reactions of the Carboxylic Acid Family

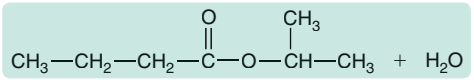
Problem Predict the organic product(s) of the following reactions:

(a) $CH_3—CH_2—CH_2—C(=O)—OH + CH_3—CH(OH)—CH_3 \xrightleftharpoons{H^+}$

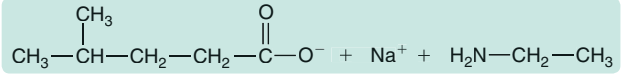
(b) $CH_3—CH(CH_3)—CH_2—CH_2—C(=O)—NH—CH_2—CH_3 \xrightarrow[H_2O]{NaOH}$

Plan **(a)** A carboxylic acid and an alcohol react, so the reaction must be a substitution to form an ester and water. **(b)** An amide reacts with OH^-, so it is hydrolyzed to an amine and a sodium carboxylate.

Solution **(a)** Formation of an ester:



(b) Basic hydrolysis of an amide:



Check Note that in part (b), the carboxylate ion forms, rather than the acid, because the aqueous NaOH that is present reacts with any carboxylic acid as it forms.

SOME SIMILAR PROBLEMS 15.67–15.74

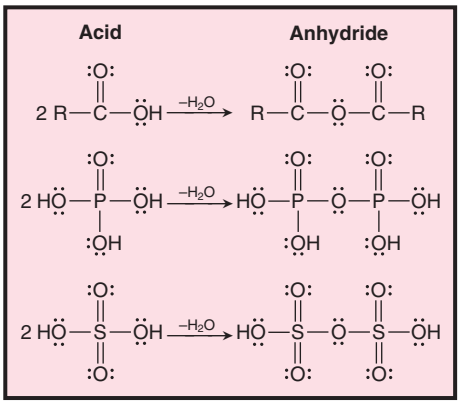

Figure 15.25 The formation of carboxylic, phosphoric, and sulfuric acid anhydrides.

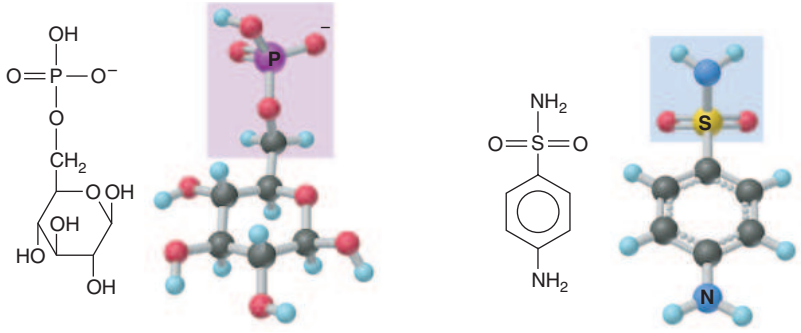
Variations on a Theme: Oxoacids, Esters, and Amides of Other Nonmetals

A nonmetal that has both double and single bonds to oxygens occurs in most inorganic oxoacids, such as phosphoric, sulfuric, and chlorous acids. Those with additional O atoms are stronger acids than carboxylic acids.

Diphosphoric and disulfuric acids are acid anhydrides formed by dehydration-condensation reactions, like the one that yields a carboxylic acid anhydride (Figure 15.25). Inorganic oxoacids form esters and amides that are part of many biological molecules. We already saw that certain lipids are phosphate esters (see Figure 15.23). The first compound formed when glucose is digested is a phosphate ester (Figure 15.26A); a similar phosphate ester is a major structural feature of nucleic acids, as we'll see shortly. Amides of organic sulfur-containing oxoacids, called *sulfonamides,* are potent antibiotics; the simplest of these is depicted in Figure 15.26B. More than 10,000 different sulfonamides have been synthesized.



A Glucose-6-phosphate **B** Sulfanilamide

Figure 15.26 A phosphate ester and a sulfonamide.

Functional Groups with Triple Bonds

Alkynes and nitriles are the only two important functional groups with triple bonds.

Alkynes Alkynes, with an electron-rich —C≡C— group, undergo addition (by H_2O, H_2, HX, X_2, and so forth) to form double-bonded or saturated compounds:

$$\underset{\text{propyne}}{CH_3—C{\equiv}CH} \xrightarrow{H_2} \underset{\text{propene}}{CH_3—CH{=}CH_2} \xrightarrow{H_2} \underset{\text{propane}}{CH_3—CH_2—CH_3}$$

Nitriles Nitriles (R—C≡N) contain the **nitrile** group (—C≡N:) and are made by substituting a CN^- (cyanide) ion for X^- in a reaction with an alkyl halide:

$$CH_3—CH_2—Cl + NaCN \longrightarrow CH_3—CH_2—C{\equiv}N + NaCl$$

This reaction is useful because it *increases the chain by one C atom.* Nitriles are versatile because once they are formed, they can be reduced to amines or hydrolyzed to carboxylic acids:

$$CH_3—CH_2—CH_2—NH_2 \xleftarrow{\text{reduction}} CH_3—CH_2—C{\equiv}N \xrightarrow[\text{hydrolysis}]{H_3O^+,\ H_2O} CH_3—CH_2—C(=O)—OH + NH_4^+$$

Variations on a Theme: Inorganic Compounds with Triple Bonds

Triple bonds are as scarce in the inorganic world as in the organic world. Carbon monoxide (:C≡O:), elemental nitrogen (:N≡N:), and the cyanide ion ([:C≡N:]$^-$) are the only common examples.

You've seen quite a few functional groups by this time, and it is especially important that you can recognize them in a complex organic molecule. Sample Problem 15.7 provides some practice.

SOME SIMILAR PROBLEMS 15.59 and 15.60

Summary of Section 15.4

- Organic reactions are initiated when regions of high and low electron density in reactant molecules attract each other.
- Functional groups containing only single bonds—alcohols, amines, and alkyl halides—undergo substitution and elimination reactions.
- Functional groups with double or triple bonds—alkenes, aldehydes, ketones, alkynes, and nitriles—mostly undergo addition reactions.
- Aromatic compounds typically undergo substitution, rather than addition, because delocalization of the π electrons stabilizes the ring.
- Functional groups with both double and single bonds—carboxylic acids, esters, and amides—undergo substitution (addition plus elimination) reactions.
- Many reactions change one functional group to another, but some, including reactions with organometallic compounds and with the cyanide ion, change the carbon skeleton.

15.5 THE MONOMER-POLYMER THEME I: SYNTHETIC MACROMOLECULES

In Chapter 12, you saw that polymers are extremely large molecules that consist of many monomeric repeat units. There, we focused on the mass, shape, and physical properties of polymers. Now we'll discuss the two types of organic reactions that link monomers covalently into a chain. To name a polymer, we add the prefix *poly-* to the monomer name, as in *polyethylene* or *polystyrene*. When the monomer has a two-word name, parentheses are used, as in *poly(vinyl chloride)*.

The two major types of reaction processes that form synthetic polymers lend their names to the resulting classes of polymer—addition and condensation.

Addition Polymers

Addition polymers form when monomers undergo an addition reaction with one another. These substances are also called *chain-reaction* (or *chain-growth*) *polymers* because as each monomer adds to the chain, it forms a new reactive site to continue the process. The monomers of most addition polymers have the $\diagdown C{=}C \diagup$ grouping. As you can see from Table 15.6, the remarkably different physical behaviors of an acrylic sweater, a plastic grocery bag, and a bowling ball result from the different groups that are attached to the double-bonded C atoms of the monomers.

The *free-radical polymerization* of ethene (ethylene, $CH_2{=}CH_2$) to polyethylene is a simple example of the addition process (Figure 15.27). The monomer reacts to form a *free radical,* a species with an unpaired electron, which forms a covalent bond with an electron from another monomer:

Step 1. The process begins when an *initiator,* usually a peroxide, generates a free radical.

Step 2. The free radical attacks the π bond of an ethylene molecule, forming a σ bond with one of the *p* electrons and leaving the other unpaired, creating a new free radical.

Step 3. This new free radical attacks the π bond of another ethylene, joining it to the chain end, and the backbone of the polymer grows one unit longer.

Step 4. This process stops when two free radicals form a covalent bond or when a very stable free radical is formed by addition of an *inhibitor* molecule.

Recent progress in controlling the high reactivity of free-radical species promises an even wider range of polymers. In one method, polymerization is initiated by the formation of a cation (or anion) instead of a free radical. The cationic (or anionic) reactive end of the chain attacks the π bond of another monomer to form a new cationic (or anionic) end, and the process continues.

The most important polymerization reactions take place under relatively mild conditions through the use of catalysts that incorporate transition metals. In 1963, Karl Ziegler and Giulio Natta received the Nobel Prize in chemistry for developing *Ziegler-Natta catalysts,* which employ an organoaluminum compound, such as $Al(C_2H_5)_3$, and the tetrachloride of titanium or vanadium. Today, chemists use organometallic catalysts that are *stereoselective* to create polymers whose repeat units have groups spatially oriented in particular ways. Use of these catalysts with varying conditions and reagents allows polyethylene chains with molar masses of 10^4 to 10^5 g/mol to be made.

Similar methods are used to make polypropylenes, $\text{–}(CH_2{-}\underset{\displaystyle CH_3}{\underset{|}{CH}})_n\text{–}$, that have all the CH_3 groups of the repeat units oriented either on one side of the chain or on alternating sides. The different orientations lead to different packing efficiencies of the chains and, thus, different degrees of crystallinity, which lead to differences in such physical properties as density, rigidity, and elasticity (Section 12.7).

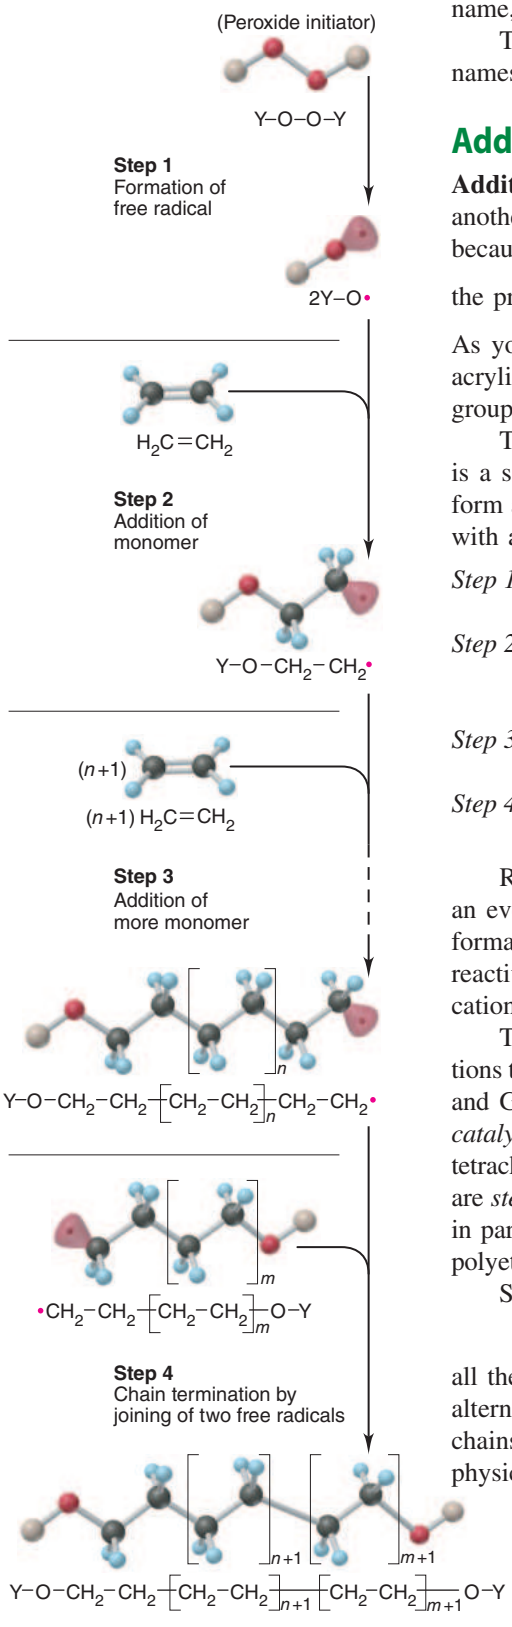

Figure 15.27 Steps in the free-radical polymerization of ethylene.

Table 15.6 Some Major Addition Polymers

Monomer	Polymer	Applications
	polyethylene ($R_1 = R_2 = R_3 = R_4 = H$)	Plastic bags; bottles; toys
 	polytetrafluoroethylene ($R_1 = R_2 = R_3 = R_4 = F$)	Cooking utensils (e.g., Teflon)
 	polypropylene ($R_1 = R_2 = R_3 = H$; $R_4 = CH_3$)	Carpeting (indoor-outdoor); bottles
 	poly(vinyl chloride) ($R_1 = R_2 = R_3 = H$; $R_4 = Cl$)	Plastic wrap; garden hose; indoor plumbing
 	polystyrene ($R_1 = R_2 = R_3 = H$; $R_4 = C_6H_5$)	Insulation; furniture; packing materials
 	polyacrylonitrile ($R_1 = R_2 = R_3 = H$; $R_4 = CN$)	Yarns (e.g., Orlon, Acrilan); fabrics; wigs
 	poly(vinyl acetate) ($R_1 = R_2 = R_3 = H$; $R_4 = OCCH_3$, with O)	Adhesives; paints; textile coatings; computer disks
 	poly(vinylidene chloride) ($R_1 = R_2 = H$; $R_3 = R_4 = Cl$)	Food wrap (e.g., Saran)
 	poly(methyl methacrylate) ($R_1 = R_2 = H$; $R_3 = CH_3$; $R_4 = COCH_3$, with O)	Glass substitute (e.g., Lucite, Plexiglas); bowling balls; paint

Condensation Polymers

The monomers of **condensation polymers** must have *two functional groups;* we can designate such a monomer as A—**R**—B (where A and B may or may not be the same, and **R** is the rest of the molecule). Most commonly, the monomers link when an A group on one undergoes a *dehydration-condensation reaction* with a B group on another:

$$\tfrac{1}{2}n\text{H—A—}\mathbf{R}\text{—B—OH} + \tfrac{1}{2}n\text{H—A—}\mathbf{R}\text{—B—OH} \xrightarrow{-(n-1)\text{HOH}} \text{H}\left[\text{A—}\mathbf{R}\text{—B}\right]_n\text{OH}$$

Many condensation polymers are *copolymers,* those consisting of two or more different repeat units (Section 12.7). Two major types are polyamides and polyesters.

1. *Polyamides.* Condensation of carboxylic acid and amine monomers forms *polyamides (nylons).* One of the most common is *nylon-66,* manufactured by mixing equimolar amounts of a six-C diamine (1,6-diaminohexane) and a six-C diacid (1,6-hexanedioic acid). The basic amine reacts with the acid to form a "nylon salt." Heating drives off water and forms the amide bonds:

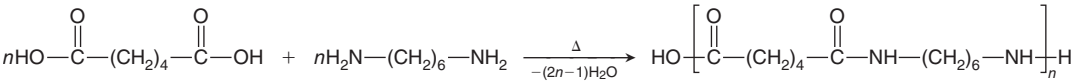

Figure 15.28 The formation of nylon-66. In the laboratory, the six-C diacid chloride, which is more reactive than the diacid, is used as one monomer; the polyamide forms between the two liquid phases.

In the laboratory, this nylon is made without heating by using a more reactive acid component (Figure 15.28). Covalent bonds within the chains give nylons great strength, and H bonds between chains give them great flexibility (see Table 2.8, p. 76). About half of all nylons are made to reinforce automobile tires; the others are used for rugs, clothing, fishing line, and so forth.

2. *Polyesters.* Condensation of carboxylic acid and alcohol monomers forms *polyesters.* Dacron, a popular polyester fiber, is woven from polymer strands formed when equimolar amounts of 1,4-benzenedicarboxylic acid and 1,2-ethanediol react. Blending these polyester fibers with various amounts of cotton gives fabrics that are durable, easily dyed, and crease resistant. Extremely thin Mylar films, used for recording tape and food packaging, are also made from this polymer.

Variations on a Theme: Inorganic Polymers You already know that some synthetic polymers have inorganic backbones. In Chapter 14, we discussed the silicones, polymers with the repeat unit $—(R_2)Si—O—$. Depending on the chain crosslinks and the R groups, silicones range from oily liquids to elastic sheets to rigid solids and have applications that include artificial limbs and space suits. Polyphosphazenes exist as flexible chains even at low temperatures and have the repeat unit $—(R_2)P{=}N—$.

Summary of Section 15.5

- Polymers are extremely large molecules that are made of repeat units called monomers.
- Addition polymers are formed from unsaturated monomers that commonly link through free-radical reactions.
- Most condensation polymers are formed by linking monomers that each have two functional groups through a dehydration-condensation reaction.
- Reaction conditions, catalysts, and monomers can be varied to produce polymers with different properties.

15.6 THE MONOMER-POLYMER THEME II: BIOLOGICAL MACROMOLECULES

The monomer-polymer theme was being played out in nature eons before humans employed it to such great advantage. Biological macromolecules are condensation polymers created by nature's reaction chemistry and improved through evolution. These remarkable molecules are the best demonstration of the versatility of carbon and its handful of atomic partners.

Natural polymers, such as polysaccharides, proteins, and nucleic acids, are the "stuff of life." Some have structures that make wood strong, fingernails hard, and wool flexible. Others speed up the myriad reactions that occur in every cell or defend the body against infection. Still others possess the genetic information organisms need to forge other biomolecules and reproduce themselves. Remarkable as these giant molecules are, the functional groups of their monomers and the reactions that link them are identical to those of other, smaller organic molecules. Moreover, as you saw in Section 13.2, the same intermolecular forces that dissolve smaller molecules stabilize these giant molecules in the aqueous medium of the cell.

Sugars and Polysaccharides

In essence, the same chemical change occurs when you burn a piece of wood or eat a piece of bread. Wood and bread are mixtures of *carbohydrates,* substances that provide energy through oxidation.

Monomer Structure and Linkage Glucose and other simple sugars, from the three-C *trioses* to the seven-C *heptoses*, are called **monosaccharides** and consist of carbon chains with attached hydroxyl and carbonyl groups. In aqueous solution, *an OH (alcohol) group and a C═O (aldehyde or keytone) group of the same monosaccharide react with each other to form a cyclic molecule that has either a five- or*

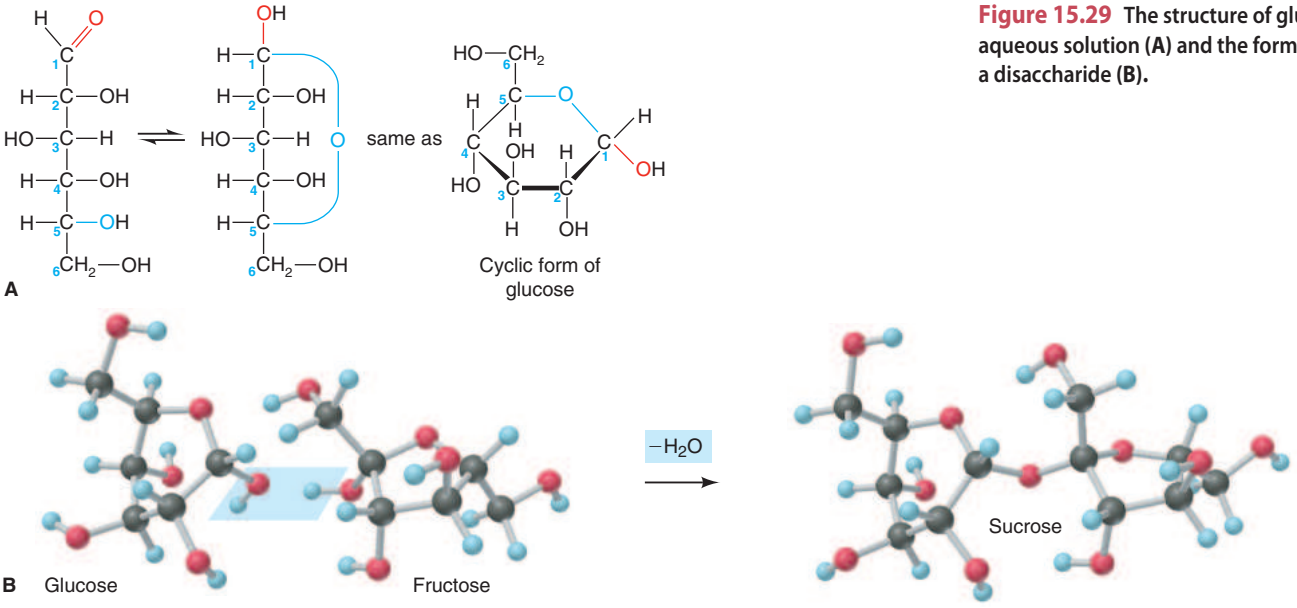

Figure 15.29 The structure of glucose in aqueous solution (A) and the formation of a disaccharide (B).

six-membered ring. For example, glucose undergoes an internal addition reaction between the aldehyde group of C-1 and the alcohol group of C-5 (Figure 15.29A).

When two monosaccharides undergo a dehydration-condensation reaction, a **disaccharide** forms. For example, sucrose (table sugar) is a disaccharide of glucose (linked at C-1) and fructose (linked at C-2) (Figure 15.29B); lactose (milk sugar) is a disaccharide of glucose (C-1) and galactose (C-4); and maltose, used in brewing and as a sweetener, is a disaccharide of two glucose units (linked from C-1 to C-4).

Three Major Types of Polysaccharides In addition to their roles as individual molecules engaged in energy metabolism, monosaccharides serve as the monomer units of **polysaccharides.** The three major natural polysaccharides—cellulose, starch, and glycogen—consist entirely of glucose units, but they differ in the ring positions of the links, in the orientation of certain bonds, and in the extent of crosslinking. Some other polysaccharides contain nitrogen in their attached groups. *Chitin* (pronounced "KY-tin"), the main component of the tough, external skeletons of insects and crustaceans *(see photo),* has an acetamide group at C-2 of the glucose ring.

Lobster shells contain a polysaccharide called *chitin.*

1. *Cellulose* is the most abundant organic chemical on Earth. More than 50% of the carbon in plants occurs in the cellulose of stems and leaves, and wood is largely cellulose. Cellulose consists of long chains of glucose. The great strength of wood is due largely to the countless H bonds between cellulose chains. The monomers are linked in a particular way from C-1 in one unit to C-4 in the next. Humans lack the enzymes to break this link, so we cannot digest cellulose (unfortunately!); however, microorganisms in the digestive tracts of some animals, such as cows, sheep, and termites, can.

2. *Starch* is a mixture of polysaccharides of glucose and serves as an *energy store* in plants. When a plant needs energy, some starch is broken down by hydrolysis of the bonds between units, and the released glucose is oxidized through a multistep metabolic pathway. Starch occurs in plant cells as insoluble granules of amylose, a helical molecule of several thousand glucose units, and amylopectin, a highly branched, bushlike molecule of up to a million glucose units. Most of the glucose units are linked by C-1 to C-4 bonds, as in cellulose, but a different orientation around the chiral C-1 allows our digestive enzymes to break starch down into monomers, which we metabolize for energy. A C-6 to C-1 crosslink joins chains every 24 to 30 units.

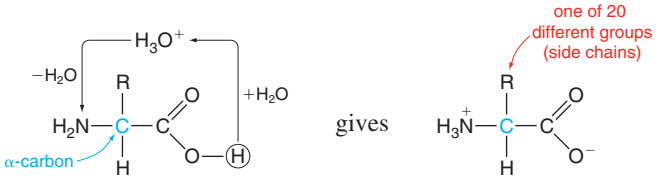
3. *Glycogen* functions as the energy storage molecule in animals. It occurs in liver and muscle cells as large, insoluble granules consisting of polymer molecules made from 1000 to more than 500,000 glucose units. In glycogen, these units are linked by C-1 to C-4 bonds, as in starch, but the molecule is more highly crosslinked than starch, with C-6 to C-1 crosslinks every 8 to 12 units.

Amino Acids and Proteins

As you saw in Section 15.5, synthetic polyamides (such as nylon-66) are formed from two monomers, one with a carboxyl group at each end and the other with an amine group at each end. **Proteins,** the polyamides of nature, are *unbranched* polymers formed from monomers called **amino acids:** *each amino acid molecule has both a carboxyl group and an amine group* (Section 13.2).

Monomer Structure and Linkage An amino acid has both its carboxyl group and its amine group attached to the α-*carbon*, the second C atom in the chain. Proteins are made up of about 20 different types of amino acids, distinguished by their R groups, which range from an H atom to a polycyclic N-containing aromatic structure (Figure 15.30). The R groups play a major role in the shape and function of the protein.

In the aqueous cell fluid, the NH_2 and COOH groups of amino acids are charged because the carboxyl groups each transfer an H^+ ion to H_2O to form H_3O^+ ions, which effectively transfer the H^+ to the amine groups. Occurring throughout the solution, the overall process can be viewed as an intramolecular acid-base reaction:



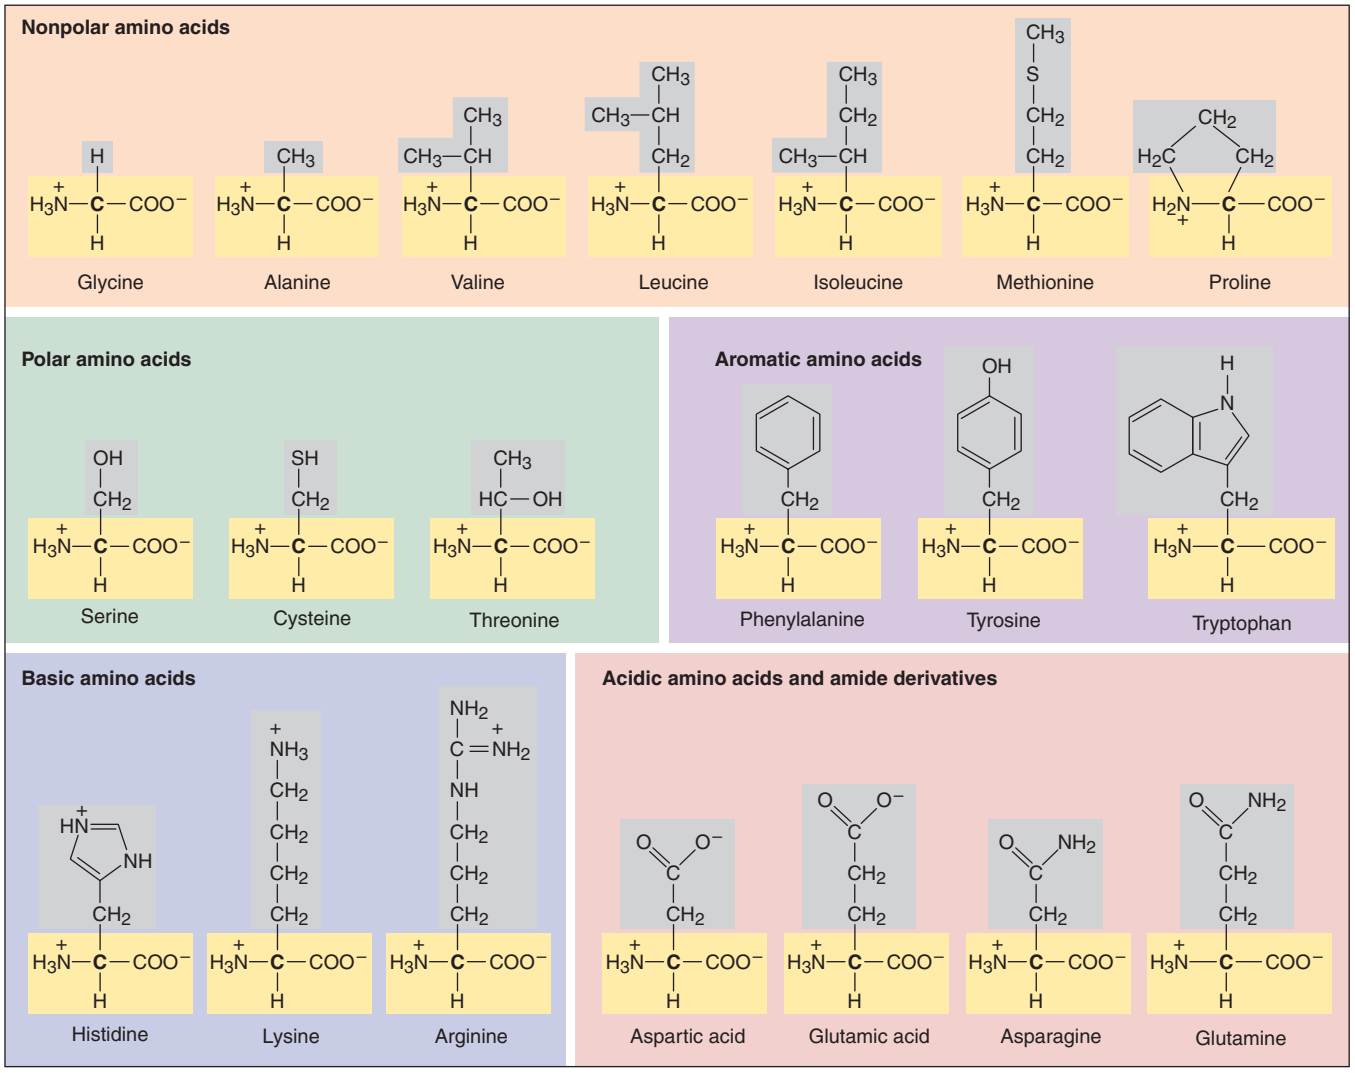


Figure 15.30 The common amino acids. The R groups are screened gray, and the α-carbons *(boldface),* with carboxyl and amino groups, are screened yellow. Here the amino acids are shown with the charges they have under physiological conditions.

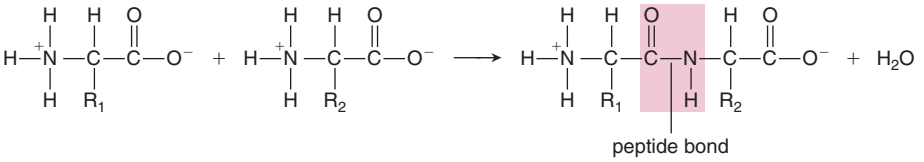
An H atom is the third group bonded to the α-carbon, and the fourth is the R group (also called the *side chain*).

Each amino acid is linked to the next through a *peptide (amide) bond* formed by a dehydration-condensation reaction in which the carboxyl group of one monomer reacts with the amine group of the next.



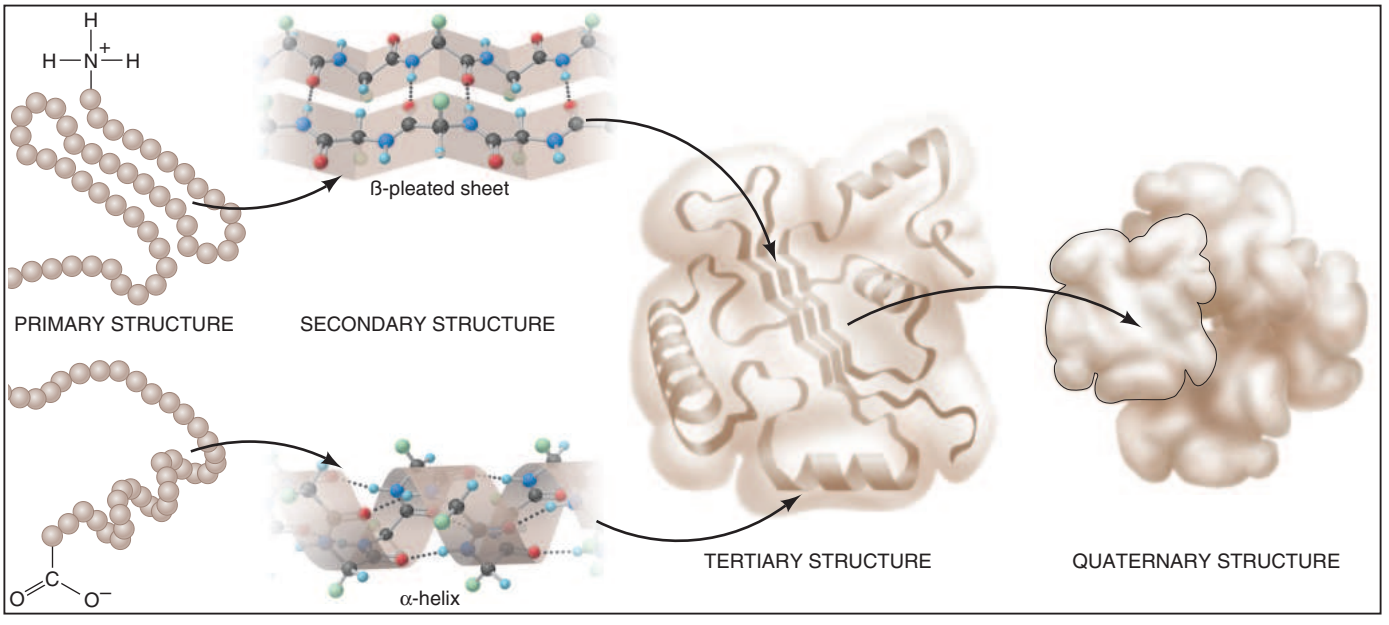
Therefore, the polypeptide chain—the backbone of the protein—has a repeating structure that consists of an α-*carbon bonded to a peptide group bonded to the next* α-*carbon bonded to the next peptide group,* and so forth (see Figure 13.6, p. 523). The various R groups dangle from the α-carbons on alternate sides of the chain.

The Hierarchy of Protein Structure *Each protein has its own amino acid composition,* specific proportions of the various amino acids. However, it is not the composition that defines the protein's role in the cell; rather, *the sequence of amino acids determines the protein's shape and function.* Proteins range from about 50 to several thousand amino acids, yet from a purely mathematical point of view, even a small protein of 100 amino acids has a virtually limitless number of possible sequences of 20 different amino acids ($20^{100} \approx 10^{130}$). In fact, though, only a tiny fraction of these possibilities occur in actual proteins. For example, even in an organism as complex as a human being, there are only about 10^5 different types of proteins.

A protein folds into its native shape as it is being synthesized in the cell. Some shapes are simple—long helical tubes or undulating sheets. Others are far more complex—baskets, Y shapes, spheroid blobs, and countless other globular forms. Biochemists define a hierarchy for the overall structure of a protein (Figure 15.31):

1. *Primary (1°) structure,* the most basic level, refers to the sequence of covalently bonded amino acids in the polypeptide chain.
2. *Secondary (2°) structure* refers to sections of the chain that, as a result of H bonding between nearby peptide groupings, adopt shapes called α-helices and β-pleated sheets.
3. *Tertiary (3°) structure* refers to the three-dimensional folding of the whole polypeptide chain, which results from a combination of mostly intermolecular forces (Figure 13.7, p. 524). In many proteins, characteristic folding patterns form

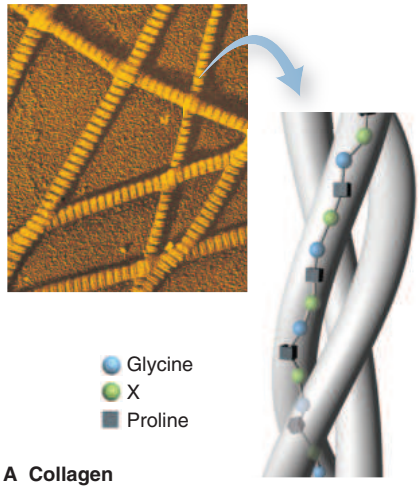
Figure 15.31 **The structural hierarchy of proteins.**



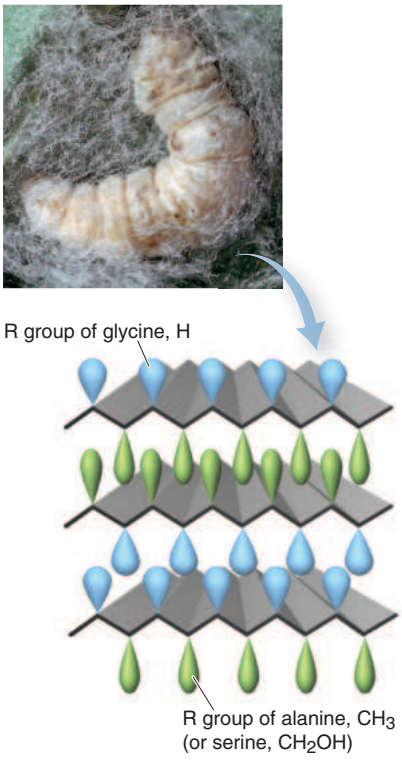
regions that play a role in the protein's function—binding a hormone, attaching to a membrane, forming a membrane channel, and so forth.

4. *Quaternary (4°) structure,* the most complex level, occurs in proteins made up of several polypeptide chains (subunits) and refers to the way the chains assemble, typically through intermolecular forces, into the overall multi-subunit protein. Hemoglobin, for example, consists of four subunits (rightmost structure in Figure 15.31).

The key point is that *only the 1° structure relies on covalent bonds; the 2°, 3°, and 4° structures rely primarily on intermolecular forces* (Section 13.2).



A Collagen



B Silk fibroin

Figure 15.32 **The shapes of fibrous proteins.**

The Relation Between Structure and Function Two broad classes of proteins differ in the complexity of their amino acid compositions and sequences and, therefore, in their structure and function:

1. *Fibrous proteins* have relatively simple amino acid compositions and correspondingly simple structures. They are key components of hair, wool, skin, and connective tissue—materials that require strength and flexibility. Like synthetic polymers, these proteins have a small number of different amino acids in a repeating sequence.

- *Collagen,* the most common animal protein, makes up as much as 40% of human body weight. More than 30% of its amino acids are glycine (G) and another 20% are proline (P). It consists of three chains, each an extended helix, that wind around each other. The peptide C═O groups in one chain form H bonds to the peptide N—H groups in another. The result is a long, triple-helical cable with the sequence —G—X—P—G—X—P— and so on (where X is another amino acid) (Figure 15.32A). As the main protein component of tendons, skin, and blood-vessel walls, collagen has a high tensile strength: a collagen strand 1-mm in diameter can support a 10-kg weight!
- *Silk fibroin,* which is secreted by the silk moth caterpillar, has glycine, alanine, and serine making up more than 85% of its amino acids (Figure 15.32B). Running back and forth alongside each other, fibroin chain segments form interchain H bonds to create a *pleated sheet*. Stacks of sheets interact through dispersion forces, which make fibroin strong and flexible but not very stretchable—perfect for a silkworm's cocoon.

2. *Globular proteins* have much more complex compositions, often containing all 20 amino acids in varying proportions. As the name implies, globular proteins are typically more rounded and compact, with a wide variety of shapes and a correspondingly wide range of functions: defenders against bacterial invasion, messengers that trigger cell actions, catalysts of chemical change, membrane gatekeepers that maintain cellular concentrations, and many others.

The locations of particular amino-acid R groups are crucial to the protein's function. For example, in catalytic proteins, a few R groups form a crevice that closely matches the shapes of reactant molecules. These groups typically hold the reactants through intermolecular forces and speed their reaction to products by bringing them together and twisting and stretching their bonds (Section 16.7). Experiment has established that a slight change in one of these critical R groups decreases the catalytic function dramatically. This fact supports the essential idea that *the protein's amino acid sequence determines its structure, which in turn determines its function:*

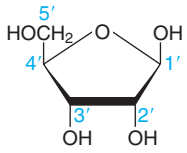
SEQUENCE ⟹ STRUCTURE ⟹ FUNCTION

Nucleotides and Nucleic Acids

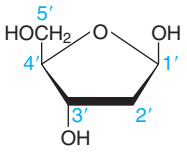
The amino acid sequence of every protein in every organism is prescribed by the genetic information held within the organism's nucleic acids. And, given that the proteins determine how an organism looks and behaves, no role could be more essential.

Monomer Structure and Linkage **Nucleic acids** are *unbranched* polymers made up of monomers called **mononucleotides,** which consist of an N-containing base, a sugar, and a phosphate group. The two types of nucleic acid differ in the sugar portions of their mononucleotides: ***ribo**nucleic **a**cid* (RNA) contains *ribose*, a five-C sugar, and ***deoxyribo**nucleic **a**cid* (DNA) contains *deoxyribose*, in which H replaces OH on the

2′ position. (Carbon atoms in the sugar portion are given numbers with primes to distinguish them from carbon atoms in the base.)

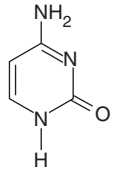


Ribose in RNA

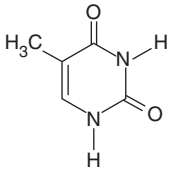


Deoxyribose in DNA

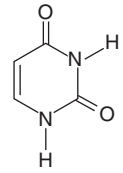
Attached to the sugar molecule at the 1′ carbon is one of four N-containing bases, either a pyrimidine (six-membered ring) or a purine (six- and five-membered rings sharing a side). The pyrimidines are cytosine (C), thymine (T), and uracil (U); thymine occurs in DNA and uracil occurs in RNA. The purines are guanine (G) and adenine (A).



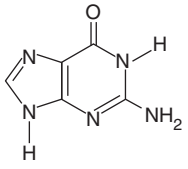
Cytosine (C)
DNA, RNA



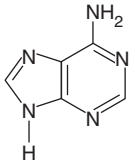
Thymine (T)
DNA



Uracil (U)
RNA

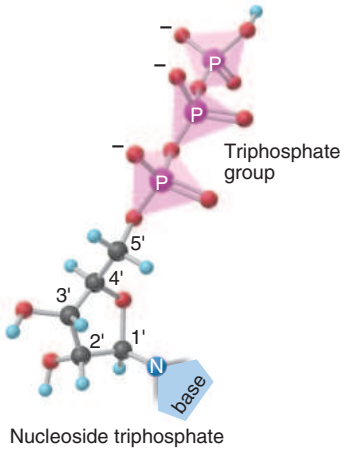


Guanine (G)
DNA, RNA

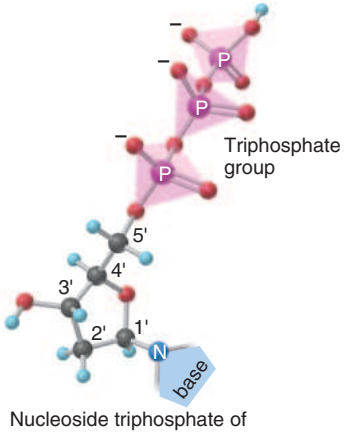


Adenine (A)
DNA, RNA

A phosphate group is attached to the 5′ carbon of the sugar. The cellular precursors that form a nucleic acid are *nucleoside triphosphates* (Figure 15.33A). Dehydration-condensation reactions between them release inorganic diphosphate ($HO_3P—O—PO_3H^{2-}$) and create a *phosphodiester bond* between the phosphate group

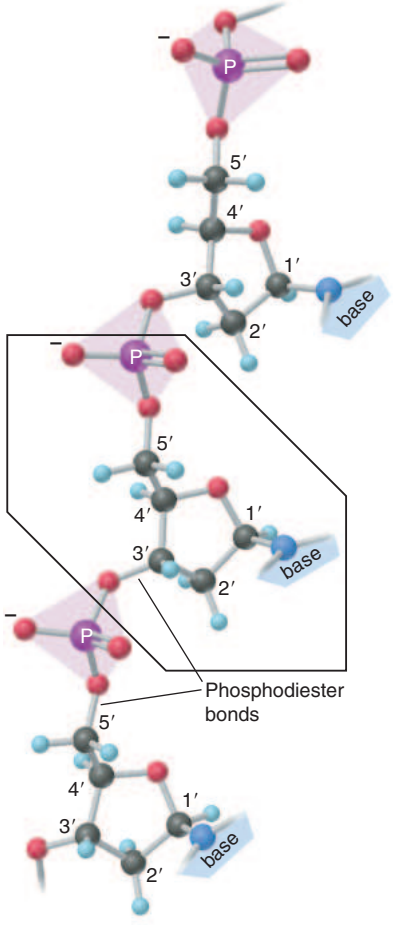


Nucleoside triphosphate of ribonucleic acid (RNA)



Nucleoside triphosphate of deoxyribonucleic acid (DNA)

A



Portion of DNA polynucleotide chain

B

Figure 15.33 Nucleic acid precursors and their linkage.

on the 5′ carbon of one sugar and the —OH group on the 3′ carbon of a second sugar, thereby building up a polynucleotide chain. Therefore, *the repeating pattern of the nucleic acid backbone is sugar-phosphate-sugar-phosphate,* and so on (Figure 15.33B), with the bases dangling off the chain, much as R groups dangle off the polypeptide chain of a protein.

The Central Importance of Base Pairing In the cell nucleus, DNA exists as two chains wrapped around each other in a **double helix** (Figure 15.34). The polar sugar-phosphate backbone of each chain interacts with water. In the DNA core, the *nonpolar bases form intrachain H bonds,* which hold the chains together. A double helical DNA molecule may contain many millions of H-bonded bases. Two features of these **base pairs** are crucial to the structure and function of DNA:

- A pyrimidine and a purine are always paired, which gives the double helix a constant diameter.
- Each base is paired with the same partner: A always with T, and G always with C. Thus, *the base sequence on one chain is the complement of the base sequence on the other.* For example, the sequence A—C—T on one chain is *always* paired with the sequence T—G—A on the other: A with T, C with G, and T with A.

Each DNA molecule is crumpled into a tangled mass that forms one of the cell's *chromosomes.* But, the DNA molecule is amazingly long and thin: if the largest human chromosome were stretched out, it would be 4 cm (more than 1.5 in) long; in the cell nucleus, however, it is wound into a structure only 5 nm in diameter—8 million times shorter! Segments of the DNA chains are the *genes* that contain the chemical information for synthesizing the organism's proteins.

Protein Synthesis *The information content of a gene resides in its base sequence.* In the **genetic code,** each base acts as a "letter," each three-base sequence as a "word," and *each word codes for a specific amino acid.* For example, the sequence C—A—C codes for the amino acid histidine, A—A—G codes for lysine, and so on. Through an amazingly complex series of interactions, greatly simplified in Figure 15.35, one

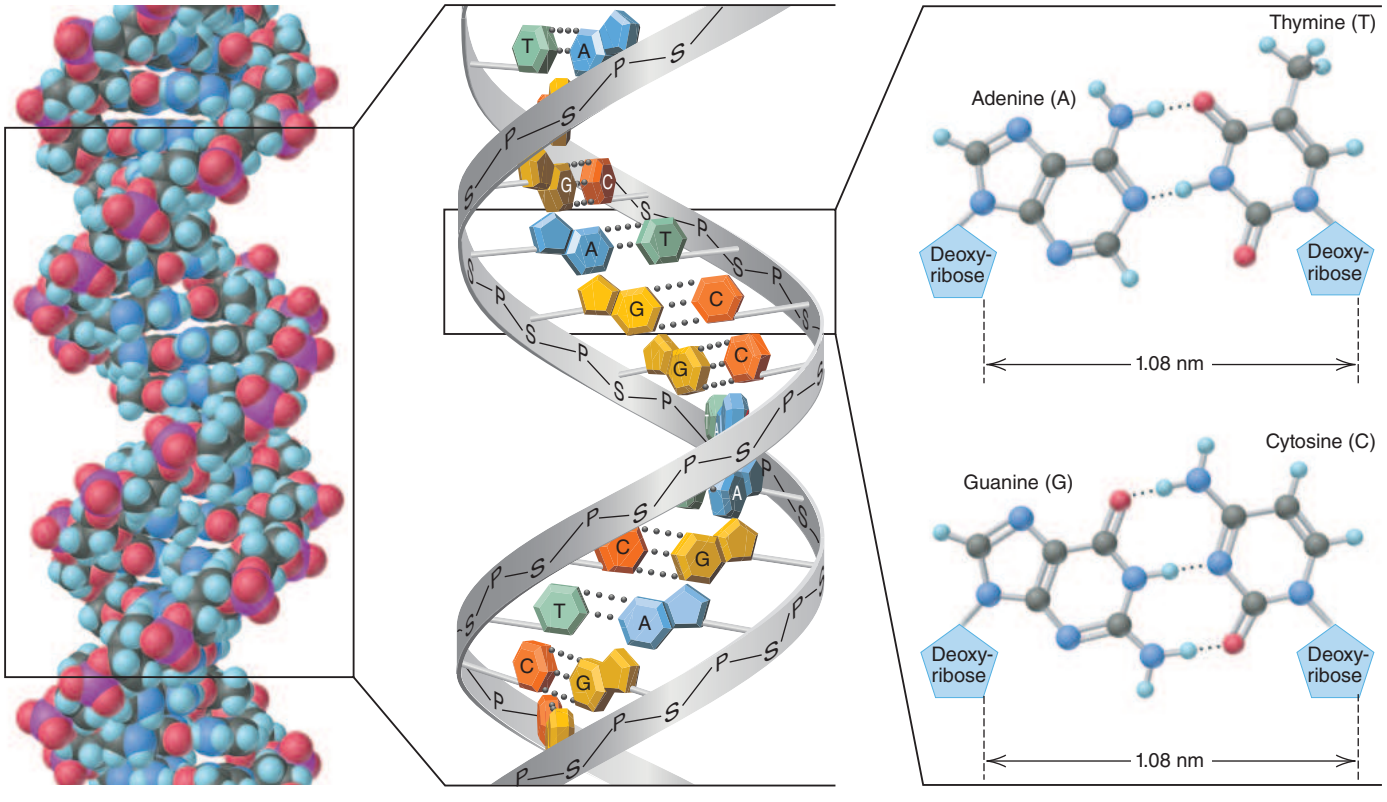


Figure 15.34 The double helix of DNA and a section showing base pairs.

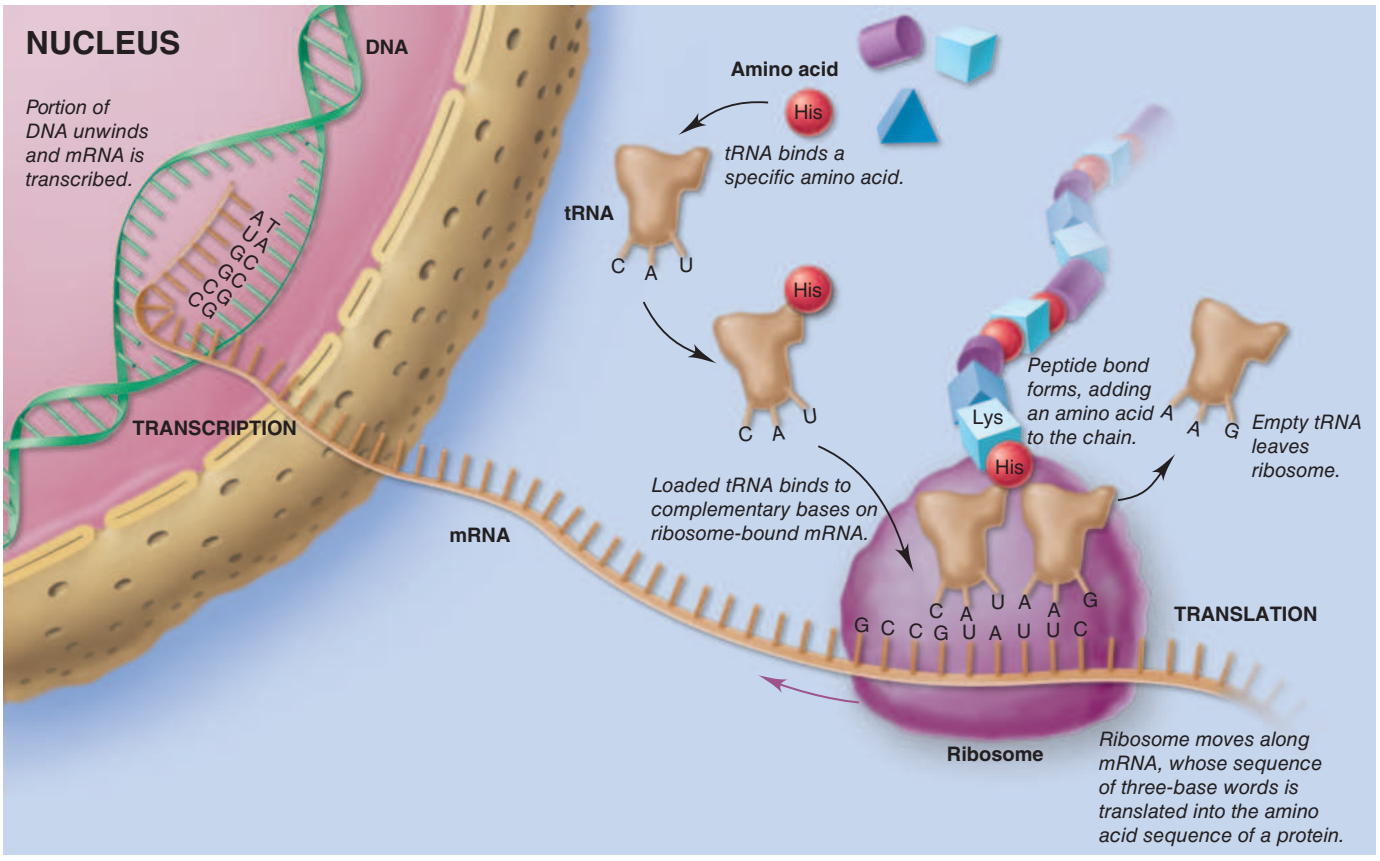

Figure 15.35 Key stages in protein synthesis.

amino acid at a time is positioned and linked to the next to synthesize a protein. To fully appreciate this aspect of the chemical basis of biology, keep in mind that *this complex process occurs largely through H bonding between base pairs.*

There are two main steps in protein synthesis, transcription and translation. DNA occurs in the cell nucleus, but the genetic message is decoded in the cytoplasm of the cell. Therefore, the information must be sent from the DNA to the synthesis site. RNA serves this messenger role.

Transcription produces a *messenger RNA* (mRNA) copy of the DNA information; that is, the information is "transcribed" from one nucleic acid to another:

1. A portion of the DNA is temporarily unwound, and one chain segment acts as a template for the formation of a complementary chain of mRNA made by linking individual mononucleoside triphosphates.
2. The DNA code words are transcribed into RNA code words through base pairing. Cytosine (C) and guanine (G) are complementary bases. Adenine (A) is the complementary base for thymine (T) in DNA, and for uracil (U) in RNA.
3. The DNA rewinds, and mRNA moves out of the nucleus through pores in its membrane.

Translation uses the mRNA to synthesize the protein; that is, the genetic message is "translated" from the language of nucleotides to that of amino acids:

1. The mRNA binds, again through base pairing, to an RNA-rich particle in the cell called a *ribosome,* which moves along the mRNA strand.
2. *Transfer RNA* (tRNA), smaller nucleic acid molecules, bring amino acid molecules to the mRNA that is bound to the ribosome. Each tRNA molecule has two key portions. On one end is a three-base sequence that is *the complement of a three-base "word" on the mRNA.* On the opposite end is a *covalent binding site for the amino acid* (greatly enlarged for clarity) that is coded by that word. The tRNA then "shuttles" the correct amino acid to the correct position on the mRNA.

3. The ribosome moves along the bound mRNA, one three-base word at a time, while each tRNA molecule H-bonds to the mRNA, thereby positioning its amino acid next to the previous one.
4. When a tRNA molecule attaches to the mRNA at the ribosome, it releases its amino acid, and an enzyme (not shown) catalyzes formation of a peptide bond to the growing chain of amino acids. Once empty of its amino acid, the tRNA molecule leaves the site.

In essence, then, protein synthesis involves *transcribing* the DNA three-base words into an RNA message of three-base words, and then *translating* the word, via three-base RNA carriers, into the sequence of linked amino acids that make up a protein:

DNA BASE SEQUENCE ⇒ RNA BASE SEQUENCE ⇒ PROTEIN AMINO ACID SEQUENCE

DNA Replication Another complex series of interactions leads to *DNA replication,* the process by which DNA copies itself. When a cell divides, its chromosomes are replicated, or reproduced, ensuring that the new cells have the same number and types of genes. In this process (Figure 15.36):

1. A small portion of the double helix is "unzipped," so each DNA chain can act as a template for a new chain.
2. The bases in each DNA chain are H-bonded with the complementary bases of free mononucleoside triphosphate units.
3. The new units are linked through phosphodiester bonds into a new chain in a process catalyzed by an enzyme called *DNA polymerase*. Gradually, each of the unzipped chains forms the complementary half of a double helix, which results in *two* double helices.

Because each base always pairs with its complement, the original double helix is copied and the genetic makeup of the cell preserved. (Base pairing is central to methods for learning the sequence of nucleotides in genes, and for analyzing evidence in criminal investigations, as the upcoming Chemical Connections essay shows.)

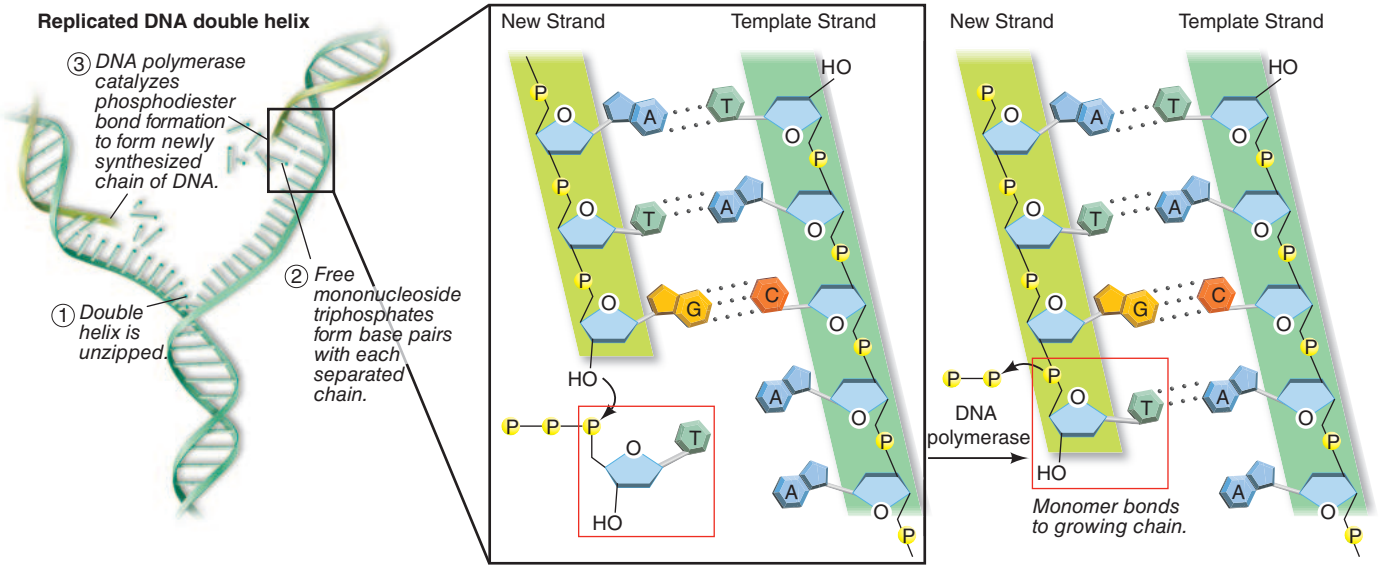

Figure 15.36 Key stages in DNA replication.

Thanks to *DNA sequencing,* the process of determining the identity and order of DNA bases, we now know the sequence of the 3 billion nucleotide base pairs in the DNA of the entire human genome! Sequencing has become indispensable to molecular biology and biochemical genetics.

Just as indispensable to forensic science is *DNA fingerprinting* (or *DNA profiling*), a different process that employs similar methods. Since the discovery that portions of an individual's DNA are as unique as fingerprints, this technique has been applied in countless situations, from confirming the parents of a child to identifying the victims of a terrorist attack.

DNA Sequencing

A given chromosome in the nucleus may have 100 million nucleotide bases, but most common sequencing processes cut the DNA into fragments of a few thousand bases. The chromosome is first broken into pieces by enzymes that cleave at specific sites. Then, to obtain enough sample for analysis, the DNA is replicated through a variety of "amplification" methods, which make many copies of the individual DNA "target" fragments.

One of the most popular approaches is the *Sanger chain-termination method,* which uses chemically altered bases to stop the growth of a complementary DNA chain at specific locations. As you've seen, the chain consists of linked 2′-deoxyribonucleoside monophosphate units (dNMP, where N represents A, T, G, or C). The link is a phosphodiester bond from the 3′-OH of one unit to the 5′-OH of the next, and the free monomers used to construct the chain are 2′-deoxyribonucleoside triphosphates (dNTP) (Figure B15.5A). The Sanger method uses a modified monomer, called a *di*deoxyribonucleoside triphosphate (ddNTP), in which the 3′-OH group is also missing from the ribose unit (Figure B15.5B). Once a ddNTP is incorporated into the growing chain, polymerization stops because there is no 3′-OH group to form a phosphodiester bond to the next dNTP unit.

The procedure is shown in Figure B15.6. After several preparation steps, the sample to be sequenced consists of single-stranded DNA target fragments, each of which is attached to one strand of a double-stranded segment of DNA (Figure B15.6A). This sample is divided into four tubes, and to each tube is added

(continued)

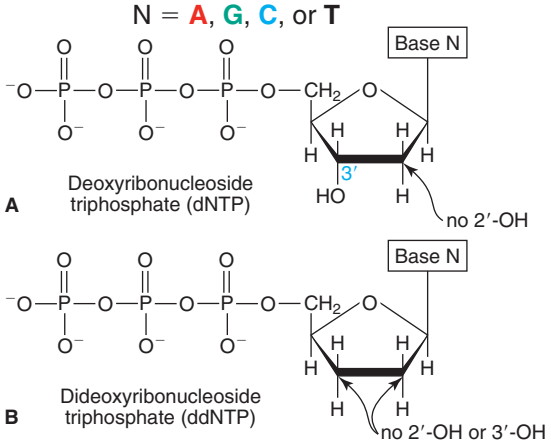

Figure B15.5 Nucleoside triphosphate monomers.

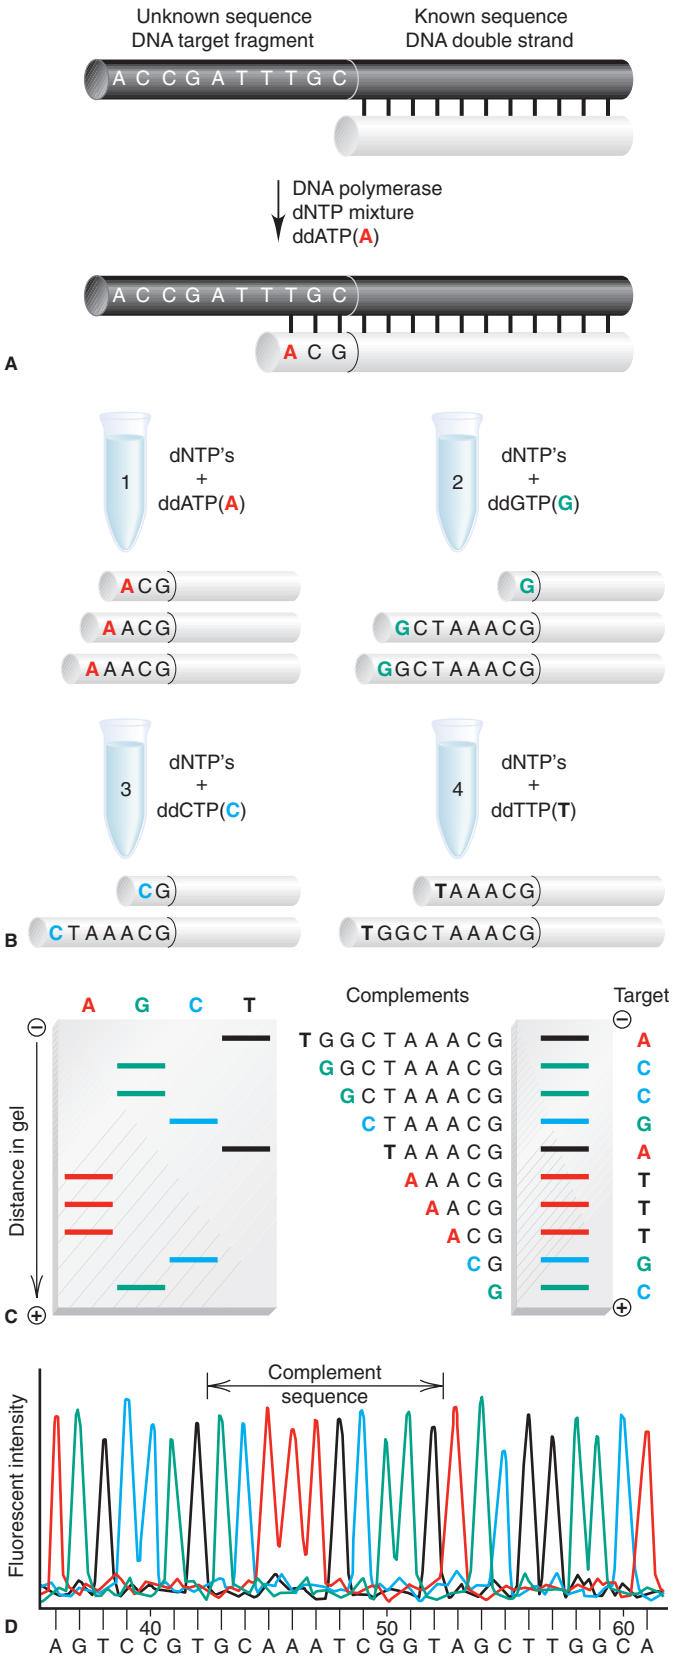

Figure B15.6 Steps in the Sanger method of DNA sequencing.

a mixture of DNA polymerase, large amounts of all four dNTP's, and a small amount of one of the four ddNTP's. Thus, tube 1 contains polymerase, dATP, dGTP, dCTP, and dTTP, and, say, ddATP; tube 2 contains the same mixture with ddGTP instead of ddATP; and so forth. After polymerization is complete, each tube contains the original target fragments paired to complementary chains of varying length (Figure B15.6B). The lengths vary because in tube 1, each complementary chain ends in ddA (designated **A** in the figure); in tube 2, each ends in ddG (**G**); in tube 3, each ends in ddC (**C**); and in tube 4, each ends in ddT (**T**).

Each double-stranded product is divided into single strands, and then the complementary chains are separated by means of *high-resolution polyacrylamide-gel electrophoresis.* This technique applies an electric field to separate charged species through differences in their rate of migration through pores in a gel: the smaller the species, the faster it moves. Polynucleotide fragments can be separated by electrophoresis because they have charged phosphate groups. High-resolution gels have pores that vary so slightly in size they can separate fragments differing by only a single nucleotide.

In this step, each sample is applied to its own "lane" on a gel. After electrophoresis, the gel is scanned to locate the chains, which appear in bands. Because all four ddNTP's were used, all possible chain fragments are formed, so the sequence of the original DNA fragment can be determined (Figure B15.6C).

An automated approach begins with each ddNTP tagged with a different fluorescent dye that emits light of a distinct color. The entire mixture of complementary chains is introduced onto the gel and separated. The gel is scanned by a laser, which activates the dyes. The variation in fluorescent intensity versus distance along the chain is detected and plotted by a computer (Figure B15.6D).

DNA Fingerprinting

Modern techniques of DNA fingerprinting require less than 1 ng of DNA. Thus, in addition to blood and semen, licked stamps and envelopes, chewed gum, and clothing containing dead skin cells can also be sources of DNA.

Currently, the most successful and widely used DNA profiling procedure is called *short tandem repeat (STR) analysis.* STRs are specific areas on a chromosome that contain short (three to seven bases) sequences that repeat themselves within the DNA molecule. There are hundreds of different types of STRs, but each person has a unique number and assortment of types. Therefore, the more STRs that are characterized, the more discriminating the analysis.

Once the STRs have been amplified (multiple copies made), they are separated by electrophoresis, and an analyst determines the number of base repeats within each STR. In Figure B15.7, stained gels containing the STRs of DNA in blood samples from several suspects are compared with STRs from a blood stain at the crime scene. Suspect 3 has a pattern of STRs identical to that in the crime scene sample.

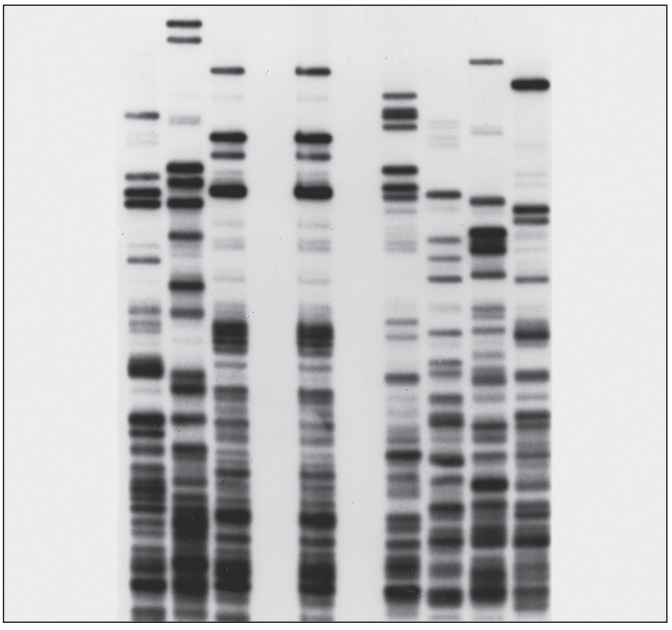

Figure B15.7 **STR analysis of DNA in the blood of seven suspects and in a blood stain found at the crime scene.**

Problems

B15.4 If you were analyzing a DNA fragment with the base sequence TACAGGTTCAGT, how many complementary chain pieces would you obtain in the tube containing ddATP? In the tube containing ddCTP?

B15.5 A DNA fragment is sequenced and the following complementary chain pieces are obtained from the four tubes:

1. The ddATP tube contains ATG and ATATG.
2. The ddTTP tube contains TG and TATG.
3. The ddCTP tube contains CATATG.
4. The ddGPT tube contains G.

What is the sequence of bases in the DNA fragment? Draw a sketch of the electrophoresis gel for this fragment similar to the one shown in Figure B15.6C.

Summary of Section 15.6

- The three types of natural polymers—polysaccharides, proteins, and nucleic acids—are formed by dehydration-condensation reactions.
- Polysaccharides are formed from cyclic monosaccharides, such as glucose. Cellulose, starch, and glycogen have structural or energy-storage roles.
- Proteins are polyamides formed from as many as 20 different types of amino acids. Fibrous proteins have extended shapes and play structural roles. Globular proteins have compact shapes and play metabolic, immunologic, and hormonal roles. The amino acid sequence of a protein determines its shape and function.
- Nucleic acids (DNA and RNA) are polynucleotides consisting of four different types of mononucleotides. The base sequence of the DNA chain determines the sequence of amino acids in an organism's proteins. Hydrogen bonding between specific base pairs is the key to protein synthesis and DNA replication.
- DNA sequencing is used to determine the identity and order of nucleotides in a fragment of a DNA chain; DNA fingerprinting is used to identify a person from the unique sequence of bases in his or her DNA.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How carbon's atomic properties give rise to its ability to form four strong covalent bonds, multiple bonds, and chains, which results in the great structural diversity of organic compounds (§15.1)
2. How carbon's atomic properties give rise to its ability to bond to various heteroatoms, which creates regions of charge imbalance that result in functional groups (§15.1)
3. Structures and names of alkanes, alkenes, and alkynes (§15.2)
4. The distinctions among constitutional, optical, and geometric isomers (§15.2)
5. The importance of optical isomerism in organisms (§15.2)
6. The effect of restricted rotation around a π bond on the structures and properties of alkenes (§15.2)
7. The nature of organic addition, elimination, and substitution reactions (§15.3)
8. The properties and reaction types of the various functional groups (§15.4):
   - Substitution and elimination for alcohols, alkyl halides, and amines
   - Addition for alkenes, alkynes, and aldehydes and ketones
   - Substitution for the carboxylic acid family (acids, esters, and amides)
9. Why delocalization of electrons causes aromatic rings to have lower reactivity than alkenes (§15.4)
10. The polarity of the carbonyl bond and the importance of organometallic compounds in addition reactions of carbonyl compounds (§15.4)
11. How addition plus elimination lead to substitution in the reactions of the carboxylic acid family (§15.4)
12. How addition and condensation polymers form (§15.5)
13. The three types of biopolymers and their monomers (§15.6)
14. How amino acid sequence determines protein shape, which determines function (§15.6)
15. How complementary base pairing controls the processes of protein synthesis and DNA replication (§15.6)
16. How DNA base sequence determines RNA base sequence, which determines amino acid sequence (§15.6)

Master These Skills

1. Drawing hydrocarbon structures given the number(s) of C atoms, multiple bonds, and rings (SP 15.1)
2. Naming hydrocarbons and drawing expanded, condensed, and carbon skeleton formulas (§15.2 and SP 15.2)
3. Drawing geometric isomers and identifying chiral centers of molecules (SP 15.2)
4. Recognizing the type of organic reaction from the structures of reactants and products (SP 15.3)
5. Recognizing an organic reaction as an oxidation or reduction from the structures of reactants and products (§15.3)
6. Determining reactants and products in reactions of alcohols, alkyl halides, and amines (SP 15.4)
7. Determining the products in a stepwise reaction sequence (SP 15.5)
8. Determining the reactants in reactions involving aldehydes and ketones (SP 15.5)
9. Determining reactants and products in reactions of the carboxylic acid family (SP 15.6)
10. Recognizing and naming the functional groups in organic molecules (SP 15.7)
11. Drawing an abbreviated synthetic polymer structure based on monomer structures (§15.5)
12. Drawing small peptides from amino acid structures (§15.6)
13. Using the base-paired sequence of one DNA strand to predict the sequence of the other (§15.6)

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

The Special Nature of Carbon and the Characteristics of Organic Molecules

Concept Review Questions

15.1 Give the names and formulas of two carbon compounds that are organic and two that are inorganic.

15.2 Explain each statement in terms of atomic properties:
(a) Carbon engages in covalent rather than ionic bonding.
(b) Carbon has four bonds in all its organic compounds.
(c) Carbon forms neither stable cations, like many metals, nor stable anions, like many nonmetals.
(d) Carbon bonds to itself more extensively than does any other element.
(e) Carbon forms stable multiple bonds.

15.3 Carbon bonds to many elements other than itself.
(a) Name six elements that commonly bond to carbon in organic compounds.
(b) Which of these elements are heteroatoms?
(c) Which of these elements are more electronegative than carbon? Less electronegative?
(d) How does bonding of carbon to heteroatoms increase the number of organic compounds?

15.4 Silicon lies just below carbon in Group 4A(14) and also forms four covalent bonds. Why aren't there as many silicon compounds as carbon compounds?

15.5 What is the range of oxidation states for carbon? Name a compound in which carbon has its highest oxidation state and one in which it has its lowest.

15.6 Which of these bonds to carbon would you expect to be relatively reactive: C—H, C—C, C—I, C=O, C—Li? Explain.

The Structures and Classes of Hydrocarbons

(Sample Problems 15.1 and 15.2)

Concept Review Questions

15.7 (a) What structural feature is associated with each type of hydrocarbon: alkane, cycloalkane, alkene, and alkyne?
(b) Give the general formula for each type.
(c) Which hydrocarbons are considered saturated?

15.8 Define each type of isomer: (a) constitutional; (b) geometric; (c) optical. Which types of isomers are stereoisomers?

15.9 Among alkenes, alkynes, and aromatic hydrocarbons, only alkenes exhibit *cis-trans* isomerism. Why don't the others?

15.10 Which objects are asymmetric (have no plane of symmetry): (a) a circular clock face; (b) a football; (c) a dime; (d) a brick; (e) a hammer; (f) a spring?

15.11 Explain how a polarimeter works and what it measures.

15.12 How does an aromatic hydrocarbon differ from a cycloalkane in terms of its bonding? How does this difference affect structure?

Skill-Building Exercises (grouped in similar pairs)

15.13 Draw all possible skeletons for a 7-C compound with
(a) A 6-C chain and 1 double bond
(b) A 5-C chain and 1 double bond
(c) A 5-C ring and no double bonds

15.14 Draw all possible skeletons for a 6-C compound with
(a) A 5-C chain and 2 double bonds
(b) A 5-C chain and 1 triple bond
(c) A 4-C ring and no double bonds

15.15 Add the correct number of hydrogens to each of the skeletons in Problem 15.13.

15.16 Add the correct number of hydrogens to each of the skeletons in Problem 15.14.

15.17 Draw correct structures, by making a single change, for any that are incorrect:

(a) $CH_3-\underset{\displaystyle CH_3}{\overset{\displaystyle CH_3}{\underset{|}{\overset{|}{CH}}}}-CH_2-CH_3$ (b) $CH_3=CH-CH_2-CH_3$

(c) $CH\equiv C-\underset{\displaystyle CH_3}{\overset{\displaystyle CH_2}{\underset{|}{\overset{|}{CH_2}}}}-CH_3$ (d) 
15.18 Draw correct structures, by making a single change, for any that are incorrect:

(a) $CH_3-CH=CH-CH_2-CH_3$ (b) 
(c) $CH_3-C\equiv CH-CH_2-CH_3$ (d) $CH_3-CH_2-\underset{\displaystyle CH_3}{\overset{}{\underset{|}{\overset{|}{C}}}}-CH_2-CH_2-CH_3$

15.19 Draw the structure or give the name of each compound:
(a) 2,3-dimethyloctane (b) 1-ethyl-3-methylcyclohexane

(c) $CH_3-CH_2-\underset{\displaystyle CH_3}{\overset{}{\underset{|}{\overset{|}{CH}}}}-\underset{\displaystyle CH_2-CH_3}{\overset{\displaystyle CH_3}{\underset{|}{\overset{|}{CH}}}}-CH_2$ (d) 
15.20 Draw the structure or give the name of each compound:

(a)  (b) 
(c) 1,2-diethylcyclopentane (d) 2,4,5-trimethylnonane

15.21 Each of the following names is wrong. Draw structures based on them, and correct the names:
(a) 4-methylhexane (b) 2-ethylpentane
(c) 2-methylcyclohexane (d) 3,3-methyl-4-ethyloctane

15.22 Each of the following names is wrong. Draw structures based on them, and correct the names:
(a) 3,3-dimethylbutane (b) 1,1,1-trimethylheptane
(c) 1,4-diethylcyclopentane (d) 1-propylcyclohexane

15.23 Each of the following compounds can exhibit optical activity. Circle the chiral center(s) in each:

(a)  (b) 
15.24 Each of the following compounds can exhibit optical activity. Circle the chiral center(s) in each:

(a)  (b) 
15.25 Draw structures from the following names, and determine which compounds are optically active:
(a) 3-bromohexane (b) 3-chloro-3-methylpentane
(c) 1,2-dibromo-2-methylbutane

15.26 Draw structures from the following names, and determine which compounds are optically active:
(a) 1,3-dichloropentane (b) 3-chloro-2,2,5-trimethylhexane
(c) 1-bromo-1-chlorobutane

15.27 Which of the following structures exhibit geometric isomerism? Draw and name the two isomers in each case:

(a) $CH_3-CH_2-CH=CH-CH_3$ (b) 
(c) $CH_3-\underset{\displaystyle CH_3}{\overset{}{\underset{|}{\overset{|}{C}}}}=CH-\underset{\displaystyle CH_3}{\overset{}{\underset{|}{\overset{|}{CH}}}}-CH_2-CH_3$

15.28 Which of the following structures exhibit geometric isomerism? Draw and name the two isomers in each case:

(a) $CH_3—\underset{\displaystyle CH_3}{\overset{\displaystyle CH_3}{\overset{|}{\underset{|}{C}}}}—CH=CH—CH_3$ (b) 
(c) $Cl—CH_2—CH=\overset{\displaystyle CH_3}{\overset{|}{C}}—CH_2—CH_2—CH_2—CH_3$

15.29 Which compounds exhibit geometric isomerism? Draw and name the two isomers in each case:

(a) propene (b) 3-hexene
(c) 1,1-dichloroethene (d) 1,2-dichloroethene

15.30 Which compounds exhibit geometric isomerism? Draw and name the two isomers in each case:

(a) 1-pentene (b) 2-pentene
(c) 1-chloropropene (d) 2-chloropropene

15.31 Draw and name all the constitutional isomers of dichlorobenzene.

15.32 Draw and name all the constitutional isomers of trimethylbenzene.

Problems in Context

15.33 Butylated hydroxytoluene (BHT) is a common preservative added to cereals and other dry foods. Its systematic name is 1-hydroxy-2,6-di-*tert*-butyl-4-methylbenzene (where "*tert*-butyl" is 1,1-dimethylethyl). Draw the structure of BHT.

15.34 There are two compounds with the name 2-methyl-3-hexene, but only one with the name 2-methyl-2-hexene. Explain with structures.

15.35 Any tetrahedral atom with four different groups attached can be a chiral center. Which of these species is optically active?

(a) CHClBrF (b) $NBrCl_2H^+$
(c) $PFClBrI^+$ (d) SeFClBrH

15.36 Breaking the C=C π bond in the molecule retinal in the eye requires approximately 250 kJ/mol of energy. Find the longest wavelength (in nm) of visible light that has the energy to break the π bond.

Some Important Classes of Organic Reactions

(Sample Problem 15.3)

Concept Review Questions

15.37 In terms of numbers of reactant and product substances, which organic reaction type corresponds to (a) a combination reaction, (b) a decomposition reaction, (c) a displacement reaction?

15.38 The same type of bond is broken in an addition reaction and formed in an elimination reaction. Name the type.

15.39 Can a redox reaction also be an addition, elimination, or substitution reaction? Explain with examples.

Skill-Building Exercises (grouped in similar pairs)

15.40 Determine the type of each of the following reactions:

(a) $CH_3—CH_2—\overset{\displaystyle Br}{\overset{|}{C}}H—CH_3 \xrightarrow[\Delta]{NaOH} CH_3—CH=CH—CH_3 + NaBr + H_2O$

(b) $CH_3—CH=CH—CH_2—CH_3 + H_2 \xrightarrow{Pt} CH_3—CH_2—CH_2—CH_2—CH_3$

15.41 Determine the type of each of the following reactions:

(a) $CH_3—\overset{\displaystyle O}{\overset{\|}{C}}H + HCN \longrightarrow CH_3—\overset{\displaystyle OH}{\overset{|}{C}}H—CN$

(b) $CH_3—\overset{\displaystyle O}{\overset{\|}{C}}—O—CH_3 + CH_3—NH_2 \xrightarrow{H^+} CH_3—\overset{\displaystyle O}{\overset{\|}{C}}—NH—CH_3 + CH_3—OH$

15.42 Write equations for the following: (a) an addition reaction between H_2O and 3-hexene (H^+ is a catalyst); (b) an elimination reaction between 2-bromopropane and hot potassium ethoxide, $CH_3—CH_2—OK$ (KBr and ethanol are also products); (c) a light-induced substitution reaction between Cl_2 and ethane to form 1,1-dichloroethane.

15.43 Write equations for the following: (a) a substitution reaction between 2-bromopropane and KI; (b) an addition reaction between cyclohexene and Cl_2; (c) an addition reaction between 2-propanone and H_2 (Ni metal is a catalyst).

15.44 Based on the number of bonds and the nature of the bonded atoms, state whether each of the following changes is an oxidation or a reduction:

(a) $=CH_2$ becomes $—CH_2—OH$

(b) $=CH—$ becomes $—CH_2—$

(c) $\equiv C—$ becomes $—CH_2—$

15.45 Based on the number of bonds and the nature of the bonded atoms, state whether each of the following changes is an oxidation or a reduction:

(a) $—\overset{|}{\underset{|}{C}}—OH$ becomes $—\overset{|}{\underset{|}{C}}=O$

(b) $—CH_2—OH$ becomes $=CH_2$

(c) $—\overset{\displaystyle O}{\overset{\|}{C}}—\overset{|}{\underset{|}{C}}—$ becomes $—\overset{\displaystyle O}{\overset{\|}{C}}—O—$

15.46 Is the organic reactant oxidized, reduced, or neither in each of the following reactions?

(a) 2-hexene $\xrightarrow[\text{cold OH}^-]{KMnO_4}$ 2,3-dihydroxyhexane

(b) cyclohexane $\xrightarrow[\text{catalyst}]{\Delta}$ benzene + $3H_2$

15.47 Is the organic reactant oxidized, reduced, or neither in each of the following reactions?

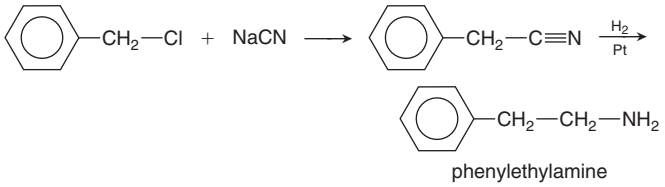
(a) 1-butyne + $H_2 \xrightarrow{Pt}$ 1-butene

(b) toluene $\xrightarrow[H_3O^+, \Delta]{KMnO_4}$ benzoic acid

Problems in Context

15.48 Phenylethylamine is a natural substance that is structurally similar to amphetamine. It is found in sources as diverse as almond oil and human urine, where it occurs at elevated concentrations as a result of stress and certain forms of schizophrenia.

One method of synthesizing the compound for pharmacological and psychiatric studies involves two steps:



Classify each step as an addition, elimination, or substitution.

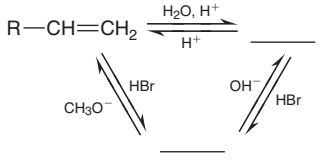
Properties and Reactivities of Common Functional Groups

(Sample Problems 15.4 to 15.7)

Concept Review Questions

15.49 Compounds with nearly identical molar masses often have very different physical properties. Choose the compound with the higher value for each of the following properties, and explain your choice.
(a) Solubility in water: chloroethane or methylethylamine
(b) Melting point: diethyl ether or 1-butanol
(c) Boiling point: trimethylamine or propylamine

15.50 Fill in each blank with a general formula for the type of compound formed:



15.51 Of the three major types of organic reactions, which do *not* occur readily with benzene? Why?

15.52 Why does the C=O group react differently from the C=C group? Show an example of the difference.

15.53 Many substitution reactions are initiated by electrostatic attraction between reactants. Show where this attraction arises in the formation of an amide from an amine and an ester.

15.54 Although both carboxylic acids and alcohols contain an —OH group, one is acidic in water and the other is not. Explain.

15.55 What reaction type is common to the formation of esters and acid anhydrides? What is the other product?

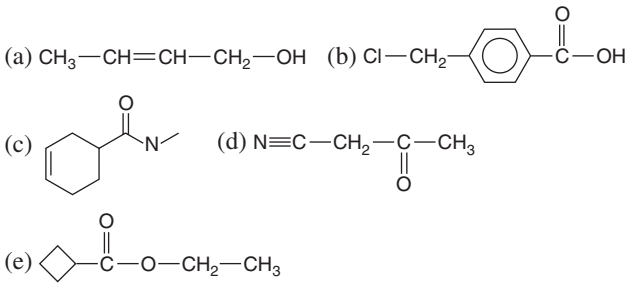
15.56 Both alcohols and carboxylic acids undergo substitution, but the processes are very different. Explain.

Skill-Building Exercises (grouped in similar pairs)

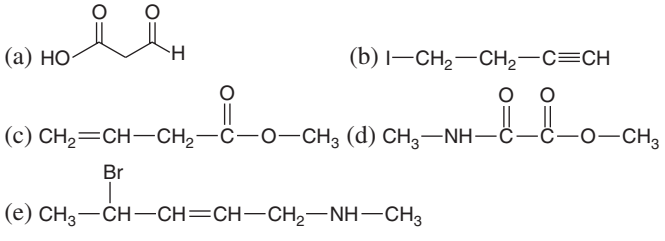
15.57 Name the type of organic compound from each description of the functional group: (a) polar group that has only single bonds and does not include O or N; (b) group that is polar and has a triple bond; (c) group that has single and double bonds and is acidic in water; (d) group that has a double bond and must be at the end of a C chain.

15.58 Name the type of organic compound from each description of the functional group: (a) N-containing group with single and double bonds; (b) group that is not polar and has a double bond; (c) polar group that has a double bond and cannot be at the end of a C chain; (d) group that has only single bonds and is basic in water.

15.59 Circle and name the functional group(s) in each molecule:



15.60 Circle and name the functional group(s) in each molecule:



15.61 Draw all alcohols with the formula $C_5H_{12}O$.

15.62 Draw all aldehydes and ketones with the formula $C_5H_{10}O$.

15.63 Draw all amines with the formula $C_4H_{11}N$.

15.64 Draw all carboxylic acids with the formula $C_5H_{10}O_2$.

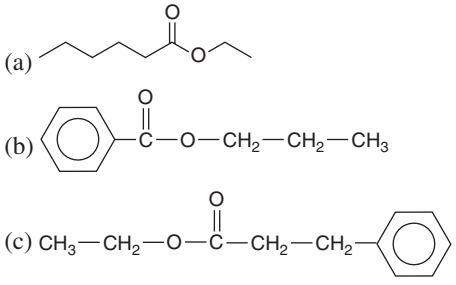
15.65 Draw the product resulting from mild oxidation of (a) 2-butanol; (b) 2-methylpropanal; (c) cyclopentanol.

15.66 Draw the alcohol you'd oxidize to produce (a) 2-methylpropanal; (b) 2-pentanone; (c) 3-methylbutanoic acid.

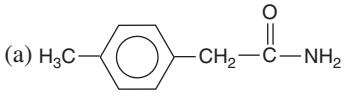
15.67 Draw the organic product formed when the following compounds undergo a substitution reaction: (a) acetic acid and methylamine; (b) butanoic acid and 2-propanol; (c) formic acid and 2-methyl-1-propanol.

15.68 Draw the organic product formed when the following compounds undergo a substitution reaction: (a) acetic acid and 1-hexanol; (b) propanoic acid and dimethylamine; (c) ethanoic acid and diethylamine.

15.69 Draw condensed formulas for the carboxylic acid and alcohol that form the following esters:



15.70 Draw condensed formulas for the carboxylic acid and amine that form the following amides:



(b)  (c) 
15.71 Fill in the expected organic substances:

(a) $CH_3—CH_2—Br \xrightarrow{OH^-}$ ____ $\xrightarrow[H^+]{CH_3—CH_2—C(=O)—OH}$ ____

(b) $CH_3—CH_2—\underset{\displaystyle Br}{\underset{|}{CH}}—CH_3 \xrightarrow{CN^-}$ ____ $\xrightarrow{H_3O^+,\ H_2O}$ ____

15.72 Fill in the expected organic substances:

(a) $CH_3—CH_2—CH=CH_2 \xrightarrow{H^+,\ H_2O}$ ____ $\xrightarrow{Cr_2O_7^{2-},\ H^+}$ ____

(b) $CH_3—CH_2—C(=O)—CH_3 \xrightarrow{CH_3—CH_2—Li}$ ____ $\xrightarrow{H_2O}$ ____

15.73 Supply the missing organic and/or inorganic substances:

(a) $CH_3—CH_2—OH + \underline{\quad ? \quad} \xrightarrow{H_3O^+,\ H_2O} CH_3—CH_2—O—C(=O)—CH_2—CH_3$

(b) $CH_3—C(=O)—O—CH_3 \xrightarrow{?} CH_3—CH_2—NH—C(=O)—CH_3$

15.74 Supply the missing organic and/or inorganic substances:

(a) $CH_3—\underset{\displaystyle Cl}{\underset{|}{CH}}—CH_3 \xrightarrow{?} CH_3—CH=CH_2 \xrightarrow{?} CH_3—\underset{\displaystyle Br}{\underset{|}{CH}}—\underset{\displaystyle Br}{\underset{|}{CH_2}}$

(b) $CH_3—CH_2—CH_2—OH \xrightarrow{?} CH_3—CH_2—C(=O)—OH + \underline{\quad ? \quad} \xrightarrow{?} CH_3—CH_2—C(=O)—O—CH_2—C_6H_5$

Problems in Context

15.75 (a) Draw the four isomers of $C_5H_{12}O$ that can be oxidized to an aldehyde. (b) Draw the three isomers of $C_5H_{12}O$ that can be oxidized to a ketone. (c) Draw the isomers of $C_5H_{12}O$ that cannot be easily oxidized to an aldehyde or ketone. (d) Name any isomer that is an alcohol.

15.76 Ethyl formate ($HC(=O)—O—CH_2—CH_3$) is added to foods to give them the flavor of rum. How would you synthesize ethyl formate from ethanol, methanol, and any inorganic reagents?

The Monomer-Polymer Theme I: Synthetic Macromolecules

Concept Review Questions

15.77 Name the reaction processes that lead to the two types of synthetic polymers.

15.78 Which functional group occurs in the monomers of addition polymers? How are these polymers different from one another?

15.79 What is a free radical? How is it involved in polymer formation?

15.80 Which intermolecular force is primarily responsible for the different types of polyethylene? Explain.

15.81 Which of the two types of synthetic polymer is more similar chemically to biopolymers? Explain.

15.82 Which functional groups react to form nylons? Polyesters?

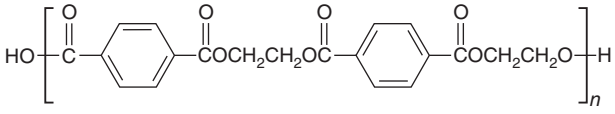
Skill-Building Exercises (grouped in similar pairs)

15.83 Draw an abbreviated structure for the following polymers, with brackets around the repeat unit:

(a) Poly(vinyl chloride) (PVC) from 
(b) Polypropylene from 
15.84 Draw an abbreviated structure for the following polymers, with brackets around the repeat unit:

(a) Teflon from  (b) Polystyrene from 
Problems in Context

15.85 Polyethylene terephthalate (PET) is used to make synthetic fibers, such as Dacron, thin films, such as Mylar, and bottles for carbonated beverages.



PET

PET is produced from ethylene glycol and either of two monomers, depending on whether the reaction proceeds by dehydration-condensation or by displacement. Write equations for the two syntheses. (*Hint:* The displacement is reversed by adding methanol to PET at high T and P.)

15.86 Write a balanced equation for the reaction of dihydroxydimethylsilane *(right)* to form the condensation polymer known as Silly Putty. 
The Monomer-Polymer Theme II: Biological Macromolecules

Concept Review Questions

15.87 Which type of polymer is formed from each of the following monomers: (a) amino acids; (b) alkenes; (c) simple sugars; (d) mononucleotides?

15.88 What is the key structural difference between fibrous and globular proteins? How is it related, in general, to the proteins' amino acid composition?

15.89 Protein shape, function, and amino acid sequence are interrelated. Which determines which?

15.90 What linkage joins the monomers in each strand of DNA?

15.91 What is base pairing? How does it pertain to DNA structure?

15.92 RNA base sequence, protein amino acid sequence, and DNA base sequence are interrelated. Which determines which in the process of protein synthesis?

Skill-Building Exercises (grouped in similar pairs)

15.93 Draw the R group of (a) alanine; (b) histidine; (c) methionine.

15.94 Draw the R group of (a) glycine; (b) isoleucine; (c) tyrosine.

15.95 Draw the structure of each of the following tripeptides:
(a) Aspartic acid-histidine-tryptophan
(b) Glycine-cysteine-tyrosine with the charges that exist in cell fluid

15.96 Draw the structure of each of the following tripeptides:
(a) Lysine-phenylalanine-threonine
(b) Alanine-leucine-valine with the charges that exist in cell fluid

15.97 Write the sequence of the complementary DNA strand that pairs with each of the following DNA base sequences:
(a) TTAGCC (b) AGACAT

15.98 Write the sequence of the complementary DNA strand that pairs with each of the following DNA base sequences:
(a) GGTTAC (b) CCCGAA

15.99 Write the base sequence of the DNA template from which this RNA sequence was derived: UGUUACGGA. How many amino acids are coded for in this sequence?

15.100 Write the base sequence of the DNA template from which this RNA sequence was derived: GUAUCAAUGAACUUG. How many amino acids are coded for in this sequence?

Problems in Context

15.101 Protein shapes are maintained by a variety of forces that arise from interactions between the amino-acid R groups. Name the amino acid that possesses each R group and the force that could arise in each of the following interactions:

(a) $-CH_2-SH$ with $HS-CH_2-$

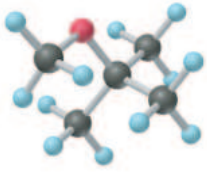
(b) $-(CH_2)_4-NH_3^+$ with $^-O-\overset{\overset{O}{\|}}{C}-CH_2-$

(c) $-CH_2-\overset{\overset{O}{\|}}{C}-NH_2$ with $HO-CH_2-$

(d) $-\underset{\underset{CH_3}{|}}{CH}-CH_3$ with 
15.102 Amino acids have an average molar mass of 100 g/mol. How many bases on a single strand of DNA are needed to code for a protein with a molar mass of 5×10^5 g/mol?

Comprehensive Problems

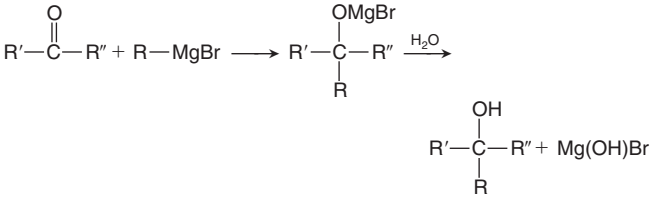
15.103 Ethers (general formula R—O—R′) have many important uses. Until recently, methyl *tert*-butyl ether (MTBE, *below*) was used as an octane booster and fuel additive for gasoline. It increases the oxygen content of the fuel, which reduces CO emissions. MTBE is synthesized by the catalyzed reaction of 2-methylpropene with methanol.



(a) Write a balanced equation for the synthesis of MTBE. (*Hint:* Alcohols add to alkenes similarly to the way water does.)
(b) If the government required that auto fuel mixtures contain 2.7% oxygen by mass to reduce CO emissions, how many grams of MTBE would have to be added to each 100. g of gasoline?
(c) How many liters of MTBE would be in each liter of fuel mixture? (The density of both gasoline and MTBE is 0.740 g/mL.)
(d) How many liters of air (21% O_2 by volume) are needed at 24°C and 1.00 atm to fully combust 1.00 L of MTBE?

15.104 An alcohol is oxidized to a carboxylic acid, and 0.2003 g of the acid is titrated with 45.25 mL of 0.03811 *M* NaOH. (a) What is the molar mass of the acid? (b) What are the molar mass and molecular formula of the alcohol?

15.105 Some of the most useful compounds for organic synthesis are Grignard reagents (general formula R—MgX, where X is a halogen), which are made by combining an alkyl halide, R—X, with Mg. They are used to change the carbon skeleton of a starting carbonyl compound in a reaction similar to that with R—Li:



(a) What is the product, after a final step with water, of the reaction between ethanal and the Grignard reagent of bromobenzene? (b) What is the product, after a final step with water, of the reaction between 2-butanone and the Grignard reagent of 2-bromopropane? (c) There are often two (or more) combinations of Grignard reagent and carbonyl compound that will give the same product. Choose another pair of reactants to give the product in (a). (d) What carbonyl compound must react with a Grignard reagent to yield a product with the —OH group at the *end* of the carbon chain? (e) What Grignard reagent and carbonyl compound would you use to prepare 2-methyl-2-butanol?

15.106 Starting with the given organic reactant and any necessary inorganic reagents, explain how you would perform each of the following syntheses:

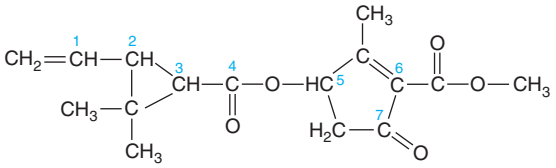
(a) From $CH_3-CH_2-CH_2-OH$, make $CH_3-\underset{\underset{Br}{|}}{CH}-CH_2-Br$

(b) From $CH_3-CH_2-CH_2-OH$, make $CH_3-\overset{\overset{O}{\|}}{C}-O-CH_2-CH_3$

15.107 Compound A, composed of C, H, and O, is heated in a 1.00-L flask to 160.°C until all of the A has vaporized and displaced the air. The flask is then cooled, and 2.48 g of A remains. When 0.500 g of A burns in O_2, 0.409 g of H_2O and 1.00 g of CO_2 are produced. Compound A is not acidic, but it can be oxidized to compound B, which is weakly acidic: 1.000 g of B is neutralized with 33.9 mL of 0.5 *M* sodium hydroxide. When B is heated to 260°C, it gives off water and forms C, whose solution in $CDCl_3$ (where D is deuterium, ^2H) has one peak in its ^1H-NMR spectrum. (a) What are the structures of A, B, and C? (b) Compound A is a controlled substance because it is metabolized to the weakly acidic "date rape" drug GHB, $C_4H_8O_3$. What are the structure and name of GHB?

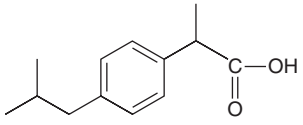
15.108 Cadaverine (1,5-diaminopentane) and putrescine (1,4-diaminobutane) are two compounds that are formed by bacterial action and are responsible for the odor of rotting flesh. Draw their structures. Suggest a series of reactions to synthesize putrescine from 1,2-dibromoethane and any inorganic reagents.

15.109 Pyrethrins, such as jasmolin II *(facing page),* are a group of natural compounds synthesized by flowers of the genus *Chrysanthemum* (known as pyrethrum flowers) to act as insecticides.
(a) Circle and name the functional groups in jasmolin II.
(b) What is the hybridization of the numbered carbons?
(c) Which, if any, of the numbered carbons are chiral centers?

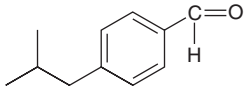


15.110 Compound A is branched and optically active and contains C, H, and O. (a) A 0.500-g sample burns in excess O_2 to yield 1.25 g of CO_2 and 0.613 g of H_2O. Determine the empirical formula. (b) When 0.225 g of compound A vaporizes at 755 torr and 97°C, the vapor occupies 78.0 mL. Determine the molecular formula. (c) Careful oxidation of the compound yields a ketone. Name and draw compound A, and circle the chiral center.

15.111 Ibuprofen is one of the most common anti-inflammatory drugs. (a) Identify the functional group(s) and chiral center(s) in ibuprofen. (b) Write a four-step synthesis of a racemic mixture of ibuprofen from 4-isobutylbenzaldehyde, using inorganic reactants and one organometallic reactant (see Problem 15.105).



ibuprofen



4-isobutylbenzaldehyde

15.112 Which features of retinal make it so useful as a photon absorber in the visual systems of organisms?

15.113 The polypeptide chain in proteins does not exhibit free rotation because of the partial double-bond character of the peptide bond. Explain this fact with resonance structures.

15.114 Other nonmetals form compounds that are structurally analogous to those of carbon, but these inorganic compounds are usually more reactive. Predict any missing products and write balanced equations for each reaction: (a) the decomposition and chlorination of diborane to boron trichloride; (b) the combustion of pentaborane (B_5H_9) in O_2; (c) the hydrolysis of trisilane (Si_3H_8) to silica (SiO_2) and H_2; (d) the complete halogenation of disilane with Cl_2; (e) the thermal decomposition of H_2S_5 to hydrogen sulfide and sulfur molecules; (f) the hydrolysis of PCl_5.

15.115 In addition to their use in water treatment, ion-exchange resins are used to extract Au, Ag, and Pt ions from solution. One of the most common resins consists of a polymer with a benzene-containing backbone to which sulfonic acid groups (—SO_3H) have been added. (a) What monomer can be used to prepare the polymer backbone? (b) This polymer typically contains 4–16% crosslinking. Draw the structure of the benzene-containing monomer used to crosslink the polymer.

15.116 Complete hydrolysis of a 100.00-g sample of a peptide gave the following amounts of individual amino acids (molar masses, in g/mol, appear in parentheses):

3.00 g of glycine (75.07)	0.90 g of alanine (89.10)
3.70 g of valine (117.15)	6.90 g of proline (115.13)
7.30 g of serine (105.10)	86.00 g of arginine (174.21)

(a) Why does the total mass of amino acids exceed the mass of peptide? (b) What are the relative numbers of amino acids in the peptide? (c) What is the minimum molar mass of the peptide?

15.117 2-Butanone is reduced by hydride ion donors, such as sodium borohydride ($NaBH_4$), to the alcohol 2-butanol. Even though the alcohol has a chiral center, the product isolated from the redox reaction is not optically active. Explain.

15.118 Wastewater from a cheese factory has the following composition: 8.0 g/L protein ($C_{16}H_{24}O_5N_4$); 12 g/L carbohydrate (CH_2O); and 2.0 g/L fat ($C_8H_{16}O$). What is the total organic carbon (TOC) of the wastewater in g of C/L?

15.119 Structures A, B, and C show the three common forms of vitamin A. (a) Match each structure with the correct vitamin A compound: retinal (an aldehyde), retinol (an alcohol), and retinoic acid (a carboxylic acid). (b) Retinal, the molecule responsible for the chemistry of vision, can be converted to retinol or to retinoic acid. Identify each of these reactions as a reduction or an oxidation. (c) Structure D is that of beta-carotene, found in carrots. Suggest a reason for the importance of beta-carotene in the vision process.

Concepts and Skills to Review Before You Study This Chapter

› influence of temperature on molecular speed and collision frequency (Section 5.5)

You are part of a small, thermoregulatory minority. About 85% of animal species—all reptiles and most amphibians, insects, and fish—rely predominantly on heat from the environment to maintain the speeds of the reactions that keep them alive. Only mammals (like us) and birds generate enough heat within their bodies for these reactions to proceed at a life-sustaining pace. Temperature, as you'll see, has a critical effect on the speed, or rate, of a reaction.

Until now, we haven't focused quantitatively on factors affecting reactions, other than the amounts of reactants and products and their molecular nature. Yet, while a balanced equation is essential for calculating yields, it tells us nothing about three dynamic aspects of chemical change:

- How fast is the reaction proceeding?
- How far will the reaction proceed toward completion?
- Will the reaction proceed by releasing energy or by absorbing it?

This chapter addresses the first of these questions and focuses on the field of *kinetics*. We'll address the other two questions in upcoming chapters. Answering all three is crucial to understanding modern technology, the environment, and the reactions in living things.

IN THIS CHAPTER . . . *We examine the rate of a reaction, the factors that affect it, the theories that explain those effects, and the stepwise changes reactants undergo as they transform into products.*

› We introduce some general ideas about reaction rates and overview three key factors that affect them—concentration, physical state, and temperature.
› We express rate through a rate law and determine its components.
› We see how concentrations change as a reaction proceeds and discuss the meaning of reaction half-life.
› To understand the effects of concentration and temperature on rate, we examine two related theories of chemical kinetics.
› We discuss reaction mechanisms, noting the steps a reaction goes through and picturing the chemical species that exists as reactant bonds are breaking and product bonds are forming.
› We see how catalysts increase reaction rates, highlighting two vital examples— the reactions in a living cell and the depletion of stratospheric ozone.

16.1 FOCUSING ON REACTION RATE

By definition, in a chemical reaction, reactants change into products. **Chemical kinetics,** the study of how fast that change occurs, focuses on the **reaction rate,** the change in the concentrations of reactants (or products) as a function of time. Different reactions have different rates: *in a faster reaction (higher rate), the reactant concentration decreases quickly, whereas in a slower reaction (lower rate), it decreases slowly* (Figure 16.1, *next page*). Under any given set of conditions, a rate is determined by the nature of the reactants. At room temperature, for example, hydrogen reacts explosively with fluorine but extremely slowly with nitrogen:

$$H_2(g) + F_2(g) \longrightarrow 2HF(g) \quad \text{[very fast]}$$
$$3H_2(g) + N_2(g) \longrightarrow 2NH_3(g) \quad \text{[very slow]}$$

Furthermore, any given reaction has a different rate under different conditions.

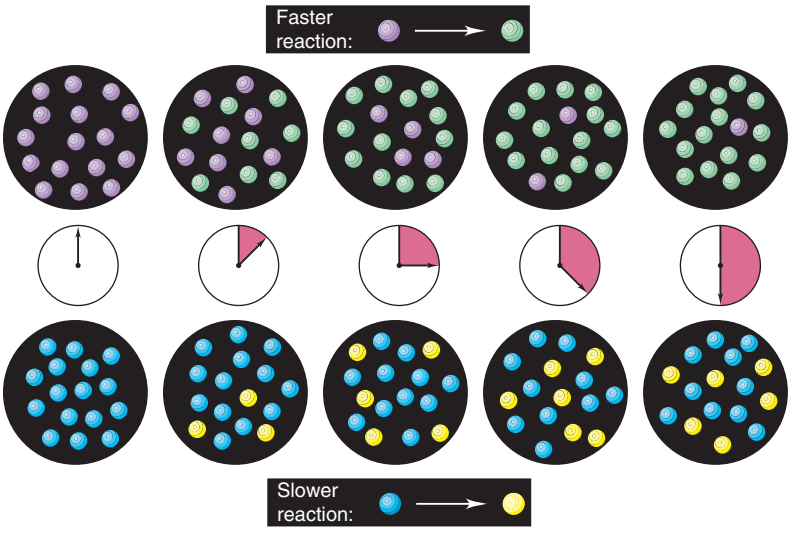

Figure 16.1 A faster reaction *(top)* and a slower reaction *(bottom).* As time elapses, reactant *decreases* and product *increases.*

Chemical processes occur over a wide range of rates (Figure 16.2). Some—like a neutralization, a precipitation, or an explosion—may take a second or less. Processes that include many reactions—like the ripening of fruit—take days to months. Human aging continues for decades, and the formation of coal from dead plants takes hundreds of millions of years. Knowing the reaction rate can be essential: how quickly a medicine acts can make the difference between life and death, and how long a commercial product takes to form can make the difference between profit and loss.

We can control four factors that affect rate: the concentrations of reactants, their physical state, the temperature of the reaction, and the use of a catalyst. We consider the first three here and the fourth in Section 16.7.

1. *Concentration: molecules must collide to react.* A major factor influencing reaction rate is reactant concentration. Consider the reaction between ozone and nitrogen monoxide (nitric oxide):

$$NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g)$$

This reaction occurs in the stratosphere, where the oxide is released in the exhaust gases of supersonic aircraft, but it can be simulated in the lab. In a reaction vessel, the molecules zoom every which way, crashing into each other and the vessel walls, but a reaction can occur only when NO and O_3 molecules collide. The more molecules present, the more frequently they collide, and the more often they react. Thus, *reaction rate is proportional to the number of collisions, which depends on the concentration of reactants:*

$$\text{Rate} \propto \text{collision frequency} \propto \text{concentration}$$

Figure 16.2 The wide range of reaction rates.

Figure 16.3 The effect of surface area on reaction rate.

2. *Physical state: molecules must mix to collide.* Collision frequency, and thus reaction rate, also depends on physical state, which determines how easily the reactants mix. When the reactants are in the same phase, as in an aqueous solution, random thermal motion brings them into contact, but gentle stirring mixes them further. When the reactants are in different phases, contact occurs only at the interface between the phases, so vigorous stirring or even grinding may be needed. Thus, *the more finely divided a solid or liquid reactant, the greater its surface area, the more contact it makes with the other reactant, and the faster the reaction occurs.* In Figure 16.3, a hot steel nail *(left)* placed in oxygen gas glows feebly, but the same mass of steel wool *(right)* bursts into flame. For the same reason, you start a campfire with twigs, not logs.

3. *Temperature: molecules must collide with enough energy.* Temperature usually has a major effect on the rate of a reaction. Two kitchen appliances employ this effect: a refrigerator slows down chemical processes that spoil food, whereas an oven speeds up other chemical processes that cook it. Temperature affects reaction rate by increasing the *frequency* and, more importantly, the *energy* of collisions:

- *Frequency of collisions*. Recall that molecules in a sample of gas have a range of speeds, with the most probable speed being a function of the temperature (see Figure 5.14, p. 225). Thus, *at a higher temperature, collisions occur more frequently, and so more molecules react:*

Rate ∝ collision **frequency** ∝ temperature

- *Energy of collisions*. Even more important is that *temperature affects the kinetic energy* of the molecules. In the jumble of NO and O_3 molecules in the reaction vessel, most collisions have only enough energy for the molecules to bounce off each other. However, some collisions occur with sufficient energy for the molecules to react (Figure 16.4). *At a higher temperature, more sufficiently energetic collisions occur, and so more molecules react:*

Rate ∝ collision **energy** ∝ temperature

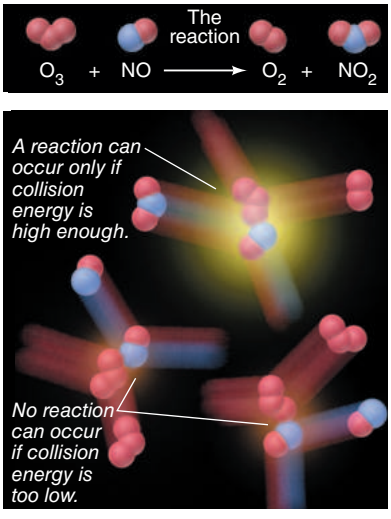

Figure 16.4 Sufficient collision energy is required for a reaction to occur.

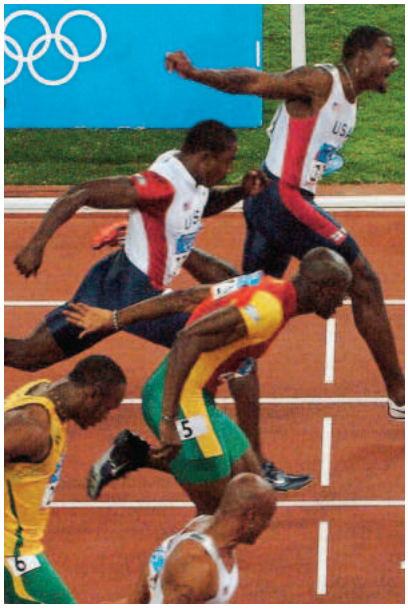
Summary of Section 16.1

- Chemical kinetics focuses on reaction rate and the factors that affect it.
- Under a given set of conditions, each reaction has its own rate.
- Concentration affects rate by influencing the frequency of collisions between reactant molecules.
- Physical state affects rate by determining how well reactants can mix.
- Temperature affects rate by influencing the frequency and, more importantly, the energy of the collisions between reactant molecules.



Runners change positions with time.

16.2 EXPRESSING THE REACTION RATE

In general terms, a *rate* is a change in some variable per unit of time. The most familiar examples relate to speed *(see photo),* the change in position of an object divided by the change in time. For instance, if we measure a runner's initial position, x_1, at time t_1, and final position, x_2, at time t_2, the average speed is

$$\text{Rate of motion (speed)} = \frac{\text{change in position}}{\text{change in time}} = \frac{x_2 - x_1}{t_2 - t_1} = \frac{\Delta x}{\Delta t}$$

For the rate of a *reaction,* we measure the changes in concentrations of reactants or products per unit time: *reactant concentrations decrease while product concentrations increase.* For the general reaction A ⟶ B, we measure the initial reactant concentration (A_1) at t_1, allow the reaction to proceed, and then quickly measure the final reactant concentration (A_2) at t_2. The change in concentration divided by the change in time gives the rate:

$$\text{Rate} = -\frac{\text{change in concentration of A}}{\text{change in time}} = -\frac{\text{conc } A_2 - \text{conc } A_1}{t_2 - t_1} = -\frac{\Delta(\text{conc A})}{\Delta t}$$

The negative sign is important because, by convention, reaction rate is a *positive* number. But, since conc A_2 must be *lower* than conc A_1, the *change in concentration (final − initial) of reactant A is negative.* Therefore, we use the negative sign to convert the negative change in reactant concentration to a positive value for the rate. Suppose the concentration of A changes from 1.2 mol/L (conc A_1) to 0.75 mol/L (conc A_2) over a 125-s period. The rate is

$$\text{Rate} = -\frac{0.75 \text{ mol/L} - 1.2 \text{ mol/L}}{125 \text{ s} - 0 \text{ s}} = 3.6\times10^{-3} \text{ mol/L·s}$$

Square brackets, [ ], *indicate a concentration in moles per liter.* For example, [A] is the concentration of A in mol/L, and the rate expressed in terms of A is

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} \qquad (16.1)$$

The units for the rate are moles per liter per second (mol L^{-1} s^{-1}, or mol/L·s), or any time unit convenient for the reaction (minutes, years, and so on).

If instead we measure the *product* concentrations to determine the rate, we find that conc B_2 is always *higher* than conc B_1. Thus, the *change* in product concentration, Δ[B], is *positive,* and the reaction rate for A ⟶ B expressed in terms of B is

$$\text{Rate} = +\frac{\Delta[\text{B}]}{\Delta t}$$

The plus sign is usually understood and not shown.

Average, Instantaneous, and Initial Reaction Rates

In most cases, *the rate varies as a reaction proceeds.* Consider the reversible gas-phase reaction between ethylene and ozone, one of many reactions that may be involved in the formation of smog:

$$C_2H_4(g) + O_3(g) \rightleftharpoons C_2H_4O(g) + O_2(g)$$

The equation shows that for every molecule of C_2H_4 that reacts, a molecule of O_3 reacts; thus, $[O_3]$ and $[C_2H_4]$ decrease at the same rate:

$$\text{Rate} = -\frac{\Delta[C_2H_4]}{\Delta t} = -\frac{\Delta[O_3]}{\Delta t}$$

When we start with a known $[O_3]$ in a closed vessel at 30°C (303 K) and measure $[O_3]$ at 10.0-s intervals during the first minute after adding C_2H_4, we obtain the concentration vs. time data shown in the Figure 16.5 table, which gives the black curve. Note that

- The data points in Figure 16.5 result in a curved line, which means that the rate is changing over time (a straight line would mean that the rate was constant).
- The rate *decreases* during the course of the reaction because we are plotting *reactant* concentration vs. time: as O_3 molecules react, fewer are present to collide with C_2H_4 molecules, and the rate, the change in $[O_3]$ over time, therefore decreases.

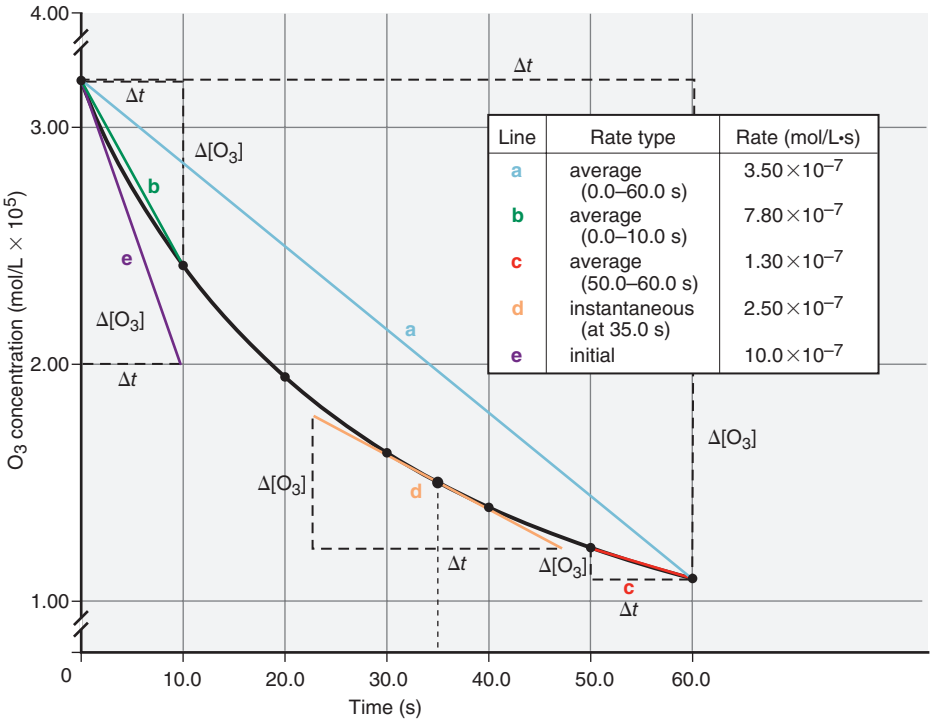


Figure 16.5 Three types of reaction rates for the reaction of O_3 and C_2H_4.

Time (s)	Concentration of O_3 (mol/L)
0.0	3.20×10^{-5}
10.0	2.42×10^{-5}
20.0	1.95×10^{-5}
30.0	1.63×10^{-5}
40.0	1.40×10^{-5}
50.0	1.23×10^{-5}
60.0	1.10×10^{-5}

Three types of reaction rates are shown in the figure:

1. *Average rate.* Over a given period of time, the **average rate** is the slope of the line joining two points along the curve. The rate over the entire 60.0 s is the total change in concentration divided by the total change in time (Figure 16.5, line a):

$$\text{Rate} = -\frac{\Delta[O_3]}{\Delta t} = -\frac{(1.10\times10^{-5}\ \text{mol/L}) - (3.20\times10^{-5}\ \text{mol/L})}{60.0\ \text{s} - 0.0\ \text{s}} = 3.50\times10^{-7}\ \text{mol/L·s}$$

This quantity, which is the slope of line a (that is, $\Delta[O_3]/\Delta t$), is the average rate over the entire period: during the first 60.0 s of the reaction, $[O_3]$ decreases an *average* of 3.50×10^{-7} mol/L each second.

But, when you drive a car or ride a bike for a few miles, your speed over shorter distances may be lower or higher than your average speed. In the same sense, the decrease in $[O_3]$ over the whole time period does not show the rate over any shorter time period. This *change* in reaction rate is evident when we calculate the average rate over two shorter periods. For the first 10.0 s, between 0.0 s and 10.0 s, the average rate (Figure 16.5, line b) is

$$\text{Rate} = -\frac{\Delta[O_3]}{\Delta t} = -\frac{(2.42\times10^{-5}\ \text{mol/L}) - (3.20\times10^{-5}\ \text{mol/L})}{10.0\ \text{s} - 0.0\ \text{s}} = 7.80\times10^{-7}\ \text{mol/L·s}$$

And, for the last 10.0 s, between 50.0 s and 60.0 s, the average rate (Figure 16.5, line c) is

$$\text{Rate} = -\frac{\Delta[O_3]}{\Delta t} = -\frac{(1.10\times10^{-5}\ \text{mol/L}) - (1.23\times10^{-5}\ \text{mol/L})}{60.0\ \text{s} - 50.0\ \text{s}} = 1.30\times10^{-7}\ \text{mol/L·s}$$

The reaction rate over the first 10.0 s is six times faster than the rate over the last 10.0 s.

2. *Instantaneous rate.* The shorter the time period we choose, the closer we come to the **instantaneous rate,** the rate at a particular instant during the reaction. *The slope of a line tangent to the curve at any point gives the instantaneous rate at that time.* For example, the rate at 35.0 s is 2.50×10^{-7} mol/L·s, the slope of the line tangent to the curve through the point at $t = 35.0$ s (Figure 16.5, line d). In general, we use the term *reaction rate* to mean *instantaneous* reaction rate.

3. *Initial rate.* The instantaneous rate at the moment the reactants are mixed (that is, at $t = 0$) is the **initial rate.** We use this rate to avoid a complication: as a reaction proceeds in the *forward* direction (reactants ⟶ products), product increases, causing the *reverse* reaction (reactants ⟵ products), to occur more quickly. To find the overall (net) rate, we would have to calculate the difference between the forward and reverse rates. But, for the initial rate, $t = 0$, so product concentrations are negligible, and so is the reverse rate. We find the initial rate from the slope of the line tangent to the curve at $t = 0$ s (Figure 16.5, line e). Since reactant concentrations are the largest at $t = 0$, the initial rate is faster than the instantaneous rate at *any* later time during the reaction. We typically use initial rates to find other kinetic parameters.

Expressing Rate in Terms of Reactant and Product Concentrations

So far, for the reaction between C_2H_4 and O_3, we've expressed the rate in terms of $[O_3]$, which is *decreasing,* and the rate would be expressed the same way in terms of $[C_2H_4]$. However, the rate is exactly the opposite in terms of the product concentrations because they are *increasing*. From the balanced equation, we see that one molecule each of C_2H_4O and of O_2 appear for every molecule of C_2H_4 and of O_3 that disappear. Thus, we can express the rate in terms of any of the four substances:

$$\text{Rate} = -\frac{\Delta[C_2H_4]}{\Delta t} = -\frac{\Delta[O_3]}{\Delta t} = \frac{\Delta[C_2H_4O]}{\Delta t} = \frac{\Delta[O_2]}{\Delta t}$$

Figure 16.6A plots the changes in concentrations of one reactant (C_2H_4) and one product (O_2) simultaneously. The curves have the same shape but are inverted relative to each other, because, *for this reaction,* product appears at the same rate that reactant disappears.

For many other reactions, though, reactants disappear and products appear at different rates. Consider the reaction between hydrogen and iodine to form hydrogen iodide:

$$H_2(g) + I_2(g) \longrightarrow 2HI(g)$$

From the balancing coefficients, we see that, for every molecule of H_2 that disappears, one molecule of I_2 disappears and *two* molecules of HI appear. In other words, the rate of $[H_2]$ decrease is the same as the rate of $[I_2]$ decrease, but both are only half the rate

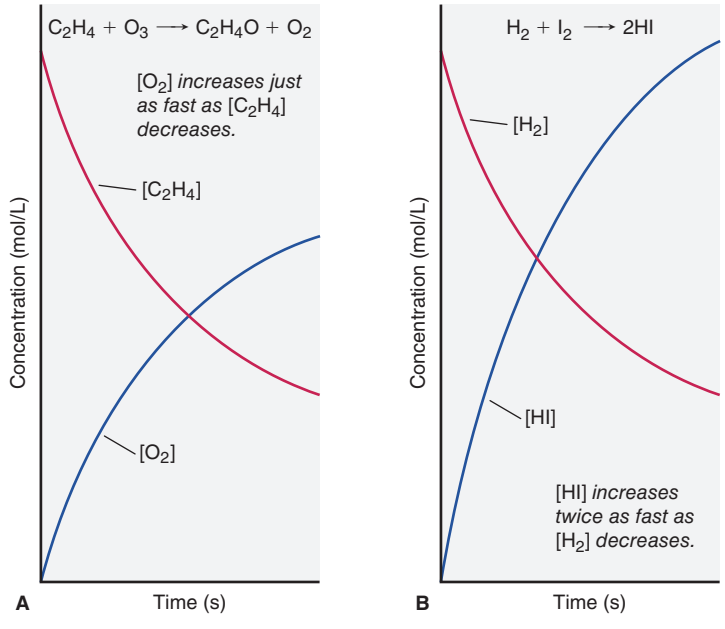

Figure 16.6 **Plots of [reactant] and [product] vs. time. A,** C_2H_4 and O_2. **B,** H_2 and HI.

of [HI] increase. Thus, in Figure 16.6B, the [HI] curve rises twice as fast as the $[H_2]$ curve drops. If we refer the changes in $[I_2]$ and [HI] to the change in $[H_2]$, we have

$$\text{Rate} = -\frac{\Delta[H_2]}{\Delta t} = -\frac{\Delta[I_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[HI]}{\Delta t}$$

If, instead, we refer the changes in $[H_2]$ and $[I_2]$ to the change in [HI], we obtain

$$\text{Rate} = \frac{\Delta[HI]}{\Delta t} = -2\frac{\Delta[H_2]}{\Delta t} = -2\frac{\Delta[I_2]}{\Delta t}$$

Note that this expression gives a rate that is double the previous one. Thus, *the expression for the rate of a reaction and its numerical value depend on which substance serves as the reference.*

We can summarize these results for any reaction,

$$aA + bB \longrightarrow cC + dD$$

where a, b, c, and d are coefficients of the balanced equation, as follows:

$$\text{Rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = \frac{1}{c}\frac{\Delta[C]}{\Delta t} = \frac{1}{d}\frac{\Delta[D]}{\Delta t} \qquad \textbf{(16.2)}$$

SAMPLE PROBLEM 16.1 Expressing Rate in Terms of Changes in Concentration with Time

Problem Hydrogen gas has a nonpolluting combustion product (water vapor). It is used as a fuel aboard the space shuttle and in earthbound cars with prototype engines:

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

(a) Express the rate in terms of changes in $[H_2]$, $[O_2]$, and $[H_2O]$ with time.
(b) When $[O_2]$ is decreasing at 0.23 mol/L·s, at what rate is $[H_2O]$ increasing?

Plan **(a)** Of the three substances in the equation, let's choose O_2 as the reference because its coefficient is 1. For every molecule of O_2 that disappears, two molecules of H_2 disappear. Thus, the rate of $[O_2]$ decrease is one-half the rate of $[H_2]$ decrease. By similar reasoning, the rate of $[O_2]$ decrease is one-half the rate of $[H_2O]$ increase.
(b) Because $[O_2]$ is decreasing, the change in its concentration must be negative. We substitute the given rate as a negative value (−0.23 mol/L·s) into the expression and solve for $\Delta[H_2O]/\Delta t$.

Solution **(a)** Expressing the rate in terms of each component:

$$\text{Rate} = -\frac{\Delta[O_2]}{\Delta t} = -\frac{1}{2}\frac{\Delta[H_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[H_2O]}{\Delta t}$$

(b) Calculating the rate of change of $[H_2O]$:

$$\frac{1}{2}\frac{\Delta[H_2O]}{\Delta t} = -\frac{\Delta[O_2]}{\Delta t} = -(-0.23 \text{ mol/L·s})$$

$$\frac{\Delta[H_2O]}{\Delta t} = 2(0.23 \text{ mol/L·s}) = 0.46 \text{ mol/L·s}$$

Check **(a)** A good check is to use the rate expression to obtain the balanced equation: $[H_2]$ changes twice as fast as $[O_2]$, so two H_2 molecules react for each O_2. $[H_2O]$ changes twice as fast as $[O_2]$, so two H_2O molecules form from each O_2. Thus, we get $2H_2 + O_2 \longrightarrow 2H_2O$. The values of $[H_2]$ and $[O_2]$ decrease, so they have negative signs; $[H_2O]$ increases, so it has a plus sign. Another check is to use Equation 16.2, with A = H_2, $a = 2$; B = O_2, $b = 1$; and C = H_2O, $c = 2$:

$$\text{Rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = \frac{1}{c}\frac{\Delta[C]}{\Delta t}$$

or

$$\text{Rate} = -\frac{1}{2}\frac{\Delta[H_2]}{\Delta t} = -\frac{\Delta[O_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[H_2O]}{\Delta t}$$

(b) Given the rate expression, it makes sense that the numerical value of the rate of $[H_2O]$ increase is twice that of $[O_2]$ decrease.

Comment Thinking through this type of problem at the molecular level is the best approach, but use Equation 16.2 to confirm your answer.

FOLLOW-UP PROBLEMS

*Brief Solutions for **all** Follow-up Problems appear at the end of the chapter.*

16.1A **(a)** Balance the following equation and express the rate in terms of the change in concentration with time for each substance:

$$NO(g) + O_2(g) \longrightarrow N_2O_3(g)$$

(b) How fast is $[O_2]$ decreasing when [NO] is decreasing at a rate of 1.60×10^{-4} mol/L·s?

16.1B For a particular reaction, the reaction rate in terms of the change in concentration with time for each substance is

$$\text{Rate} = -\frac{1}{4}\frac{\Delta[NH_3]}{\Delta t} = -\frac{1}{5}\frac{\Delta[O_2]}{\Delta t} = \frac{1}{4}\frac{\Delta[NO]}{\Delta t} = \frac{1}{6}\frac{\Delta[H_2O]}{\Delta t}$$

(a) Write a balanced equation for this gaseous reaction.

(b) When $[H_2O]$ is increasing at a rate of 2.52×10^{-2} mol/L·s, how fast is $[O_2]$ decreasing?

SOME SIMILAR PROBLEMS 16.14–16.19

Summary of Section 16.2

- The average reaction rate is the change in reactant (or product) concentration over a change in time, Δt. The rate slows as the reaction proceeds because reactants are used up.
- The instantaneous rate at time t is the slope of the tangent to a curve that plots concentration vs. time.
- The initial rate, the instantaneous rate at $t = 0$, occurs when reactants have just been mixed and before any product accumulates.
- The expression for a reaction rate and its numerical value depend on which reaction component is being referenced.

16.3 THE RATE LAW AND ITS COMPONENTS

The centerpiece of any kinetic study of a reaction is the **rate law** (or **rate equation**), which expresses the rate as a function of concentrations and temperature. The rate law is based on experiment, so any hypothesis about how the reaction occurs on the molecular level must conform to it.

In this discussion, we generally consider reactions for which the products do not appear in the rate law, so the rate depends only on *reactant* concentrations and temperature. For a general reaction occurring at a fixed temperature,

$$aA + bB + \cdots \longrightarrow cC + dD + \cdots$$

the rate law is

$$\text{Rate} = k[A]^m[B]^n \cdots \qquad (16.3)$$

The term k is a proportionality constant, called the **rate constant,** that is specific for a given reaction at a given temperature and does *not* change as the reaction proceeds. (As we'll see in Section 16.5, k *does* change with temperature.) The exponents m and n, called the **reaction orders,** define how the rate is affected by reactant concentration; we'll see how to determine them shortly. Two key points to remember are

- *The balancing coefficients a and b in the reaction equation are **not** necessarily related in any way to the reaction orders m and n.*
- *The components of the rate law—rate, reaction orders, and rate constant—**must** be found by experiment.*

In the remainder of this section, we'll find the components of the rate law by measuring concentrations to determine the *initial rate,* using initial rates to determine

the *reaction orders,* and using these values to calculate the *rate constant*. With the rate law for a reaction, we can predict the rate for any initial concentrations.

Some Laboratory Methods for Determining the Initial Rate

We determine an initial rate from a plot of concentration vs. time, so we need a quick, accurate method for measuring concentration as the reaction proceeds. Let's briefly discuss three common approaches.

1. *Spectrometric methods* measure the concentration of a component that absorbs (or emits) characteristic wavelengths of light. For example, in the reaction of NO and O_3, only NO_2 has a color (an indication that NO_2 absorbs some wavelength of visible light):

$$NO(g, \text{colorless}) + O_3(g, \text{colorless}) \longrightarrow O_2(g, \text{colorless}) + NO_2(g, \text{brown})$$

Known amounts of reactants are injected into a tube of known volume within a spectrometer (see Tools of the Laboratory, pp. 300–301), which is set to measure the wavelength and intensity of the color. The rate of NO_2 formation is proportional to the increase in that intensity over time.

2. *Conductometric methods* rely on the change in electrical conductivity of the reaction solution when nonionic reactants form ionic products, or vice versa. Consider the reaction between an organic halide, such as 2-bromo-2-methylpropane, and water:

$$(CH_3)_3C{-}Br(l) + H_2O(l) \longrightarrow (CH_3)_3C{-}OH(l) + H^+(aq) + Br^-(aq)$$

The HBr that forms is a strong acid, so it dissociates completely in the water. As time passes, more ions form, so the conductivity of the reaction mixture increases.

3. *Manometric methods* employ a manometer attached to a reaction vessel of fixed volume and temperature. The manometer measures the pressure over time of a reaction that involves a change in the number of moles of gas. Consider the decomposition reaction of hydrogen peroxide:

$$2H_2O_2(aq) \longrightarrow 2H_2O(l) + O_2(g)$$

The rate is directly proportional to the increase in pressure as O_2 gas forms.

Determining Reaction Orders

With the initial rate in hand, we can determine reaction orders. Let's first discuss what reaction orders are and then see how to determine them by controlling reactant concentrations.

First, Second, and Zero Orders A reaction has an *individual* order "with respect to" or "in" each reactant, and an *overall* order, the sum of the individual orders.

Consider first the simplest case, a reaction with only one reactant, A:

$$A \longrightarrow \text{products}$$

- *First order.* If the rate doubles when [A] doubles, the rate depends on [A] raised to the first power, $[A]^1$ (the superscript 1 is generally omitted). Thus, the reaction is *first order* in (or with respect to) A and *first order* overall:

$$\text{Rate} = k[A]^1 = k[A]$$

- *Second order*. If the rate quadruples when [A] doubles, the rate depends on [A] squared, $[A]^2$. In this case, the reaction is *second order* in A and *second order* overall:

$$\text{Rate} = k[A]^2$$

- *Zero order*. If the rate does not change when [A] doubles, the rate does *not* depend on [A], but we express this fact mathematically by saying that the rate depends on [A] raised to the zero power, $[A]^0$. The reaction is *zero order* in A and *zero order* overall:

$$\text{Rate} = k[A]^0 = k(1) = k$$

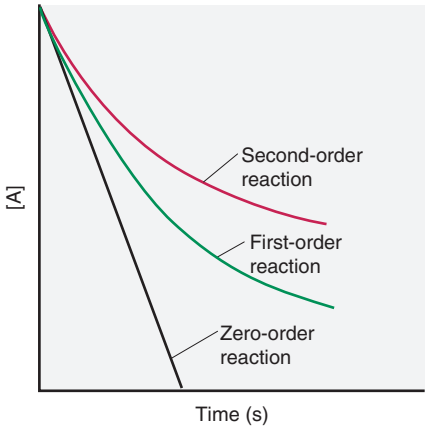

Figure 16.7 Plots of reactant concentration, [A], vs. time for first-, second-, and zero-order reactions.

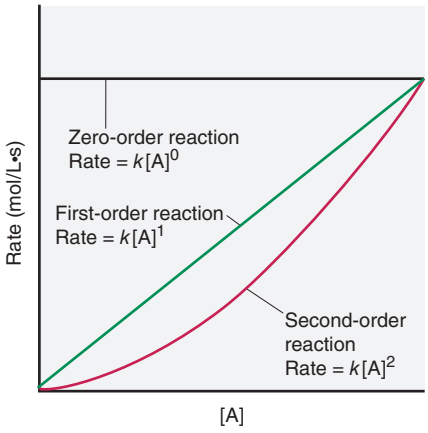

Figure 16.8 Plots of rate vs. reactant concentration, [A], for first-, second-, and zero-order reactions.

Figure 16.7 shows plots of [A] vs. time for first-, second-, and zero-order reactions. (In all cases, the value of k was assumed to be the same.) Notice that

- The decrease in [A] doesn't change as time goes on for a zero-order reaction.
- The decrease slows down as time goes on for a first-order reaction.
- The decrease slows even more for a second-order reaction.

These results are reflected in Figure 16.8, which shows plots of rate vs. [A] for the same reaction orders. Notice that

- The plot is a horizontal line for the zero-order reaction because the rate doesn't change regardless of the value of [A].
- The plot is an upward-sloping *line* for the first-order reaction because the rate is directly proportional to [A].
- The plot is an upward-sloping *curve* for the second-order reaction because the rate increases exponentially with [A].

Let's look at some examples of observed rate laws and note the reaction orders. For the reaction between nitrogen monoxide and ozone,

$$NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g)$$

the rate law is

$$\text{Rate} = k[NO][O_3]$$

This reaction is first order with respect to NO and first order with respect to O_3, so it is second order overall ($1 + 1 = 2$).

For the hydrolysis of 2-bromo-2-methylpropane,

$$(CH_3)_3C{-}Br(l) + H_2O(l) \longrightarrow (CH_3)_3C{-}OH(l) + H^+(aq) + Br^-(aq)$$

the rate law is

$$\text{Rate} = k[(CH_3)_3CBr]$$

This reaction is first order in 2-bromo-2-methylpropane and zero order with respect to H_2O, despite its coefficient of 1 in the balanced equation. If we want to note that water is a reactant, we can write

$$\text{Rate} = k[(CH_3)_3CBr][H_2O]^0$$

Overall, this is a first-order reaction ($1 + 0 = 1$).

Finally, for the reaction between NO and hydrogen gas,

$$2NO(g) + 2H_2(g) \longrightarrow N_2(g) + 2H_2O(g)$$

the rate law is

$$\text{Rate} = k[NO]^2[H_2]$$

This reaction is second order in NO. And even though H_2 has a coefficient of 2 in the balanced equation, the reaction is first order in H_2. It is third order overall ($2 + 1 = 3$).

The larger the reaction order for a reactant, the greater the effect the concentration of that reactant has on the rate. For example, consider the result of doubling both [NO] and [H_2]:

$$\text{Rate} = k[NO]^2[H_2] = k(2)^2(2) = k \times 4 \times 2 = k \times 8, \text{ or } 8k$$

Since the change in [NO] is squared, doubling [NO] results in the rate increasing by a factor of 4, while doubling [H_2] increases the rate only by a factor of 2; the net effect of the change in both concentrations is that the rate increases by a factor of 8.

These examples reiterate an important point: *reaction orders **cannot** be deduced from the balanced equation but **must** be determined from experimental data.*

Other Reaction Orders Although usually positive integers or zero, reaction orders can also be fractional or negative. For the reaction

$$CHCl_3(g) + Cl_2(g) \longrightarrow CCl_4(g) + HCl(g)$$

a fractional order appears in the rate law:

$$\text{Rate} = k[CHCl_3][Cl_2]^{1/2}$$

This *fractional reaction order* means that if, for example, [Cl_2] increases by a factor of 4, the rate increases by a factor of 2, the square root of the change in [Cl_2], or $(4)^{1/2}$. The overall order of this reaction is $\frac{3}{2}$.

A *negative reaction order* means the rate *decreases* when the concentration of that component increases. Negative orders are often seen when the rate law includes products. For example, for the atmospheric reaction

$$2O_3(g) \rightleftharpoons 3O_2(g)$$

the rate law is

$$\text{Rate} = k[O_3]^2[O_2]^{-1} = k\frac{[O_3]^2}{[O_2]}$$

If $[O_2]$ doubles, the reaction proceeds half as fast. This reaction is second order in O_3 and negative first order in O_2, so it is first order overall $[2 + (-1) = 1]$.

SAMPLE PROBLEM 16.2 Determining Reaction Orders from Rate Laws

Problem For each of the following reactions, use the given rate law to determine the reaction order with respect to each reactant and the overall order; for the reaction in (a), determine the factor by which the rate changes if [NO] is tripled and $[O_2]$ is doubled.

(a) $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$; rate $= k[NO]^2[O_2]$

(b) $CH_3CHO(g) \longrightarrow CH_4(g) + CO(g)$; rate $= k[CH_3CHO]^{3/2}$

(c) $H_2O_2(aq) + 3I^-(aq) + 2H^+(aq) \longrightarrow I_3^-(aq) + 2H_2O(l)$; rate $= k[H_2O_2][I^-]$

Plan We inspect the exponents in the rate law, *not* the coefficients of the balanced equation, to find the individual orders, and then take their sum to find the overall reaction order. To find the change in rate in **(a),** we substitute 3 for [NO] in the rate law (since that concentration changes by a factor of 3) and 2 for $[O_2]$ (since that concentration changes by a factor of 2), and solve for rate.

Solution **(a)** The exponent of [NO] is 2, so the reaction is second order with respect to NO, first order with respect to O_2, and third order overall.

Finding the change in rate:

$$\text{Rate} = k[NO]^2[O_2] = k(3)^2(2) = k \times 18 = 18k$$

The rate increases by a factor of 18.

(b) The reaction is $\frac{3}{2}$ order in CH_3CHO and $\frac{3}{2}$ order overall.

(c) The reaction is first order in H_2O_2, first order in I^-, and second order overall.

The reactant H^+ does not appear in the rate law, so the reaction is zero order in H^+.

Check Be sure that each reactant has an order and that the sum of the individual orders gives the overall order. For the rate change in (a), be sure that the 3 used to indicate a tripled concentration is squared since the reaction is second order in NO.

FOLLOW-UP PROBLEMS

16.2A Experiment shows that the reaction

$$6I^-(aq) + BrO_3^-(aq) + 6H^+(aq) \longrightarrow 3I_2(aq) + Br^-(aq) + 3H_2O(l)$$

obeys this rate law: rate $= k[I^-][BrO_3^-][H^+]^2$. **(a)** What is the reaction order in each reactant and the overall reaction order? **(b)** By what factor does the rate change if $[I^-]$ and $[BrO_3^-]$ are tripled and $[H^+]$ is doubled?

16.2B The rate law for the reaction

$$2ClO_2(aq) + 2OH^-(aq) \longrightarrow ClO_3^-(aq) + ClO_2^-(aq) + H_2O(l)$$

is rate $= k[ClO_2]^2[OH^-]$. **(a)** What is the reaction order in each reactant and the overall reaction order? **(b)** By what factor does the rate change if $[ClO_2]$ is halved and $[OH^-]$ is doubled?

SOME SIMILAR PROBLEMS 16.26–16.33

Determining Reaction Orders by Changing Reactant Concentrations Now let's see how reaction orders are found *before* the rate law is known. Before looking at a real reaction, we'll go through the process for substances A and B in this reaction:

$$A + 2B \longrightarrow C + D$$

The rate law, expressed in general terms, is

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n$$

To find the values of m and n, *we run a series of experiments in which one reactant concentration changes while the other is kept constant, and we measure the effect on the initial rate in each case.* Table 16.1 shows the results.

Table 16.1 Initial Rates for the Reaction Between A and B

Experiment	Initial Rate (mol/L·s)	Initial [A] (mol/L)	Initial [B] (mol/L)
1	1.75×10^{-3}	2.50×10^{-2}	3.00×10^{-2}
2	3.50×10^{-3}	5.00×10^{-2}	3.00×10^{-2}
3	3.50×10^{-3}	2.50×10^{-2}	6.00×10^{-2}
4	7.00×10^{-3}	5.00×10^{-2}	6.00×10^{-2}

1. *Finding m, the order with respect to A.* By comparing experiments 1 and 2, in which [A] doubles and [B] is constant, we can obtain m. First, we take the ratio of the general rate laws for these two experiments:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[\text{A}]_2^m[\text{B}]_2^n}{k[\text{A}]_1^m[\text{B}]_1^n}$$

where $[\text{A}]_2$ is the concentration of A in experiment 2, $[\text{B}]_1$ is the concentration of B in experiment 1, and so forth. Because k is a constant and [B] does not change between these two experiments, those quantities cancel:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{\cancel{k}[\text{A}]_2^m\cancel{[\text{B}]_2^n}}{\cancel{k}[\text{A}]_1^m\cancel{[\text{B}]_1^n}} = \frac{[\text{A}]_2^m}{[\text{A}]_1^m} = \left(\frac{[\text{A}]_2}{[\text{A}]_1}\right)^m$$

Substituting the values from Table 16.1, we have

$$\frac{3.50\times10^{-3}\ \text{mol/L·s}}{1.75\times10^{-3}\ \text{mol/L·s}} = \left(\frac{5.00\times10^{-2}\ \text{mol/L}}{2.50\times10^{-2}\ \text{mol/L}}\right)^m$$

Dividing, we obtain

$$2.00 = (2.00)^m \qquad \text{so} \qquad m = 1$$

Thus, the reaction is first order in A, because when [A] doubles, the rate doubles.

2. *Finding n, the order with respect to B.* To find n, we compare experiments 3 and 1 in which [A] is held constant and [B] doubles:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[\text{A}]_3^m[\text{B}]_3^n}{k[\text{A}]_1^m[\text{B}]_1^n}$$

As before, k is a constant, and in this pair of experiments, [A] does not change, so those quantities cancel, and we have

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{\cancel{k}\cancel{[\text{A}]_3^m}[\text{B}]_3^n}{\cancel{k}\cancel{[\text{A}]_1^m}[\text{B}]_1^n} = \frac{[\text{B}]_3^n}{[\text{B}]_1^n} = \left(\frac{[\text{B}]_3}{[\text{B}]_1}\right)^n$$

The actual values give

$$\frac{3.50\times10^{-3}\ \text{mol/L·s}}{1.75\times10^{-3}\ \text{mol/L·s}} = \left(\frac{6.00\times10^{-2}\ \text{mol/L}}{3.00\times10^{-2}\ \text{mol/L}}\right)^n$$

Dividing, we obtain

$$2.00 = (2.00)^n \qquad \text{so} \qquad n = 1$$

Thus, the reaction is also first order in B because when [B] doubles, the rate doubles. We can check this conclusion from experiments 1 and 4: when *both* [A] and [B]

double, the rate should quadruple, and it does. Thus, the rate law, with m and n equal to 1, is

$$\text{Rate} = k[\text{A}][\text{B}]$$

Note, especially, that while the order with respect to B is 1, the coefficient of B in the balanced equation is 2. Thus, as we said earlier, *reaction orders must be determined from experiment*, not from the balanced equation.

Next, let's go through this process for a real reaction, the one between oxygen and nitrogen monoxide, a key step in the formation of acid rain and in the industrial production of nitric acid:

$$O_2(g) + 2NO(g) \longrightarrow 2NO_2(g)$$

The general rate law is

$$\text{Rate} = k[O_2]^m[NO]^n$$

Table 16.2 shows experiments that change one reactant concentration while keeping the other constant. If we compare experiments 1 and 2, we see the effect of doubling $[O_2]$ on the rate. First, we take the ratio of their rate laws:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[O_2]_2^m[NO]_2^n}{k[O_2]_1^m[NO]_1^n}$$

As before, the constant quantities—k and [NO]—cancel:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{\cancel{k}[O_2]_2^m\cancel{[NO]_2^n}}{\cancel{k}[O_2]_1^m\cancel{[NO]_1^n}} = \frac{[O_2]_2^m}{[O_2]_1^m} = \left(\frac{[O_2]_2}{[O_2]_1}\right)^m$$

Table 16.2 Initial Rates for the Reaction Between O_2 and NO

Experiment	Initial Rate (mol/L·s)	Initial Reactant Concentrations (mol/L)	
		$[O_2]$	[NO]
1	3.21×10^{-3}	1.10×10^{-2}	1.30×10^{-2}
2	6.40×10^{-3}	2.20×10^{-2}	1.30×10^{-2}
3	12.8×10^{-3}	1.10×10^{-2}	2.60×10^{-2}
4	9.60×10^{-3}	3.30×10^{-2}	1.30×10^{-2}
5	28.8×10^{-3}	1.10×10^{-2}	3.90×10^{-2}

Substituting the values from Table 16.2, we obtain

$$\frac{6.40\times10^{-3}\ \text{mol/L·s}}{3.21\times10^{-3}\ \text{mol/L·s}} = \left(\frac{2.20\times10^{-2}\ \text{mol/L}}{1.10\times10^{-2}\ \text{mol/L}}\right)^m$$

Dividing, we obtain

$$1.99 = (2.00)^m$$

Rounding to one significant figure gives

$$2 = 2^m, \qquad \text{so } m = 1$$

Sometimes, the exponent is not as easy to find by inspection as it is here. In those cases, we solve for m with an equation of the form $a = b^m$, which in this case gives

$$\log a = m \log b \qquad \text{or} \qquad m = \frac{\log a}{\log b} = \frac{\log 1.99}{\log 2.00} = 0.993$$

which rounds to 1. Thus, the reaction is first order in O_2: when $[O_2]$ doubles, the rate doubles.

To find the order with respect to NO, we compare experiments 3 and 1, in which $[O_2]$ is held constant and [NO] is doubled:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[O_2]_3^m[NO]_3^n}{k[O_2]_1^m[NO]_1^n}$$

Canceling the constant k and the unchanging $[O_2]$, we have

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \left(\frac{[NO]_3}{[NO]_1}\right)^n$$

The actual values give

$$\frac{12.8\times10^{-3}\ \text{mol/L·s}}{3.21\times10^{-3}\ \text{mol/L·s}} = \left(\frac{2.60\times10^{-2}\ \text{mol/L}}{1.30\times10^{-2}\ \text{mol/L}}\right)^n$$

Dividing, we obtain

$$3.99 = (2.00)^n$$

Solving for n:

$$n = \frac{\log 3.99}{\log 2.00} = 2.00 \quad \text{(or 2)}$$

The reaction is second order in NO: when [NO] doubles, the rate quadruples. Thus, the actual rate law is

$$\text{Rate} = k[O_2][NO]^2$$

In this case, the reaction orders happen to be the same as the equation coefficients; nevertheless, they must *always* be determined by experiment.

Determining the Rate Constant

Let's find the rate constant for the reaction of O_2 and NO. With the rate, reactant concentrations, and reaction orders known, the sole remaining unknown in the rate law is the rate constant, k. We can use data from any of the experiments in Table 16.2 to solve for k. From experiment 1, for instance, we have

$$\text{Rate} = k[O_2]_1[NO]_1^2$$

$$k = \frac{\text{rate 1}}{[O_2]_1[NO]_1^2} = \frac{3.21\times10^{-3}\ \text{mol/L·s}}{(1.10\times10^{-2}\ \text{mol/L})(1.30\times10^{-2}\ \text{mol/L})^2}$$

$$= \frac{3.21\times10^{-3}\ \text{mol/L·s}}{1.86\times10^{-6}\ \text{mol}^3/\text{L}^3} = 1.73\times10^3\ \text{L}^2/\text{mol}^2\text{·s}$$

Always check that the values of k for a series of experiments are constant within experimental error. To three significant figures, the average value of k for the five experiments in Table 16.2 is $1.72\times10^3\ \text{L}^2/\text{mol}^2\text{·s}$.

With concentrations in mol/L and the reaction rate in units of mol/L·time, the units for k depend on the order of the reaction and, of course, the time unit. For this reaction, the units for k, $\text{L}^2/\text{mol}^2\text{·s}$, are required to give a rate with units of mol/L·s:

$$\frac{\text{mol}}{\text{L·s}} = \frac{\text{L}^2}{\text{mol}^2\text{·s}} \times \frac{\text{mol}}{\text{L}} \times \left(\frac{\text{mol}}{\text{L}}\right)^2$$

The rate constant will *always* have these units for an overall third-order reaction with the time unit of seconds. Table 16.3 shows the units of k for common integer overall orders, but you can always determine the units mathematically.

Figure 16.9 summarizes the steps for studying the kinetics of a reaction. The next two sample problems offer practice in applying this approach; the first is based on data and the second on molecular scenes.

Table 16.3 Units of the Rate Constant k for Several Overall Reaction Orders

Overall Reaction Order	Units of k (t in seconds)
0	mol/L·s (or mol L^{-1} s^{-1})
1	1/s (or s^{-1})
2	L/mol·s (or L mol^{-1} s^{-1})
3	L^2/mol^2·s (or L^2 mol^{-2} s^{-1})

General formula:

$$\text{Units of } k = \frac{\left(\frac{\text{L}}{\text{mol}}\right)^{\text{order}-1}}{\text{unit of } t}$$

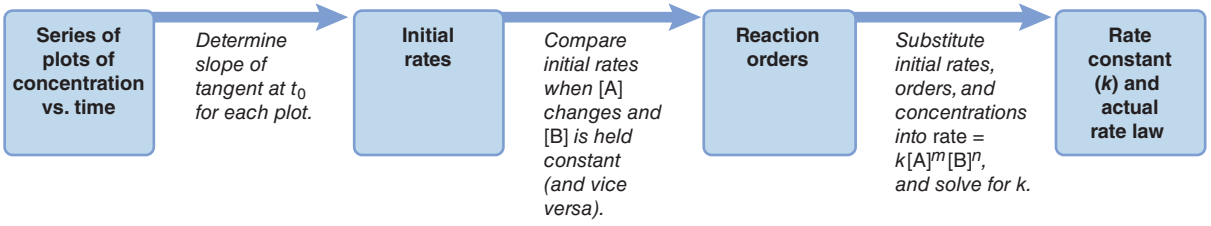

Figure 16.9 Information sequence to determine the kinetic parameters of a reaction.

SAMPLE PROBLEM 16.3 Determining Reaction Orders and Rate Constants from Rate Data

Problem Many gaseous reactions occur in car engines and exhaust systems. One of these is

$$NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g) \qquad \text{Rate} = k[NO_2]^m[CO]^n$$

(a) Use the following data to determine the individual and overall reaction orders.
(b) Calculate k using the data from experiment 1.

Experiment	Initial Rate (mol/L·s)	Initial $[NO_2]$ (mol/L)	Initial [CO] (mol/L)
1	0.0050	0.10	0.10
2	0.080	0.40	0.10
3	0.0050	0.10	0.20

Plan **(a)** We need to solve the general rate law for m and for n and then add those orders to get the overall order. To solve for each exponent, we proceed as in the text, taking the ratio of the rate laws for two experiments in which only the reactant in question changes. **(b)** We substitute the values for the rate and the reactant concentrations from experiment 1 into the rate law and solve for k.

Solution **(a)** Calculating m in $[NO_2]^m$: We take the ratio of the rate laws for experiments 1 and 2, in which $[NO_2]$ varies but [CO] is constant:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[NO_2]_2^m[CO]_2^n}{k[NO_2]_1^m[CO]_1^n} = \left(\frac{[NO_2]_2}{[NO_2]_1}\right)^m \quad \text{or} \quad \frac{0.080 \text{ mol/L·s}}{0.0050 \text{ mol/L·s}} = \left(\frac{0.40 \text{ mol/L}}{0.10 \text{ mol/L}}\right)^m$$

This gives $16 = (4.0)^m$, so we have $m = \log 16/\log 4.0 = 2.0$. The reaction is second order in NO_2.

Calculating n in $[CO]^n$: We take the ratio of the rate laws for experiments 1 and 3, in which [CO] varies but $[NO_2]$ is constant:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{k[NO_2]_3^2[CO]_3^n}{k[NO_2]_1^2[CO]_1^n} = \left(\frac{[CO]_3}{[CO]_1}\right)^n \quad \text{or} \quad \frac{0.0050 \text{ mol/L·s}}{0.0050 \text{ mol/L·s}} = \left(\frac{0.20 \text{ mol/L}}{0.10 \text{ mol/L}}\right)^n$$

We have $1.0 = (2.0)^n$, so $n = 0$. The rate does not change when [CO] varies, so the reaction is zero order in CO.

Therefore, the rate law is

$$\text{Rate} = k[NO_2]^2[CO]^0 = k[NO_2]^2(1) = k[NO_2]^2$$

The reaction is second order overall.

(b) From experiment 1, rate = 0.0050 mol/L·s and $[NO_2]$ = 0.10 mol/L. Calculating k:

$$\text{Rate} = k[NO_2]^2$$

$$k = \frac{\text{rate}}{[NO_2]^2} = \frac{0.0050 \text{ mol/L·s}}{(0.10 \text{ mol/L})^2}$$

$$= 0.50 \text{ L/mol·s}$$

Check A good check is to reason through the orders. If $m = 1$, quadrupling $[NO_2]$ would quadruple the rate; but the rate *more* than quadruples, so $m > 1$. If $m = 2$, quadrupling $[NO_2]$ would increase the rate by a factor of 16 (4^2). The ratio of rates is $0.080/0.005 = 16$, so $m = 2$. In contrast, increasing [CO] has no effect on the rate, which can happen only if $[CO]^n = 1$, so $n = 0$. The calculated value for the rate constant can be verified using the data from experiments 2 and 3.

FOLLOW-UP PROBLEMS

16.3A Find the rate law, the individual and overall reaction orders, and the average value of k for the reaction $H_2 + I_2 \longrightarrow 2HI$ using the following data at 450°C:

Experiment	Initial Rate (mol/L·s)	Initial $[H_2]$ (mol/L)	Initial $[I_2]$ (mol/L)
1	1.9×10^{-23}	0.0113	0.0011
2	1.1×10^{-22}	0.0220	0.0033
3	9.3×10^{-23}	0.0550	0.0011
4	1.9×10^{-22}	0.0220	0.0056

16.3B For the reaction

$$H_2SeO_3(aq) + 6I^-(aq) + 4H^+(aq) \longrightarrow Se(s) + 2I_3^-(aq) + 3H_2O(l)$$

at 0°C, the following data were obtained:

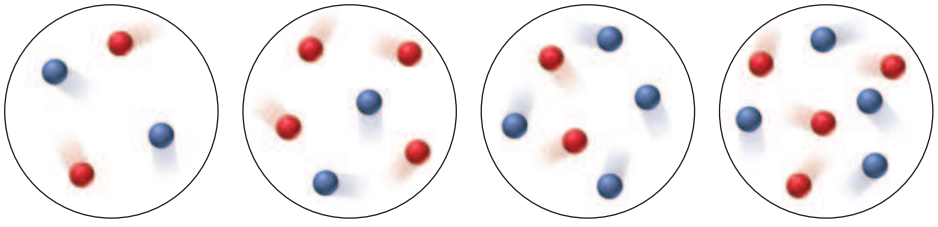
Experiment	Initial Rate (mol/L·s)	Initial [H_2SeO_3] (mol/L)	Initial [I^-] (mol/L)	Initial [H^+] (mol/L)
1	9.85×10^{-7}	2.5×10^{-3}	1.5×10^{-2}	1.5×10^{-2}
2	7.88×10^{-6}	2.5×10^{-3}	3.0×10^{-2}	1.5×10^{-2}
3	3.94×10^{-6}	1.0×10^{-2}	1.5×10^{-2}	1.5×10^{-2}
4	3.15×10^{-5}	2.5×10^{-3}	3.0×10^{-2}	3.0×10^{-2}

(a) Find the rate law for the reaction.
(b) Find the value of k (using the data in experiment 1).

SOME SIMILAR PROBLEMS 16.34–16.35 and 16.38

SAMPLE PROBLEM 16.4 Determining Reaction Orders from Molecular Scenes

Problem At a particular temperature and volume, two gases, A *(red)* and B *(blue)*, react. The following molecular scenes represent starting mixtures for four experiments:



Expt no.:	1	2	3	4
Initial rate (mol/L·s):	0.50×10^{-4}	1.0×10^{-4}	2.0×10^{-4}	?

(a) What is the reaction order with respect to A? With respect to B? The overall order?
(b) Write the rate law for the reaction.
(c) Predict the initial rate of Expt 4.

Plan **(a)** As before, we find the individual reaction orders by seeing how a change in each reactant changes the rate. In this case, however, instead of using concentration data, we count numbers of particles. The sum of the individual orders is the overall order. **(b)** To write the rate law, we use the orders from part (a) as exponents in the general rate law. **(c)** Using the results from Expts 1 through 3 and the rate law from part (b), we find the unknown initial rate of Expt 4.

Solution **(a)** Finding the individual and overall orders. For reactant A *(red):* Expts 1 and 2 show that when the number of particles of A doubles (from 2 to 4), with the number of particles of B constant (at 2), the rate doubles (from 0.5×10^{-4} mol/L·s to 1.0×10^{-4} mol/L·s). Thus, the order with respect to A is 1. For reactant B *(blue):* Expts 1 and 3 show that when the number of particles of B doubles (from 2 to 4), with the number of particles of A constant (at 2), the rate quadruples (from 0.5×10^{-4} mol/L·s to 2.0×10^{-4} mol/L·s). Thus, the order with respect to B is 2. The overall order is $1 + 2 = 3$.

(b) Writing the rate law: The general rate law is rate $= k[A]^m[B]^n$, so we have

$$\text{Rate} = k[A][B]^2$$

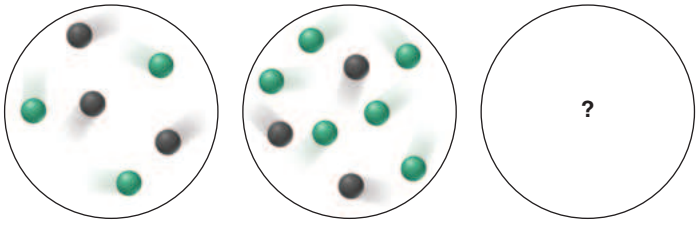
(c) Finding the initial rate of Expt 4: There are several possibilities, but let's compare Expts 3 and 4, in which the number of particles of A doubles (from 2 to 4) and the number of particles of B doesn't change. Since the rate law shows that the reaction is first order in A, the initial rate in Expt 4 should be double the initial rate in Expt 3, or 4.0×10^{-4} mol/L·s.

Check A good check is to compare other pairs of experiments. **(a)** Comparing Expts 2 and 3 shows that the number of B doubles, which causes the rate to quadruple, and the number of A decreases by half, which causes the rate to halve; so the overall rate change should double (from 1.0×10^{-4} mol/L·s to 2.0×10^{-4} mol/L·s), which it does.

(c) Comparing Expts 2 and 4, in which the number of A is constant and the number of B doubles, the rate should quadruple, which means the initial rate of Expt 4 would be 4.0×10^{-4} mol/L·s, as we found.

FOLLOW-UP PROBLEMS

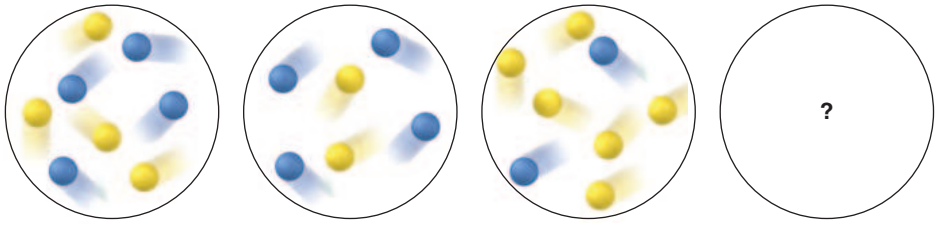
16.4A The molecular scenes below show three experiments at a given temperature and volume involving reactants X *(black)* and Y *(green)*:



Expt no.:	1	2	3
Initial rate (mol/L·s):	0.25×10^{-5}	?	1.0×10^{-5}

If the rate law for the reaction is rate $= k[X]^2$: **(a)** What is the initial rate of Expt 2? **(b)** Draw a scene for Expt 3 that involves a single change of the scene for Expt 1.

16.4B The scenes below show mixtures of reactants A *(blue)* and B *(yellow)* at a given temperature and volume:



Expt no.:	1	2	3	4
Initial rate (mol/L·s):	1.6×10^{-3}	1.6×10^{-3}	8.0×10^{-4}	3.2×10^{-3}

(a) Write the rate law for the reaction.
(b) How many particles of A should be shown in the scene for Expt 4?

SOME SIMILAR PROBLEMS 16.91, 16.121(a), and 16.121(b)

Summary of Section 16.3

- An experimentally determined rate law shows how the rate of a reaction depends on concentration. Considering only initial rates (that is, no products), the expression for a general rate law is rate $= k[A]^m[B]^n\cdots$. This reaction is mth order with respect to A and nth order with respect to B; the overall reaction order is $m + n$.
- With an accurate method for obtaining initial rates, reaction orders are determined experimentally by varying the concentration of one reactant at a time to see its effect on the rate.
- By substituting the known rate, concentrations, and reaction orders into the rate law, we solve for the rate constant, k.

16.4 INTEGRATED RATE LAWS: CONCENTRATION CHANGES OVER TIME

The rate laws we've developed so far tell us the rate or concentration at a given instant, allowing us to answer questions such as "How fast is the reaction proceeding at the moment y moles per liter of A are mixed with z moles per liter of B?" and "What is [B], when [A] is x moles per liter?" By employing different forms of the rate laws, called **integrated rate laws,** we can include time as a variable and answer questions such as "How long will it take to use up x moles per liter of A?" and "What is [A] after y minutes of reaction?"

Integrated Rate Laws for First-, Second-, and Zero-Order Reactions

As we've seen, for a *general first-order reaction,* the rate is the negative of the change in [A] divided by the change in time:

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t}$$

It can also be expressed in terms of the rate law:

$$\text{Rate} = k[\text{A}]$$

Setting these two expressions equal to each other gives

$$-\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}] \qquad \text{or} \qquad -\frac{\Delta[\text{A}]}{[\text{A}]} = k\Delta t$$

Through the methods of calculus, we integrate over time to obtain the integrated rate law for a first-order reaction:

$$\ln\frac{[\text{A}]_0}{[\text{A}]_t} = kt \qquad \text{(first-order reaction; rate} = k[\text{A}]) \tag{16.4}$$

where ln is the natural logarithm, $[\text{A}]_0$ is the concentration of A at $t = 0$, and $[\text{A}]_t$ is the concentration of A at any time t.

For a *general second-order reaction* involving two reactants, A and B, the expression including time is complex. In the simpler case, the rate law contains only reactant A. Setting the two rate expressions equal to each other gives

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]^2 \qquad \text{or} \qquad -\frac{\Delta[\text{A}]}{[\text{A}]^2} = k\Delta t$$

Integrating over time gives the integrated rate law for a second-order reaction involving one reactant:

$$\frac{1}{[\text{A}]_t} - \frac{1}{[\text{A}]_0} = kt \qquad \text{(second-order reaction; rate} = k[\text{A}]^2) \tag{16.5}$$

For a *general zero-order reaction,* setting the two rate expressions equal to each other gives

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]^0 = k \qquad \text{or} \qquad -\Delta[\text{A}] = k\Delta t$$

Integrating over time gives the integrated rate law for a zero-order reaction:

$$[\text{A}]_t - [\text{A}]_0 = -kt \qquad \text{(zero-order reaction; rate} = k[\text{A}]^0 = k) \tag{16.6}$$

Sample Problem 16.5 shows one way integrated rate laws are applied.

SAMPLE PROBLEM 16.5 Determining the Reactant Concentration After a Given Time

Problem At 1000°C, cyclobutane (C_4H_8) decomposes in a first-order reaction, with the very high rate constant of 87 s^{-1}, to two molecules of ethylene (C_2H_4).
(a) The initial C_4H_8 concentration is 2.00 *M*. What is the concentration after 0.010 s?
(b) What fraction of C_4H_8 has decomposed in this time?

Plan **(a)** We must find the concentration of cyclobutane at time t, $[C_4H_8]_t$. We are told that this is a first-order reaction, so we use the integrated first-order rate law:

$$\ln\frac{[C_4H_8]_0}{[C_4H_8]_t} = kt$$

We know k (87 s^{-1}), t (0.010 s), and $[C_4H_8]_0$ (2.00 *M*), so we can solve for $[C_4H_8]_t$.

(b) The fraction decomposed is the concentration that has decomposed divided by the initial concentration:

$$\text{Fraction decomposed} = \frac{[C_4H_8]_0 - [C_4H_8]_t}{[C_4H_8]_0}$$

Solution **(a)** Substituting the data into the integrated rate law:

$$\ln \frac{2.00 \text{ mol/L}}{[C_4H_8]_t} = (87 \text{ s}^{-1})(0.010 \text{ s}) = 0.87$$

Taking the antilog of both sides:

$$\frac{2.00 \text{ mol/L}}{[C_4H_8]_t} = e^{0.87} = 2.4$$

Solving for $[C_4H_8]_t$:

$$[C_4H_8]_t = \frac{2.00 \text{ mol/L}}{2.4} = 0.83 \text{ mol/L}$$

(b) Finding the fraction that has decomposed after 0.010 s:

$$\frac{[C_4H_8]_0 - [C_4H_8]_t}{[C_4H_8]_0} = \frac{2.00 \text{ mol/L} - 0.83 \text{ mol/L}}{2.00 \text{ mol/L}} = 0.58$$

Check The concentration remaining after 0.010 s (0.83 mol/L) is less than the starting concentration (2.00 mol/L), which makes sense. Raising e to an exponent slightly less than 1 should give a number (2.4) slightly less than the value of e (2.718). Moreover, the final result makes sense: a high rate constant indicates a fast reaction, so it's not surprising that so much decomposes in such a short time.

FOLLOW-UP PROBLEMS

16.5A At 25°C, hydrogen iodide breaks down very slowly to hydrogen and iodine: rate $= k[HI]^2$. The rate constant at 25°C is 2.4×10^{-21} L/mol·s. If 0.0100 mol of HI(g) is placed in a 1.0-L container, how long will it take for [HI] to reach 0.00900 mol/L (10.0% reacted)?

16.5B Hydrogen peroxide (H_2O_2) decomposes to water and oxygen in a first-order reaction. **(a)** If 1.28 M H_2O_2 changes to 0.85 M in 10.0 min at a given temperature, what is the rate constant for the decomposition reaction? **(b)** How long will it take for 25% of an initial amount of H_2O_2 to decompose? (*Hint:* Assume that $[H_2O_2]_0 = 1.0$ M.)

SOME SIMILAR PROBLEMS 16.41–16.44

Determining Reaction Orders from an Integrated Rate Law

In Sample Problem 16.3, we found the reaction orders using rate data. If rate data are not available, we rearrange the integrated rate law into an equation for a straight line, $y = mx + b$, where m is the slope and b is the y-axis intercept. We then use a graphical method to find the order:

- For a *first-order reaction,* we have

$$\ln \frac{[A]_0}{[A]_t} = kt$$

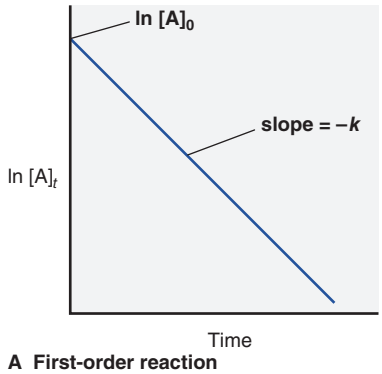
From Appendix A, we know that $\ln \dfrac{a}{b} = \ln a - \ln b$, so we have

$$\ln [A]_0 - \ln [A]_t = kt$$

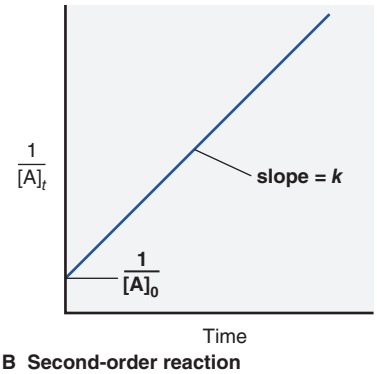
Rearranging gives

$$\ln [A]_t = -kt + \ln [A]_0$$
$$y = mx + b$$

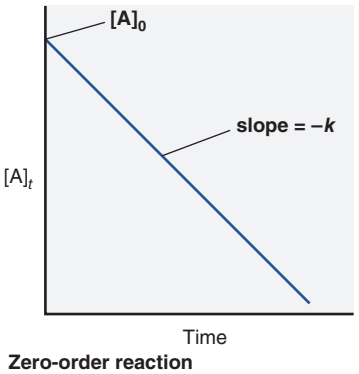
Therefore, a plot of $\ln [A]_t$ vs. t gives a straight line with slope $= -k$ and y-intercept $= \ln [A]_0$ (Figure 16.10A, *next page*).



A First-order reaction



B Second-order reaction



C Zero-order reaction

Figure 16.10 Graphical method for finding the reaction order from the integrated rate law.

- For a *second-order reaction* with one reactant, we have

$$\frac{1}{[A]_t} - \frac{1}{[A]_0} = kt$$

Rearranging gives

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$$
$$y = mx + b$$

In this case, a plot of $1/[A]_t$ vs. t gives a straight line with slope $= k$ and y-intercept $= 1/[A]_0$ (Figure 16.10B).

- For a *zero-order reaction,* we have

$$[A]_t - [A]_0 = -kt$$

Rearranging gives

$$[A]_t = -kt + [A]_0$$
$$y = mx + b$$

A plot of $[A]_t$ vs. t gives a straight line with slope $= -k$ and y-intercept $= [A]_0$ (Figure 16.10C).

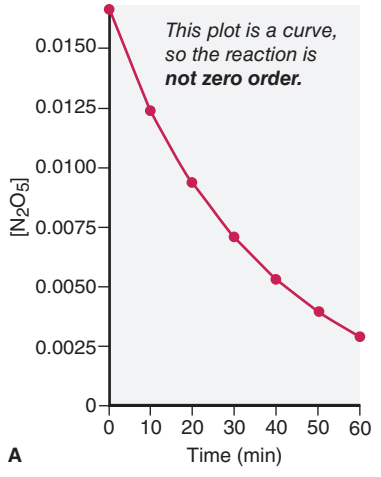
Some trial-and-error graphical plotting is required to find the reaction order from the concentration and time data:

- If you obtain a straight line when you plot ln [reactant] vs. t, the reaction is *first order* with respect to that reactant.
- If you obtain a straight line when you plot 1/[reactant] vs. t, the reaction is *second order* with respect to that reactant.
- If you obtain a straight line when you plot [reactant] vs. t, the reaction is *zero order* with respect to that reactant.

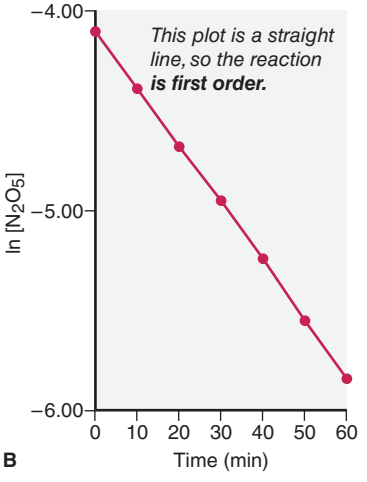
In Figure 16.11 we use this approach to determine the order for the decomposition of N_2O_5. When we plot the data from each column in the table vs. time, we find that the plot of ln $[N_2O_5]$ vs. t *is* linear (part B), while the plots of $[N_2O_5]$ vs. t (part A) and of $1/[N_2O_5]$ vs. t (part C) are *not;* therefore, the decomposition is first order in N_2O_5.

Figure 16.11 Graphical determination of the reaction order for the decomposition of N_2O_5. The time and concentration data in the table are used to obtain the three plots, **A, B,** and **C.**

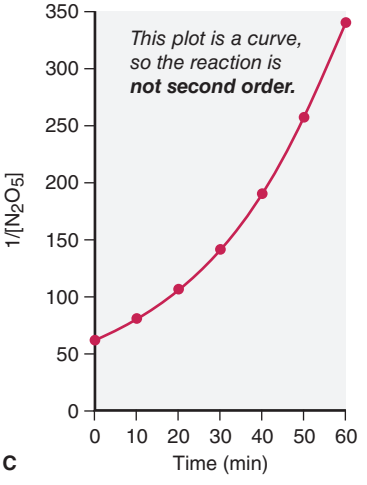
Time (min)	$[N_2O_5]$	ln $[N_2O_5]$	$1/[N_2O_5]$
0	0.0165	−4.104	60.6
10	0.0124	−4.390	80.6
20	0.0093	−4.68	1.1×10^2
30	0.0071	−4.95	1.4×10^2
40	0.0053	−5.24	1.9×10^2
50	0.0039	−5.55	2.6×10^2
60	0.0029	−5.84	3.4×10^2



A



B



C

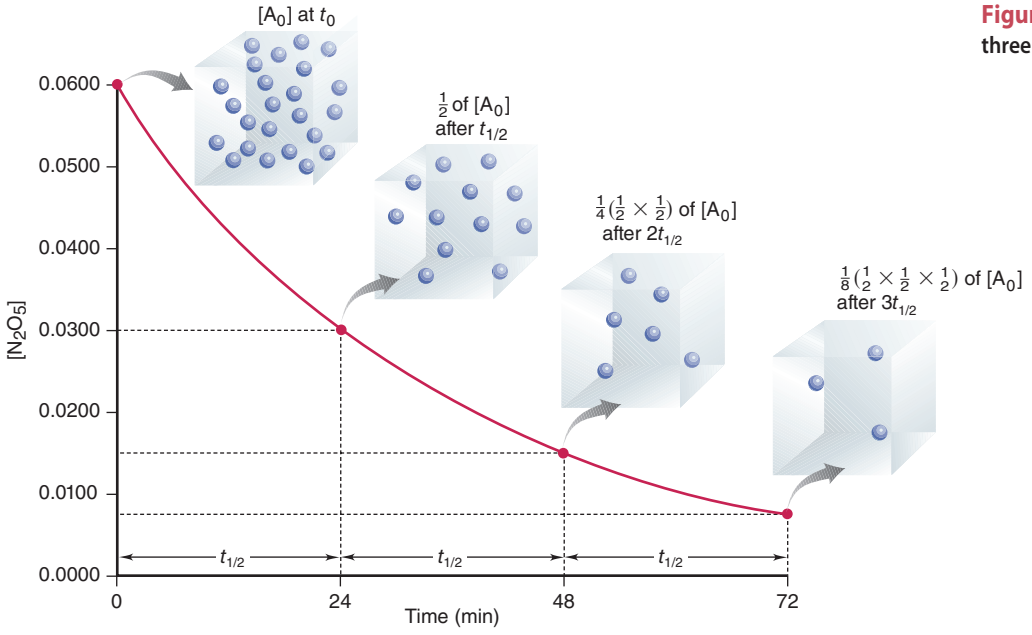


Figure 16.12 A plot of $[N_2O_5]$ vs. time for three reaction half-lives.

Reaction Half-Life

The **half-life ($t_{1/2}$)** of a reaction is the time it takes for the reactant concentration to reach *half its initial value*. A half-life has time units appropriate for the specific reaction and is characteristic of that reaction at a given temperature. For example, at 45°C, the half-life for the decomposition of N_2O_5, which we know is first order, is 24.0 min. Therefore, if we start with, say, 0.0600 mol/L of N_2O_5 at 45°C, 0.0300 mol/L will have reacted after 24 min (one half-life), and 0.0300 mol/L will remain; after 48 min (two half-lives), 0.0150 mol/L will remain; after 72 min (three half-lives), 0.0075 mol/L will remain, and so forth (Figure 16.12). The mathematical expression for the half-life depends on the overall order of the reaction.

First-Order Reactions We can derive an expression for the half-life of a first-order reaction from the integrated rate law, which is

$$\ln \frac{[A]_0}{[A]_t} = kt$$

By definition, after one half-life, $t = t_{1/2}$, and $[A]_t = \frac{1}{2}[A]_0$. Substituting and canceling $[A]_0$ gives

$$\ln \frac{\cancel{[A]_0}}{\frac{1}{2}\cancel{[A]_0}} = kt_{1/2} \qquad \text{or} \qquad \ln 2 = kt_{1/2}$$

Then, solving for $t_{1/2}$, we have

$$t_{1/2} = \frac{\ln 2}{k} = \frac{0.693}{k} \qquad \text{(first-order process; rate} = k[A]) \qquad \textbf{(16.7)}$$

Notice that $t_{1/2}$ *and* k *are inversely proportional*. Thus, a fast reaction, one with a relatively large rate constant, has a short half-life, and a slow reaction, one with a small rate constant, has a long half-life:

$$k\uparrow,\ t_{1/2}\downarrow \qquad \text{and} \qquad k\downarrow,\ t_{1/2}\uparrow$$

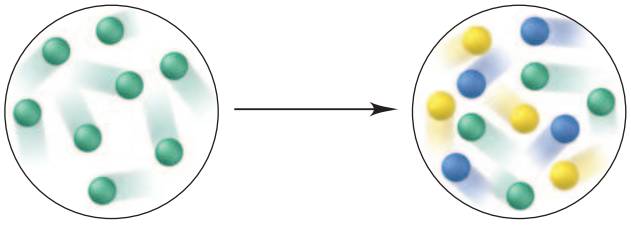
Because no concentration term appears, *for a first-order reaction, the time it takes to reach one-half the starting concentration is a constant and, thus, independent of reactant concentration.*

Decay of an unstable, radioactive nucleus is an example of a first-order process that does not involve a *chemical* change. For example, the half-life for the decay of uranium-235 is 7.1×10^8 years. Thus, a sample of ore containing uranium-235 will have half the original mass of uranium-235 after 7.1×10^8 years: a sample containing 1 kg will contain 0.5 kg of uranium-235, a sample containing 1 mg will contain 0.5 mg, and so forth. (We discuss radioactive decay thoroughly in Chapter 24.)

The next two sample problems show some ways to use half-life in calculations: the first is based on molecular scenes.

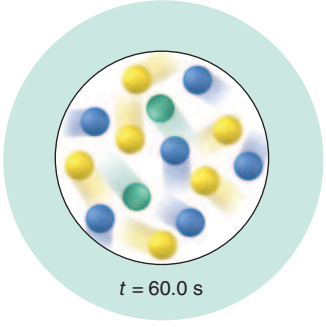
SAMPLE PROBLEM 16.6 Using Molecular Scenes to Find Quantities at Various Times

Problem Substance A *(green)* decomposes to two other substances, B *(blue)* and C *(yellow),* in a first-order gaseous reaction. The molecular scenes below show a portion of the reaction mixture at two different times:



(a) Draw a similar molecular scene of the reaction mixture at $t = 60.0$ s.
(b) Find the rate constant for the reaction.
(c) If the total pressure (P_{total}) of the mixture is 5.00 atm at 90.0 s, what is the partial pressure of substance B (P_B)?

Plan We are shown molecular scenes of a reaction at two times with various numbers of reactant and product particles and have to predict quantities at two later times. **(a)** We count the number of A particles and see that A has decreased by half after 30.0 s; thus, the half-life is 30.0 s. The time $t = 60.0$ s represents two half-lives, so the number of A will decrease by half again, and each A forms one B and one C. **(b)** We substitute the value of the half-life in Equation 16.7 to find k. **(c)** First, we find the numbers of particles at $t = 90.0$ s, which represents three half-lives. To find P_B, we multiply the mole fraction of B, X_B, by P_{total} (5.00 atm) (Chapter 5). To find X_B, we know that the number of particles is equivalent to the number of moles, so we divide the number of B particles by the total number of particles.



Solution **(a)** The number of A particles decreased from 8 to 4 in one half-life (30.0 s), so after two half-lives (60.0 s), the number would be 2 (1/2 of 4) A particles. Each A decomposes to 1 B and 1 C, so 6 (8 − 2) particles of A form 6 of B and 6 of C *(see margin).*
(b) Finding the rate constant, k:

$$t_{1/2} = \frac{0.693}{k} \qquad \text{so} \qquad k = \frac{0.693}{t_{1/2}} = \frac{0.693}{30.0\ \text{s}} = 2.31\times10^{-2}\ \text{s}^{-1}$$

(c) Finding the number of particles after 90.0 s: After a third half-life, there would be 1 A, 7 B, and 7 C particles.
Finding the mole fraction of B, X_B:

$$X_B = \frac{7}{1 + 7 + 7} = \frac{7}{15} = 0.467$$

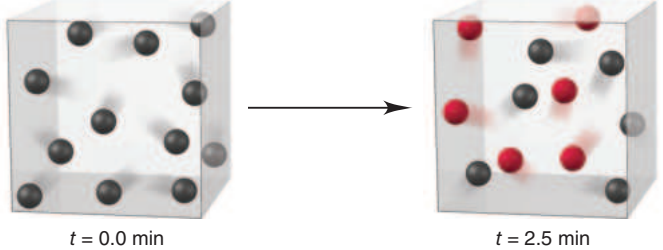
Finding the partial pressure of B, P_B:

$$P_B = X_B \times P_{total} = 0.467 \times 5.00\ \text{atm} = 2.33\ \text{atm}$$

Check For (b), rounding gives 0.7/30, which is a bit over 0.02, so the answer seems correct. For (c), X_B is almost 0.5, so P_B is a bit less than half of 5 atm, or <2.5 atm.

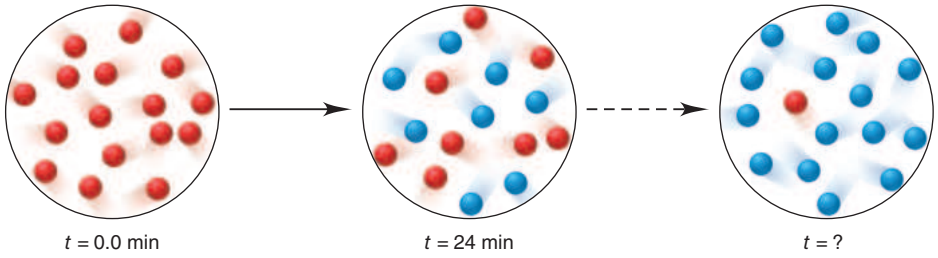
FOLLOW-UP PROBLEMS

16.6A Substance X *(black)* changes to substance Y *(red)* in a first-order gaseous reaction. The scenes below represent the reaction mixture in cubic containers at two different times:



(a) Draw a scene that represents the mixture at 5.0 min.
(b) If each particle in the container actually represents 0.20 mol of particles and the volume of the cubic container is 0.50 L, what is the molarity of X at 10.0 min?

16.6B Substance A *(red)* changes to substance B *(blue)* in a first-order gaseous reaction. The scenes below represent the reaction mixture at three different times:



(a) What is the time at which the third scene occurs?
(b) If each particle in the circle actually represents 0.10 mol of particles and the volume of the container is 0.25 L, what is the molarity of A at 72 min?

A SIMILAR PROBLEM 16.116(b)

SAMPLE PROBLEM 16.7 Determining the Half-Life of a First-Order Reaction

Problem Cyclopropane is the smallest cyclic hydrocarbon. Because its 60° bond angles reduce orbital overlap, its bonds are weak. As a result, it is thermally unstable and rearranges to propene at 1000°C via the following first-order reaction:

$$\begin{array}{l} \quad\quad CH_2 \\ \quad\quad /\ \backslash \\ H_2C{-}CH_2(g) \end{array} \xrightarrow{\Delta} CH_3{-}CH{=}CH_2(g)$$

The rate constant is 9.2 s^{-1}.
(a) What is the half-life of the reaction?
(b) How long does it take for the concentration of cyclopropane to reach one-quarter of the initial value?

Plan **(a)** The cyclopropane rearrangement is first order, so to find $t_{1/2}$ we use Equation 16.7 and substitute for k (9.2 s^{-1}). **(b)** Each half-life decreases the concentration to one-half of its initial value, so two half-lives decrease it to one-quarter.

Solution **(a)** Solving for $t_{1/2}$:

$$t_{1/2} = \frac{\ln 2}{k} = \frac{0.693}{9.2\ s^{-1}}$$
$$= 0.075\ s$$

It takes 0.075 s for half the cyclopropane to form propene at this temperature.
(b) Finding the time to reach one-quarter of the initial concentration:

$$\text{Time} = 2(t_{1/2}) = 2(0.075\ s)$$
$$= 0.15\ s$$

Check For part (a), rounding gives 0.7/9 s^{-1} = 0.08 s, so the answer seems correct.

FOLLOW-UP PROBLEMS

16.7A Iodine-123 is used to study thyroid gland function. This radioactive isotope breaks down in a first-order process with a half-life of 13.1 h. What is the rate constant for the process?

16.7B The half-life of a pesticide determines its persistence in the environment. A common pesticide degrades in a first-order process with a rate constant of $9\times10^{-2}\ day^{-1}$.
(a) What is the half-life of the breakdown reaction?
(b) What fraction of the pesticide remains in the environment after 40 days?

SOME SIMILAR PROBLEMS 16.43 and 16.44

Second-Order Reactions In contrast to the half-life of a first-order reaction, the half-life of a second-order reaction *does* depend on reactant concentration:

$$t_{1/2} = \frac{1}{k[\mathrm{A}]_0} \qquad \text{(second-order process; rate} = k[\mathrm{A}]^2\text{)}$$

Note that here *the half-life is **inversely** proportional to the initial reactant concentration.* This relationship means that a second-order reaction with a high initial reactant concentration has a *shorter* half-life, and one with a low initial reactant concentration has a *longer* half-life. It also means that, for a particular reaction, each successive half-life is double the preceding one, since [A] is halved during each half-life.

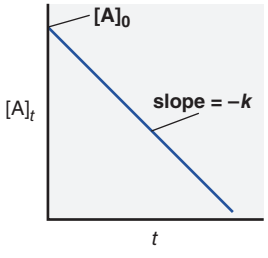
Zero-Order Reactions In contrast to the half-life of a second-order reaction, *the half-life of a zero-order reaction is **directly** proportional to the initial reactant concentration:*

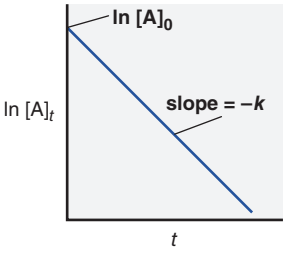
$$t_{1/2} = \frac{[\mathrm{A}]_0}{2k} \qquad \text{(zero-order process; rate} = k\text{)}$$

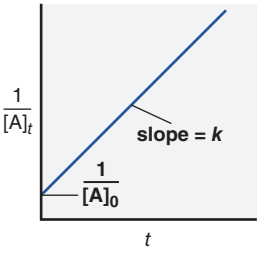
Thus, if a zero-order reaction begins with a high reactant concentration, it has a longer half-life than if it begins with a low reactant concentration.

Table 16.4 summarizes the features of zero-, first-, and second-order reactions.

Table 16.4 An Overview of Zero-Order, First-Order, and Simple Second-Order Reactions

	Zero Order	First Order	Second Order
Rate law	rate $= k$	rate $= k[\mathrm{A}]$	rate $= k[\mathrm{A}]^2$
Units for k	mol/L·s	1/s	L/mol·s
Half-life	$\frac{[\mathrm{A}]_0}{2k}$	$\frac{\ln 2}{k}$	$\frac{1}{k[\mathrm{A}]_0}$
Integrated rate law in straight-line form	$[\mathrm{A}]_t = -kt + [\mathrm{A}]_0$	$\ln [\mathrm{A}]_t = -kt + \ln [\mathrm{A}]_0$	$1/[\mathrm{A}]_t = kt + 1/[\mathrm{A}]_0$
Plot for straight line	$[\mathrm{A}]_t$ vs. t	$\ln [\mathrm{A}]_t$ vs. t	$1/[\mathrm{A}]_t$ vs. t
Slope, y-intercept	$-k$, $[\mathrm{A}]_0$	$-k$, $\ln [\mathrm{A}]_0$	k, $1/[\mathrm{A}]_0$
			






Summary of Section 16.4

- Integrated rate laws are used to find either the time needed to reach a certain concentration of reactant or the concentration present after a given time.
- Rearrangements of the integrated rate laws that give equations in the form of a straight line allow us to determine reaction orders and rate constants graphically.
- The half-life is the time needed for the reactant concentration to reach half its initial value; for first-order reactions, the half-life is constant, that is, independent of concentration.

16.5 THEORIES OF CHEMICAL KINETICS

As was pointed out at the beginning of the chapter, concentration and temperature have major effects on reaction rate. Chemists employ two models—*collision theory* and *transition state theory*—to explain these effects.

Collision Theory: Basis of the Rate Law

The basic tenet of **collision theory** is that particles—atoms, molecules, or ions—must collide to react. But number of collisions can't be the only factor determining rate, or all reactions would be over in an instant. For example, at 1 atm and 20°C, the N_2 and O_2 molecules in 1 mL of air experience about 10^{27} collisions per second. If all that was needed for a reaction to occur was an N_2 molecule colliding with an O_2 molecule, our atmosphere would consist of almost all NO; in fact, only traces are present. Thus, this theory also relies on the concepts of collision energy and molecular structure to explain the effects of concentration and temperature on rate.

Why Concentrations Are Multiplied in the Rate Law Particles must collide to react, so the collision frequency, the number of collisions per unit time, provides an *upper limit* on how fast a reaction can take place. In its basic form, collision theory deals with one-step reactions, those in which two particles collide and form products: A + B ⟶ products. Suppose we have only two particles of A and two of B confined in a vessel. Figure 16.13 shows that four A-B collisions are possible. The laws of probability tell us that the number of collisions depends on the *product* of the numbers of reactant particles, not their sum. Thus, when we add another particle of A, six A-B collisions (3 × 2) are possible, not just five (3 + 2). Similarly, when we add another particle of B, nine A-B collisions (3 × 3) are possible, not just six (3 + 3). Thus, collision theory explains why we *multiply* the concentrations in the rate law to obtain the observed rate.

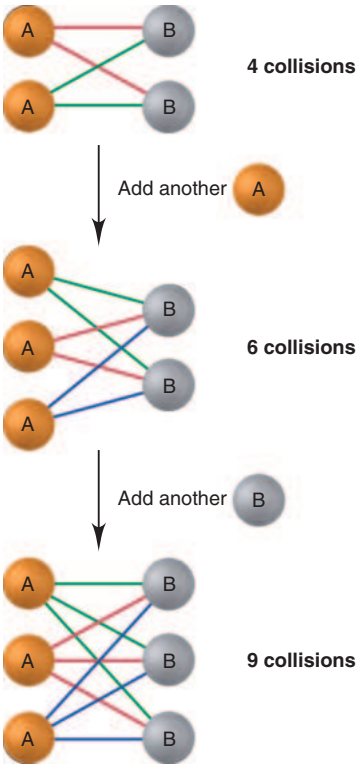


Figure 16.13 The number of possible collisions is the product, not the sum, of reactant concentrations.

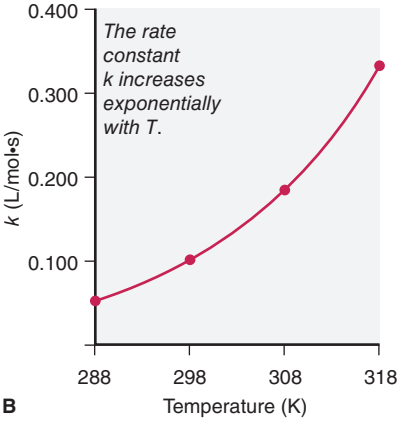
The Effect of Temperature on the Rate Constant and the Rate Temperature typically has a dramatic effect on reaction rate: for many reactions near room temperature, an increase of 10 K (10°C) doubles or triples the rate. Figure 16.14A shows kinetic data for an organic reaction—hydrolysis, or reaction with water, of the organic compound ethyl acetate. To understand the effect of temperature, we measure concentrations and times for the reaction run at different temperatures. Solving each rate expression for k and plotting the results (Figure 16.14B), we find that *k increases exponentially as T increases*.

A

Expt	[Ester]	[H_2O]	T (K)	Rate (mol/L•s)	k (L/mol•s)
1	0.100	0.200	288	1.04×10^{-3}	0.0521
2	0.100	0.200	298	2.02×10^{-3}	0.101
3	0.100	0.200	308	3.68×10^{-3}	0.184
4	0.100	0.200	318	6.64×10^{-3}	0.332

Figure 16.14 Increase of the rate constant with temperature for the hydrolysis of an ester.



B

These results are consistent with findings obtained in 1889 by the Swedish chemist Svante Arrhenius. In its modern form, the **Arrhenius equation** is

$$k = Ae^{-E_a/RT} \qquad (16.8)$$

where k is the rate constant, e is the base of natural logarithms, T is the absolute temperature, and R is the universal gas constant. (We'll focus on the term E_a in the

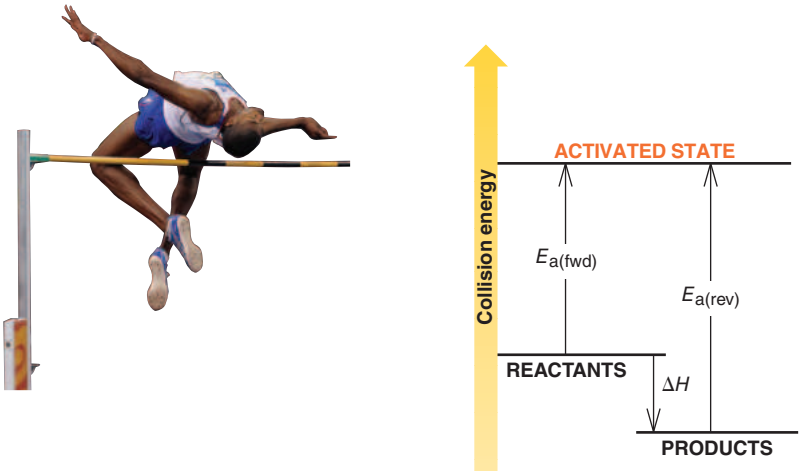


Figure 16.15 **Energy-level diagram for a reaction.** Like a high jumper with enough energy to go over the bar, molecules must collide with enough energy, E_a, to reach an activated state. (This reaction is reversible and is exothermic in the forward direction.)

next subsection and the term A a bit later.) Note the relationship between k and T, especially that T is in the denominator of a negative exponent. Thus, *as T increases, the value of the negative exponent becomes smaller, which means k becomes larger, so the rate increases:*

$$\text{Higher } T \implies \text{larger } k \implies \text{increased rate}$$

The Central Importance of Activation Energy The effect of temperature on k is closely related to the **activation energy (E_a)** of a reaction, an energy *threshold* that the colliding molecules must exceed in order to react. As an analogy, in order to succeed at the high jump, an athlete must exert at least enough energy to get over the bar. Similarly, if reactant molecules collide with a certain minimum energy, they reach an *activated state,* from which they can change to products (Figure 16.15); collisions that occur with an energy below this minimum leave the reactants unchanged.

As you can see from Figure 16.15, a reversible reaction has two activation energies. The activation energy for the forward reaction, $E_{a(fwd)}$, is the energy difference between the activated state and the reactants; the activation energy for the reverse reaction, $E_{a(rev)}$, is the energy difference between the activated state and the products. The reaction represented in the diagram is exothermic ($\Delta H_{rxn} < 0$) in the forward direction. Thus, the products are at a lower energy than the reactants, and $E_{a(fwd)}$ is less than $E_{a(rev)}$. This difference equals the enthalpy of reaction, ΔH_{rxn}:

$$\Delta H_{rxn} = E_{a(fwd)} - E_{a(rev)} \qquad \textbf{(16.9)}$$

The Effect of Temperature on Collision Energy As we mentioned in Section 16.1, a rise in temperature has two effects on moving particles: it causes a higher collision *frequency* and a higher collision *energy*. Let's see how each affects rate.

- *Collision frequency*. If particles move faster, they collide more often. Calculations show that a 10 K rise in temperature from, say, 288 K to 298 K, increases the average molecular speed by 2%, which would lead to, at most, a 4% increase in rate. Thus, higher collision frequency cannot possibly account for the doubling or tripling of rates observed with a 10 K rise. Indeed, the effect of temperature on collision *frequency* is only a minor factor.

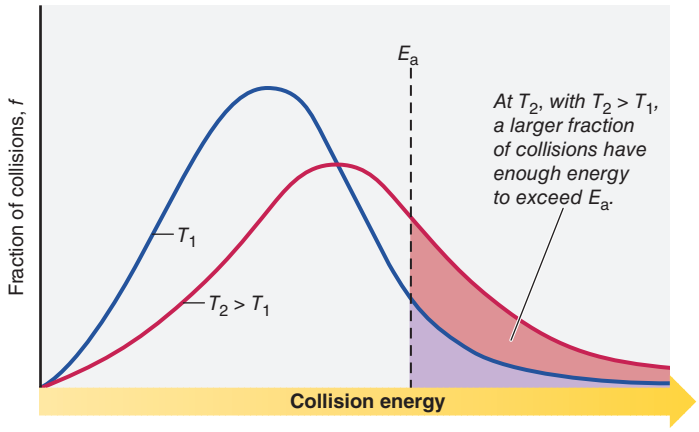

Figure 16.16 The effect of temperature on the distribution of collision energies.

- *Collision energy.* On the other hand, the effect of temperature on collision *energy* is a major factor. At a given temperature, the fraction f of collisions with energy equal to or greater than E_a is

$$f = e^{-E_a/RT}$$

where e is the base of natural logarithms, T is the absolute temperature, and R is the universal gas constant. The right side of this expression appears in the Arrhenius equation (Equation 16.8), which shows that a rise in T causes a larger k. We now see why—*a rise in temperature increases the kinetic energy of the reactant particles and enlarges the fraction of collisions with enough energy to exceed* E_a (Figure 16.16).

Table 16.5 shows that the magnitudes of *both* E_a *and* T *affect the size of this fraction* for the hydrolysis of ethyl acetate that we discussed above. In the top portion, temperature is held constant, and the fraction of sufficiently energetic collisions shrinks several orders of magnitude with each 25-kJ/mol increase in E_a. (To extend the high jump analogy, as the height of the bar is raised, a smaller fraction of the athletes have enough energy to jump over it.) In the bottom portion, E_a is held constant, and the fraction nearly doubles for each 10 K (10°C) rise in temperature.

Therefore, *the smaller the activation energy (or the higher the temperature), the larger the fraction of sufficiently energetic collisions, the larger the value of k, and the higher the reaction rate:*

Smaller E_a (or higher T) $\Longrightarrow$ larger f $\Longrightarrow$ larger k $\Longrightarrow$ higher rate

Table 16.5 The Effect of E_a and T on the Fraction (f) of Collisions with Sufficient Energy to Allow Reaction

E_a (kJ/mol)	f (at T = 298 K)
50	1.70×10^{-9}
75	7.03×10^{-14}
100	2.90×10^{-18}
T	**f (at E_a = 50 kJ/mol)**
25°C (298 K)	1.70×10^{-9}
35°C (308 K)	3.29×10^{-9}
45°C (318 K)	6.12×10^{-9}

Calculating the Activation Energy We can calculate E_a from the Arrhenius equation by taking the natural logarithm of both sides of the equation, which recasts it into the form of an equation for a straight line:

$$k = Ae^{-E_a/RT}$$

$$\ln k = \ln A - \frac{E_a}{R}\left(\frac{1}{T}\right)$$

$$y = b + mx$$

A plot of ln k vs. $1/T$ gives a straight line whose slope is $-E_a/R$ and whose y-intercept is ln A (Figure 16.17). We know the constant R, so we can determine E_a graphically from a series of k values at different temperatures.

We can find E_a in another way if we know the rate constants at two temperatures, T_2 and T_1:

$$\ln k_2 = \ln A - \frac{E_a}{R}\left(\frac{1}{T_2}\right) \qquad \ln k_1 = \ln A - \frac{E_a}{R}\left(\frac{1}{T_1}\right)$$

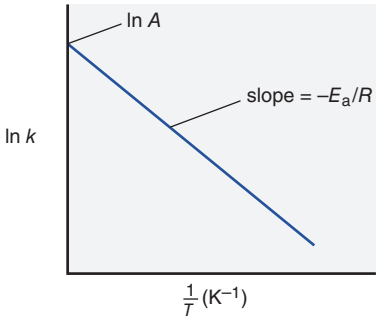

Figure 16.17 Graphical determination of the activation energy.

When we subtract ln k_1 from ln k_2, the term ln A drops out and the other terms can be rearranged to give

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right) \qquad (16.10)$$

Then, we can solve for E_a, as in the next sample problem.

SAMPLE PROBLEM 16.8 Determining the Energy of Activation

Problem The decomposition of hydrogen iodide, $2HI(g) \longrightarrow H_2(g) + I_2(g)$, has rate constants of 9.51×10^{-9} L/mol·s at 500. K and 1.10×10^{-5} L/mol·s at 600. K. Find E_a.

Plan We are given the rate constants, k_1 and k_2, at two temperatures, T_1 and T_2, so we substitute into Equation 16.10 and solve for E_a.

Solution Rearranging Equation 16.10 to solve for E_a:

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

$$E_a = R\left(\ln \frac{k_2}{k_1}\right)\left(\frac{1}{T_1} - \frac{1}{T_2}\right)^{-1}$$

$$= (8.314 \text{ J/mol·K})\left(\ln \frac{1.10\times10^{-5} \text{ L/mol·s}}{9.51\times10^{-9} \text{ L/mol·s}}\right)\left(\frac{1}{500. \text{ K}} - \frac{1}{600. \text{ K}}\right)^{-1}$$

$$= 1.76\times10^{5} \text{ J/mol} = 1.76\times10^{2} \text{ kJ/mol}$$

Comment Be sure to retain the same number of significant figures in $1/T$ as you have in T, or a significant error could be introduced. Round to the correct number of significant figures only at the final answer. On most pocket calculators, the expression $(1/T_1 - 1/T_2)$ is entered as follows: $(T_1)(1/x) - (T_2)(1/x) =$.

FOLLOW-UP PROBLEMS

16.8A The reaction $2NOCl(g) \longrightarrow 2NO(g) + Cl_2(g)$ has an E_a of 1.00×10^{2} kJ/mol and a rate constant of 0.286 L/mol·s at 500. K. What is the rate constant at 490. K?

16.8B The decomposition reaction $2NO_2(g) \longrightarrow 2NO(g) + O_2(g)$ has an E_a of 1.14×10^{5} J/mol and a rate constant of 7.02×10^{-3} L/mol·s at 500. K. At what temperature will the rate be twice as fast?

SOME SIMILAR PROBLEMS 16.59, 16.60, and 16.63

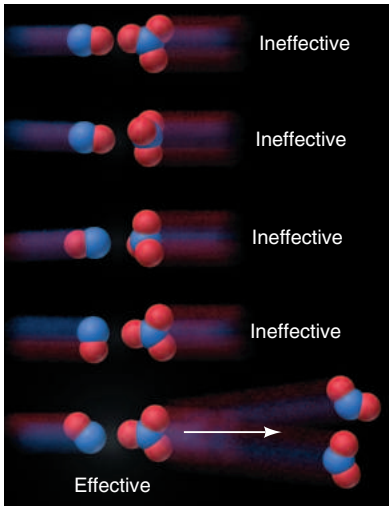

Figure 16.18 The importance of molecular orientation to an effective collision. In the one effective orientation *(bottom)*, contact occurs between the atoms that become bonded in the product.

The Effect of Molecular Structure on Rate At ordinary temperatures, the enormous number of collisions per second between reactant particles is reduced by six or more orders of magnitude by counting only those with enough energy to react. And, even this tiny fraction of all collisions is typically much larger than the number of **effective collisions,** those that actually lead to product because *the atoms that become bonded in the product make contact.* Thus, to be effective, a collision must have enough energy *and* the appropriate *molecular orientation.*

In the Arrhenius equation, molecular orientation is contained in the term A:

$$k = Ae^{-E_a/RT}$$

This term is the **frequency factor,** the product of the collision frequency Z and an *orientation probability factor, p,* which is specific for each reaction:

$$A = pZ$$

The factor p is related to the structural complexity of the reactants. You can think of p as the ratio of effectively oriented collisions to all possible collisions. Figure 16.18 shows a few of the possible collision orientations for the following reaction:

$$NO(g) + NO_3(g) \longrightarrow 2NO_2(g)$$

Of the five orientations shown, only one has the effective orientation, with the N of NO making contact with an O of NO_3 to form a new nitrogen-oxygen bond.

Actually, the *p* value for this reaction is 0.006: only 6 collisions in every 1000 (1 in 167) have the correct orientation.

The more complex the molecular structure, the smaller the p value is. Individual atoms are spherical, so reactions between them have *p* values near 1: as long as reacting atoms collide with enough energy, the product can form. At the other extreme are biochemical reactions in which two small molecules (or portions of larger molecules) react only when they collide with enough energy on a specific tiny region of a giant protein. The *p* value for these reactions is often much less than 10^{-6}, fewer than one in a million. The fact that countless such biochemical reactions are occurring in you right now attests to the astounding number of collisions per second!

Transition State Theory: What the Activation Energy Is Used For

Collision theory explains the importance of effective collisions, and **transition state theory** focuses on the high-energy species that exists at the moment of an effective collision when reactants are becoming products.

Visualizing the Transition State As two molecules approach each other, repulsions between their electron clouds continually increase, so they slow down as some of their kinetic energy is converted to potential energy. If they collide, but the energy of the collision is *less* than the activation energy, the molecules bounce off each other and no reaction occurs.

However, in a tiny fraction of collisions in which the molecules are moving fast enough, *their kinetic energies push them together with enough force to overcome the repulsions and surpass the activation energy.* And, in an even tinier fraction of these sufficiently energetic collisions, the molecules are oriented effectively. In those cases, nuclei in one molecule attract electrons in the other, atomic orbitals overlap, electron densities shift, and some bonds lengthen and weaken while others shorten and strengthen. At some point during this smooth transformation, *a species with partial bonds exists* that is neither reactant nor product. This very unstable species, called the **transition state** (or **activated complex**) exists only at the instant of highest potential energy. Thus, *the activation energy of a reaction is used to reach the transition state.*

Transition states cannot be isolated, but the work of Ahmed H. Zewail, who received the 1999 Nobel Prize in chemistry, greatly expanded our knowledge of them. Using lasers pulsing at the time scale of bond vibrations (10^{-15} s), his team observed transition states forming and decomposing. A few, such as the one that forms as methyl bromide reacts with hydroxide ion, have been well studied:

$$BrCH_3 + OH^- \longrightarrow Br^- + CH_3OH$$

The electronegative bromine makes the carbon in $BrCH_3$ partially positive, and the carbon attracts the negatively charged oxygen in OH^-. As a C—O bond begins to form, the Br—C bond begins to weaken. In the transition state (Figure 16.19), C is surrounded by five atoms (trigonal bipyramidal; Section 10.2), which never occurs in carbon's stable compounds. This high-energy species has three normal C—H bonds and two partial bonds, one from C to O and the other from Br to C.

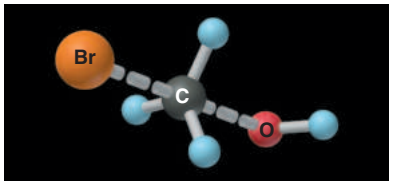

Figure 16.19 The transition state of the reaction between $BrCH_3$ and OH^-. Note the partial *(dashed)* Br—C and C—O bonds and the trigonal bipyramidal shape.

Reaching the transition state does not guarantee that a reaction will proceed to products because *a transition state can change in either direction*. In this case, if the C—O bond continues to strengthen, products form; but, if the Br—C bond becomes stronger again, the transition state reverts to reactants.

Depicting the Change with a Reaction Energy Diagram A useful way to depict these events is with a **reaction energy diagram,** which plots how potential energy changes as the reaction proceeds from reactants to products (the *reaction progress*). The diagram shows the relative energy levels of reactants, products, and transition state, as well as the forward and reverse activation energies and the enthalpy of reaction.

The bottom of Figure 16.20 shows the diagram for the reaction of $BrCH_3$ and OH^-. This reaction is exothermic, so reactants are higher in energy than products, which means $E_{a(fwd)}$ is less than $E_{a(rev)}$. Above the diagram are molecular-scale views at various points during the reaction and corresponding structural formulas. At the top of the figure are electron density relief maps of the Br, C, and O atoms: note the gradual change in electron density from C overlapping Br *(left)* to C overlapping O *(right)*.

Transition state theory proposes that *every reaction (or every step in an overall reaction) goes through its own transition state.* Figure 16.21 presents reaction energy diagrams for two gas-phase reactions. In each case, the structure of the transition state is predicted from the orientations of the reactant atoms that must become bonded in the product.

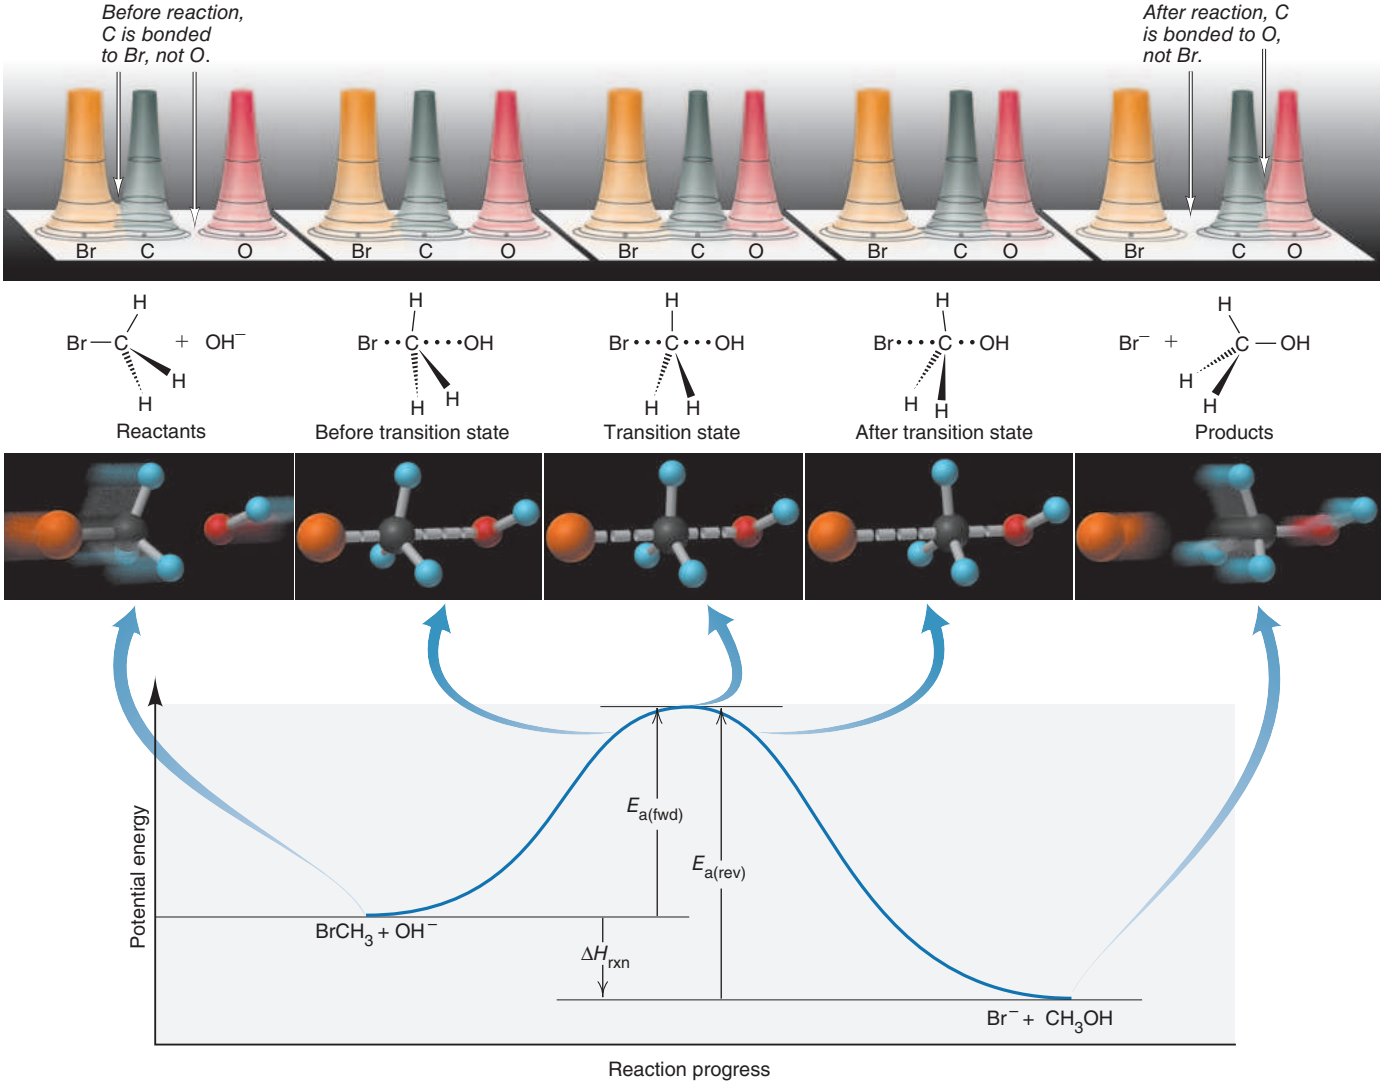

Figure 16.20 Depicting the reaction between $BrCH_3$ and OH^-. In order *(bottom to top)* are the reaction energy diagram with blow-up arrows at five points during the reaction, molecular-scale views, structural formulas, and electron density relief maps. Note the gradual, simultaneous C—O bond forming and Br—C bond breaking.

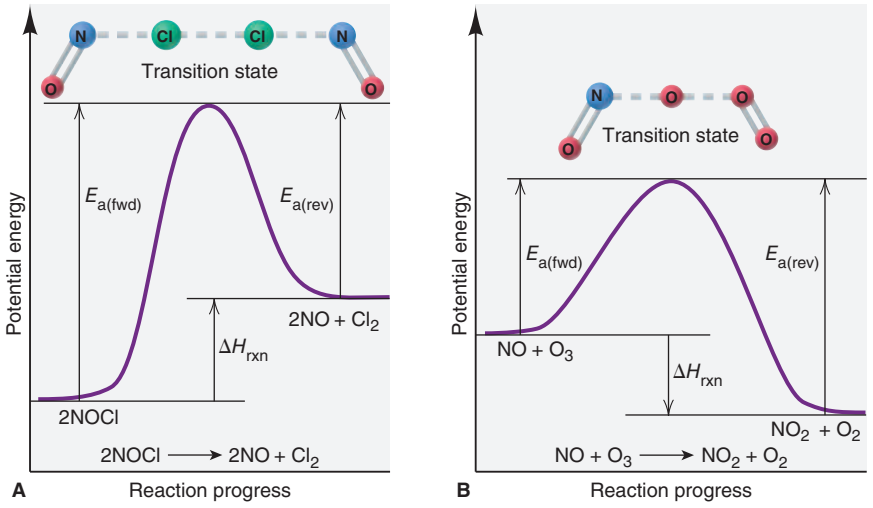

Figure 16.21 Reaction energy diagrams and possible transition states for two reactions.

SAMPLE PROBLEM 16.9 Drawing Reaction Energy Diagrams and Transition States

Problem A key reaction in the upper atmosphere is

$$O_3(g) + O(g) \longrightarrow 2O_2(g)$$

The $E_{a(fwd)}$ is 19 kJ, and the ΔH_{rxn} for the reaction as written is −392 kJ. Draw a reaction energy diagram, predict a structure for the transition state, and calculate $E_{a(rev)}$.

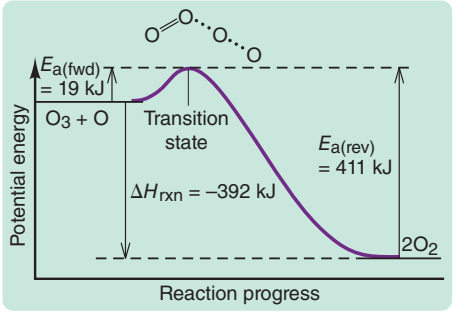
Plan The reaction is highly exothermic ($\Delta H_{rxn} = -392$ kJ), so the products are much lower in energy than the reactants. The small $E_{a(fwd)}$ (19 kJ) means the energy of the reactants lies slightly below that of the transition state. We use Equation 16.9 to calculate $E_{a(rev)}$. To predict the transition state, we sketch the species and note that one of the bonds in O_3 weakens, and this partially bonded O begins forming a bond to the separate O atom.

Solution Solving for $E_{a(rev)}$:

$$\Delta H_{rxn} = E_{a(fwd)} - E_{a(rev)}$$

So,
$$E_{a(rev)} = E_{a(fwd)} - \Delta H_{rxn} = 19 \text{ kJ} - (-392 \text{ kJ}) = 411 \text{ kJ}$$

The reaction energy diagram (not drawn to scale), with transition state, is shown in the margin.



Check Rounding to find $E_{a(rev)}$ gives ~20 + 390 = 410.

FOLLOW-UP PROBLEMS

16.9A The following reaction energy diagram depicts another key atmospheric reaction. Label the axes, identify $E_{a(fwd)}$, $E_{a(rev)}$, and ΔH_{rxn}, draw and label the transition state, and calculate $E_{a(rev)}$ for the reaction.

16.9B For the gas phase reaction $Cl(g) + HBr(g) \longrightarrow HCl(g) + Br(g)$, $E_{a(fwd)} = 7$ kJ and $E_{a(rev)} = 72$ kJ. Draw a reaction energy diagram; include a predicted structure for the transition state and the value of ΔH_{rxn}.

SOME SIMILAR PROBLEMS 16.61, 16.62, and 16.64

Summary of Section 16.5

- According to collision theory, reactant particles must collide to react, and the number of possible collisions is found by multiplying the number of reactant particles.
- As the Arrhenius equation shows, a rise in temperature increases the rate because it increases the rate constant.
- The activation energy, E_a, is the minimum energy needed for colliding particles to react.
- The relative E_a values for the forward and reverse reactions depend on whether the overall reaction is exothermic or endothermic.
- At higher temperatures, more collisions have enough energy to exceed E_a.
- E_a can be determined graphically from k values obtained at different T values.
- Molecules must collide with an effective orientation for them to react, so structural complexity decreases rate.
- Transition state theory focuses on the change of kinetic energy to potential energy as reactant particles collide and form an unstable transition state.
- Given a sufficiently energetic collision and an effective molecular orientation, the reactant species form the transition state, which either continues toward product(s) or reverts to reactant(s).
- A reaction energy diagram depicts the changing potential energy throughout a reaction's progress from reactants through transition states to products.

16.6 REACTION MECHANISMS: THE STEPS FROM REACTANT TO PRODUCT

You can't understand how a car works by examining the body, wheels, and dashboard, or even the engine as a whole. You need to look inside the engine to see how its parts fit together and function. Similarly, by examining the overall balanced equation, we can't know how a reaction "works." We must look "inside the reaction" to see how reactants change into products.

Most reactions occur through a **reaction mechanism,** a sequence of single reaction steps that sum to the overall equation. For example, a possible mechanism for the overall reaction

$$2A + B \longrightarrow E + F$$

might involve these three simpler steps:

(1) $A + B \longrightarrow C$

(2) $C + A \longrightarrow D$

(3) $D \longrightarrow E + F$

Adding the steps and canceling common substances gives the overall equation:

$$A + B + \cancel{C} + A + \cancel{D} \longrightarrow \cancel{C} + \cancel{D} + E + F \quad \text{or} \quad 2A + B \longrightarrow E + F$$

A mechanism is a hypothesis about how a reaction occurs; chemists *propose* a mechanism and then *test* to see that it fits with the observed rate law.

Elementary Reactions and Molecularity

The individual steps that make up a reaction mechanism are called **elementary reactions** (or **elementary steps**). Each describes a *single molecular event*—one particle decomposing, two particles combining, and so forth.

An elementary step is characterized by its **molecularity,** the number of *reactant* particles in the step. Consider the mechanism for the breakdown of ozone in the stratosphere. The overall equation is

$$2O_3(g) \longrightarrow 3O_2(g)$$

A two-step mechanism has been proposed:

(1) $O_3(g) \longrightarrow O_2(g) + O(g)$

(2) $O_3(g) + O(g) \longrightarrow 2O_2(g)$

The first step is a **unimolecular reaction,** one that involves the decomposition or rearrangement of a single particle (O_3). The second step is a **bimolecular reaction,** one in which two particles (O_3 and O) collide and react. Some *termolecular* elementary steps occur, but they are extremely rare because the probability of three particles colliding simultaneously with enough energy and an effective orientation is very small. Higher molecularities are not known. Therefore, in general, *we propose unimolecular and/or bimolecular reactions as reasonable steps in a mechanism.*

Because an elementary reaction occurs in one step, its rate law, unlike that for an overall reaction, *can* be deduced from the reaction stoichiometry: *reaction order equals molecularity*. Therefore, *only* for an elementary step, *we use the equation coefficients as the reaction orders in the rate law* (Table 16.6).

Table 16.6 Rate Laws for General Elementary Steps

Elementary Step	Molecularity	Rate Law
A ⟶ product	Unimolecular	Rate = k[A]
2A ⟶ product	Bimolecular	Rate = k[A]^2
A + B ⟶ product	Bimolecular	Rate = k[A][B]
2A + B ⟶ product	Termolecular	Rate = k[A]^2[B]

SAMPLE PROBLEM 16.10 Determining Molecularities and Rate Laws for Elementary Steps

Problem The following elementary steps are proposed for a reaction mechanism:

(1) $Cl_2(g) \rightleftharpoons 2Cl(g)$

(2) $Cl(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_3(g)$

(3) $Cl(g) + CCl_3(g) \longrightarrow CCl_4(g)$

(a) Write the balanced equation for the overall reaction.
(b) Determine the molecularity of each step.
(c) Write the rate law for each step.

Plan We find the overall equation by adding the elementary steps. The molecularity of each step equals the total number of *reactant* particles. We write the rate law for each step using the equation coefficients as reaction orders.

Solution **(a)** Writing the overall balanced equation:

$$Cl_2(g) \rightleftharpoons 2Cl(g)$$
$$Cl(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_3(g)$$
$$Cl(g) + CCl_3(g) \longrightarrow CCl_4(g)$$

$$Cl_2(g) + \cancel{Cl(g)} + CHCl_3(g) + \cancel{Cl(g)} + \cancel{CCl_3(g)} \longrightarrow 2\cancel{Cl(g)} + HCl(g) + \cancel{CCl_3(g)} + CCl_4(g)$$

$$Cl_2(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_4(g)$$

(b) Determining the molecularity of each step: The first step has one reactant, Cl_2, so it is unimolecular. The second and third steps each have two reactants (Cl and $CHCl_3$; Cl and CCl_3), so they are bimolecular.

(c) Writing the rate laws for the elementary steps:

(1) $Rate_1 = k_1[Cl_2]$

(2) $Rate_2 = k_2[Cl][CHCl_3]$

(3) $Rate_3 = k_3[Cl][CCl_3]$

Check In part (a), be sure the equation is balanced; in part (c), be sure the substances in brackets are the *reactants* of each elementary step.

FOLLOW-UP PROBLEMS

16.10A The mechanism below is proposed for the decomposition of hydrogen peroxide:

(1) $H_2O_2(aq) \longrightarrow 2OH(aq)$

(2) $H_2O_2(aq) + OH(aq) \longrightarrow H_2O(l) + HO_2(aq)$

(3) $HO_2(aq) + OH(aq) \longrightarrow H_2O(l) + O_2(g)$

(a) Write the balanced equation for the overall reaction. **(b)** Determine the molecularity of each step. **(c)** Write the rate law for each step.

16.10B The following elementary steps are proposed for a reaction mechanism:

(1) $2NO(g) \rightleftharpoons N_2O_2(g)$

(2) $N_2O_2(g) + H_2(g) \longrightarrow N_2O(g) + H_2O(g)$

(3) $N_2O(g) + H_2(g) \longrightarrow N_2(g) + H_2O(g)$

(a) Write the balanced equation for the overall reaction. **(b)** Determine the molecularity of each step. **(c)** Write the rate law for each step.

SOME SIMILAR PROBLEMS 16.72(a), 16.72(c), 16.73(a), and 16.73(c)

A Rate-Determining Step for Traffic Flow

Imagine driving home on a wide street that goes over a toll bridge. Traffic flows smoothly until the road narrows at the approach to the toll booth. Past the bridge, traffic returns to normal, and you proceed a couple of miles further to your destination. Getting through the bottleneck to pay the toll takes longer than the rest of the trip combined and, therefore, largely determines the time for the whole trip.

The Rate-Determining Step of a Reaction Mechanism

All the elementary steps in a mechanism have their own rates. However, one step is usually *much* slower than the others. This step, called the **rate-determining step** (or **rate-limiting step**), limits how fast the overall reaction proceeds. Therefore, *the rate law of the rate-determining step becomes the rate law for the overall reaction.*

Consider the reaction between nitrogen dioxide and carbon monoxide:

$$NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$$

If this reaction were an elementary step—that is, if the mechanism consisted of only one step—we could immediately write the overall rate law as

$$\text{Rate} = k[NO_2][CO]$$

But, as you saw in Sample Problem 16.3, experimental data show the rate law is

$$\text{Rate} = k[NO_2]^2$$

Thus, the overall reaction cannot be elementary.

A proposed two-step mechanism is

(1) $NO_2(g) + NO_2(g) \longrightarrow NO_3(g) + NO(g)$ [slow; rate determining]

(2) $NO_3(g) + CO(g) \longrightarrow NO_2(g) + CO_2(g)$ [fast]

In this mechanism, NO_3 functions as a **reaction intermediate,** a substance formed and used up during the reaction. Even though it does not appear in the overall balanced equation, a reaction intermediate is essential for the reaction to occur. Intermediates are less stable than the reactants and products, but unlike *much* less stable transition states, they have normal bonds and can sometimes be isolated.

Rate laws for the two elementary steps listed above are

(1) $\text{Rate}_1 = k_1[NO_2][NO_2] = k_1[NO_2]^2$

(2) $\text{Rate}_2 = k_2[NO_3][CO]$

Three key points to notice about this mechanism are

- If $k_1 = k$, the rate law for the rate-determining step (step 1) becomes identical to the observed rate law.
- Because the first step is slow, $[NO_3]$ is low. As soon as any NO_3 forms, it is consumed by the fast second step, so the reaction takes as long as the first step does.
- CO does not appear in the rate law (reaction order = 0) because it takes part in the mechanism *after* the rate-determining step.

Correlating the Mechanism with the Rate Law

Coming up with a reasonable reaction mechanism is a classic demonstration of the scientific method. Using observations and data from rate experiments, we hypothesize the individual steps and then test our hypothesis with further evidence. If the evidence supports our mechanism, we can accept it; if not, we must propose a different one. We can never *prove* that a mechanism represents the *actual* chemical change, only that it is consistent with the data.

A valid mechanism must meet three criteria:

1. *The elementary steps must add up to the overall balanced equation.*
2. *The elementary steps must be reasonable.* They should generally involve one reactant particle (unimolecular) or two (bimolecular).
3. *The mechanism must correlate with the rate law,* not the other way around.

Mechanisms with a Slow Initial Step The reaction between NO_2 and CO that we considered earlier has a mechanism with a slow initial step; that is, the first step is rate-determining. The reaction between nitrogen dioxide and fluorine is another example:

$$2NO_2(g) + F_2(g) \longrightarrow 2NO_2F(g)$$

The experimental rate law is first order in NO_2 and in F_2,

$$\text{Rate} = k[NO_2][F_2]$$

and the accepted mechanism is

(1) $NO_2(g) + F_2(g) \longrightarrow NO_2F(g) + F(g)$ [slow; rate determining]

(2) $NO_2(g) + F(g) \longrightarrow NO_2F(g)$ [fast]

Note that the free fluorine atom is a reaction intermediate.

Let's see how this mechanism meets the three criteria.

1. The elementary reactions sum to the balanced equation:

$$NO_2(g) + NO_2(g) + F_2(g) + \cancel{F(g)} \longrightarrow NO_2F(g) + NO_2F(g) + \cancel{F(g)}$$

or $$2NO_2(g) + F_2(g) \longrightarrow 2NO_2F(g)$$

2. Both steps are bimolecular and, thus, reasonable.
3. To determine whether the mechanism is consistent with the observed rate law, we first write the rate laws for the elementary steps:

   (1) $\text{Rate}_1 = k_1[NO_2][F_2]$

   (2) $\text{Rate}_2 = k_2[NO_2][F]$

   Step 1 is the rate-determining step, and with $k_1 = k$, it is the same as the overall rate law, so the third criterion is met.

Note that the second molecule of NO_2 is involved *after* the rate-determining step, so it does not appear in the overall rate law. Thus, as in the mechanism for the reaction of NO_2 and CO, *the overall rate law includes all the reactants involved in the rate-determining step.*

Mechanisms with a Fast Initial Step If the rate-limiting step in a mechanism is *not* the initial step, the product of the fast initial step builds up and starts reverting to reactant. With time, this *fast, reversible step reaches equilibrium,* as product changes to reactant as fast as it forms. As you'll see, this situation allows us to fit the mechanism to the overall rate law.

Consider the oxidation of nitrogen monoxide:

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

The observed rate law is

$$\text{Rate} = k[NO]^2[O_2]$$

and a proposed mechanism is

(1) $NO(g) + O_2(g) \rightleftharpoons NO_3(g)$ [fast, reversible]

(2) $NO_3(g) + NO(g) \longrightarrow 2NO_2(g)$ [slow; rate determining]

Let's go through the three criteria to see if this mechanism is valid. With cancellation of the reaction intermediate, NO_3, the sum of the steps gives the overall equation, so the first criterion is met:

$$NO(g) + O_2(g) + \cancel{NO_3(g)} + NO(g) \longrightarrow \cancel{NO_3(g)} + 2NO_2(g)$$

or $$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

Both steps are bimolecular, so the second criterion is met.

To see whether the third criterion—that the mechanism is consistent with the observed rate law—is met, we first write rate laws for the elementary steps:

(1) $\text{Rate}_{1(\text{fwd})} = k_1[NO][O_2]$

$\text{Rate}_{1(\text{rev})} = k_{-1}[NO_3]$

where k_{-1} is the rate constant and NO_3 is the reactant for the reverse reaction.

(2) $\text{Rate}_2 = k_2[NO_3][NO]$

Next, we show that the rate law for the rate-determining step (step 2) gives the overall rate law. As written, it does not, because it contains the intermediate NO_3, and *an overall rate law includes only reactants (and products).* We eliminate $[NO_3]$ from the rate law for step 2 by expressing it in terms of reactants, as follows. Step 1 reaches equilibrium when the forward and reverse rates are equal:

$$\text{Rate}_{1(\text{fwd})} = \text{Rate}_{1(\text{rev})} \qquad \text{or} \qquad k_1[\text{NO}][\text{O}_2] = k_{-1}[\text{NO}_3]$$

To express $[NO_3]$ in terms of reactants, we isolate it algebraically:

$$[\text{NO}_3] = \frac{k_1}{k_{-1}}[\text{NO}][\text{O}_2]$$

Then, substituting for $[NO_3]$ in the rate law for the slow step, step 2, we obtain

$$\text{Rate}_2 = k_2[\text{NO}_3][\text{NO}] = k_2\underbrace{\left(\frac{k_1}{k_{-1}}[\text{NO}][\text{O}_2]\right)}_{[\text{NO}_3]}[\text{NO}] = \frac{k_2k_1}{k_{-1}}[\text{NO}]^2[\text{O}_2]$$

With $k = \dfrac{k_2k_1}{k_{-1}}$, this rate law is identical to the overall rate law.

To summarize, we assess the validity of a mechanism with a fast initial step by

1. Writing rate laws for the fast step (both directions) and for the slow step.
2. Expressing [intermediate] in terms of [reactant] by setting the forward rate law of the reversible step equal to the reverse rate law, and solving for [intermediate].
3. Substituting the expression for [intermediate] into the rate law for the slow step to obtain the overall rate law.

An important point to note is that, *for any mechanism, only reactants involved up to and including the slow (rate-determining) step appear in the overall rate law.*

SAMPLE PROBLEM 16.11 Identifying Intermediates and Correlating Rate Laws and Reaction Mechanisms

Problem Consider the reaction mechanism in Sample Problem 16.10.
(a) Identify the intermediates in the mechanism.
(b) Assuming that step 2 is the slow (rate-determining) step, show that the mechanism is consistent with the observed rate law: Rate $= k[\text{Cl}_2]^{1/2}[\text{CHCl}_3]$.

Plan **(a)** We write each elementary step and sum to get the overall reaction. Intermediates are substances that are produced in one elementary step and consumed as reactants in a subsequent elementary step. **(b)** We use the reactants in the slow step to write its rate law; if an intermediate is present in the rate law, we eliminate it by expressing it in terms of reactants.

Solution **(a)** Determining the intermediates:

$$\text{Cl}_2(g) \rightleftharpoons 2\text{Cl}(g) \qquad \text{[fast]}$$
$$\text{Cl}(g) + \text{CHCl}_3(g) \longrightarrow \text{HCl}(g) + \text{CCl}_3(g) \qquad \text{[slow]}$$
$$\text{Cl}(g) + \text{CCl}_3(g) \longrightarrow \text{CCl}_4(g) \qquad \text{[fast]}$$

$$\text{Cl}_2(g) + \cancel{\text{Cl}(g)} + \text{CHCl}_3(g) + \cancel{\text{Cl}(g)} + \cancel{\text{CCl}_3(g)} \longrightarrow$$
$$\cancel{2\text{Cl}(g)} + \text{HCl}(g) + \cancel{\text{CCl}_3(g)} + \text{CCl}_4(g)$$
$$\text{Cl}_2(g) + \text{CHCl}_3(g) \longrightarrow \text{HCl}(g) + \text{CCl}_4(g)$$

Cl and CCl_3 are formed and used up, so the intermediates are Cl(*g*) and CCl_3(*g*).
(b) Correlating the reaction mechanism and the rate law:
Step 2 is the rate-determining step:

$$\text{Cl}(g) + \text{CHCl}_3(g) \longrightarrow \text{HCl}(g) + \text{CCl}_3(g) \qquad \text{[slow]}$$
$$\text{Rate} = k_2[\text{Cl}][\text{CHCl}_3]$$

Since it is an intermediate, [Cl] must be expressed in terms of reactants:
From step 1: $\text{Rate}_{1(\text{fwd})} = \text{Rate}_{1(\text{rev})}$ or $k_1[\text{Cl}_2] = k_{-1}[\text{Cl}]^2$

Thus, $[\text{Cl}]^2 = \dfrac{k_1}{k_{-1}}[\text{Cl}_2]$ and $[\text{Cl}] = \sqrt{\dfrac{k_1}{k_{-1}}[\text{Cl}_2]} = \sqrt{\dfrac{k_1}{k_{-1}}}[\text{Cl}_2]^{1/2}$

Substituting for [Cl] in the rate law for the slow step:

$$\text{Rate} = k_2[\text{Cl}][\text{CHCl}_3] = k_2\sqrt{\frac{k_1}{k_{-1}}}[\text{Cl}_2]^{1/2}[\text{CHCl}_3]$$

With $k = k_2\sqrt{\frac{k_1}{k_{-1}}}$, this rate law is consistent with the observed rate law.

Check Be sure that the substances identified as intermediates are not included in the overall balanced equation. In part (b), be sure that the rate-determining step is used to write the rate law and that no intermediates are included in the rate law.

FOLLOW-UP PROBLEMS

16.11A Examine the reaction mechanism in Follow-up Problem 16.10A. **(a)** Identify the intermediates in the mechanism. **(b)** The observed rate law for the decomposition of hydrogen peroxide is Rate $= k[H_2O_2]$. For the reaction mechanism to be consistent with this rate law, which step must be the rate-determining step?

16.11B The observed rate law for the overall reaction whose mechanism is shown in Follow-up Problem 16.10B is Rate $= k[NO]^2[H_2]$. **(a)** Identify the intermediates in this mechanism. **(b)** Assuming that step 2 is the slow (rate-determining) step, show that this mechanism is consistent with the observed rate law.

SOME SIMILAR PROBLEMS 16.72(b), 16.72(d), 16.72(e), 16.73(b), and 16.73(d)

Depicting a Multistep Mechanism with a Reaction Energy Diagram Figure 16.22 shows reaction energy diagrams for two reactions, each of which has a two-step mechanism. The reaction of NO_2 and F_2 (part A) starts with a slow step, and the reaction of NO and O_2 (part B) starts with a fast step. Both overall reactions are exothermic, so the product is lower in energy than the reactants. Note these key points:

- *Each step in the mechanism has its own peak with the transition state at the top.*
- The intermediates (F in part A and NO_3 in part B) are reactive, unstable species, so they are higher in energy than the reactants or product.
- The slow (rate-determining) step (step 1 in A and step 2 in B) has a *larger* E_a than the other step.

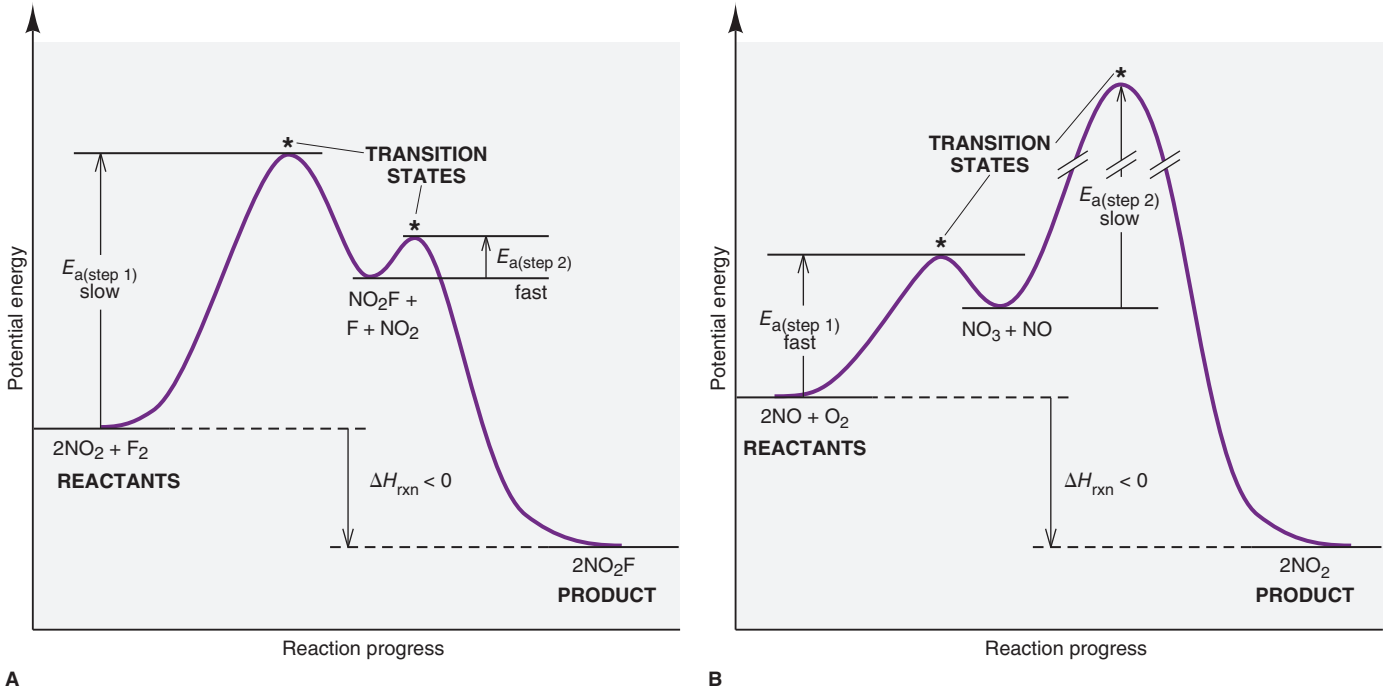


Figure 16.22 Reaction energy diagrams for the two-step reaction of (**A**) NO_2 and F_2 and of (**B**) NO and O_2.

Summary of Section 16.6

- The mechanisms of most common reactions consist of two or more elementary steps, each of which shows a single molecular event.
- The molecularity of an elementary step equals the number of reactant particles and is the same as the total reaction order of the step. Only unimolecular and bimolecular steps are reasonable.
- The rate-determining (slowest) step in a mechanism determines how fast the overall reaction occurs, and its rate law is equivalent to the overall rate law.
- Reaction intermediates are species that form in one step and react in a later one.
- For a mechanism to be valid, (1) the elementary steps must add up to the overall balanced equation, (2) the steps must be reasonable, and (3) the mechanism must correlate with the rate law.
- If a mechanism begins with a slow step, only those reactants involved in the slow step appear in the overall rate law.
- If a mechanism begins with a fast step, the product of the fast step accumulates as an intermediate, and the step reaches equilibrium. To show that the mechanism is valid, we express [intermediate] in terms of [reactant].
- Only reactants involved in steps up to and including the slow (rate-determining) step appear in the overall rate law.
- Each step in a mechanism has its own transition state, which appears at the top of a peak in the reaction energy diagram. A slower step has a higher peak (larger E_a).

16.7 CATALYSIS: SPEEDING UP A REACTION

Increasing the rate of a reaction has countless applications, in both engineering and biology. Higher temperature can speed up a reaction, but energy for industrial processes is costly and many organic and biological substances are heat sensitive. More commonly, by far, a reaction is accelerated by a **catalyst,** a substance that increases the rate *without* being consumed. Thus, only a small, nonstoichiometric amount of the catalyst is required to speed the reaction. Despite this, catalysts are employed in so many processes that several million tons are produced annually in the United States alone. Nature is the master designer and user of catalysts: every organism relies on protein catalysts, known as *enzymes,* to speed up life-sustaining reactions, and even the simplest bacterium employs thousands of them.

The Basis of Catalytic Action

Each catalyst has its own specific way of functioning, but in general, *a catalyst causes a lower activation energy, which in turn makes the rate constant larger and, thus, the reaction rate higher:*

$$\text{Catalyst} \Longrightarrow \text{lower } E_a \Longrightarrow \text{larger } k \Longrightarrow \text{higher rate}$$

Consider a general *uncatalyzed* reaction that proceeds by a one-step mechanism involving a bimolecular collision between the reactants A and B (Figure 16.23). The activation energy is relatively large, so the rate is relatively low:

$$A + B \longrightarrow \text{product} \qquad [\text{larger } E_a \Longrightarrow \text{lower rate}]$$

In the *catalyzed* reaction, reactant A interacts with the catalyst in one step to form the intermediate C, and then C reacts with B in a second step to form product and regenerate the catalyst:

$$(1)\ A + \text{catalyst} \longrightarrow C \qquad [\text{smaller } E_a \Longrightarrow \text{higher rate}]$$

$$(2)\ C + B \longrightarrow \text{product} + \text{catalyst} \qquad [\text{smaller } E_a \Longrightarrow \text{higher rate}]$$

Three points to note in Figure 16.23 are

- A catalyst speeds up the forward *and* reverse reactions. Thus, a reaction has the *same yield* with or without a catalyst, but the product forms *faster*.
- A catalyst causes a *lower total activation energy* by providing a *different mechanism* for the reaction. The total of the activation energies for both steps of the catalyzed pathway [$E_{a1(fwd)} + E_{a2(fwd)}$] is less than the forward activation energy of the uncatalyzed pathway.
- The catalyst is *not* consumed, but rather used and then regenerated.

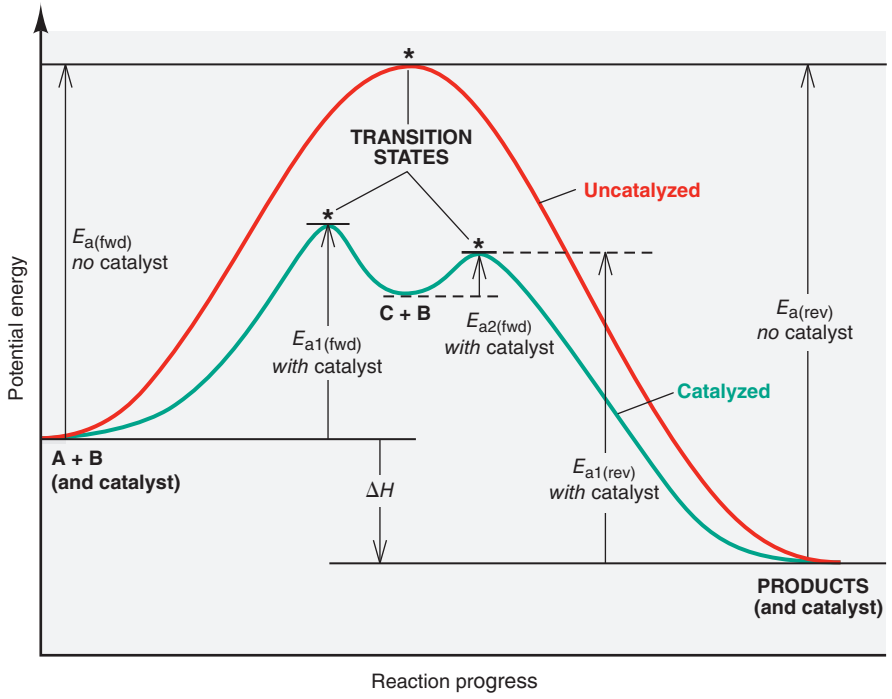

Figure 16.23 **Reaction energy diagram for a catalyzed *(green)* and an uncatalyzed *(red)* process.** A catalyst speeds a reaction by providing a different, lower energy pathway *(green)*. (Only the first step of the catalyzed reverse reaction is labeled.)

Homogeneous Catalysis

Chemists classify catalysts based on whether or not they act in the same phase as the reactants and products. A **homogeneous catalyst** exists in solution with the reaction mixture, so it must be a gas, liquid, or soluble solid.

A thoroughly studied example of homogeneous catalysis in the gas phase was formerly used in sulfuric acid manufacture. The key step, the oxidation of sulfur dioxide to sulfur trioxide, occurs so slowly that it is not economical:

$$SO_2(g) + \tfrac{1}{2}O_2(g) \longrightarrow SO_3(g)$$

In the presence of nitrogen monoxide, however, the overall reaction rate speeds up dramatically:

$$NO(g) + \tfrac{1}{2}O_2(g) \longrightarrow NO_2(g)$$
$$NO_2(g) + SO_2(g) \longrightarrow NO(g) + SO_3(g)$$

Note that NO and NO_2 cancel to give the overall reaction. Also, note that NO_2 acts as an intermediate (formed and then consumed) and NO as a catalyst (used and then regenerated).

Another well-studied example of homogeneous catalysis involves the decomposition of hydrogen peroxide in aqueous solution:

$$2H_2O_2(aq) \longrightarrow 2H_2O(l) + O_2(g)$$

Commercial H_2O_2 decomposes in light and in the presence of the small amounts of ions dissolved from glass, but it is quite stable in dark plastic containers. Many other substances speed its decomposition, including bromide ion, Br^- (Figure 16.24). The catalyzed process is thought to occur in two steps:

$$2Br^-(aq) + H_2O_2(aq) + 2H^+(aq) \longrightarrow Br_2(aq) + 2H_2O(l)$$
$$Br_2(aq) + H_2O_2(aq) \longrightarrow 2Br^-(aq) + 2H^+(aq) + O_2(g)$$

In this case, Br_2, Br^-, and H^+ cancel to give the overall balanced equation, Br^- (in the presence of H^+) is the catalyst, and Br_2 is the intermediate.

Figure 16.24 **The catalyzed decomposition of H_2O_2.** **A,** Solid NaBr is dissolved in an aqueous solution of H_2O_2. **B,** Bubbles of O_2 gas form quickly as $Br^-(aq)$ catalyzes the decomposition of H_2O_2. Note the intermediate Br_2 turns the solution orange. **C,** The solution becomes colorless when the Br_2 is consumed in the final step of the mechanism.

Heterogeneous Catalysis

A **heterogeneous catalyst** speeds up a reaction in a different phase. Most often solids interacting with gaseous or liquid reactants, these catalysts have enormous surface areas, sometimes as much as 500 m^2/g. Very early in the reaction, the rate depends on reactant concentration, but almost immediately, the reaction becomes zero order: the rate-determining step occurs on the catalyst's surface, so once the reactant covers it, adding more reactant cannot increase the rate further.

A very important organic example of heterogeneous catalysis is **hydrogenation,** the addition of H_2 to C═C bonds to form C—C bonds. The petroleum, plastics, and food industries employ this process on an enormous scale. The simplest hydrogenation converts ethylene (ethene) to ethane:

$$H_2C{=}CH_2(g) + H_2(g) \longrightarrow H_3C{-}CH_3(g)$$

In the absence of a catalyst, the reaction is very slow. But, at high H_2 pressure (high $[H_2]$) and in the presence of finely divided Ni, Pd, or Pt metal, it is rapid even at ordinary temperatures. The Group 8B(10) metals catalyze by *chemically adsorbing the reactants onto their surface* (Figure 16.25). In the rate-determining step, the adsorbed H_2 splits into two H atoms that become weakly bonded to the catalyst's surface (catM):

$$H{-}H(g) + 2\text{catM}(s) \longrightarrow 2\text{catM}{-}H \text{ (H atoms bound to metal surface)}$$

Then, C_2H_4 adsorbs and reacts with the H atoms, one at a time, to form C_2H_6. Thus, the catalyst acts by lowering the activation energy of the slow step (H—H bond breakage) as part of a different mechanism.

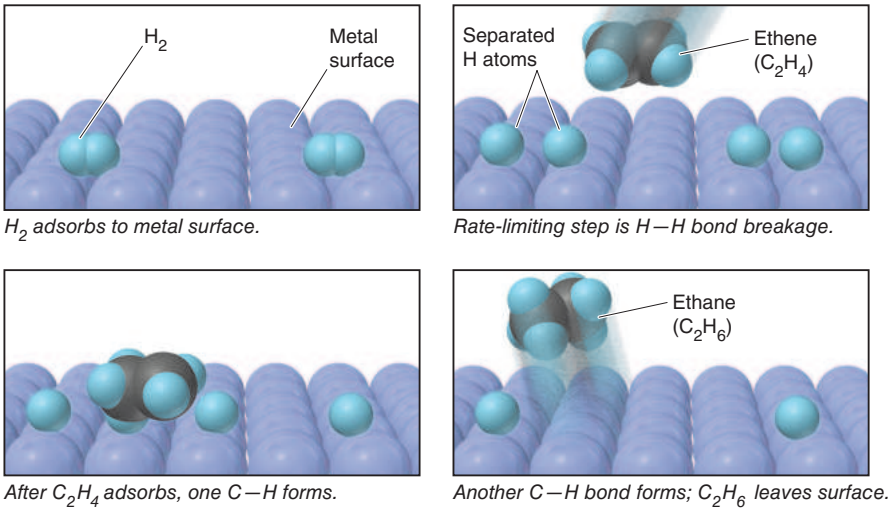

Figure 16.25 The metal-catalyzed hydrogenation of ethene.

A solid mixture of transition metals and their oxides forms a heterogeneous catalyst in your car's exhaust system. The catalytic converter speeds both the oxidation of toxic CO and unburned gasoline to CO_2 and H_2O *and* the reduction of the pollutant NO to N_2. As in the hydrogenation mechanism, the catalyst adsorbs the molecules, which weakens and splits their bonds, thus allowing the atoms to form new bonds more quickly. The process is extremely efficient: for example, an NO molecule is split into catalyst-bound N and O atoms in less than 2×10^{-12} s.

Kinetics and Function of Biological Catalysts

Whereas most industrial chemical reactions occur under extreme conditions with high concentrations, thousands of complex reactions occur in every living cell in dilute solution at ordinary temperatures and pressures. Moreover, the rate of each

reaction responds to the rates of other reactions, chemical signals from other cells, and environmental stress. In this marvelous chemical harmony, each rate is controlled by an **enzyme,** a protein catalyst whose function has been perfected through evolution.

Enzymes are globular proteins with complex shapes (Section 15.6) and molar masses ranging from about 15,000 to 1,000,000 g/mol. A small part of an enzyme's surface—like a hollow carved into a mountainside—is the **active site,** a region whose shape results from the amino-acid side chains involved in catalyzing the reaction. Often far apart in the sequence of the polypeptide chain, these groups lie near each other because of the chain's three-dimensional folding. When the reactant molecules, called **substrates,** collide effectively with the active site, they become attached through *intermolecular forces,* and the chemical change begins.

Characteristics of Enzyme Action The catalytic behavior of enzymes has several common features:

1. *Catalytic activity*. An enzyme behaves like both types of catalyst. Enzymes are typically *much* larger than the substrate, and many enzymes are embedded within cell membranes. Thus, like a heterogeneous catalyst, an enzyme provides a surface on which one reactant is temporarily immobilized to wait until the other reactant lands nearby. But, like many homogeneous catalysts, the active site groups interact with the substrate(s) in multistep sequences in the presence of solvent and other species.

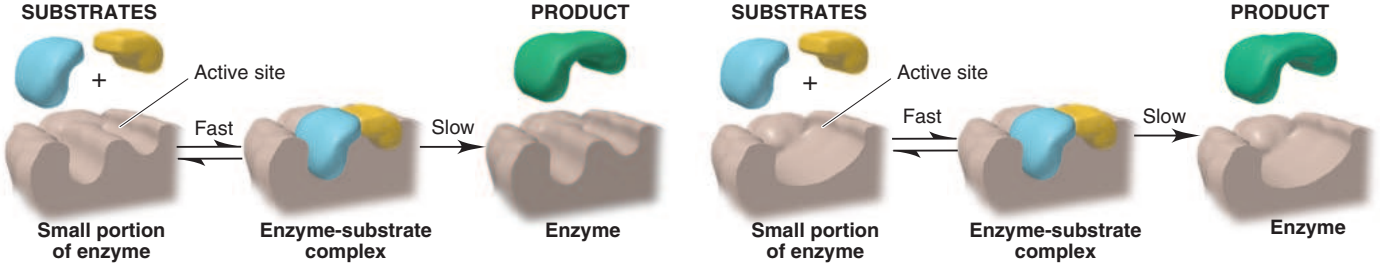
2. *Catalytic efficiency*. Enzymes are incredibly *efficient* in terms of the number of reactions catalyzed per unit time. For example, for the hydrolysis of urea,

$$(NH_2)_2C{=}O(aq) + 2H_2O(l) + H^+(aq) \longrightarrow 2NH_4^+(aq) + HCO_3^-(aq)$$

the rate constant is 3×10^{-10} s^{-1} for the uncatalyzed reaction in water at room temperature. Under the same conditions in the presence of the enzyme *urease* (pronounced "*yur*-ee-ase"), the rate constant is 3×10^{4} s^{-1}, a 10^{14}-fold increase. Enzymes typically increase rates by 10^8 to 10^{20} times, values that industrial chemists who use catalysts can only dream of!

3. *Catalytic specificity*. As a result of the particular groups at the active site, enzymes are also highly *specific:* each enzyme generally catalyzes only one reaction. Urease catalyzes *only* the hydrolysis of urea, and no other enzyme does this.

Models of Enzyme Action Two models of enzyme action have been proposed. According to the older **lock-and-key model** (Figure 16.26A), when the "key" (substrate) fits the "lock" (active site), the chemical change begins. However, x-ray crystallographic and spectroscopic methods show that, in most cases, *the enzyme changes shape when the substrate lands at the active site.* Thus, according to the more current **induced-fit model** (Figure 16.26B), the substrate induces the active site to adopt a perfect fit. Rather than a rigid key in a lock, we picture a flexible hand in a glove; the "glove" (active site) does not attain its functional shape until the "hand" (substrate) moves into it.



A Lock-and-key model: *fixed shape of active site matches shape of substrate(s).*

B Induced-fit model: *active site changes shape to bind substrate(s) more effectively.*

Figure 16.26 **Two models of enzyme action.**

CHEMICAL CONNECTIONS TO ATMOSPHERIC SCIENCE

Depletion of Earth's Ozone Layer

The stratospheric ozone layer absorbs UV radiation with wavelengths between 280 and 320 nm that is emitted by the Sun. If it reaches Earth's suface, this radiation has enough energy to damage genes by breaking bonds in DNA. Thus, depletion of stratospheric ozone increases human health risks, particularly the risks of skin cancer and cataracts (clouding of the eye's lens). The radiation may also damage plant life, especially forms at the bottom of the food chain. Both homogeneous and heterogeneous catalysts play roles in the depletion of ozone.

Before 1976, stratospheric ozone concentration varied seasonally but remained nearly constant from year to year as a result of a series of atmospheric reactions:

$$O_2 \xrightarrow{UV} 2O \qquad \text{[dissociation of } O_2 \text{ by UV]}$$
$$O + O_2 \longrightarrow O_3 \qquad \text{[ozone formation]}$$
$$O_3 + O \longrightarrow 2O_2 \qquad \text{[ozone breakdown]}$$

Then, in 1985, British scientists reported that a severe reduction of ozone, an *ozone hole,* appeared in the stratosphere over the Antarctic when the Sun ended the long winter darkness. Subsequent research by Paul J. Crutzen, Mario J. Molina, and F. Sherwood Rowland, for which they received the Nobel Prize in chemistry in 1995, revealed that industrial chlorofluorocarbons (CFCs) were lowering $[O_3]$ in the stratosphere by catalyzing the breakdown reaction.

Widely used as aerosol propellants, foaming agents, and air-conditioning coolants, large quantities of CFCs were released for years. Unreactive in the troposphere, CFC molecules gradually reach the stratosphere, where UV radiation splits them:

$$CF_2Cl_2 \xrightarrow{UV} \cdot CF_2Cl + Cl\cdot$$

(The dots are lone electrons resulting from C—Cl bond cleavage.)

Like many species with a lone electron (free radicals), atomic Cl is very reactive. It reacts with stratospheric O_3 to produce the intermediate chlorine monoxide ($ClO\cdot$), which then reacts with a free O atom to regenerate a Cl atom:

$$O_3 + Cl\cdot \longrightarrow ClO\cdot + O_2$$
$$ClO\cdot + O \longrightarrow Cl\cdot + O_2$$

The sum of these steps is the ozone breakdown reaction:

$$O_3 + \cancel{Cl\cdot} + \cancel{ClO\cdot} + O \longrightarrow \cancel{ClO\cdot} + O_2 + \cancel{Cl\cdot} + O_2$$

or

$$O_3 + O \longrightarrow 2O_2$$

Studies finding high $[ClO\cdot]$ over Antarctica supported this mechanism. Figure B16.1 shows the ozone hole expanding over the years in which CFCs accumulated.

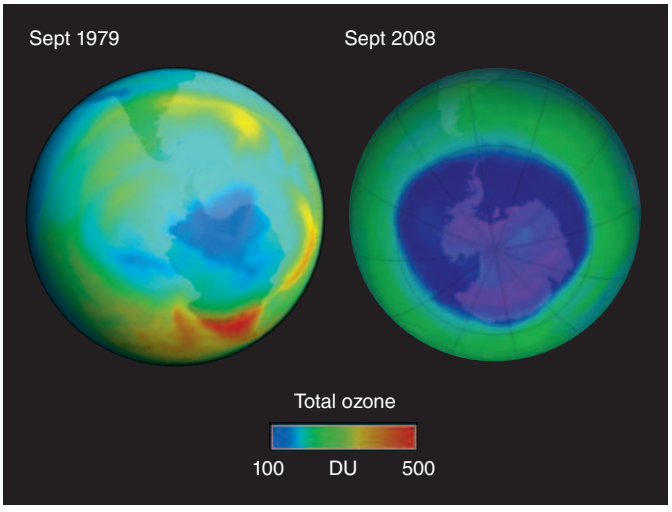


Figure B16.1 **Satellite images of the increasing size of the Antarctic ozone hole *(purple)*.**

Kinetics of Enzyme Action Kinetic studies of enzyme catalysis show that substrate (S) and enzyme (E) form an intermediate **enzyme-substrate complex (ES),** whose concentration determines the rate of formation of product (P). In other words, the rate of an enzyme-catalyzed reaction is proportional to the concentration of ES, that is, of reactant bound to catalyst. The steps common to virtually all enzyme-catalyzed reactions are

$$(1)\ E + S \rightleftharpoons ES \qquad \text{[fast, reversible]}$$
$$(2)\ ES \longrightarrow E + P \qquad \text{[slow; rate-determining]}$$

Thus, rate $= k[ES]$. As in the heterogeneous catalysis of hydrogenation (Figure 16.25), [S] is much greater than [E], and once all the enzyme molecules are bound to substrate, [ES] is as high as possible. Then, increasing [S] has no effect on rate, and the process is zero order.

Mechanisms of Enzyme Action Enzymes employ a variety of reaction mechanisms. In some cases, the active site groups bring specific atoms of the substrate close together. In others, the groups bound to the substrate move apart, stretching the bond to be broken. Many *hydrolases* have acidic groups that provide H^+ ions to speed bond cleavage. Two examples are lysozyme, an enzyme found in tears, which hydrolyzes a polysaccharide in bacterial cell walls to protect the eyes from infection, and chymotrypsin, an enzyme found in the small intestine, which hydrolyzes proteins during digestion.

Figure B16.2 shows the reaction energy diagram for the process. Note that *chlorine acts as a homogeneous catalyst:* it exists in the same phase as the reactants, lowers the total activation energy via a different mechanism, and is regenerated. Each Cl atom has a stratospheric half-life of about 2 years, during which it speeds the breakdown of about 100,000 ozone molecules.

Later studies showed that the ozone hole enlarges by heterogeneous catalysis. Stratospheric clouds provide a surface for reactions that convert inactive chlorine compounds, such as HCl and chlorine nitrate ($ClONO_2$), to substances, such as Cl_2, that are cleaved by UV radiation to Cl atoms. Fine particles in the stratosphere act in the same way: dust from the 1991 eruption of Mt. Pinatubo reduced stratospheric ozone for 2 years. The Montreal Protocol of 1987 and later amendments curtailed CFC production and proposed substituting hydrocarbon propellants, such as isobutane, $(CH_3)_3CH$. Nevertheless, because of the long lifetimes of CFCs, complete recovery of the ozone layer may take another century! The good news is that tropospheric halogen levels have begun to fall.

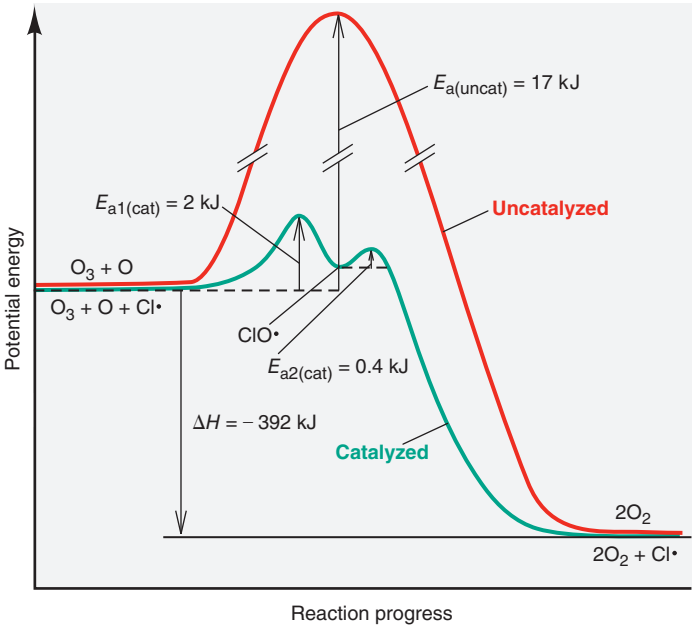

Figure B16.2 Reaction energy diagram for breakdown of O_3 by Cl atoms. (Not drawn to scale.)

Problems

B16.1 The catalytic destruction of ozone occurs via a two-step mechanism, where X can be one of several species:

(1) $X + O_3 \longrightarrow XO + O_2$ [slow]
(2) $XO + O \longrightarrow X + O_2$ [fast]

(a) Write the overall reaction and the rate law for each step.
(b) X acts as _____, and XO acts as _____.

B16.2 Aircraft in the stratosphere release NO, which catalyzes ozone breakdown by the mechanism shown in Problem B16.1.
(a) Write the mechanism.
(b) When the $[O_3]$ is 5×10^{12} molecules/cm^3 and the [NO] is 1.0×10^{9} molecules/cm^3, what is the rate of O_3 depletion (k for the rate-determining step is 6×10^{-15} cm^3/molecule·s)?

B16.3 In the mechanism for O_3 breakdown in Problem B16.1:
(a) Which would you expect to have a higher value for the p factor, step 1 with NO or step 1 with Cl? Explain.
(b) Draw a possible transition state for the step with Cl.

No matter what their mode of action, *all enzymes catalyze by stabilizing the reaction's transition state.* For instance, in the lysozyme-catalyzed reaction, the transition state is a portion of the polysaccharide whose bonds have been twisted and stretched by the active site groups until it fits the active site well. Stabilizing the transition state lowers the activation energy and thus increases the rate.

Like enzyme-catalyzed reactions, the process of stratospheric ozone depletion, discussed in the Chemical Connections essay, includes both homogeneous and heterogeneous catalysis.

Summary of Section 16.7

- A catalyst increases the rate of a reaction without being consumed. It accomplishes this by providing another mechanism with a lower activation energy.
- Homogeneous catalysts function in the same phase as the reactants. Heterogeneous catalysts act in a different phase from the reactants.
- The hydrogenation of carbon-carbon double bonds takes place on a solid metal catalyst, which speeds up the rate-determining step, the breakage of the H_2 bond.
- Enzymes are protein catalysts of high efficiency and specificity that act by stabilizing the transition state and, thus, lowering the activation energy.
- Chlorine atoms from CFC molecules speed the breakdown of stratospheric O_3 by a process that has aspects of both homogeneous and heterogeneous catalysis.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How reaction rate depends on concentration, physical state, and temperature (§16.1)
2. The meaning of reaction rate in terms of changing concentrations over time (§16.2)
3. How the rate can be expressed in terms of reactant or product concentrations (§16.2)
4. The distinction between average and instantaneous rate and why the instantaneous rate changes during a reaction (§16.2)
5. The interpretation of reaction rate in terms of reactant and product concentrations (§16.2)
6. The experimental basis of the rate law and the information needed to determine it—initial rate data, reaction orders, and rate constant (§16.3)
7. The importance of reaction order in determining the rate (§16.3)
8. How reaction order is determined from initial rates at different concentrations (§16.3)
9. How integrated rate laws show the dependence of concentration on time (§16.4)
10. What reaction half-life means and why it is constant for a first-order reaction (§16.4)
11. Why concentrations are multiplied in the rate law (§16.5)
12. Activation energy and the effect of temperature on the rate constant (Arrhenius equation) (§16.5)
13. How temperature affects rate by influencing collision energy and, thus, the fraction of collisions with energy exceeding the activation energy (§16.5)
14. Why molecular orientation and complexity influence the number of effective collisions and the rate (§16.5)
15. The transition state as the momentary species between reactants and products whose formation requires the activation energy (§16.5)
16. How an elementary step represents a single molecular event and its molecularity equals the number of colliding particles (§16.6)
17. How a reaction mechanism consists of several elementary steps, with the slowest step determining the overall rate (§16.6)
18. The criteria for a valid reaction mechanism (§16.6)
19. How a catalyst speeds a reaction by lowering the activation energy (§16.7)
20. The distinction between homogeneous and heterogeneous catalysis (§16.7)

Master These Skills

1. Calculating instantaneous rate from the slope of a tangent to a concentration vs. time plot (§16.2)
2. Expressing reaction rate in terms of changes in concentration over time (SP 16.1)
3. Determining reaction orders from a known rate law (SP 16.2)
4. Determining reaction orders from rate data or molecular scenes (SPs 16.3, 16.4)
5. Calculating the rate constant and its units (§16.3 and SP 16.3)
6. Using an integrated rate law to find concentration at a given time or the time to reach a given concentration (SP 16.5)
7. Determining reaction order graphically with a rearranged integrated rate law (§16.4)
8. Determining the half-life of a reaction (SPs 16.6, 16.7)
9. Using a form of the Arrhenius equation to calculate the activation energy (SP 16.8)
10. Using reaction energy diagrams to depict the energy changes during a reaction (SP 16.9)
11. Predicting a transition state for a simple reaction (SP 16.9)
12. Determining the molecularity and rate law for an elementary step (SP 16.10)
13. Constructing a mechanism with either a slow or a fast initial step (§16.6)
14. Identifying intermediates and correlating rate laws and reaction mechanisms (SP 16.11)

Key Equations and Relationships

Page numbers appear in parentheses.

16.1 Expressing reaction rate in terms of reactant A (678):

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t}$$

16.2 Expressing the rate of a general reaction (681):

$$\text{Rate} = -\frac{1}{a}\frac{\Delta[\text{A}]}{\Delta t} = -\frac{1}{b}\frac{\Delta[\text{B}]}{\Delta t} = \frac{1}{c}\frac{\Delta[\text{C}]}{\Delta t} = \frac{1}{d}\frac{\Delta[\text{D}]}{\Delta t}$$

16.3 Writing a general rate law (in which products do not appear) (682):

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n \cdots$$

16.4 Calculating the time to reach a given [A] in a first-order reaction (rate = k[A]) (692):

$$\ln\frac{[\text{A}]_0}{[\text{A}]_t} = kt$$

16.5 Calculating the time to reach a given [A] in a simple second-order reaction (rate = k[A]^2) (692):

$$\frac{1}{[\text{A}]_t} - \frac{1}{[\text{A}]_0} = kt$$

16.6 Calculating the time to reach a given [A] in a zero-order reaction (rate = k) (692):

$$[\text{A}]_t - [\text{A}]_0 = -kt$$

16.7 Finding the half-life of a first-order process (695):

$$t_{1/2} = \frac{\ln 2}{k} = \frac{0.693}{k}$$

16.8 Relating the rate constant to the temperature (Arrhenius equation) (699):

$$k = Ae^{-E_a/RT}$$

16.9 Relating the heat of reaction to the forward and reverse activation energies (700):

$$\Delta H_{rxn} = E_{a(fwd)} - E_{a(rev)}$$

16.10 Calculating the activation energy (rearranged form of Arrhenius equation) (702):

$$\ln\frac{k_2}{k_1} = \frac{E_a}{R}\left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

16.1A (a) $4NO(g) + O_2(g) \longrightarrow 2N_2O_3(g)$;

$$\text{Rate} = -\frac{\Delta[\text{O}_2]}{\Delta t} = -\frac{1}{4}\frac{\Delta[\text{NO}]}{\Delta t} = \frac{1}{2}\frac{\Delta[\text{N}_2\text{O}_3]}{\Delta t}$$

(b) $$-\frac{\Delta[\text{O}_2]}{\Delta t} = -\frac{1}{4}\frac{\Delta[\text{NO}]}{\Delta t} = -\frac{1}{4}(-1.60\times10^{-4}\ \text{mol/L·s})$$
$$= 4.00\times10^{-5}\ \text{mol/L·s}$$

16.1B (a) $4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$

(b) $$-\frac{1}{5}\frac{\Delta[\text{O}_2]}{\Delta t} = \frac{1}{6}\frac{\Delta[\text{H}_2\text{O}]}{\Delta t}$$
$$-\frac{\Delta[\text{O}_2]}{\Delta t} = \frac{5}{6}\frac{\Delta[\text{H}_2\text{O}]}{\Delta t} = \frac{5}{6}(2.52\times10^{-2}\ \text{mol/L·s})$$
$$= 2.10\times10^{-2}\ \text{mol/L·s}$$

16.2A (a) First order in I^-, first order in BrO_3^-, second order in H^+; fourth order overall.
(b) Rate = $k[I^-][BrO_3^-][H^+]^2 = k(3)(3)(2)^2 = 36k$; the rate increases by a factor of 36.

16.2B (a) Second order in ClO_2, first order in OH^-; third order overall.
(b) Rate = $k[ClO_2]^2[OH^-] = k(0.5)^2(2) = 0.5$; the rate decreases by a factor of ½.

16.3A Rate = $k[H_2]^m[I_2]^n$. From experiments 1 and 3, $m = 1$. From experiments 2 and 4, $n = 1$. Therefore, rate = $k[H_2][I_2]$; second order overall. From experiment 1:

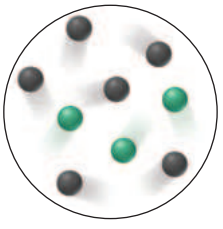
$$k = \frac{\text{rate}}{[\text{H}_2][\text{I}_2]} = \frac{1.9\times10^{-23}\ \text{mol/L·s}}{(0.0113\ \text{mol/L})(0.0011\ \text{mol/L})}$$
$$= 1.5\times10^{-18}\ \text{L/mol·s}$$

The average value of k from all four experiments is 1.5×10^{-18} L/mol·s.

16.3B (a) Rate = $k[H_2SeO_3]^m[I^-]^n[H^+]^p$. From experiments 1 and 3, $m = 1$. From experiments 1 and 2, $n = 3$. From experiments 2 and 4, $p = 2$. Therefore, rate = $k[H_2SeO_3][I^-]^3[H^+]^2$.
(b)

$$k = \frac{\text{rate}}{[\text{H}_2\text{SeO}_3][\text{I}^-]^3[\text{H}^+]^2}$$
$$= \frac{9.85\times10^{-7}\ \text{mol/L·s}}{(2.5\times10^{-3}\ \text{mol/L})(1.5\times10^{-2}\ \text{mol/L})^3(1.5\times10^{-2}\ \text{mol/L})^2}$$
$$= 5.2\times10^5\ \text{L}^5/\text{mol}^5\text{·s}$$

16.4A (a) The rate law shows the reaction is zero order in Y, so the rate is not affected by doubling Y: rate of Expt 2 = 0.25×10^{-5} mol/L·s
(b) The rate of Expt 3 is four times that of Expt 1, so [X] doubles.



16.4B (a) Rate = $k[A]^m[B]^n$. From Expts 1 and 2, $n = 0$. From Expts 1 and 3, $m = 1$. Therefore, rate = $k[A][B]^0$ or rate = $k[A]$.
(b) The rate for Expt 4 is twice as great as the rate for Expt 1; since [A] has a reaction order of 1, twice as many A particles should appear in the scene for Expt 4: 2 × 4 particles = 8 particles.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

16.5A $1/[HI]_t - 1/[HI]_0 = kt$

$111\ \text{L/mol} - 100.\ \text{L/mol} = (2.4\times10^{-21}\ \text{L/mol·s})(t)$

$t = 4.6\times10^{21}\ \text{s (or } 1.5\times10^{14}\ \text{yr)}$

16.5B (a) $\ln\dfrac{[H_2O_2]_0}{[H_2O_2]_t} = kt$

$$\ln\frac{1.28\ \text{mol/L}}{0.85\ \text{mol/L}} = k(10.0\ \text{min})$$

$$k = 0.041/\text{min}$$

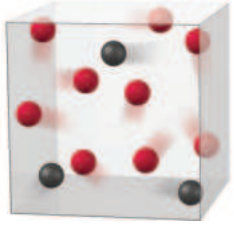
(b) If 25% of the H_2O_2 decomposes, 75% remains. Assuming an initial concentration of 1.0 *M* means that the concentration is 0.75 *M* at time *t*:

$$\ln\frac{[H_2O_2]_0}{[H_2O_2]_t} = kt$$

$$\ln\frac{1.0\ \text{mol/L}}{0.75\ \text{mol/L}} = (0.041/\text{min})(t)$$

$$t = 7.0\ \text{min}$$

16.6A (a)



(b) At 10.0 min (four half-lives), there are 0.75 particles of X.

$$\text{Amount (mol)} = 0.75\ \text{particles} \times \frac{0.20\ \text{mol X}}{1\ \text{particle}} = 0.15\ \text{mol X}$$

$$M = \frac{0.15\ \text{mol X}}{0.50\ \text{L}} = 0.30\ M$$

16.6B (a) The half-life is 24 min; the third scene represents four half-lives (1 particle is $\frac{1}{16}$ of the initial amount; $\frac{1}{2}\times\frac{1}{2}\times\frac{1}{2}\times\frac{1}{2} = \frac{1}{16}$). Four half-lives is $4 \times 24\ \text{min} = 96\ \text{min}$.

(b) At 72 min (three half-lives), there are 2 particles of A.

$$\text{Amount (mol)} = 2\ \text{particles} \times \frac{0.10\ \text{mol A}}{1\ \text{particle}} = 0.20\ \text{mol A}$$

$$M = \frac{0.20\ \text{mol A}}{0.25\ \text{L}} = 0.80\ M$$

16.7A $t_{1/2} = (\ln 2)/k$; $k = 0.693/13.1\ \text{h} = 5.29\times10^{-2}\ \text{h}^{-1}$

16.7B (a) $t_{1/2} = (\ln 2)/k = 0.693/9\times10^{-2}\ \text{day}^{-1} = 8\ \text{days}$

(b) 40 days is five half-lives; $\frac{1}{2}\times\frac{1}{2}\times\frac{1}{2}\times\frac{1}{2}\times\frac{1}{2} = (\frac{1}{2})^5 = \frac{1}{32}$ remains in the environment.

16.8A $$\ln\frac{0.286\ \text{L/mol·s}}{k_1} = \frac{1.00\times10^5\ \text{J/mol}}{8.314\ \text{J/mol·K}} \times\left(\frac{1}{490.\ \text{K}} - \frac{1}{500.\ \text{K}}\right) = 0.491$$

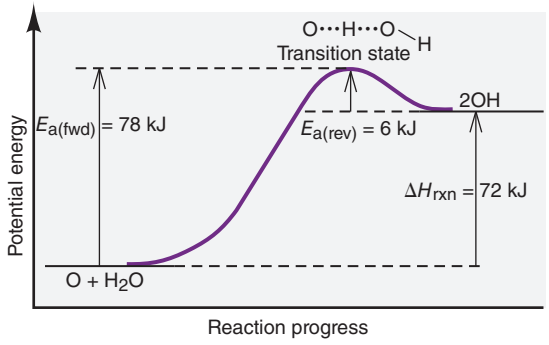
$$k_1 = 0.175\ \text{L/mol·s}$$

16.8B

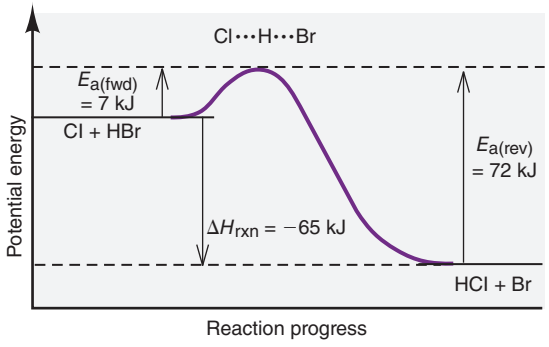
$$\ln\frac{1.40\times10^{-2}\ \text{L/mol·s}}{7.02\times10^{-3}\ \text{L/mol·s}} = \frac{1.14\times10^5\ \text{J/mol}}{8.314\ \text{J/mol·K}} \times\left(\frac{1}{500.\ \text{K}} - \frac{1}{T_2}\right)$$

$$T_2 = 513\ \text{K}$$

16.9A



16.9B



16.10A (a) Balanced equation: $2H_2O_2(aq) \longrightarrow 2H_2O(l) + O_2(g)$

(b) Step 1 is unimolecular; steps 2 and 3 are bimolecular.

(c) $\text{Rate}_1 = k_1[H_2O_2]$; $\text{Rate}_2 = k_2[H_2O_2][OH]$; $\text{Rate}_3 = k_3[HO_2][OH]$

16.10B (a) Balanced equation:

$2NO(g) + 2H_2(g) \longrightarrow N_2(g) + 2H_2O(g)$

(b) All steps are bimolecular.

(c) $\text{Rate}_1 = k_1[NO]^2$; $\text{Rate}_2 = k_2[N_2O_2][H_2]$; $\text{Rate}_3 = k_3[N_2O][H_2]$

16.11A (a) The intermediates are OH and HO_2.

(b) The reaction is first order in H_2O_2; step 1 must be the rate-determining step.

16.11B (a) The intermediates are N_2O_2 and N_2O.

(b) From step 2, rate $= k_2[N_2O_2][H_2]$; from step 1, $k_1[NO]^2 = k_{-1}[N_2O_2]$ or $[N_2O_2] = \dfrac{k_1}{k_{-1}}[NO]^2$. Substituting into the rate law from step 2 gives

rate $= k_2\dfrac{k_1}{k_{-1}}[NO]^2[H_2]$, or rate $= k[NO]^2[H_2]$.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Focusing on Reaction Rate

Concept Review Questions

16.1 What variable of a chemical reaction is measured over time to obtain the reaction rate?

16.2 How does an increase in pressure affect the rate of a gas-phase reaction? Explain.

16.3 A reaction is carried out with water as the solvent. How does the addition of more water to the reaction vessel affect the rate of the reaction? Explain.

16.4 A gas reacts with a solid that is present in large chunks. Then the reaction is run again with the solid pulverized. How does the increase in the surface area of the solid affect the rate of its reaction with the gas? Explain.

16.5 How does an increase in temperature affect the rate of a reaction? Explain the two factors involved.

16.6 In a kinetics experiment, a chemist places crystals of iodine in a closed reaction vessel, introduces a given quantity of H_2 gas, and obtains data to calculate the rate of HI formation. In a second experiment, she uses the same amounts of iodine and hydrogen, but first warms the flask to 130°C, a temperature above the sublimation point of iodine. In which of these experiments does the reaction proceed at a higher rate? Explain.

Expressing the Reaction Rate

(Sample Problem 16.1)

Concept Review Questions

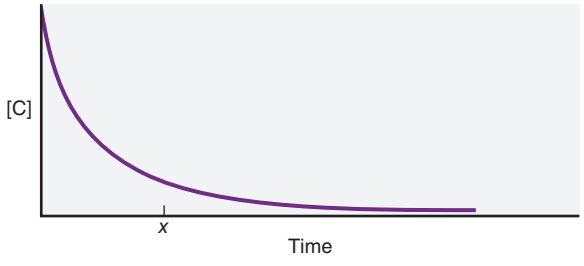
16.7 Define *reaction rate*. Assuming constant temperature and a closed reaction vessel, why does the rate change with time?

16.8 (a) What is the difference between an average rate and an instantaneous rate? (b) What is the difference between an initial rate and an instantaneous rate?

16.9 Give two reasons to measure initial rates in a kinetics study.

16.10 For the reaction $A(g) \longrightarrow B(g)$, sketch two curves on the same set of axes that show
(a) The formation of product as a function of time
(b) The consumption of reactant as a function of time

16.11 For the reaction $C(g) \longrightarrow D(g)$, [C] vs. time is plotted:



How do you determine each of the following?
(a) The average rate over the entire experiment
(b) The reaction rate at time x
(c) The initial reaction rate
(d) Would the values in parts (a), (b), and (c) be different if you plotted [D] vs. time? Explain.

Skill-Building Exercises (grouped in similar pairs)

16.12 The compound AX_2 decomposes according to the equation $2AX_2(g) \longrightarrow 2AX(g) + X_2(g)$. In one experiment, $[AX_2]$ was measured at various times and these data were obtained:

Time (s)	$[AX_2]$ (mol/L)
0.0	0.0500
2.0	0.0448
6.0	0.0300
8.0	0.0249
10.0	0.0209
20.0	0.0088

(a) Find the average rate over the entire experiment.
(b) Is the initial rate higher or lower than the rate in part (a)? Use graphical methods to estimate the initial rate.

16.13 (a) Use the data from Problem 16.12 to calculate the average rate from 8.0 to 20.0 s.
(b) Is the rate at exactly 5.0 s higher or lower than the rate in part (a)? Use graphical methods to estimate the rate at 5.0 s.

16.14 Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

$$2A(g) \longrightarrow B(g) + C(g)$$

When [C] is increasing at 2 mol/L·s, how fast is [A] decreasing?

16.15 Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

$$D(g) \longrightarrow \tfrac{3}{2}E(g) + \tfrac{5}{2}F(g)$$

When [E] is increasing at 0.25 mol/L·s, how fast is [F] increasing?

16.16 Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

$$A(g) + 2B(g) \longrightarrow C(g)$$

When [B] is decreasing at 0.5 mol/L·s, how fast is [A] decreasing?

16.17 Express the rate of this reaction in terms of the change in concentration of each of the reactants and products:

$$2D(g) + 3E(g) + F(g) \longrightarrow 2G(g) + H(g)$$

When [D] is decreasing at 0.1 mol/L·s, how fast is [H] increasing?

16.18 Reaction rate is expressed in terms of changes in concentration of reactants and products. Write a balanced equation for

$$\text{Rate} = -\frac{1}{2}\frac{\Delta[N_2O_5]}{\Delta t} = \frac{1}{4}\frac{\Delta[NO_2]}{\Delta t} = \frac{\Delta[O_2]}{\Delta t}$$

16.19 Reaction rate is expressed in terms of changes in concentration of reactants and products. Write a balanced equation for

$$\text{Rate} = -\frac{\Delta[CH_4]}{\Delta t} = -\frac{1}{2}\frac{\Delta[O_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[H_2O]}{\Delta t} = \frac{\Delta[CO_2]}{\Delta t}$$

Problems in Context

16.20 The decomposition of NOBr is studied manometrically because the number of moles of gas changes; it cannot be studied colorimetrically because both NOBr and Br_2 are reddish brown:

$$2NOBr(g) \longrightarrow 2NO(g) + Br_2(g)$$

Use the data below to answer the following:
(a) Determine the average rate over the entire experiment.
(b) Determine the average rate between 2.00 and 4.00 s.
(c) Use graphical methods to estimate the initial reaction rate.
(d) Use graphical methods to estimate the rate at 7.00 s.
(e) At what time does the instantaneous rate equal the average rate over the entire experiment?

Time (s)	[NOBr] (mol/L)
0.00	0.0100
2.00	0.0071
4.00	0.0055
6.00	0.0045
8.00	0.0038
10.00	0.0033

16.21 The formation of ammonia is one of the most important processes in the chemical industry:

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

Express the rate in terms of changes in $[N_2]$, $[H_2]$, and $[NH_3]$.

16.22 Although the depletion of stratospheric ozone threatens life on Earth today, its accumulation was one of the crucial processes that allowed life to develop in prehistoric times:

$$3O_2(g) \longrightarrow 2O_3(g)$$

(a) Express the reaction rate in terms of $[O_2]$ and $[O_3]$.
(b) At a given instant, the reaction rate in terms of $[O_2]$ is 2.17×10^{-5} mol/L·s. What is it in terms of $[O_3]$?

The Rate Law and Its Components

(Sample Problems 16.2 to 16.4)

Concept Review Questions

16.23 The rate law for the general reaction

$$aA + bB + \cdots \longrightarrow cC + dD + \cdots$$

is rate $= k[A]^m[B]^n\cdots$. (a) Explain the meaning of k. (b) Explain the meanings of m and n. Does $m = a$ and $n = b$? Explain. (c) If the reaction is first order in A and second order in B, and time is measured in minutes (min), what are the units for k?

16.24 You are studying the reaction

$$A_2(g) + B_2(g) \longrightarrow 2AB(g)$$

to determine its rate law. Assuming that you have a valid experimental procedure for obtaining $[A_2]$ and $[B_2]$ at various times, explain how you determine (a) the initial rate, (b) the reaction orders, and (c) the rate constant.

16.25 By what factor does the rate change in each of the following cases (assuming constant temperature)?
(a) A reaction is first order in reactant A, and [A] is doubled.
(b) A reaction is second order in reactant B, and [B] is halved.
(c) A reaction is second order in reactant C, and [C] is tripled.

Skill-Building Exercises (grouped in similar pairs)

16.26 Give the individual reaction orders for all substances and the overall reaction order from the following rate law:

$$\text{Rate} = k[BrO_3^-][Br^-][H^+]^2$$

16.27 Give the individual reaction orders for all substances and the overall reaction order from the following rate law:

$$\text{Rate} = k\frac{[O_3]^2}{[O_2]}$$

16.28 By what factor does the rate in Problem 16.26 change if each of the following changes occurs: (a) $[BrO_3^-]$ is doubled; (b) $[Br^-]$ is halved; (c) $[H^+]$ is quadrupled?

16.29 By what factor does the rate in Problem 16.27 change if each of the following changes occurs: (a) $[O_3]$ is doubled; (b) $[O_2]$ is doubled; (c) $[O_2]$ is halved?

16.30 Give the individual reaction orders for all substances and the overall reaction order from this rate law:

$$\text{Rate} = k[NO_2]^2[Cl_2]$$

16.31 Give the individual reaction orders for all substances and the overall reaction order from this rate law:

$$\text{Rate} = k\frac{[HNO_2]^4}{[NO]^2}$$

16.32 By what factor does the rate in Problem 16.30 change if each of the following changes occurs: (a) $[NO_2]$ is tripled; (b) $[NO_2]$ and $[Cl_2]$ are doubled; (c) $[Cl_2]$ is halved?

16.33 By what factor does the rate in Problem 16.31 change if each of the following changes occurs: (a) $[HNO_2]$ is doubled; (b) [NO] is doubled; (c) $[HNO_2]$ is halved?

16.34 For the reaction

$$4A(g) + 3B(g) \longrightarrow 2C(g)$$

the following data were obtained at constant temperature:

Experiment	Initial Rate (mol/L·min)	Initial [A] (mol/L)	Initial [B] (mol/L)
1	5.00	0.100	0.100
2	45.0	0.300	0.100
3	10.0	0.100	0.200
4	90.0	0.300	0.200

(a) What is the order with respect to each reactant? (b) Write the rate law. (c) Calculate k (using the data from Expt 1).

16.35 For the reaction

$$A(g) + B(g) + C(g) \longrightarrow D(g)$$

the following data were obtained at constant temperature:

Expt	Initial Rate (mol/L·s)	Initial [A] (mol/L)	Initial [B] (mol/L)	Initial [C] (mol/L)
1	6.25×10^{-3}	0.0500	0.0500	0.0100
2	1.25×10^{-2}	0.1000	0.0500	0.0100
3	5.00×10^{-2}	0.1000	0.1000	0.0100
4	6.25×10^{-3}	0.0500	0.0500	0.0200

(a) What is the order with respect to each reactant? (b) Write the rate law. (c) Calculate k (using the data from Expt 1).

16.36 Without consulting Table 16.3, give the units of the rate constants for reactions with the following overall orders: (a) first order; (b) second order; (c) third order; (d) $\frac{5}{2}$ order.

16.37 Give the overall reaction order that corresponds to a rate constant with each of the following units: (a) mol/L·s; (b) yr^{-1}; (c) $(mol/L)^{1/2}\cdot s^{-1}$; (d) $(mol/L)^{-5/2}\cdot min^{-1}$.

Problems in Context

16.38 Phosgene is a toxic gas prepared by the reaction of carbon monoxide with chlorine:

$$CO(g) + Cl_2(g) \longrightarrow COCl_2(g)$$

These data were obtained in a kinetics study of its formation:

Experiment	Initial Rate (mol/L·s)	Initial [CO] (mol/L)	Initial [Cl_2] (mol/L)
1	1.29×10^{-29}	1.00	0.100
2	1.33×10^{-30}	0.100	0.100
3	1.30×10^{-29}	0.100	1.00
4	1.32×10^{-31}	0.100	0.0100

(a) Write the rate law for the formation of phosgene.
(b) Calculate the average value of the rate constant.

Integrated Rate Laws: Concentration Changes over Time

(Sample Problems 16.5 to 16.7)

Concept Review Questions

16.39 How are integrated rate laws used to determine reaction order? What is the order in reactant if a plot of
(a) The natural logarithm of [reactant] vs. time is linear?
(b) The inverse of [reactant] vs. time is linear?
(c) [Reactant] vs. time is linear?

16.40 Define the *half-life* of a reaction. Explain on the molecular level why the half-life of a first-order reaction is constant.

Skill-Building Exercises (grouped in similar pairs)

16.41 For the simple decomposition reaction

$$AB(g) \longrightarrow A(g) + B(g)$$

rate = $k[AB]^2$ and $k = 0.2$ L/mol·s. How long will it take for [AB] to reach one-third of its initial concentration of 1.50 *M*?

16.42 For the reaction in Problem 16.41, what is [AB] after 10.0 s?

16.43 In a first-order decomposition reaction, 50.0% of a compound decomposes in 10.5 min. (a) What is the rate constant of the reaction? (b) How long does it take for 75.0% of the compound to decompose?

16.44 A decomposition reaction has a rate constant of 0.0012 yr^{-1}. (a) What is the half-life of the reaction? (b) How long does it take for [reactant] to reach 12.5% of its original value?

Problems in Context

16.45 In a study of ammonia production, an industrial chemist discovers that the compound decomposes to its elements N_2 and H_2 in a first-order process. She collects the following data:

Time (s)	0	1.000	2.000
[NH_3] (mol/L)	4.000	3.986	3.974

(a) Use graphical methods to determine the rate constant.
(b) What is the half-life for ammonia decomposition?

Theories of Chemical Kinetics

(Sample Problems 16.8 and 16.9)

Concept Review Questions

16.46 What is the central idea of collision theory? How does this model explain the effect of concentration on reaction rate?

16.47 Is collision frequency the only factor affecting rate? Explain.

16.48 Arrhenius proposed that each reaction has an energy threshold that must be reached for the particles to react. The kinetic theory of gases proposes that the average kinetic energy of the particles is proportional to the absolute temperature. How do these concepts relate to the effect of temperature on rate?

16.49 Use the exponential term in the Arrhenius equation to explain how temperature affects reaction rate.

16.50 How is the activation energy determined from the Arrhenius equation?

16.51 (a) Graph the relationship between k (vertical axis) and T (horizontal axis). (b) Graph the relationship between ln k (vertical axis) and $1/T$ (horizontal axis). How is the activation energy determined from this graph?

16.52 (a) For a reaction with a given E_a, how does an increase in T affect the rate? (b) For a reaction at a given T, how does a decrease in E_a affect the rate?

16.53 In the reaction AB + CD $\rightleftharpoons$ EF, 4×10^{-5} mol of AB molecules collide with 4×10^{-5} mol of CD molecules. Will 4×10^{-5} mol of EF form? Explain.

16.54 Assuming the activation energies are equal, which of the following reactions will proceed at a higher rate at 50°C? Explain.

$$NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$$
$$N(CH_3)_3(g) + HCl(g) \longrightarrow (CH_3)_3NHCl(s)$$

Skill-Building Exercises (grouped in similar pairs)

16.55 For the reaction $A(g) + B(g) \longrightarrow AB(g)$, how many unique collisions between A and B are possible if there are four particles of A and three particles of B present in the vessel?

16.56 For the reaction $A(g) + B(g) \longrightarrow AB(g)$, how many unique collisions between A and B are possible if 1.01 mol of $A(g)$ and 2.12 mol of $B(g)$ are present in the vessel?

16.57 At 25°C, what is the fraction of collisions with energy equal to or greater than an activation energy of 100. kJ/mol?

16.58 If the temperature in Problem 16.57 is increased to 50.°C, by what factor does the fraction of collisions with energy equal to or greater than the activation energy change?

16.59 The rate constant of a reaction is 4.7×10^{-3} s^{-1} at 25°C, and the activation energy is 33.6 kJ/mol. What is k at 75°C?

16.60 The rate constant of a reaction is 4.50×10^{-5} L/mol·s at 195°C and 3.20×10^{-3} L/mol·s at 258°C. What is the activation energy of the reaction?

16.61 For the reaction ABC + D $\rightleftharpoons$ AB + CD, $\Delta H^\circ_{rxn} = -55$ kJ/mol and $E_{a(fwd)} = 215$ kJ/mol. Assuming a one-step reaction, (a) draw a reaction energy diagram; (b) calculate $E_{a(rev)}$; and (c) sketch a possible transition state if ABC is V shaped.

16.62 For the reaction $A_2 + B_2 \longrightarrow 2AB$, $E_{a(fwd)} = 125$ kJ/mol and $E_{a(rev)} = 85$ kJ/mol. Assuming the reaction occurs in one step, (a) draw a reaction energy diagram; (b) calculate ΔH°_{rxn}; and (c) sketch a possible transition state.

Problems in Context

16.63 Understanding the high-temperature formation and breakdown of the nitrogen oxides is essential for controlling the pollutants generated from power plants and cars. The first-order

breakdown of dinitrogen monoxide to its elements has rate constants of 0.76/s at 727°C and 0.87/s at 757°C. What is the activation energy of this reaction?

16.64 Aqua regia, a mixture of HCl and HNO_3, has been used since alchemical times to dissolve many metals, including gold. Its orange color is due to the presence of nitrosyl chloride. Consider this one-step reaction for the formation of this compound:

$$NO(g) + Cl_2(g) \longrightarrow NOCl(g) + Cl(g) \qquad \Delta H^\circ = 83 \text{ kJ}$$

(a) Draw a reaction energy diagram, given $E_{a(fwd)} = 86$ kJ/mol.
(b) Calculate $E_{a(rev)}$.
(c) Sketch a possible transition state for the reaction. (*Note:* The atom sequence of nitrosyl chloride is Cl—N—O.)

Reaction Mechanisms: The Steps from Reactant to Product

(Sample Problems 16.10 and 16.11)

Concept Review Questions

16.65 Is the rate of an overall reaction lower, higher, or equal to the average rate of the individual steps? Explain.

16.66 Explain why the coefficients of an elementary step equal the reaction orders of its rate law but those of an overall reaction do not.

16.67 Is it possible for more than one mechanism to be consistent with the rate law of a given reaction? Explain.

16.68 What is the difference between a reaction intermediate and a transition state?

16.69 Why is a bimolecular step more reasonable physically than a termolecular step?

16.70 If a slow step precedes a fast step in a two-step mechanism, do the substances in the fast step appear in the rate law? Explain.

16.71 If a fast step precedes a slow step in a two-step mechanism, how is the fast step affected? How is this effect used to determine the validity of the mechanism?

Skill-Building Exercises (grouped in similar pairs)

16.72 The proposed mechanism for a reaction is

(1) $A(g) + B(g) \rightleftharpoons X(g)$ [fast]
(2) $X(g) + C(g) \longrightarrow Y(g)$ [slow]
(3) $Y(g) \longrightarrow D(g)$ [fast]

(a) What is the overall equation?
(b) Identify the intermediate(s), if any.
(c) What are the molecularity and the rate law for each step?
(d) Is the mechanism consistent with the actual rate law: Rate = k[A][B][C]?
(e) Is the following one-step mechanism equally valid: $A(g) + B(g) + C(g) \longrightarrow D(g)$?

16.73 Consider the following mechanism:

(1) $ClO^-(aq) + H_2O(l) \rightleftharpoons HClO(aq) + OH^-(aq)$ [fast]
(2) $I^-(aq) + HClO(aq) \longrightarrow HIO(aq) + Cl^-(aq)$ [slow]
(3) $OH^-(aq) + HIO(aq) \longrightarrow H_2O(l) + IO^-(aq)$ [fast]

(a) What is the overall equation?
(b) Identify the intermediate(s), if any.
(c) What are the molecularity and the rate law for each step?
(d) Is the mechanism consistent with the actual rate law: Rate = $k[ClO^-][I^-]$?

Problems in Context

16.74 In a study of nitrosyl halides, a chemist proposes the following mechanism for the synthesis of nitrosyl bromide:

$$NO(g) + Br_2(g) \rightleftharpoons NOBr_2(g) \qquad \text{[fast]}$$
$$NOBr_2(g) + NO(g) \longrightarrow 2NOBr(g) \qquad \text{[slow]}$$

If the rate law is rate = $k[NO]^2[Br_2]$, is the proposed mechanism valid? If so, show that it satisfies the three criteria for validity.

16.75 The rate law for $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$ is rate = $k[NO]^2[O_2]$. In addition to the mechanism in the text (p. 709), the following ones have been proposed:

I $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$
II $2NO(g) \rightleftharpoons N_2O_2(g)$ [fast]
$N_2O_2(g) + O_2(g) \longrightarrow 2NO_2(g)$ [slow]
III $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$ [fast]
$N_2(g) + 2O_2(g) \longrightarrow 2NO_2(g)$ [slow]

(a) Which of these mechanisms is consistent with the rate law?
(b) Which of these mechanisms is most reasonable? Why?

Catalysis: Speeding Up a Reaction

Concept Review Questions

16.76 Consider the reaction $N_2O(g) \xrightarrow{Au} N_2(g) + \frac{1}{2}O_2(g)$.
(a) Does the gold catalyst (Au, above the arrow) act as a homogeneous or a heterogeneous catalyst?
(b) On the same set of axes, sketch the reaction energy diagrams for the catalyzed and the uncatalyzed reaction.

16.77 Does a catalyst increase reaction rate by the same means as a rise in temperature does? Explain.

16.78 In a classroom demonstration, hydrogen gas and oxygen gas are mixed in a balloon. The mixture is stable under normal conditions, but if a spark is applied to it or some powdered metal is added, the mixture explodes. (a) Is the spark acting as a catalyst? Explain. (b) Is the metal acting as a catalyst? Explain.

16.79 A principle of green chemistry is that the energy needs of industrial processes should have minimal environmental impact. How can the use of catalysts lead to "greener" technologies?

16.80 Enzymes are remarkably efficient catalysts that can increase reaction rates by as many as 20 orders of magnitude.
(a) How does an enzyme affect the transition state of a reaction, and how does this effect increase the reaction rate?
(b) What characteristics of enzymes give them this effectiveness as catalysts?

Comprehensive Problems

16.81 Experiments show that each of the following redox reactions is second order overall:

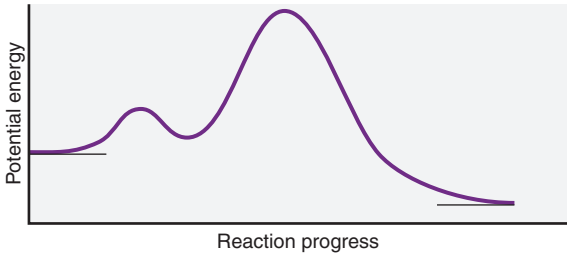
Reaction 1: $NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$

Reaction 2: $NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g)$

(a) When [NO_2] in reaction 1 is doubled, the rate quadruples. Write the rate law for this reaction.
(b) When [NO] in reaction 2 is doubled, the rate doubles. Write the rate law for this reaction.
(c) In each reaction, the initial concentrations of the reactants are equal. For each reaction, what is the ratio of the initial rate to the rate when the reaction is 50% complete?

(d) In reaction 1, the initial [NO_2] is twice the initial [CO]. What is the ratio of the initial rate to the rate at 50% completion?
(e) In reaction 2, the initial [NO] is twice the initial [O_3]. What is the ratio of the initial rate to the rate at 50% completion?

16.82 Consider the following reaction energy diagram:



(a) How many elementary steps are in the reaction mechanism?
(b) Which step is rate limiting?
(c) Is the overall reaction exothermic or endothermic?

16.83 Reactions between certain organic (alkyl) halides and water produce alcohols. Consider the overall reaction for *t*-butyl bromide (2-bromo-2-methylpropane):

$$(CH_3)_3CBr(aq) + H_2O(l) \longrightarrow (CH_3)_3COH(aq) + H^+(aq) + Br^-(aq)$$

The experimental rate law is rate = $k[(CH_3)_3CBr]$. The accepted mechanism for the reaction is

(1) $(CH_3)_3C{-}Br(aq) \longrightarrow (CH_3)_3C^+(aq) + Br^-(aq)$ [slow]
(2) $(CH_3)_3C^+(aq) + H_2O(l) \longrightarrow (CH_3)_3C{-}OH_2^+(aq)$ [fast]
(3) $(CH_3)_3C{-}OH_2^+(aq) \longrightarrow H^+(aq) + (CH_3)_3C{-}OH(aq)$ [fast]

(a) Why doesn't H_2O appear in the rate law?
(b) Write rate laws for the elementary steps.
(c) What reaction intermediates appear in the mechanism?
(d) Show that the mechanism is consistent with the experimental rate law.

16.84 Archeologists can determine the age of an artifact made of wood or bone by measuring the amount of the radioactive isotope ^{14}C present in the object. The amount of this isotope decreases in a first-order process. If 15.5% of the original amount of ^{14}C is present in a wooden tool at the time of analysis, what is the age of the tool? The half-life of ^{14}C is 5730 yr.

16.85 A slightly bruised apple will rot extensively in about 4 days at room temperature (20°C). If it is kept in the refrigerator at 0°C, the same extent of rotting takes about 16 days. What is the activation energy for the rotting reaction?

16.86 Benzoyl peroxide, the substance most widely used against acne, has a half-life of 9.8×10^3 days when refrigerated. How long will it take to lose 5% of its potency (95% remaining)?

16.87 The rate law for the reaction

$$NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$$

is rate = $k[NO_2]^2$; one possible mechanism is shown on p. 708.
(a) Draw a reaction energy diagram for that mechanism, given that $\Delta H^\circ_{overall} = -226$ kJ/mol.
(b) Consider the following alternative mechanism:

(1) $2NO_2(g) \longrightarrow N_2(g) + 2O_2(g)$ [slow]
(2) $2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$ [fast]
(3) $N_2(g) + O_2(g) \longrightarrow 2NO(g)$ [fast]

Is the alternative mechanism consistent with the rate law? Is one mechanism more reasonable physically? Explain.

16.88 Consider the following general reaction and data:

$$2A + 2B + C \longrightarrow D + 3E$$

Expt	Initial Rate (mol/L·s)	Initial [A] (mol/L)	Initial [B] (mol/L)	Initial [C] (mol/L)
1	6.0×10^{-6}	0.024	0.085	0.032
2	9.6×10^{-5}	0.096	0.085	0.032
3	1.5×10^{-5}	0.024	0.034	0.080
4	1.5×10^{-6}	0.012	0.170	0.032

(a) What is the reaction order with respect to each reactant?
(b) Calculate the rate constant.
(c) Write the rate law for this reaction.
(d) Express the rate in terms of changes in concentration with time for each of the components.

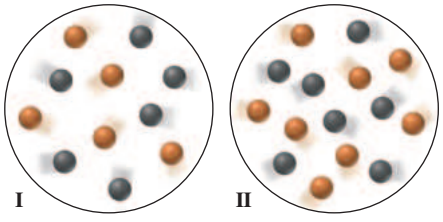
16.89 In acidic solution, the breakdown of sucrose into glucose and fructose has this rate law: Rate = $k[H^+]$[sucrose]. The initial rate of sucrose breakdown is measured in a solution that is 0.01 *M* H^+, 1.0 *M* sucrose, 0.1 *M* fructose, and 0.1 *M* glucose. How does the rate change if
(a) [Sucrose] is changed to 2.5 *M*?
(b) [Sucrose], [fructose], and [glucose] are all changed to 0.5 *M*?
(c) $[H^+]$ is changed to 0.0001 *M*?
(d) [Sucrose] and $[H^+]$ are both changed to 0.1 *M*?

16.90 The citric acid cycle is the central reaction sequence in the cellular metabolism of humans and many other organisms. One of the key steps is catalyzed by the enzyme isocitrate dehydrogenase and the oxidizing agent NAD^+. In yeast, the reaction is eleventh order:

$$\text{Rate} = k[\text{enzyme}][\text{isocitrate}]^4[\text{AMP}]^2[NAD^+]^m[Mg^{2+}]^2$$

What is the order with respect to NAD^+?

16.91 The following molecular scenes represent starting mixtures I and II for the reaction of A *(black)* with B *(orange):*



Each sphere represents 0.010 mol, and the volume is 0.50 L. If the reaction is first order in A and first order in B and the initial rate for I is 8.3×10^{-4} mol/L·min, what is the initial rate for II?

16.92 Experiment shows that the rate of formation of carbon tetrachloride from chloroform,

$$CHCl_3(g) + Cl_2(g) \longrightarrow CCl_4(g) + HCl(g)$$

is first order in $CHCl_3$, $\frac{1}{2}$ order in Cl_2, and $\frac{3}{2}$ order overall. Show that the following mechanism is consistent with the rate law:

(1) $Cl_2(g) \rightleftharpoons 2Cl(g)$ [fast]
(2) $Cl(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_3(g)$ [slow]
(3) $CCl_3(g) + Cl(g) \longrightarrow CCl_4(g)$ [fast]

16.93 A biochemist studying the breakdown of the insecticide DDT finds that it decomposes by a first-order reaction with a half-life of 12 yr. How long does it take DDT in a soil sample to decrease from 275 ppbm to 10. ppbm (parts per billion by mass)?

16.94 Insulin is a polypeptide hormone that is released into the blood from the pancreas and stimulates fat and muscle to take up

glucose; the insulin is used up in a first-order process. In a certain patient, it has a half-life of 3.5 min. To maintain an adequate blood concentration of insulin, it must be replenished in a time interval equal to $1/k$. How long is the time interval for this patient?

16.95 For the reaction $A(g) + B(g) \longrightarrow AB(g)$, the rate is 0.20 mol/L·s, when $[A]_0 = [B]_0 = 1.0$ mol/L. If the reaction is first order in B and second order in A, what is the rate when $[A]_0 = 2.0$ mol/L and $[B]_0 = 3.0$ mol/L?

16.96 The acid-catalyzed hydrolysis of sucrose occurs by the following overall reaction, whose kinetic data are given below:

$$\underset{\text{sucrose}}{C_{12}H_{22}O_{11}(s)} + H_2O(l) \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6(aq)} + \underset{\text{fructose}}{C_6H_{12}O_6(aq)}$$

[Sucrose] (mol/L)	Time (h)
0.501	0.00
0.451	0.50
0.404	1.00
0.363	1.50
0.267	3.00

(a) Determine the rate constant and the half-life of the reaction.
(b) How long does it take to hydrolyze 75% of the sucrose?
(c) Other studies have shown that this reaction is actually second order overall but appears to follow first-order kinetics. (Such a reaction is called a *pseudo–first-order reaction.*) Suggest a reason for this apparent first-order behavior.

16.97 At body temperature (37°C), the rate constant of an enzyme-catalyzed decomposition is 2.3×10^{14} times that of the uncatalyzed reaction. If the frequency factor, A, is the same for both processes, by how much does the enzyme lower the E_a?

16.98 Is each of these statements true? If not, explain why.
(a) At a given T, all molecules have the same kinetic energy.
(b) Halving the P of a gaseous reaction doubles the rate.
(c) A higher activation energy gives a lower reaction rate.
(d) A temperature rise of 10°C doubles the rate of any reaction.
(e) If reactant molecules collide with greater energy than the activation energy, they change into product molecules.
(f) The activation energy of a reaction depends on temperature.
(g) The rate of a reaction increases as the reaction proceeds.
(h) Activation energy depends on collision frequency.
(i) A catalyst increases the rate by increasing collision frequency.
(j) Exothermic reactions are faster than endothermic reactions.
(k) Temperature has no effect on the frequency factor (A).
(l) The activation energy of a reaction is lowered by a catalyst.
(m) For most reactions, ΔH_{rxn} is lowered by a catalyst.
(n) The orientation probability factor (p) is near 1 for reactions between single atoms.
(o) The initial rate of a reaction is its maximum rate.
(p) A bimolecular reaction is generally twice as fast as a unimolecular reaction.
(q) The molecularity of an elementary reaction is proportional to the molecular complexity of the reactant(s).

16.99 For the decomposition of gaseous dinitrogen pentoxide,

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$$

the rate constant is $k = 2.8\times10^{-3}\ s^{-1}$ at 60°C. The initial concentration of N_2O_5 is 1.58 mol/L. (a) What is $[N_2O_5]$ after 5.00 min? (b) What fraction of the N_2O_5 has decomposed after 5.00 min?

16.100 Even when a mechanism is consistent with the rate law, later work may show it to be incorrect. For example, the reaction between hydrogen and iodine has this rate law: Rate $= k[H_2][I_2]$. The long-accepted mechanism had a single bimolecular step; that is, the overall reaction was thought to be elementary:

$$H_2(g) + I_2(g) \longrightarrow 2HI(g)$$

In the 1960s, however, spectroscopic evidence showed the presence of free I atoms during the reaction. Kineticists have since proposed a three-step mechanism:

(1) $I_2(g) \rightleftharpoons 2I(g)$ [fast]
(2) $H_2(g) + I(g) \rightleftharpoons H_2I(g)$ [fast]
(3) $H_2I(g) + I(g) \longrightarrow 2HI(g)$ [slow]

Show that this mechanism is consistent with the rate law.

16.101 Suggest an experimental method for measuring the change in concentration with time for each of the following reactions:
(a) $CH_3CH_2Br(l) + H_2O(l) \longrightarrow CH_3CH_2OH(l) + HBr(aq)$
(b) $2NO(g) + Cl_2(g) \longrightarrow 2NOCl(g)$

16.102 An atmospheric chemist fills a container with gaseous N_2O_5 to a pressure of 125 kPa, and the gas decomposes to NO_2 and O_2. What is the partial pressure of NO_2, P_{NO_2} (in kPa), when the total pressure is 178 kPa?

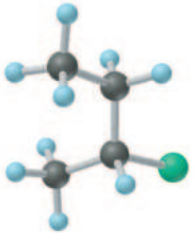
16.103 Many drugs decompose in blood by a first-order process.
(a) Two tablets of aspirin supply 0.60 g of the active compound. After 30 min, this compound reaches a maximum concentration of 2 mg/100 mL of blood. If the half-life for its breakdown is 90 min, what is its concentration (in mg/100 mL) 2.5 h after it reaches its maximum concentration?
(b) For the decomposition of an antibiotic in a person with a normal temperature (98.6°F), $k = 3.1\times10^{-5}\ s^{-1}$; for a person with a fever (temperature of 101.9°F), $k = 3.9\times10^{-5}\ s^{-1}$. If the person with the fever must take another pill when $\frac{2}{3}$ of the first pill has decomposed, how many hours should she wait to take a second pill? A third pill? (Assume that the pill is effective immediately.)
(c) Calculate E_a for decomposition of the antibiotic in part (b).

16.104 While developing a catalytic process to make ethylene glycol from synthesis gas ($CO + H_2$), a chemical engineer finds the rate is fourth order with respect to gas pressure. The uncertainty in the pressure reading is 5%. When the catalyst is modified, the rate increases by 10%. If you were the company patent attorney, would you file for a patent on this catalyst modification? Explain.

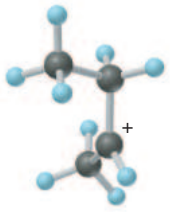
16.105 Iodide ion reacts with chloromethane to displace chloride ion in a common organic substitution reaction:

$$I^- + CH_3Cl \longrightarrow CH_3I + Cl^-$$

(a) Draw a wedge-bond structure of chloroform and indicate the most effective direction of I^- attack.
(b) The analogous reaction with 2-chlorobutane results in a major change in specific rotation as measured by polarimetry. Explain, showing a wedge-bond structure of the product.



(c) Under different conditions, 2-chlorobutane loses Cl^- in a rate-determining step to form a planar intermediate. This cationic species reacts with HI and then loses H^+ to form a product that exhibits no optical activity. Explain, showing a wedge-bond structure.



16.106 Assume that water boils at 100.0°C in Houston (near sea level), and at 90.0°C in Cripple Creek, Colorado (near 9500 ft). If it takes 4.8 min to cook an egg in Cripple Creek and 4.5 min in Houston, what is E_a for this process?

16.107 Sulfonation of benzene has the following mechanism:

(1) $2H_2SO_4 \longrightarrow H_3O^+ + HSO_4^- + SO_3$ [fast]
(2) $SO_3 + C_6H_6 \longrightarrow H(C_6H_5^+)SO_3^-$ [slow]
(3) $H(C_6H_5^+)SO_3^- + HSO_4^- \longrightarrow C_6H_5SO_3^- + H_2SO_4$ [fast]
(4) $C_6H_5SO_3^- + H_3O^+ \longrightarrow C_6H_5SO_3H + H_2O$ [fast]

(a) Write an overall equation for the reaction. (b) Write the overall rate law in terms of the initial rate of the reaction.

16.108 In the lower troposphere, ozone is one of the components of photochemical smog. It is generated in air when nitrogen dioxide, formed by the oxidation of nitrogen monoxide from car exhaust, reacts by the following mechanism:

(1) $NO_2(g) \xrightarrow[h\nu]{k_1} NO(g) + O(g)$
(2) $O(g) + O_2(g) \xrightarrow[h\nu]{k_2} O_3(g)$

Assuming the rate of formation of atomic oxygen in step 1 equals the rate of its consumption in step 2, use the data below to calculate (a) the concentration of atomic oxygen [O]; (b) the rate of ozone formation.

$k_1 = 6.0\times10^{-3}\ s^{-1}$ $\quad [NO_2] = 4.0\times10^{-9}\ M$
$k_2 = 1.0\times10^{6}\ L/mol\cdot s$ $\quad [O_2] = 1.0\times10^{-2}\ M$

16.109 Chlorine is commonly used to disinfect drinking water, and inactivation of pathogens by chlorine follows first-order kinetics. The following data show *E. coli* inactivation:

Contact Time (min)	Percent (%) Inactivation
0.00	0.0
0.50	68.3
1.00	90.0
1.50	96.8
2.00	99.0
2.50	99.7
3.00	99.9

(a) Determine the first-order inactivation constant, k. [*Hint:* % inactivation $= 100 \times (1 - [A]_t/[A]_0)$.]
(b) How much contact time is required for 95% inactivation?

16.110 The overall equation and rate law for the gas-phase decomposition of dinitrogen pentoxide are

$$2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g) \qquad \text{rate} = k[N_2O_5]$$

Which of the following can be considered valid mechanisms for the reaction?

I One-step collision

II $2N_2O_5(g) \longrightarrow 2NO_3(g) + 2NO_2(g)$ [slow]
$2NO_3(g) \longrightarrow 2NO_2(g) + 2O(g)$ [fast]
$2O(g) \longrightarrow O_2(g)$ [fast]

III $N_2O_5(g) \rightleftharpoons NO_3(g) + NO_2(g)$ [fast]
$NO_2(g) + N_2O_5(g) \longrightarrow 3NO_2(g) + O(g)$ [slow]
$NO_3(g) + O(g) \longrightarrow NO_2(g) + O_2(g)$ [fast]

IV $2N_2O_5(g) \rightleftharpoons 2NO_2(g) + N_2O_3(g) + 3O(g)$ [fast]
$N_2O_3(g) + O(g) \longrightarrow 2NO_2(g)$ [slow]
$2O(g) \longrightarrow O_2(g)$ [fast]

V $2N_2O_5(g) \longrightarrow N_4O_{10}(g)$ [slow]
$N_4O_{10}(g) \longrightarrow 4NO_2(g) + O_2(g)$ [fast]

16.111 Nitrification is a biological process for removing NH_3 from wastewater as NH_4^+:

$$NH_4^+ + 2O_2 \longrightarrow NO_3^- + 2H^+ + H_2O$$

The first-order rate constant is given as

$$k_1 = 0.47e^{0.095\,(T = 15°C)}$$

where k_1 is in day^{-1} and T is in °C.
(a) If the initial concentration of NH_3 is 3.0 mol/m^3, how long will it take to reduce the concentration to 0.35 mol/m^3 in the spring ($T = 20$°C)?
(b) In the winter ($T = 10$°C)?
(c) Using your answer to part (a), what is the rate of O_2 consumption?

16.112 Carbon disulfide, a poisonous, flammable liquid, is an excellent solvent for phosphorus, sulfur, and some other nonmetals. A kinetic study of its gaseous decomposition reveals these data:

Experiment	Initial Rate (mol/L·s)	Initial $[CS_2]$ (mol/L)
1	2.7×10^{-7}	0.100
2	2.2×10^{-7}	0.080
3	1.5×10^{-7}	0.055
4	1.2×10^{-7}	0.044

(a) Write the rate law for the decomposition of CS_2.
(b) Calculate the average value of the rate constant.

16.113 Like any catalyst, palladium, platinum, or nickel catalyzes both directions of a reaction: addition of hydrogen to (hydrogenation) and its elimination from (dehydrogenation) carbon double bonds.
(a) Which variable determines whether an alkene will be hydrogenated or dehydrogenated?
(b) Which reaction requires a higher temperature?
(c) How can all-*trans* fats arise during hydrogenation of fats that contain some *cis*- double bonds?

16.114 In a *clock reaction,* a dramatic color change occurs at a time determined by concentration and temperature. Consider the iodine clock reaction, whose overall equation is

$$2I^-(aq) + S_2O_8^{2-}(aq) \longrightarrow I_2(aq) + 2SO_4^{2-}(aq)$$

As I_2 forms, it is immediately consumed by its reaction with a fixed amount of added $S_2O_3^{2-}$:

$$I_2(aq) + 2S_2O_3^{2-}(aq) \longrightarrow 2I^-(aq) + S_4O_6^{2-}(aq)$$

Once the $S_2O_3^{2-}$ is consumed, the excess I_2 forms a blue-black product with starch present in solution:

$$I_2 + \text{starch} \longrightarrow \text{starch}\cdot I_2 \text{ (blue-black)}$$

The rate of the reaction is also influenced by the total concentration of ions, so KCl and $(NH_4)_2SO_4$ are added to maintain a constant value. Use the data below, obtained at 23°C, to determine:
(a) The average rate for each trial
(b) The order with respect to each reactant
(c) The rate constant
(d) The rate law for the overall reaction

	Expt 1	Expt 2	Expt 3
0.200 *M* KI (mL)	10.0	20.0	20.0
0.100 *M* $Na_2S_2O_8$ (mL)	20.0	20.0	10.0

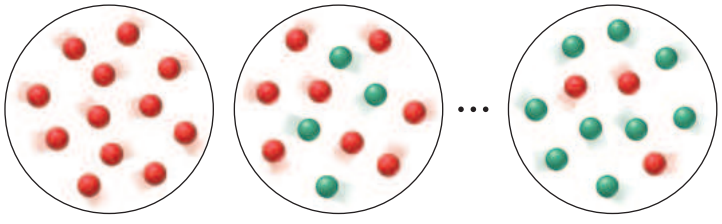
16.115 Heat transfer to and from a reaction flask is often a critical factor in controlling reaction rate. The heat transferred (q) depends on a heat transfer coefficient (h) for the flask material, the temperature difference (ΔT) across the flask wall, and the commonly "wetted" area (A) of the flask and bath, $q = hA\Delta T$. When an exothermic reaction is run at a given T, there is a bath temperature at which the reaction can no longer be controlled, and the reaction "runs away" suddenly. A similar problem is often seen when a reaction is "scaled up" from, say, a half-filled small flask to a half-filled large flask. Explain these behaviors.

16.116 The molecular scenes below represent the first-order reaction in which cyclopropane *(red)* is converted to propene *(green)*:



Determine (a) the half-life and (b) the rate constant.

16.117 The growth of *Pseudomonas* bacteria is modeled as a first-order process with $k = 0.035\ \text{min}^{-1}$ at 37°C. The initial *Pseudomonas* population density is 1.0×10^3 cells/L. (a) What is the population density after 2 h? (b) What is the time required for the population to go from 1.0×10^3 to 2.0×10^3 cells/L?

16.118 Consider the following organic reaction, in which one halogen replaces another in an alkyl halide:

$$CH_3CH_2Br + KI \longrightarrow CH_3CH_2I + KBr$$

In acetone, this particular reaction goes to completion because KI is soluble in acetone but KBr is not. In the mechanism, I^- approaches the carbon *opposite* to the Br (see Figure 16.20, p. 704, with I^- instead of OH^-). After Br^- has been replaced by I^- and precipitates as KBr, other I^- ions react with the ethyl iodide by the same mechanism.
(a) If we designate the carbon bonded to the halogen as C-1, what is the shape around C-1 and the hybridization of C-1 in ethyl iodide?
(b) In the transition state, one of the two lobes of the unhybridized $2p$ orbital of C-1 overlaps a p orbital of I, while the other lobe overlaps a p orbital of Br. What is the shape around C-1 and the hybridization of C-1 in the transition state?
(c) The deuterated reactant, CH_3CHDBr (where D is deuterium, ^2H), has two optical isomers because C-1 is chiral. If the reaction is run with one of the isomers, the ethyl iodide is *not* optically active. Explain.

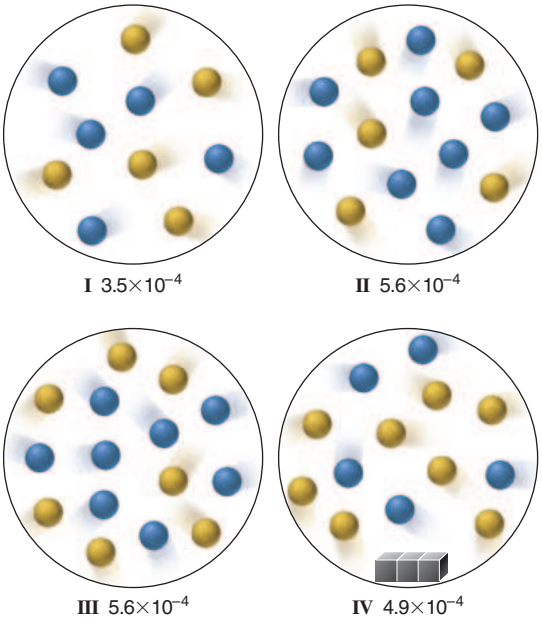
16.119 Another radioisotope of iodine, ^{131}I, is also used to study thyroid function (see Follow-up Problem 16.7A). A patient is given a sample that is $1.7\times10^{-4}\ M\ ^{131}I$. If the half-life is 8.04 days, what fraction of the radioactivity remains after 30. days?

16.120 The effect of substrate concentration on the first-order growth rate of a microbial population follows the Monod equation:

$$\mu = \frac{\mu_{max} S}{K_s + S}$$

where μ is the first-order growth rate (s^{-1}), μ_{max} is the maximum growth rate (s^{-1}), S is the substrate concentration (kg/m^3), and K_s is the value of S that gives one-half of the maximum growth rate (in kg/m^3). For $\mu_{max} = 1.5\times10^{-4}\ s^{-1}$ and $K_s = 0.03\ kg/m^3$:
(a) Plot μ vs. S for S between 0.0 and 1.0 kg/m^3.
(b) The initial population density is 5.0×10^3 cells/m^3. What is the density after 1.0 h, if the initial S is 0.30 kg/m^3?
(c) What is it if the initial S is 0.70 kg/m^3?

16.121 The scenes depict four initial reaction mixtures for the reaction of A *(blue)* and B *(yellow)*, with and without a solid present *(gray cubes)*. The initial rate, $-\Delta[A]/\Delta t$ (in mol/L·s), is shown, with each sphere representing 0.010 mol and the container volume at 0.50 L.



(a) What is the rate law in the absence of a catalyst?
(b) What is the overall reaction order?
(c) Find the rate constant.
(d) Do the gray cubes have a catalytic effect? Explain.

16.122 The mathematics of the first-order rate law can be applied to any situation in which a quantity decreases by a constant fraction per unit of time (or unit of any other variable).

(a) As light moves through a solution, its intensity decreases per unit distance traveled in the solution. Show that

$$\ln\left(\frac{\text{intensity of light leaving the solution}}{\text{intensity of light entering the solution}}\right) = -\text{fraction of light removed per unit of length} \times \text{distance traveled in solution}$$

(b) The value of your savings declines under conditions of constant inflation. Show that

$$\ln\left(\frac{\text{value remaining}}{\text{initial value}}\right) = -\text{fraction lost per unit of time} \times \text{savings time interval}$$

16.123 Figure 16.25 (p. 714) shows key steps in the metal-catalyzed (M) hydrogenation of ethylene:

$$C_2H_4(g) + H_2(g) \longrightarrow C_2H_6(g)$$

Use the following symbols to write a mechanism that gives the overall equation:

H_2(ads)	adsorbed hydrogen molecules
M—H	hydrogen atoms bonded to metal atoms
C_2H_4(ads)	adsorbed ethylene molecules
C_2H_5(ads)	adsorbed ethyl radicals

16.124 Human liver enzymes catalyze the degradation of ingested toxins. By what factor is the rate of a detoxification changed if an enzyme lowers the E_a by 5 kJ/mol at 37°C?

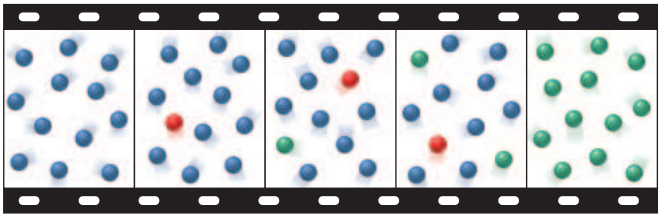
16.125 Acetone is one of the most important solvents in organic chemistry, used to dissolve everything from fats and waxes to airplane glue and nail polish. At high temperatures, it decomposes in a first-order process to methane and ketene ($CH_2{=}C{=}O$). At 600°C, the rate constant is $8.7\times10^{-3}\ s^{-1}$.

(a) What is the half-life of the reaction?

(b) How long does it take for 40.% of a sample of acetone to decompose?

(c) How long does it take for 90.% of a sample of acetone to decompose?

16.126 A *(green)*, B *(blue)*, and C *(red)* are structural isomers. The molecular filmstrip depicts them undergoing a chemical change as time proceeds.



(a) Write a mechanism for the reaction.

(b) What role does C play?

Concepts and Skills to Review Before You Study This Chapter

- reversibility of reactions (Section 4.7)
- equilibrium vapor pressure (Section 12.2)
- equilibrium nature of a saturated solution (Section 13.4)
- dependence of rate on concentration (Sections 16.2 and 16.5)
- rate laws for elementary reactions (Section 16.6)
- function of a catalyst (Section 16.7)

Just as reactions vary greatly in their speed, they also vary greatly in their extent. Indeed, kinetics and equilibrium apply to different aspects of a reaction:

- Kinetics applies to the *speed* (or rate) of a reaction, the concentration of reactant that disappears (or of product that appears) per unit time.
- Equilibrium applies to the *extent* of a reaction, the concentrations of reactant and product present after an unlimited time, that is, when no further change occurs.

As you'll see, at equilibrium, no further *net* change occurs because the forward and reverse reactions reach a *balance*. Like the downward and upward flow of water in a fountain or traffic going back and forth across a bridge or people going up and down an escalator, the change in one direction is balanced by the change in the other. A fast reaction may go almost completely, just partially, or only slightly toward products before this balance is reached. Consider acid dissociation in water. In 1 *M* HCl, virtually all the hydrogen chloride molecules are dissociated into ions, whereas fewer than 1% of the acetic acid molecules are dissociated in 1 *M* CH_3COOH. Yet both reactions take less than a second. Similarly, some slow reactions yield a large amount of product, whereas others yield very little. After a few years, a steel water tank will start to rust, and it will do so completely given enough time. But, no matter how long you wait, the water inside the tank will not decompose to hydrogen and oxygen.

Knowing the extent of a given reaction is crucial. How much product—medicine, polymer, fuel—can you obtain from a particular reaction mixture? How can you adjust conditions to obtain more? If a reaction is slow but eventually has a good yield, will a catalyst speed it up enough to make it useful?

IN THIS CHAPTER . . . *We consider the principles of equilibrium in systems of gases and pure liquids and solids.*

- We examine the equilibrium state at the macroscopic and molecular levels and see that equilibrium occurs when the forward and reverse reaction rates are equal.
- We contrast the reaction quotient, *Q*, which changes as the reaction proceeds, with the equilibrium constant, *K*, which applies to the reaction at equilibrium.
- We express the equilibrium condition in terms of concentrations or pressures and see how the two expressions are related.
- We compare values of *Q* and *K* to determine the direction in which a system must proceed to reach equilibrium.
- We develop a systematic approach to solving a variety of equilibrium problems.
- We explore Le Châtelier's principle, which explains how a change in conditions—concentration, pressure, temperature, or addition of a catalyst—affects the equilibrium state, and we apply this principle to a major industrial process.
- We introduce equilibrium concepts operating in metabolic pathways.

17.1 THE EQUILIBRIUM STATE AND THE EQUILIBRIUM CONSTANT

Experimental results from countless reactions have shown that, *given sufficient time, the concentrations of the reactants and products attain certain values that no longer change.* This apparent cessation of chemical change occurs because *all reactions are reversible and reach a state of equilibrium.* Let's examine a chemical system at the macroscopic and molecular levels to see how equilibrium arises and then consider some quantitative aspects of the process.

1. *A macroscopic view of equilibrium.* The system we'll consider is the reversible gaseous reaction between colorless dinitrogen tetroxide and brown nitrogen dioxide:

$$N_2O_4(g;\ \text{colorless}) \rightleftharpoons 2NO_2(g;\ \text{brown})$$

As soon as we introduce some liquid N_2O_4 (bp = 21°C) into a sealed container kept at 200°C, it vaporizes, and the gas begins to turn pale brown as NO_2 is produced. As time passes, the brown darkens, until, after more time, the color stops changing. The first three photos in Figure 17.1 show the color change, and the last photo shows no further change.

2. *A molecular view of equilibrium.* On the molecular level, as shown in the blow-up circles of Figure 17.1, a dynamic scene unfolds. The N_2O_4 molecules fly wildly throughout the container, a few splitting into two NO_2 molecules. As time passes, more N_2O_4 molecules decompose and the concentration of NO_2 rises. As the number of N_2O_4 molecules decreases, N_2O_4 decomposition slows down (recall that reaction rate decreases with decreasing reactant concentration for most reactions). At the same time, as the number of NO_2 molecules increases, more collide, and formation of N_2O_4 speeds up. Eventually, the system reaches equilibrium: N_2O_4 molecules are decomposing into NO_2 molecules just as fast as NO_2 molecules are forming N_2O_4.

Thus, at equilibrium, *reactant and product concentrations are constant because a change in one direction is balanced by a change in the other as the forward and reverse rates become equal:*

$$\text{At equilibrium: } \text{rate}_{fwd} = \text{rate}_{rev} \qquad \textbf{(17.1)}$$

3. *A quantitiative view of equilibrium: a constant ratio of constants.* Let's see how reactant and product concentrations affect this process. At a particular temperature, when the system reaches equilibrium, we have

$$\text{rate}_{fwd} = \text{rate}_{rev}$$

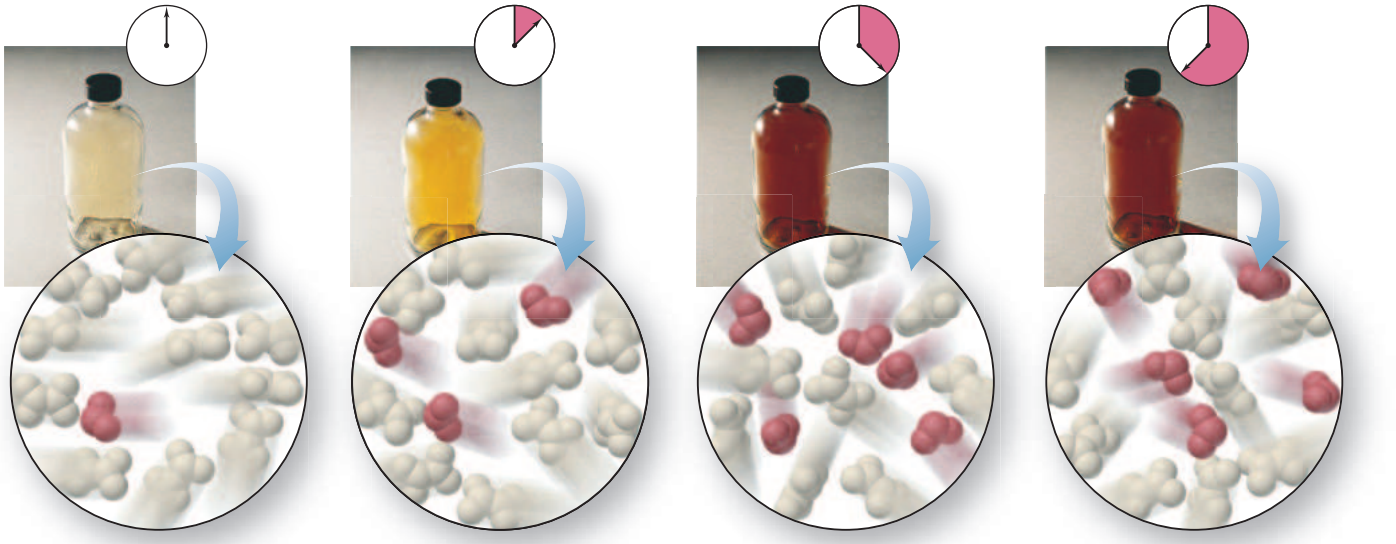
In this reaction system, both forward and reverse reactions are elementary steps (Section 16.6), so we can write their rate laws directly from the balanced equation:

$$k_{fwd}[N_2O_4]_{eq} = k_{rev}[NO_2]^2_{eq}$$

where k_{fwd} and k_{rev} are the forward and reverse rate constants, respectively, and the subscript "eq" refers to concentrations at equilibrium. By rearranging, we set the ratio of the rate constants equal to the ratio of the concentration terms:

$$\frac{k_{fwd}}{k_{rev}} = \frac{[NO_2]^2_{eq}}{[N_2O_4]_{eq}}$$

Figure 17.1 **Reaching equilibrium on the macroscopic and molecular levels.**



The reaction mixture consists mostly of colorless N_2O_4.

As N_2O_4 decomposes to NO_2, the mixture becomes pale brown.

The brown color deepens as more N_2O_4 decomposes and more NO_2 is produced, until the color reaches a maximum at equilibrium.

The reaction continues in both directions at equal rates, so the concentrations of NO_2 and N_2O_4, and therefore the color, no longer change.

The ratio of constants creates a new constant called the **equilibrium constant (*K*):**

$$K = \frac{k_{fwd}}{k_{rev}} = \frac{[NO_2]^2_{eq}}{[N_2O_4]_{eq}} \qquad (17.2)$$

Thus, *K is a number equal to a particular ratio of equilibrium concentrations of product(s) and reactant(s) at a particular temperature.*

4. *K as a measure of reaction extent.* The *magnitude* of *K* is an indication of *how far a reaction proceeds toward product at a given temperature*. Different reactions, even at the same temperature, have a wide range of concentrations at equilibrium—from almost all reactant to almost all product—and so, they have a wide range of equilibrium constants. Here are three examples of different magnitudes of *K*:

- *Small K* (Figure 17.2A). If a reaction yields little product before reaching equilibrium, the ratio of product concentration to reactant concentration is small, and the reaction has a small *K*; if *K* is very small, we may say there is "no reaction." For example, there is "no reaction" between nitrogen and oxygen at 1000 K:*

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) \qquad K = 1\times10^{-30}$$

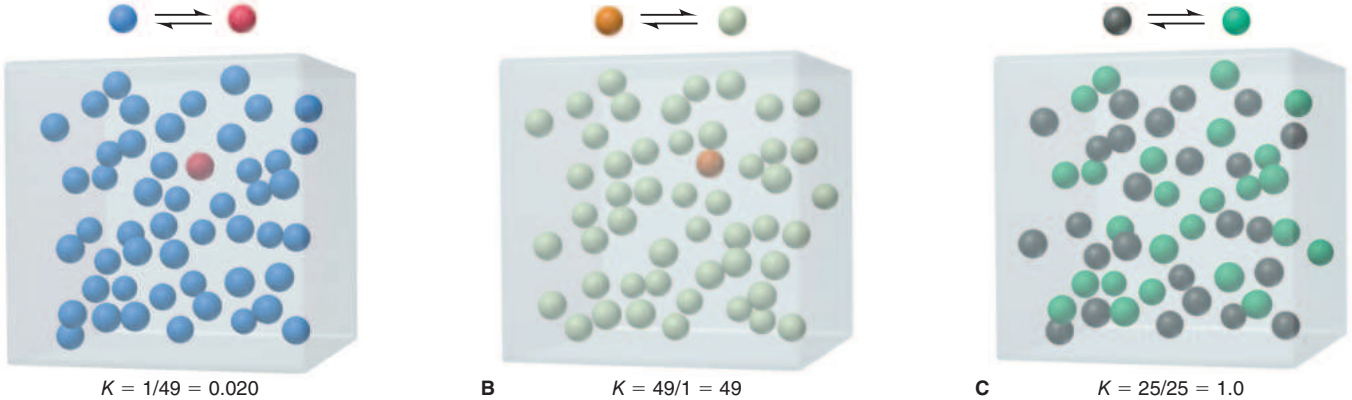
- *Large K* (Figure 17.2B). Conversely, if a reaction reaches equilibrium with little reactant remaining, its ratio of product concentration to reactant concentration is large, and it has a large *K*; if *K* is very large, we say the reaction "goes to completion." The oxidation of carbon monoxide "goes to completion" at 1000 K:

$$2CO(g) + O_2(g) \rightleftharpoons 2CO_2(g) \qquad K = 2.2\times10^{22}$$

- *Intermediate K* (Figure 17.2C). When significant amounts of both reactant and product are present at equilibrium, *K* has an intermediate value, as when bromine monochloride breaks down to its elements at 1000 K:

$$2BrCl(g) \rightleftharpoons Br_2(g) + Cl_2(g) \qquad K = 5$$

Figure 17.2 **The range of equilibrium constants.**



A $K = 1/49 = 0.020$ **B** $K = 49/1 = 49$ **C** $K = 25/25 = 1.0$

Summary of Section 17.1

- Kinetics and equilibrium are distinct aspects of a reaction system, and the rate and extent of a reaction are not necessarily related.
- When the forward and reverse reactions occur at the same rate, concentrations no longer change and the system has reached equilibrium.
- The equilibrium constant (*K*) is a number based on a particular ratio of product and reactant concentrations: *K* is small if a high concentration of reactant(s) is present at equilibrium, and it is large if a high concentration of product(s) is present at equilibrium.

*Note that the equilibrium constant is represented by a capital italic *K*, whereas the temperature unit, the kelvin, is a capital roman K. Also, since the kelvin is a unit, it always follows a number.

17.2 THE REACTION QUOTIENT AND THE EQUILIBRIUM CONSTANT

We have introduced the equilibrium constant in terms of a ratio of rate constants, but the original research on chemical equilibrium was developed many years before the principles of kinetics. In 1864, two Norwegian chemists, Cato Guldberg and Peter Waage, observed that *at a given temperature, a chemical system reaches a state in which a particular ratio of reactant and product concentrations has a constant value.* This is a statement of the **law of chemical equilibrium,** or the **law of mass action.**

The Changing Value of the Reaction Quotient

The particular ratio of concentration terms that we write for a given reaction is called the **reaction quotient** (***Q*,** also known as the *mass-action expression*). For the reversible breakdown of N_2O_4 to NO_2, the reaction quotient is

$$N_2O_4(g) \rightleftharpoons 2NO_2(g) \qquad Q = \frac{[NO_2]^2}{[N_2O_4]}$$

As the reaction proceeds toward equilibrium, the concentrations of reactants and products change continually, and so does their ratio, the value of Q: at a given temperature, at the beginning of the reaction, the concentrations have initial values, and Q has an initial value; a moment later, the concentrations have slightly different values, and so does Q; after another moment, the concentrations and the value of Q change further. These changes continue, *until the system reaches equilibrium.* At that point, reactant and product concentrations have their equilibrium values and no longer change. Thus, the value of Q no longer changes and equals K at that temperature:

$$\text{At equilibrium: } Q = K \qquad \textbf{(17.3)}$$

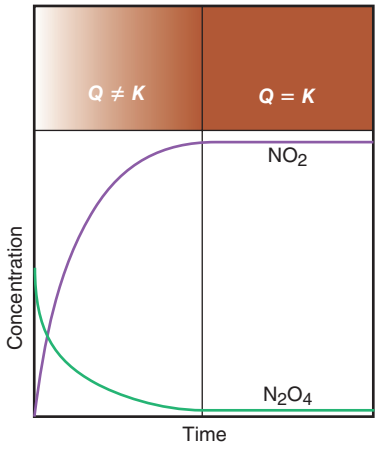


Figure 17.3 The change in *Q* during the N_2O_4-NO_2 reaction. Based on data from Experiment 1 in Table 17.1.

In formulating the law of mass action, Guldberg and Waage found that, *for a particular system and temperature, the same equilibrium state is attained regardless of starting concentrations.* For example, for the N_2O_4-NO_2 system at 200°C, the data from four experiments appear in Table 17.1. Two essential points stand out:

- The ratio of *initial* concentrations *(fourth column)* varies widely but always gives the same ratio of *equilibrium* concentrations *(rightmost column).*
- The *individual* equilibrium concentrations are different in each case, but the *ratio* of these equilibrium concentrations is constant.

Thus, monitoring Q tells whether the system has reached equilibrium or, if it hasn't, how far away it is and in which direction it is changing.

The curves in Figure 17.3 show experiment 1 in Table 17.1. Note that $[N_2O_4]$ and $[NO_2]$ change smoothly during the course of the reaction (as indicated by the changing brown color at the top), and so does the value of Q. Once the system reaches equilibrium (constant brown color), the concentrations no longer change and Q equals K. In other words, for any given chemical system, *K is a special value of Q that occurs when the reactant and product concentrations have their equilibrium values.*

Table 17.1 Initial and Equilibrium Concentration Ratios for the N_2O_4-NO_2 System at 200°C (473 K)

	Initial			Equilibrium		
Expt	$[N_2O_4]$	$[NO_2]$	Q, $[NO_2]^2/[N_2O_4]$	$[N_2O_4]_{eq}$	$[NO_2]_{eq}$	K, $[NO_2]^2_{eq}/[N_2O_4]_{eq}$
1	0.1000	0.0000	0.0000	0.00357	0.193	10.4
2	0.0000	0.1000	∞	0.000924	0.0982	10.4
3	0.0500	0.0500	0.0500	0.00204	0.146	10.4
4	0.0750	0.0250	0.00833	0.00275	0.170	10.5

Writing the Reaction Quotient in Its Various Forms

The reaction quotient *must* be written directly from the balanced equation. In contrast, as discussed in Chapter 16, the rate law for an overall reaction *cannot* be written from the balanced equation, but must be determined from rate data.

Constructing the Reaction Quotient The most common form of the reaction quotient shows reactant and product terms as molar concentrations, which are designated by square brackets, [ ]. Thus, from now on, we designate the *reaction quotient based on concentrations* as Q_c. (We also designate the *equilibrium constant based on concentrations* as K_c.) For the general equation

$$aA + bB \rightleftharpoons cC + dD$$

where a, b, c, and d are the stoichiometric coefficients, the reaction quotient is

$$Q_c = \frac{[C]^c[D]^d}{[A]^a[B]^b} \qquad (17.4)$$

Thus, *Q is a ratio of product concentration terms multiplied together and divided by reactant concentration terms multiplied together, with each term raised to the power of its balancing coefficient.*

Two steps are needed to construct a reaction quotient for any chemical system:

1. *Start with the balanced equation.* For example, for the formation of ammonia from its elements, the balanced equation (with colored coefficients for reference) is

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

2. *Arrange the terms and exponents.* Place the product terms in the numerator and the reactant terms in the denominator, multiplied by each other, and raise each term to the power of its balancing coefficient (colored as in the balanced equation):

$$Q_c = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

Why *Q* and *K* Have No Units In this text (and most others), *the values of Q and K are unitless numbers*. As we will discuss in Chapter 20, the reason is that Q and K are based on thermodynamic parameters. That is, each term in Q or K is actually an *activity,* or active concentration, the *ratio* of the concentration (or pressure) of a substance to its reference standard-state concentration (or pressure). Recall from Section 6.6 that the standard states are 1 M for a substance in solution, 1 atm for a gas, and the pure substance itself for a liquid or solid. The terms become unitless ratios as follows:

- For a concentration of, say, 1.20 M NaCl, we have

$$[NaCl] = \frac{1.20\ \cancel{M}\ (\text{measured quantity})}{1\ \cancel{M}\ (\text{standard-state quantity})} = 1.20$$

- For a pressure of, say, 0.53 atm N_2, we have

$$P_{N_2} = \frac{0.53\ \cancel{\text{atm}}\ (\text{measured quantity})}{1\ \cancel{\text{atm}}\ (\text{standard-state quantity})} = 0.53$$

- For a pure solid or a pure liquid, the concentration is the density of the substance, which when divided by its density, must equal 1.

Since each term used to write Q or K is a unitless ratio, Q and K are unitless also.

Form of *Q* for a Reaction Involving Pure Liquids or Solids The formation of gaseous NH_3 from its elements in the gas phase is an example of a *homogeneous* equilibrium system in which all the components are in the same phase. When the components are in different phases, the equilibrium system is *heterogeneous*.

Consider the decomposition of limestone to lime and carbon dioxide:

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

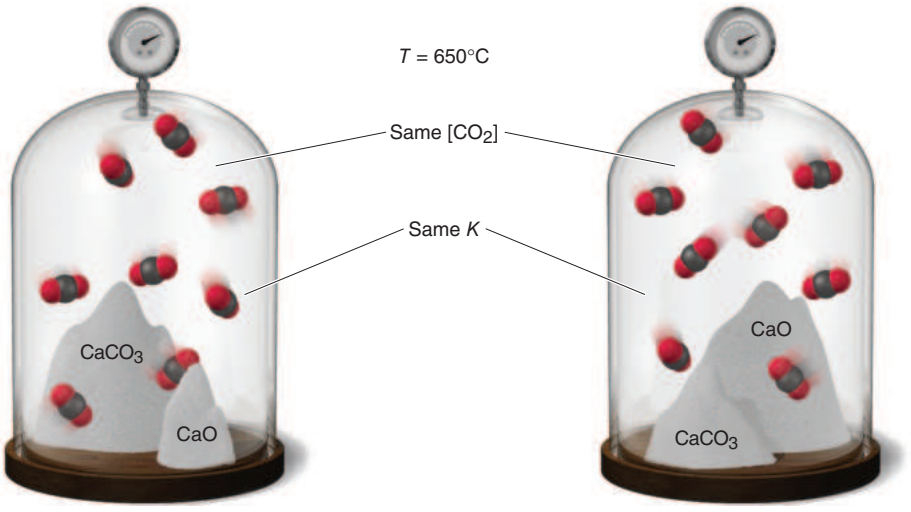

Figure 17.4 The reaction quotient for a heterogeneous system depends only on concentrations that change.

Using the rules for writing the reaction quotient, we would obtain

$$Q_c = \frac{[CaO][CO_2]}{[CaCO_3]}$$

However, as the preceding subsection about Q and K being unitless numbers stated, each term in the reaction quotient is actually the ratio of the measured quantity to the standard-state quantity and *for all pure solids and liquids, this ratio is 1*. Thus, we have

$$Q_c = \frac{(1)[CO_2]}{(1)} = [CO_2]$$

This means that as long as some CaO and some $CaCO_3$ are present, only the CO_2 concentration affects the value of Q_c (Figure 17.4).

It makes sense that *we eliminate the terms for pure solids and liquids in the expressions for Q and K* because we are concerned only with concentrations that *change* as they approach equilibrium, and the concentrations, like the densities, of pure solids and liquids are constant.

SAMPLE PROBLEM 17.1 Writing the Reaction Quotient from the Balanced Equation

Problem Write the reaction quotient, Q_c, for each of the following reactions:
(a) $N_2O_5(g) \rightleftharpoons NO_2(g) + O_2(g)$
(b) $Na(s) + H_2O(l) \rightleftharpoons NaOH(aq) + H_2(g)$
(c) $C_3H_8(g) + O_2(g) \rightleftharpoons CO_2(g) + H_2O(g)$

Plan We balance the equation and then construct the reaction quotient using Equation 17.4. Remember that concentration terms for pure liquids and solids are not included in the reaction quotient.

Solution **(a)** From the balanced equation, $2N_2O_5(g) \rightleftharpoons 4NO_2(g) + O_2(g)$, we have

$$Q_c = \frac{[NO_2]^4[O_2]}{[N_2O_5]^2}$$

(b) From the balanced equation, $2Na(s) + 2H_2O(l) \rightleftharpoons 2NaOH(aq) + H_2(g)$, we have

$$Q_c = [NaOH]^2[H_2]$$

(c) From the balanced equation, $C_3H_8(g) + 5O_2(g) \rightleftharpoons 3CO_2(g) + 4H_2O(g)$, we have

$$Q_c = \frac{[CO_2]^3[H_2O]^4}{[C_3H_8][O_2]^5}$$

Check Be sure that the exponents in the reaction quotient are the same as the balancing coefficients. A good check is to reverse the process and see if you obtain the balanced equation, except for any substances that are pure liquids or solids: change the numerator of the expression to products, the denominator to reactants, and the exponents to coefficients.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

17.1A Write the reaction quotient, Q_c, for each of the following reactions:

(a) $NH_3(g) + O_2(g) \rightleftharpoons NO(g) + H_2O(g)$

(b) $NO_2(g) + H_2(g) \rightleftharpoons NH_3(g) + H_2O(l)$

(c) $KClO_3(s) \rightleftharpoons KCl(s) + O_2(g)$

17.1B Write the reaction quotient, Q_c, for each of the following reactions:

(a) $CH_4(g) + CO_2(g) \rightleftharpoons CO(g) + H_2(g)$

(b) $H_2S(g) + SO_2(g) \rightleftharpoons S(s) + H_2O(g)$

(c) $HCN(aq) + NaOH(aq) \rightleftharpoons NaCN(aq) + H_2O(l)$

SOME SIMILAR PROBLEMS 17.12–17.15 and 17.18–17.21

Form of *Q* for an Overall Reaction We follow the same procedure for writing a reaction quotient whether an equation represents an individual reaction step or an overall multistep reaction. *If an overall reaction is the* ***sum*** *of two or more reactions, the overall reaction quotient (or equilibrium constant) is the* ***product*** *of the reaction quotients (or equilibrium constants) for the steps:*

$$Q_{overall} = Q_1 \times Q_2 \times Q_3 \times \cdots$$

and

$$K_{overall} = K_1 \times K_2 \times K_3 \times \cdots \qquad (17.5)$$

Sample Problem 17.2 demonstrates this point.

SAMPLE PROBLEM 17.2 Writing the Reaction Quotient and Finding *K* for an Overall Reaction

Problem Nitrogen dioxide is a toxic pollutant that contributes to photochemical smog. One way it forms is through the following sequence:

(1) $N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$ $\qquad K_{c1} = 4.3\times10^{-25}$

(2) $2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$ $\qquad K_{c2} = 6.4\times10^{9}$

(a) Show that the overall Q_c for this reaction sequence is the same as the product of the Q_c expressions for the individual reactions.

(b) Given that both reactions occur at the same temperature, find K_c for the overall reaction.

Plan **(a)** We first write the overall reaction by adding the individual reactions and then write the overall Q_c. Next, we write the Q_c for each step. We *add* the steps and *multiply* their Q_c's, canceling common terms, to obtain the overall Q_c. **(b)** We know the individual K_c values (4.3×10^{-25} and 6.4×10^{9}), so we multiply them to find $K_{c(overall)}$.

Solution **(a)** Writing the overall reaction and its reaction quotient:

$$\begin{array}{rl} (1) & N_2(g) + O_2(g) \rightleftharpoons \cancel{2NO(g)} \\ (2) & \cancel{2NO(g)} + O_2(g) \rightleftharpoons 2NO_2(g) \\ \hline \text{Overall:} & N_2(g) + 2O_2(g) \rightleftharpoons 2NO_2(g) \end{array}$$

$$Q_{c(overall)} = \frac{[NO_2]^2}{[N_2][O_2]^2}$$

Writing the reaction quotients for the individual steps:

For step 1, $$Q_{c1} = \frac{[NO]^2}{[N_2][O_2]}$$

For step 2, $$Q_{c2} = \frac{[NO_2]^2}{[NO]^2[O_2]}$$

Multiplying the individual reaction quotients and canceling:

$$Q_{c1} \times Q_{c2} = \frac{\cancel{[NO]^2}}{[N_2][O_2]} \times \frac{[NO_2]^2}{\cancel{[NO]^2}[O_2]} = \frac{[NO_2]^2}{[N_2][O_2]^2} = Q_{c(overall)}$$

(b) Calculating the overall K_c:

$$K_{c(overall)} = K_{c1} \times K_{c2} = (4.3\times10^{-25})(6.4\times10^{9}) = 2.8\times10^{-15}$$

Check Round off and check the calculation in part (b):

$$K_c \approx (4\times10^{-25})(6\times10^{9}) = 24\times10^{-16} = 2.4\times10^{-15}$$

FOLLOW-UP PROBLEMS

17.2A The following sequence of steps has been proposed for the overall reaction between H_2 and Br_2 to form HBr:

(1) $Br_2(g) \rightleftharpoons 2Br(g)$

(2) $Br(g) + H_2(g) \rightleftharpoons HBr(g) + H(g)$

(3) $H(g) + Br(g) \rightleftharpoons HBr(g)$

Write the overall balanced equation and show that the overall Q_c is the product of the Q_c expressions for the individual steps.

17.2B Given the following reaction sequence, write the overall balanced equation and show that the overall Q_c is the product of the Q_c expressions for the individual steps:

(1) $H_2(g) + ICl(g) \rightleftharpoons HI(g) + HCl(g)$

(2) $HI(g) + ICl(g) \rightleftharpoons I_2(g) + HCl(g)$

A SIMILAR PROBLEM 17.23

Form of *Q* for a Forward and a Reverse Reaction The form of the reaction quotient depends on the *direction* in which the balanced equation is written. Consider, for example, the oxidation of sulfur dioxide to sulfur trioxide. This reaction is a key step in acid-rain formation and sulfuric acid production. The balanced equation is

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

The reaction quotient for this equation *as written* is

$$Q_{c(fwd)} = \frac{[SO_3]^2}{[SO_2]^2[O_2]}$$

If we had written the reverse reaction, the decomposition of sulfur trioxide,

$$2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g)$$

the reaction quotient would be the *reciprocal* of $Q_{c(fwd)}$:

$$Q_{c(rev)} = \frac{[SO_2]^2[O_2]}{[SO_3]^2} = \frac{1}{Q_{c(fwd)}}$$

Thus, *a reaction quotient (or equilibrium constant) for a forward reaction is the* ***reciprocal*** *of the reaction quotient (or equilibrium constant) for the reverse reaction:*

$$Q_{c(fwd)} = \frac{1}{Q_{c(rev)}} \quad \text{and} \quad K_{c(fwd)} = \frac{1}{K_{c(rev)}} \tag{17.6}$$

The K_c values for the forward and reverse reactions shown above at 1000 K are

$$K_{c(fwd)} = 261 \quad \text{and} \quad K_{c(rev)} = \frac{1}{K_{c(fwd)}} = \frac{1}{261} = 3.83\times10^{-3}$$

These values make sense: if the forward reaction goes far to the right (high K_c), the reverse reaction does not (low K_c).

Form of *Q* for a Reaction with Coefficients Multiplied by a Common Factor Multiplying all the coefficients of the equation by some factor also changes the form of Q. For example, multiplying all the coefficients in the equation for the formation of SO_3 by $\frac{1}{2}$ gives

$$SO_2(g) + \tfrac{1}{2}O_2(g) \rightleftharpoons SO_3(g)$$

For this equation, the reaction quotient is

$$Q'_{c(fwd)} = \frac{[SO_3]}{[SO_2][O_2]^{1/2}}$$

Notice that Q_c for the halved equation equals Q_c for the original equation raised to the $\frac{1}{2}$ power:

$$Q'_{c(fwd)} = Q_{c(fwd)}^{1/2} = \left(\frac{[SO_3]^2}{[SO_2]^2[O_2]}\right)^{1/2} = \frac{[SO_3]}{[SO_2][O_2]^{1/2}}$$

Once again, the same property holds for the equilibrium constants. Relating the halved reaction to the original, we have

$$K'_{c(fwd)} = K_{c(fwd)}^{1/2} = (261)^{1/2} = 16.2$$

It may seem that we have changed the extent of the reaction, as indicated by a different K, just by changing the coefficients of the equation, but that can't be true. *A particular K has meaning only in relation to a particular equation.* If $K_{c(fwd)}$ and $K'_{c(fwd)}$ relate to different equations, we cannot compare them directly.

In general, *if all the coefficients of the balanced equation are multiplied by some factor, that factor becomes the exponent for relating the reaction quotients and the equilibrium constants.* For a multiplying factor n, which we can write as

$$n(aA + bB \rightleftharpoons cC + dD)$$

the reaction quotient and equilibrium constant are

$$Q' = Q^n = \left(\frac{[C]^c[D]^d}{[A]^a[B]^b}\right)^n \quad \text{and} \quad K' = K^n \tag{17.7}$$

SAMPLE PROBLEM 17.3 Finding the Equilibrium Constant for an Equation Multiplied by a Common Factor

Problem For the ammonia-formation reaction, the reference (ref) equation is

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

K_c is 2.4×10^{-3} at 1000 K. What are the values of K_c for the following balanced equations?

(a) $\frac{1}{3}N_2(g) + H_2(g) \rightleftharpoons \frac{2}{3}NH_3(g)$ **(b)** $NH_3(g) \rightleftharpoons \frac{1}{2}N_2(g) + \frac{3}{2}H_2(g)$

Plan We compare each equation with the reference equation to see how the direction and coefficients have changed.

Solution The reaction quotient for the reference equation is $Q_{c(ref)} = \dfrac{[NH_3]^2}{[N_2][H_2]^3}$.

(a) This equation is the reference equation multiplied by $\frac{1}{3}$, so K_c equals $K_{c(ref)}$ (2.4×10^{-3}) raised to the $\frac{1}{3}$ power.

$$Q_c = Q_{c(ref)}^{1/3} = \left(\frac{[NH_3]^2}{[N_2][H_2]^3}\right)^{1/3} = \frac{[NH_3]^{2/3}}{[N_2]^{1/3}[H_2]}$$

Thus, $$K_c = K_{c(ref)}^{1/3} = (2.4\times10^{-3})^{1/3} = 0.13$$

(b) This equation is one-half the *reverse* of the reference equation, so K_c is the reciprocal of $K_{c(ref)}$ raised to the $\frac{1}{2}$ power.

$$Q_c = \left(\frac{1}{Q_{c(ref)}}\right)^{1/2} = \left(\frac{1}{\dfrac{[NH_3]^2}{[N_2][H_2]^3}}\right)^{1/2} = \frac{[N_2]^{1/2}[H_2]^{3/2}}{[NH_3]}$$

Thus, $$K_c = \left(\frac{1}{K_{c(ref)}}\right)^{1/2} = \left(\frac{1}{2.4\times10^{-3}}\right)^{1/2} = 20.$$

Check A good check is to work the math backwards. **(a)** $(0.13)^3 = 2.2\times10^{-3}$, within rounding of 2.4×10^{-3}. The reaction goes in the same direction, so there should be mostly reactants, as $K_c < 1$ indicates. **(b)** $1/(20.)^2 = 2.5\times10^{-3}$, again within rounding. At equilibrium, the reverse reaction should yield mostly products, as $K_c > 1$ indicates.

FOLLOW-UP PROBLEMS

17.3A At 1200 K, the reaction of hydrogen and chlorine to form hydrogen chloride is

$$H_2(g) + Cl_2(g) \rightleftharpoons 2HCl(g) \qquad K_c = 7.6\times10^8$$

Calculate K_c for the following reactions:

(a) $\frac{1}{2}H_2(g) + \frac{1}{2}Cl_2(g) \rightleftharpoons HCl(g)$ **(b)** $\frac{4}{3}HCl(g) \rightleftharpoons \frac{2}{3}H_2(g) + \frac{2}{3}Cl_2(g)$

17.3B The reaction $2NO(g) + Br_2(g) \rightleftharpoons 2NOBr(g)$ has a K_c value of 1.3×10^{-2} at 1000 K. Calculate K_c for the following reactions:

(a) $4NOBr(g) \rightleftharpoons 4NO(g) + 2Br_2(g)$ **(b)** $\frac{1}{2}NO(g) + \frac{1}{4}Br_2(g) \rightleftharpoons \frac{1}{2}NOBr(g)$

SOME SIMILAR PROBLEMS 17.16 and 17.17

Table 17.2 summarizes the ways of writing Q and calculating K.

Table 17.2 Ways of Expressing Q and Calculating K

Form of Chemical Equations	Form of Q	Value of K
Reference reaction: A $\rightleftharpoons$ B	$Q_{(\text{ref})} = \dfrac{[\text{B}]}{[\text{A}]}$	$K_{(\text{ref})} = \dfrac{[\text{B}]_{\text{eq}}}{[\text{A}]_{\text{eq}}}$
Reverse reaction: B $\rightleftharpoons$ A	$Q = \dfrac{1}{Q_{(\text{ref})}} = \dfrac{[\text{A}]}{[\text{B}]}$	$K = \dfrac{1}{K_{(\text{ref})}}$
Reaction as sum of two steps: (1) A $\rightleftharpoons$ C	$Q_1 = \dfrac{[\text{C}]}{[\text{A}]}; Q_2 = \dfrac{[\text{B}]}{[\text{C}]}$	
(2) C $\rightleftharpoons$ B	$Q_{\text{overall}} = Q_1 \times Q_2 = Q_{(\text{ref})} = \dfrac{\cancel{[\text{C}]}}{[\text{A}]} \times \dfrac{[\text{B}]}{\cancel{[\text{C}]}} = \dfrac{[\text{B}]}{[\text{A}]}$	$K_{\text{overall}} = K_1 \times K_2 = K_{(\text{ref})}$
Coefficients multiplied by n	$Q = Q_{(\text{ref})}^n$	$K = K_{(\text{ref})}^n$
Reaction with pure solid or liquid component, such as A(s)	$Q = Q_{(\text{ref})}(1) = [\text{B}]$	$K = K_{(\text{ref})}(1) = [\text{B}]$

Summary of Section 17.2

- The reaction quotient based on concentration, Q_c, is a particular ratio of product to reactant concentrations. The value of Q_c changes as the reaction proceeds. When the system reaches equilibrium at a particular temperature, $Q_c = K_c$.
- The concentration terms for pure liquids or solids do not appear in Q because they are equal to 1.
- If a reaction is the sum of two or more steps, the overall Q (or K) is the product of the individual Q's (or K's).
- The *form* of Q is based on the balanced equation exactly as written, so it changes if the equation is reversed or multiplied by some factor, and K changes accordingly.
- Three criteria define a system at equilibrium:
  1. Reactant and product concentrations are constant over time.
  2. The opposing reaction rates are equal: $\text{rate}_{\text{fwd}} = \text{rate}_{\text{rev}}$.
  3. The reaction quotient equals the equilibrium constant: $Q = K$.

17.3 EXPRESSING EQUILIBRIA WITH PRESSURE TERMS: RELATION BETWEEN K_c AND K_p

It is easier to measure gas *pressure* than concentration, so when a reaction involves gases, we often express the reaction quotient in terms of partial pressures instead of concentrations. As long as the gases behave nearly ideally during the experiment, the ideal gas law (Section 5.3) allows us to relate pressure (P) to concentration (n/V):

$$PV = nRT, \quad \text{so} \quad P = \frac{n}{V}RT \quad \text{or} \quad \frac{P}{RT} = \frac{n}{V}$$

Thus, at constant T, *pressure is directly proportional to molar concentration.* For example, in the reaction between gaseous NO and O_2,

$$2\text{NO}(g) + \text{O}_2(g) \rightleftharpoons 2\text{NO}_2(g)$$

the *reaction quotient based on pressures,* Q_p, is

$$Q_p = \frac{P_{\text{NO}_2}^2}{P_{\text{NO}}^2 \times P_{\text{O}_2}}$$

The equilibrium constant obtained when all components are present at their equilibrium partial pressures is designated K_p, the *equilibrium constant based on*

pressures. In many cases, K_p has a value different from K_c. But if you know one, the *change in amount (mol) of gas,* Δn_{gas}, from the balanced equation allows you to calculate the other. Let's see how this conversion works for the oxidation of NO:

$$2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$$

As the balanced equation shows,

$$3 \text{ mol (2 mol + 1 mol) gaseous reactants} \rightleftharpoons 2 \text{ mol gaseous products}$$

With Δ meaning final *minus* initial (products *minus* reactants), we have

$$\Delta n_{gas} = \text{moles of gaseous product} - \text{moles of gaseous reactant} = 2 - 3 = -1$$

Keep this value of Δn_{gas} in mind because it appears in the conversion that follows.

The reaction quotient based on concentrations is

$$Q_c = \frac{[NO_2]^2}{[NO]^2[O_2]}$$

Rearranging the ideal gas law to $n/V = P/RT$, we write the terms in square brackets as n/V and convert them to partial pressures, P; then we collect the RT terms and cancel:

$$Q_c = \frac{\frac{n_{NO_2}^2}{V^2}}{\frac{n_{NO}^2}{V^2} \times \frac{n_{O_2}}{V}} = \frac{\frac{P_{NO_2}^2}{(RT)^2}}{\frac{P_{NO}^2}{(RT)^2} \times \frac{P_{O_2}}{RT}} = \frac{P_{NO_2}^2}{P_{NO}^2 \times P_{O_2}} \times \frac{\frac{1}{(RT)^2}}{\frac{1}{(RT)^2} \times \frac{1}{RT}}$$

$$= \frac{P_{NO_2}^2}{P_{NO}^2 \times P_{O_2}} \times RT$$

Note that the far right side of the previous expression is Q_p multiplied by RT. Thus,

$$Q_c = Q_p(RT)$$

Also, at equilibrium, $K_c = K_p(RT)$; and, solving for K_p gives

$$K_p = \frac{K_c}{RT} = K_c(RT)^{-1}$$

Note especially that *the exponent of the RT term equals the change in the amount (mol) of gas* (Δn_{gas}) *from the balanced equation,* -1. Thus, in general, we have

$$K_p = K_c(RT)^{\Delta n_{gas}} \qquad \textbf{(17.8)}$$

Based on Equation 17.8, *if the amount (mol) of gas does not change in the reaction,* $\Delta n_{gas} = 0$, so the RT term drops out (i.e., equals 1), and $K_p = K_c$. (In calculations, be sure the units for R are consistent with units for pressure.)

SAMPLE PROBLEM 17.4 Converting Between K_c and K_p

Problem A chemical engineer injects limestone ($CaCO_3$) into the hot flue gas of a coal-burning power plant to form lime (CaO), which scrubs SO_2 from the gas and forms gypsum ($CaSO_4 \cdot 2H_2O$). Find K_c for the following reaction:

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g) \qquad K_p = 2.1\times10^{-4} \text{ (at 1000. K)}$$

Plan We know K_p (2.1×10^{-4}), so to convert between K_p and K_c, we must first determine Δn_{gas} from the balanced equation. Then we rearrange Equation 17.8. (If we assume that pressure is measured in atmospheres, $R = 0.0821$ atm·L/mol·K.)

Solution Determining Δn_{gas}: There is 1 mol of gaseous product and no gaseous reactant, so $\Delta n_{gas} = 1 - 0 = 1$. (Note that only moles of *gaseous* reactants and products are used to determine Δn_{gas}.)

Rearranging Equation 17.8 and calculating K_c:

$$K_p = K_c(RT)^1$$

so

$$K_c = K_p(RT)^{-1} = (2.1\times10^{-4})(0.0821 \times 1000.)^{-1}$$
$$= 2.6\times10^{-6}$$

Check Rounding gives

$$(2\times10^{-4})(0.1\times10^{3})^{-1} = (2\times10^{-4})(10^{-2})$$
$$= 2\times10^{-6}$$

FOLLOW-UP PROBLEMS

17.4A Calculate K_p for the following reaction:

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g) \qquad K_c = 1.67 \text{ (at 500. K)}$$

17.4B Calculate K_c for the following reaction:

$$CS_2(g) + 4H_2(g) \rightleftharpoons CH_4(g) + 2H_2S(g) \qquad K_p = 3.0\times10^{-5} \text{ (at 900.°C)}$$

SOME SIMILAR PROBLEMS 17.29–17.32

Summary of Section 17.3

- For a gaseous reaction, the reaction quotient and the equilibrium constant can be expressed in terms of partial pressures (Q_p and K_p).
- If you know K_p, you can find K_c, and vice versa: $K_p = K_c(RT)^{\Delta n_{gas}}$.

17.4 COMPARING *Q* AND *K* TO DETERMINE REACTION DIRECTION

Suppose you have a mixture of reactants and products and you know K at the temperature of the reaction. By comparing the value of Q with K, you can tell whether the reaction has reached equilibrium or, if not, in which direction it is progressing. The value of K remains constant at a particular temperature, but as we've seen, the value of Q varies as the concentrations of reactants and products change. Since Q has product terms in the numerator and reactant terms in the denominator, *more product makes Q larger, and more reactant makes Q smaller:*

$$Q = \frac{[\text{product}]}{[\text{reactant}]}$$

increase in [product] → larger Q

increase in [reactant] → smaller Q

There are three possibilities for the relative sizes of Q and K (Figure 17.5):

- $Q < K$. If Q is smaller than K, the denominator (reactants) is large relative to the numerator (products). For Q to equal K, the reactants must decrease and the products increase. The reaction is not at equilibrium and will progress to the right, toward products until $Q = K$:

If $Q < K$, reactants ⟶ products

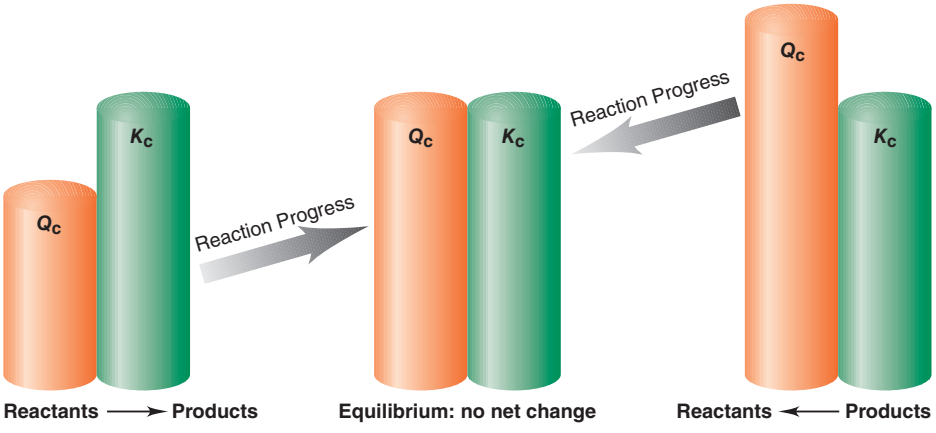

Figure 17.5 Reaction direction and the relative sizes of *Q* and *K*. When Q_c is smaller or larger than K_c, the reaction continues until $Q_c = K_c$. Note that K_c remains the same throughout.

- $Q > K$. If Q is larger than K, the numerator (products) will decrease and the denominator (reactants) will increase. The reaction is not at equilibrium and will progress to the left, toward reactants until $Q = K$:

$$\text{If } Q > K, \text{ reactants} \longleftarrow \text{products}$$

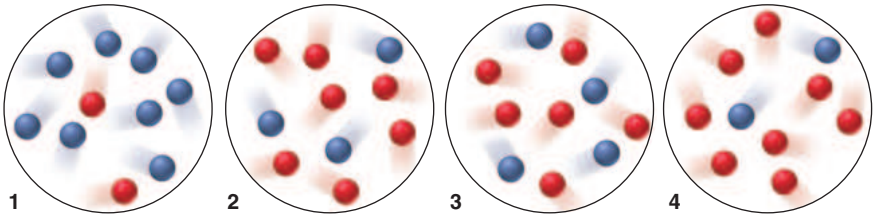
- $Q = K$. This situation occurs when the reactant and product terms equal their equilibrium values. The reaction is at equilibrium, and no further net change takes place:

$$\text{If } Q = K, \text{ reactants} \rightleftharpoons \text{products}$$

Sample Problem 17.5 relies on molecular scenes to determine reaction direction, and Sample Problem 17.6 relies on concentration data.

SAMPLE PROBLEM 17.5 Using Molecular Scenes to Determine Reaction Direction

Problem For the reaction $A(g) \rightleftharpoons B(g)$, the equilibrium mixture at 175°C is $[A] = 2.8\times10^{-4}\ M$ and $[B] = 1.2\times10^{-4}\ M$. The molecular scenes below represent four different mixtures of the reaction (A is *red;* B is *blue*). Does the reaction progress to the right or left or not at all for each mixture to reach equilibrium?



Plan We must compare Q_c with K_c to determine the reaction direction, so we first use the given equilibrium concentrations to find K_c. Then we count spheres and calculate Q_c for each mixture. If $Q_c < K_c$, the reaction progresses to the right (reactants to products); if $Q_c > K_c$, it progresses to the left (products to reactants); and if $Q_c = K_c$, there is no further net change.

Solution Writing the reaction quotient and using the data to find K_c:

$$Q_c = \frac{[B]}{[A]} = \frac{1.2\times10^{-4}}{2.8\times10^{-4}} = 0.43 = K_c$$

Counting red (A) and blue (B) spheres to calculate Q_c for each mixture:

1. $Q_c = 8/2 = 4.0$ 2. $Q_c = 3/7 = 0.43$ 3. $Q_c = 4/6 = 0.67$ 4. $Q_c = 2/8 = 0.25$

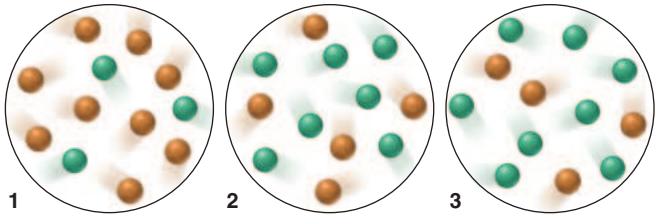
Comparing Q_c with K_c to determine reaction direction:

1. $Q_c > K_c$: left 2. $Q_c = K_c$: no net change 3. $Q_c > K_c$: left 4. $Q_c < K_c$: right

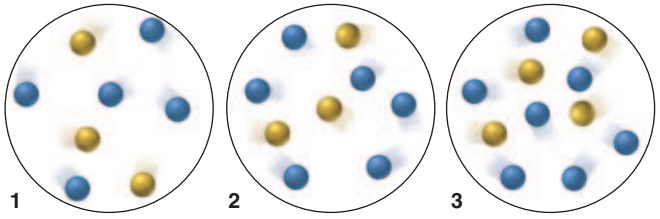
Check Making an error in the calculation for K_c would lead to incorrect conclusions throughout, so check that step: the exponents are the same, and 1.2/2.8 is a bit less than 0.5, as is the calculated K_c. You can check the final answers by inspection; for example, for the number of B (8) in mixture 1 to equal the number at equilibrium (3), more B must change to A, so the reaction must proceed to the left.

FOLLOW-UP PROBLEMS

17.5A At 338 K, the reaction $X(g) \rightleftharpoons Y(g)$ has a K_c of 1.4. The scenes below represent different mixtures at 338 K, with X *orange* and Y *green*. In which direction does the reaction proceed (if at all) for each mixture to reach equilibrium?



17.5B Scene 1 below represents the reaction $2C(g) \rightleftharpoons D(g)$ at equilibrium at 25°C (C is *yellow* and D is *blue*). Scenes 2 and 3 represent two different mixtures of C and D at 25°C. Calculate K_c for the reaction, and determine in which direction the reaction proceeds (if at all) for the mixtures in scenes 2 and 3.



A SIMILAR PROBLEM 17.34

SAMPLE PROBLEM 17.6 Using Concentrations to Determine Reaction Direction

Problem For the reaction $N_2O_4(g) \rightleftharpoons 2NO_2(g)$, $K_c = 0.21$ at 100°C. At a point during the reaction, $[N_2O_4] = 0.12\ M$ and $[NO_2] = 0.55\ M$. Is the reaction at equilibrium at that time? If not, in which direction is it progressing?

Plan We write Q_c, find its value by substituting the given concentrations, and compare its value with the given K_c.

Solution Writing the reaction quotient and solving for Q_c:

$$Q_c = \frac{[NO_2]^2}{[N_2O_4]} = \frac{0.55^2}{0.12} = 2.5$$

With $Q_c > K_c$, the reaction is not at equilibrium and will proceed to the left until $Q_c = K_c$.

Check With $[NO_2] > [N_2O_4]$, we expect to obtain a value for Q_c that is greater than 0.21. If $Q_c > K_c$, the numerator will decrease and the denominator will increase until $Q_c = K_c$; that is, this reaction will proceed toward reactants.

FOLLOW-UP PROBLEMS

17.6A Chloromethane forms by the reaction

$$CH_4(g) + Cl_2(g) \rightleftharpoons CH_3Cl(g) + HCl(g)$$

At 1500 K, $K_p = 1.6\times10^4$. In the reaction mixture, $P_{CH_4} = 0.13$ atm, $P_{Cl_2} = 0.035$ atm, $P_{CH_3Cl} = 0.24$ atm, and $P_{HCl} = 0.47$ atm. Is CH_3Cl or CH_4 forming?

17.6B Sulfur trioxide is produced by the reaction of sulfur dioxide with oxygen:

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g) \qquad K_c = 4.2\times10^{-2} \text{ (at 727°C)}$$

Suppose 3.4 mol of SO_2, 1.5 mol of O_2, and 1.2 mol of SO_3 are placed in a 2.0-L flask. Is the system at equilibrium? If not, in which direction will the reaction proceed?

SOME SIMILAR PROBLEMS 17.35–17.37

Summary of Section 17.4

- We compare the values of Q and K to determine the direction in which a reaction will proceed toward equilibrium.
  - If $Q_c < K_c$, more product forms.
  - If $Q_c > K_c$, more reactant forms.
  - If $Q_c = K_c$, there is no net change.

17.5 HOW TO SOLVE EQUILIBRIUM PROBLEMS

Many kinds of equilibrium problems arise in the real world—and on chemistry exams—but we can group most of them into two types:

1. We know the equilibrium quantities and solve for K.
2. We know K and the initial quantities and solve for the equilibrium quantities.

Using Quantities to Find the Equilibrium Constant

There are two common variations on this type of problem: one involves substituting quantities to solve for K, and the other requires first finding some of the quantities.

Substituting Equilibrium Quantities into *Q* to Find *K* In this type of problem, we use given equilibrium quantities to calculate K. Suppose, for example, that equal amounts of gaseous hydrogen and iodine are injected into a 1.50-L flask at a fixed temperature. In time, the following equilibrium is attained:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

At equilibrium, the flask contains 1.80 mol of H_2, 1.80 mol of I_2, and 0.520 mol of HI. We calculate K_c by finding the concentrations from the amounts and flask volume and substituting into the reaction quotient from the balanced equation:

$$Q_c = \frac{[HI]^2}{[H_2][I_2]}$$

We divide each amount (mol) by the volume (L) to find each concentration (mol/L):

$$[H_2] = \frac{1.80 \text{ mol}}{1.50 \text{ L}} = 1.20\ M$$

Similarly, $[I_2] = 1.20\ M$, and $[HI] = 0.347\ M$. Substituting these values into the expression for Q_c gives K_c:

$$K_c = \frac{(0.347)^2}{(1.20)(1.20)} = 8.36\times10^{-2}$$

Using a Reaction Table to Find Equilibrium Quantities and *K* When some quantities are not given, we determine them from the reaction stoichiometry and then find K. In the following example, note the use of the *reaction table.*

In a study of carbon oxidation, an evacuated vessel containing a small amount of powdered graphite is heated to 1080 K. Gaseous CO_2 is added to a pressure of 0.458 atm, and CO forms. At equilibrium, the total pressure is 0.757 atm. Calculate K_p.

As always, we start by writing the balanced equation and the reaction quotient:

$$CO_2(g) + C(\text{graphite}) \rightleftharpoons 2CO(g)$$

The data are given in atmospheres and we must find K_p, so we write the expression for Q_p; note that it does *not* include a term for the solid, C(graphite):

$$Q_p = \frac{P_{CO}^2}{P_{CO_2}}$$

We are given the initial P_{CO_2} and the P_{total} at equilibrium. To find K_p, we must find the equilibrium pressures of CO_2 and CO and then substitute them into Q_p.

Let's think through what happened in the vessel. An unknown portion of the CO_2 reacted with graphite to form an unknown amount of CO. We already know the *relative* amounts of CO_2 and CO from the balanced equation: for each mole of CO_2 that reacts, 2 mol of CO forms, which means that when x atm of CO_2 reacts, $2x$ atm of CO forms:

$$x \text{ atm } CO_2 \longrightarrow 2x \text{ atm CO}$$

The pressure of CO_2 at equilibrium, $P_{CO_2(eq)}$, is the initial pressure, $P_{CO_2(init)}$, *minus* x, the CO_2 that reacts (the change in P_{CO_2} due to the reaction):

$$P_{CO_2(init)} - x = P_{CO_2(eq)} = 0.458 - x$$

Similarly, the pressure of CO at equilibrium, $P_{CO(eq)}$, is the initial pressure, $P_{CO(init)}$, *plus* $2x$, the CO that forms (the change in P_{CO} due to the reaction). $P_{CO(init)}$ is zero, so

$$P_{CO(init)} + 2x = 0 + 2x = 2x = P_{CO(eq)}$$

We'll summarize this information in a reaction table, similar to those in Chapter 3, but the "Final" quantities are those at equilibrium. The table shows the balanced equation and

- the *initial* quantities (concentrations or pressures) of reactants and products
- the *changes* in these quantities during the reaction
- the *equilibrium* quantities

Pressure (atm)	$CO_2(g)$	+	C(graphite)	$\rightleftharpoons$	$2CO(g)$
Initial	0.458		—		0
Change	$-x$		—		$+2x$
Equilibrium	$0.458 - x$		—		$2x$

We treat each column like a list of numbers to add together: *the initial quantity plus the change in that quantity gives the equilibrium quantity*. Note that we *only* include substances whose concentrations change; thus, the column for C(graphite) is blank.

To solve for K_p, we substitute equilibrium values into Q_p, so we first have to find x. To do this, we use the other piece of data given, $P_{total(eq)}$. According to Dalton's law of partial pressures and using the equilibrium quantities from the reaction table,

$$P_{total(eq)} = 0.757 \text{ atm} = P_{CO_2(eq)} + P_{CO(eq)} = (0.458 \text{ atm} - x) + 2x$$

Thus, $0.757 \text{ atm} = 0.458 \text{ atm} + x$ and $x = 0.299 \text{ atm}$

With x known, we determine the equilibrium partial pressures:

$$P_{CO_2(eq)} = 0.458 \text{ atm} - x = 0.458 \text{ atm} - 0.299 \text{ atm} = 0.159 \text{ atm}$$
$$P_{CO(eq)} = 2x = 2(0.299 \text{ atm}) = 0.598 \text{ atm}$$

Then we substitute them into Q_p to find K_p:

$$Q_p = \frac{P^2_{CO(eq)}}{P_{CO_2(eq)}} = \frac{0.598^2}{0.159} = 2.25 = K_p$$

(From now on, the subscripts "init" and "eq" appear only when it is not clear whether a quantity is an initial or equilibrium value.)

SAMPLE PROBLEM 17.7 Calculating K_c from Concentration Data

Problem In order to study hydrogen halide decomposition, a researcher fills an evacuated 2.00-L flask with 0.200 mol of HI gas and allows the reaction to proceed at 453°C:

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

At equilibrium, [HI] = 0.078 *M*. Calculate K_c.

Plan To calculate K_c, we need the equilibrium concentrations. We can find the initial [HI] from the amount (0.200 mol) and the flask volume (2.00 L), and we are given [HI] at equilibrium (0.078 *M*). From the balanced equation, when $2x$ mol of HI reacts, x mol of H_2 and x mol of I_2 form. We set up a reaction table, use the known [HI] at equilibrium to solve for x (the change in $[H_2]$ or $[I_2]$), and substitute the concentrations into Q_c.

Solution Calculating initial [HI]:

$$[HI] = \frac{0.200 \text{ mol}}{2.00 \text{ L}} = 0.100 \, M$$

Setting up the reaction table, with $x = [H_2]$ or $[I_2]$ that forms and $2x = [HI]$ that reacts:

Concentration (*M*)	$2HI(g)$	$\rightleftharpoons$	$H_2(g)$	+	$I_2(g)$
Initial	0.100		0		0
Change	$-2x$		$+x$		$+x$
Equilibrium	$0.100 - 2x$		x		x

Solving for x, using the known [HI] at equilibrium:

$$[HI] = 0.100 \, M - 2x = 0.078 \, M \quad \text{so} \quad x = 0.011 \, M$$

Therefore, the equilibrium concentrations are

$$[H_2] = [I_2] = 0.011 \, M \quad \text{and we are given} \quad [HI] = 0.078 \, M$$

Substituting into the reaction quotient:

$$Q_c = \frac{[H_2][I_2]}{[HI]^2}$$

Thus,

$$K_c = \frac{(0.011)(0.011)}{0.078^2} = 0.020$$

Check Rounding gives $\sim 0.01^2/0.08^2 = 0.02$. Because the initial [HI] of 0.100 *M* fell slightly at equilibrium to 0.078 *M*, relatively little product formed; so we expect $K_c < 1$.

FOLLOW-UP PROBLEMS

17.7A The atmospheric oxidation of nitrogen monoxide, $2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g)$, was studied at 184°C with initial pressures of 1.000 atm of NO and 1.000 atm of O_2. At equilibrium, $P_{O_2} = 0.506$ atm. Calculate K_p.

17.7B To study the reaction between ammonia and oxygen,

$$4NH_3(g) + 7O_2(g) \rightleftharpoons 2N_2O_4(g) + 6H_2O(g)$$

a flask was filled with 2.40 *M* NH_3 and 2.40 *M* O_2 at a particular temperature; the reaction proceeded, and at equilibrium $[N_2O_4] = 0.134$ *M*. Calculate K_c.

SOME SIMILAR PROBLEMS 17.51, 17.52, 17.54, and 17.55

Using the Equilibrium Constant to Find Quantities

The type of problem that involves finding equilibrium quantities also has several variations. Sample Problem 17.8 is one variation, in which we know *K* and some of the equilibrium concentrations and must find another equilibrium concentration.

SAMPLE PROBLEM 17.8 Determining Equilibrium Concentrations from K_c

Problem In a study of the conversion of methane to other fuels, a chemical engineer mixes gaseous CH_4 and H_2O in a 0.32-L flask at 1200 K. At equilibrium, the flask contains 0.028 mol of CO, 0.084 mol of H_2, and 0.045 mol of CH_4. What is $[H_2O]$ at equilibrium ($K_c = 0.26$ for this process at 1200 K)?

Plan First, we write the balanced equation and the reaction quotient. We calculate the equilibrium concentrations from the given numbers of moles and the flask volume (0.32 L). Substituting these into Q_c and setting it equal to the given K_c (0.26), we solve for the unknown equilibrium concentration, $[H_2O]$.

Solution Writing the balanced equation and reaction quotient:

$$CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g) \qquad Q_c = \frac{[CO][H_2]^3}{[CH_4][H_2O]}$$

Determining the equilibrium concentrations:

$$[CH_4] = \frac{0.045 \text{ mol}}{0.32 \text{ L}} = 0.14\ M$$

Similarly, $[CO] = 0.088$ *M* and $[H_2] = 0.26$ *M*.

Calculating $[H_2O]$ at equilibrium: Since $Q_c = K_c$, rearranging gives

$$[H_2O] = \frac{[CO][H_2]^3}{[CH_4]K_c} = \frac{(0.088)(0.26)^3}{(0.14)(0.26)} = 0.042\ M$$

Check Always check by substituting the concentrations into Q_c to confirm that the result is equal to K_c:

$$Q_c = \frac{[CO][H_2]^3}{[CH_4][H_2O]} = \frac{(0.088)(0.26)^3}{(0.14)(0.042)} = 0.26 = K_c$$

FOLLOW-UP PROBLEMS

17.8A Nitrogen monoxide decomposes by the following equation: $2NO(g) \rightleftharpoons N_2(g) + O_2(g)$; $K_c = 2.3 \times 10^{30}$ at 298 K. In the atmosphere, $P_{O_2} = 0.209$ atm and $P_{N_2} = 0.781$ atm. What is the equilibrium partial pressure of NO in the air we breathe? (*Hint:* You need K_p to find the partial pressure.)

17.8B Phosphine decomposes by the following equation:

$$2PH_3(g) \rightleftharpoons P_2(g) + 3H_2(g) \qquad K_p = 19.6 \text{ (at 750. K)}$$

In a reaction mixture at equilibrium, $P_{PH_3} = 0.112$ atm and $P_{P_2} = 0.215$ atm. What is the equilibrium partial pressure of H_2?

SOME SIMILAR PROBLEMS 17.45 and 17.46

In a somewhat more involved variation, we know K and *initial* quantities and must find *equilibrium* quantities, for which we use a reaction table. Sample Problem 17.9 focuses on this approach.

SAMPLE PROBLEM 17.9 Determining Equilibrium Concentrations from Initial Concentrations and K_c

Problem Fuel engineers use the extent of the change from CO and H_2O to CO_2 and H_2 to regulate the proportions of synthetic fuel mixtures. If 0.250 mol of CO gas and 0.250 mol of H_2O gas are placed in a 125-mL flask at 900 K, what is the composition of the equilibrium mixture? At this temperature, K_c is 1.56.

Plan We have to find the "composition" of the equilibrium mixture, in other words, the equilibrium concentrations. As always, we write the balanced equation and use it to write the reaction quotient. We find the initial [CO] and [H_2O] from the amounts (0.250 mol of each) and volume (0.125 L), use the balanced equation to define x and set up a reaction table, substitute into Q_c, and solve for x, from which we calculate the concentrations.

Solution Writing the balanced equation and reaction quotient:

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g) \qquad Q_c = \frac{[CO_2][H_2]}{[CO][H_2O]}$$

Calculating initial reactant concentrations:

$$[CO] = [H_2O] = \frac{0.250 \text{ mol}}{0.125 \text{ L}} = 2.00\ M$$

Setting up the reaction table, with x = [CO] and [H_2O] that react:

Concentration (M)	$CO(g)$	+	$H_2O(g)$	$\rightleftharpoons$	$CO_2(g)$	+	$H_2(g)$
Initial	2.00		2.00		0		0
Change	$-x$		$-x$		$+x$		$+x$
Equilibrium	$2.00 - x$		$2.00 - x$		x		x

Substituting into the reaction quotient and solving for x:

$$Q_c = \frac{[CO_2][H_2]}{[CO][H_2O]} = \frac{(x)(x)}{(2.00 - x)(2.00 - x)} = \frac{x^2}{(2.00 - x)^2}$$

At equilibrium, we have

$$Q_c = K_c = 1.56 = \frac{x^2}{(2.00 - x)^2}$$

We can apply the following math shortcut in this case *but not in general:* Because the right side of the equation is a perfect square, we take the square root of both sides:

$$\sqrt{1.56} = \frac{x}{2.00 - x} = \pm 1.25$$

A positive number (1.56) has a positive *and* a negative root, but in this case, only the positive root has any chemical meaning, so we ignore the negative root:*

$$1.25 = \frac{x}{2.00 - x} \qquad \text{or} \qquad 2.50 - 1.25x = x$$

So $2.50 = 2.25x$ therefore $x = 1.11\ M$

Calculating equilibrium concentrations:

$$[CO] = [H_2O] = 2.00\ M - x = 2.00\ M - 1.11\ M = \boxed{0.89\ M}$$
$$[CO_2] = [H_2] = x = \boxed{1.11\ M}$$

*The negative root gives $-1.25 = \frac{x}{2.00 - x}$, or $-2.50 + 1.25x = x$.

So $2.50 = 0.25x$ and $x = 10.\ M$

This value has no chemical meaning because we started with 2.00 M as the concentration of each reactant, so it is impossible for x to be 10. M. Moreover, the square root of an equilibrium constant is another equilibrium constant, which cannot have a negative value.

Check Given the intermediate size of K_c (1.56), it makes sense that the changes in concentration are moderate. It's a good idea to check that the sign of x in the reaction table is correct—only reactants were initially present, so x has a negative sign for reactants and a positive sign for products. Also check that the equilibrium concentrations give the known K_c: $\frac{(1.11)(1.11)}{(0.89)(0.89)} = 1.56$.

FOLLOW-UP PROBLEMS

17.9A The decomposition of HI at low temperature was studied by injecting 2.50 mol of HI into a 10.32-L vessel at 25°C. What is $[H_2]$ at equilibrium for the reaction $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$; $K_c = 1.26\times10^{-3}$?

17.9B The following reaction has a K_c value of 0.18 at 500. K:

$$Cl_2O(g) + H_2O(g) \rightleftharpoons 2HOCl(g)$$

If 6.15 mol of Cl_2O gas and 6.15 mol of H_2O gas are added to a 5.00-L flask at 500. K, calculate the equilibrium concentrations of Cl_2O, H_2O, and HOCl.

SOME SIMILAR PROBLEMS 17.47, 17.53, and 17.56

Using the Quadratic Formula to Find the Unknown The shortcut we used to simplify the math in Sample Problem 17.9 is a special case that occurred because we started with equal concentrations of the reactants, but typically, we start with different concentrations of reactants. Suppose, for example, we start with 2.00 *M* CO and 1.00 *M* H_2O. Now, the reaction table becomes

Concentration (*M*)	CO(*g*)	+	$H_2O(g)$	$\rightleftharpoons$	$CO_2(g)$	+	$H_2(g)$
Initial	2.00		1.00		0		0
Change	$-x$		$-x$		$+x$		$+x$
Equilibrium	$2.00 - x$		$1.00 - x$		x		x

Substituting these values into Q_c, we obtain

$$Q_c = \frac{[CO_2][H_2]}{[CO][H_2O]} = \frac{(x)(x)}{(2.00 - x)(1.00 - x)} = \frac{x^2}{x^2 - 3.00x + 2.00}$$

At equilibrium, using the value of K_c from Sample Problem 17.9, we have

$$1.56 = \frac{x^2}{x^2 - 3.00x + 2.00}$$

To solve for x in this case, we rearrange the previous expression into the form of a *quadratic equation:*

$$a\,x^2 + b\,x + c = 0$$
$$0.56x^2 - 4.68x + 3.12 = 0$$

where $a = 0.56$, $b = -4.68$, and $c = 3.12$. Then we find x with the quadratic formula (Appendix A):

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

The $\pm$ sign means that we obtain two possible values for x:

$$x = \frac{4.68 \pm \sqrt{(-4.68)^2 - 4(0.56)(3.12)}}{2(0.56)}$$
$$x = 7.6\ M \quad \text{and} \quad x = 0.73\ M$$

But only one of the values makes sense chemically. In this case, the positive root gives the larger value and negative concentrations at equilibrium (for example, $2.00\ M - 7.6\ M = -5.6\ M$), which have no meaning. Therefore, $x = 0.73\ M$, and we have

$$[CO] = 2.00\ M - x = 2.00\ M - 0.73\ M = 1.27\ M$$
$$[H_2O] = 1.00\ M - x = 0.27\ M$$
$$[CO_2] = [H_2] = x = 0.73\ M$$

Checking to see if these values give the known K_c, we have

$$K_c = \frac{(0.73)(0.73)}{(1.27)(0.27)} = 1.6 \text{ (within rounding of 1.56)}$$

A Simplifying Assumption for Finding the Unknown In many cases, we can use chemical "common sense" to make an assumption that simplifies the math by avoiding the need to use the quadratic formula to find x. In general, *if a reaction has a relatively small K and a relatively large initial reactant concentration, the concentration change (x) can often be neglected.* This assumption does not mean that $x = 0$, because then there would be no reaction. It means that if a reaction starts with a high $[\text{reactant}]_{\text{init}}$ and proceeds very little to reach equilibrium (small K), the reactant concentration at equilibrium, $[\text{reactant}]_{\text{eq}}$, will be nearly the same as $[\text{reactant}]_{\text{init}}$.

Here's an everyday analogy for this assumption. On a bathroom scale, you weigh 158 lb. Take off your wristwatch, and you still weigh 158 lb. Within the accuracy of the scale, the weight of the watch is so small compared with your body weight that it can be neglected:

Initial body weight − weight of watch = final body weight ≈ initial body weight

Thus, let's say the initial concentration of A is 0.500 M and, because of a small K_c, the concentration of A that reacts is 0.002 M. We can then assume that

$$0.500\ M - 0.002\ M = 0.498\ M \approx 0.500\ M$$

that is,

$$[\text{A}]_{\text{init}} - [\text{A}]_{\text{reacting}} = [\text{A}]_{\text{eq}} \approx [\text{A}]_{\text{init}} \qquad \textbf{(17.9)}$$

To justify the assumption that x is negligible, we make sure the error introduced is not significant. One common criterion for "significant" is the 5% rule: *if the assumption results in a change that is less than 5% of the initial concentration, the error is not significant, and the assumption is justified.* Let's see how making this assumption simplifies the math and if it is justified in the cases of two different $[\text{reactant}]_{\text{init}}$ values.

SAMPLE PROBLEM 17.10 Making a Simplifying Assumption to Calculate Equilibrium Concentrations

Problem Phosgene is a potent chemical warfare agent that is now outlawed by international agreement. It decomposes by the reaction

$$COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g) \qquad K_c = 8.3\times10^{-4} \text{ (at 360°C)}$$

Calculate [CO], $[Cl_2]$, and $[COCl_2]$ when each of the following amounts of phosgene decomposes and reaches equilibrium in a 10.0-L flask:
(a) 5.00 mol of $COCl_2$ **(b)** 0.100 mol of $COCl_2$

Plan We know from the balanced equation that when x mol of $COCl_2$ decomposes, x mol of CO and x mol of Cl_2 form. We use the volume (10.0 L) to convert amount (5.00 mol or 0.100 mol) to molar concentration, define x and set up the reaction table, and substitute the values into Q_c. Before using the quadratic formula, we assume that x is negligibly small. After solving for x, we check the assumption and find the equilibrium concentrations. If the assumption is not justified, we use the quadratic formula to find x.

Solution **(a)** For 5.00 mol of $COCl_2$. Writing the reaction quotient:

$$Q_c = \frac{[\text{CO}][\text{Cl}_2]}{[\text{COCl}_2]}$$

Calculating the initial reactant concentration, $[COCl_2]_{\text{init}}$:

$$[\text{COCl}_2]_{\text{init}} = \frac{5.00 \text{ mol}}{10.0 \text{ L}} = 0.500\ M$$

Setting up the reaction table, with x equal to $[COCl_2]_{reacting}$:

Concentration (M)	$COCl_2(g)$	$\rightleftharpoons$	$CO(g)$	+	$Cl_2(g)$
Initial	0.500		0		0
Change	$-x$		$+x$		$+x$
Equilibrium	$0.500 - x$		x		x

If we use the equilibrium values in Q_c with the given K_c, we obtain

$$Q_c = \frac{[CO][Cl_2]}{[COCl_2]} = \frac{x^2}{0.500 - x} = K_c = 8.3\times10^{-4}$$

Because K_c is small, the reaction does not proceed very far to the right, so let's assume that x ($[COCl_2]_{reacting}$) can be neglected. In other words, we assume that the equilibrium concentration is nearly the same as the initial concentration, 0.500 M:

$$[COCl_2]_{init} - [COCl_2]_{reacting} = [COCl_2]_{eq}$$
$$0.500\ M - x \approx 0.500\ M$$

Using this assumption, we substitute and solve for x:

$$K_c = 8.3\times10^{-4} \approx \frac{x^2}{0.500}$$
$$x^2 \approx (8.3\times10^{-4})(0.500) \quad \text{so} \quad x \approx 2.0\times10^{-2}$$

Checking the assumption by seeing if the error is <5%:

$$\frac{[\text{Change}]}{[\text{Initial}]} \times 100 = \frac{2.0\times10^{-2}}{0.500} \times 100 = 4\% \quad (<5\%, \text{ so the assumption is justified})$$

Solving for the equilibrium concentrations:

$$[CO] = [Cl_2] = x = \boxed{2.0\times10^{-2}\ M}$$
$$[COCl_2] = 0.500\ M - x = \boxed{0.480\ M}$$

(b) For 0.100 mol of $COCl_2$. The calculation in this case is the same as the calculation in part (a), except that $[COCl_2]_{init}$ = 0.100 mol/10.0 L = 0.0100 M. Thus, at equilibrium,

$$Q_c = \frac{[CO][Cl_2]}{[COCl_2]} = \frac{x^2}{0.0100 - x} = K_c = 8.3\times10^{-4}$$

Making the assumption that $0.0100\ M - x \approx 0.0100\ M$ and solving for x:

$$K_c = 8.3\times10^{-4} \approx \frac{x^2}{0.0100} \qquad x \approx 2.9\times10^{-3}$$

Checking the assumption:

$$\frac{2.9\times10^{-3}}{0.0100} \times 100 = 29\% \quad (>5\%, \text{ so the assumption is } \textit{not} \text{ justified})$$

Rearranging Q_c and its value at equilibrium into the form of a quadratic equation gives

$$8.3\times10^{-4} = \frac{x^2}{0.0100 - x} \quad \text{or} \quad x^2 = 8.3\times10^{-6} - 8.3\times10^{-4}x$$

and so

$$x^2 + 8.3\times10^{-4}x - 8.3\times10^{-6} = 0$$

Solving this equation with the quadratic formula shows that

$$x = \frac{-8.3\times10^{-4} \pm \sqrt{(8.3\times10^{-4})^2 - 4(1)(-8.3\times10^{-6})}}{2(1)}$$

The only meaningful value of x is 2.5×10^{-3}.
Solving for the equilibrium concentrations:

$$[CO] = [Cl_2] = \boxed{2.5\times10^{-3}\ M}$$
$$[COCl_2] = 1.00\times10^{-2}\ M - x = \boxed{7.5\times10^{-3}\ M}$$

Check Once again, use the calculated values to be sure you obtain the given K_c.

Comment The main point is that the simplifying assumption was justified at the high $[COCl_2]_{init}$ but *not* at the low $[COCl_2]_{init}$.

FOLLOW-UP PROBLEMS

17.10A In a study of the effect of temperature on halogen decomposition, 0.50 mol of I_2 was heated in a 2.5-L vessel, and the following reaction occurred: $I_2(g) \rightleftharpoons 2I(g)$.
(a) Calculate $[I_2]$ and [I] at equilibrium at 600 K; $K_c = 2.94\times10^{-10}$.
(b) Calculate $[I_2]$ and [I] at equilibrium at 2000 K; $K_c = 0.209$.

17.10B Phosphorus pentachloride decomposes as follows:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g) \qquad K_p = 3.4\times10^{-4} \text{ (at 400. K)}$$

Calculate the equilibrium partial pressure of PCl_5 if the reaction begins with:
(a) a PCl_5 partial pressure of 0.18 atm; **(b)** a PCl_5 partial pressure of 0.025 atm.

SOME SIMILAR PROBLEMS 17.47–17.50

Predicting When the Assumption Will Be Justified To summarize, we assume that x ($[A]_{reacting}$) can be neglected if K_c is relatively small and/or $[A]_{init}$ is relatively large. The same holds for K_p and $P_{A(init)}$. But *how* small or large must these variables be? Here's a benchmark for deciding when to make the assumption:

- If $\dfrac{[A]_{init}}{K_c} > 400$, the assumption is justified: neglecting x introduces an error <5%.
- If $\dfrac{[A]_{init}}{K_c} < 400$, the assumption is *not* justified; neglecting x introduces an error >5%, so we solve a quadratic equation to find x.

For example, using the values from Sample Problem 17.10, we have

Part (a): For $[A]_{init} = 0.500\ M$, $\dfrac{0.500}{8.3\times10^{-4}} = 6.0\times10^2$, which is greater than 400.

Part (b): For $[A]_{init} = 0.0100\ M$, $\dfrac{0.0100}{8.3\times10^{-4}} = 12$, which is less than 400.

We will make a similar assumption in many problems in Chapters 18 and 19.

Problems Involving Mixtures of Reactants and Products

In the problems so far, the reaction *had* to go toward products because it started with only reactants. And therefore, in the reaction tables, we knew that the unknown change in reactant concentration had a negative sign ($-x$) and the change in product concentration had a positive sign ($+x$). If, however, we start with a *mixture* of reactants and products, the reaction direction is not obvious. In those cases, we apply the idea from Section 17.4 and first *compare the values of Q and K to find the direction the reaction is proceeding to reach equilibrium*. (To focus on this idea, Sample Problem 17.11 uses concentrations that avoid the need for the quadratic formula.)

SAMPLE PROBLEM 17.11 Predicting Reaction Direction and Calculating Equilibrium Concentrations

Problem The research and development unit of a chemical company is studying the reaction of CH_4 and H_2S, two components of natural gas:

$$CH_4(g) + 2H_2S(g) \rightleftharpoons CS_2(g) + 4H_2(g)$$

In one experiment, 1.00 mol of CH_4, 1.00 mol of CS_2, 2.00 mol of H_2S, and 2.00 mol of H_2 are mixed in a 250.-mL vessel at 960°C. At this temperature, $K_c = 0.036$.
(a) In which direction will the reaction proceed to reach equilibrium?
(b) If $[CH_4] = 5.56\ M$ at equilibrium, what are the equilibrium concentrations of the other substances?

Plan **(a)** To find the direction, we convert the given initial amounts and volume (0.250 L) to concentrations, calculate Q_c, and compare it with K_c. **(b)** Based on this information, we determine the sign of each concentration change for the reaction table and then use the known $[CH_4]$ at equilibrium (5.56 *M*) to determine x and the other equilibrium concentrations.

Solution **(a)** Calculating the initial concentrations:

$$[CH_4] = \frac{1.00 \text{ mol}}{0.250 \text{ L}} = 4.00\ M$$

Similarly, $[H_2S] = 8.00\ M$, $[CS_2] = 4.00\ M$, and $[H_2] = 8.00\ M$.
Calculating the value of Q_c:

$$Q_c = \frac{[CS_2][H_2]^4}{[CH_4][H_2S]^2} = \frac{(4.00)(8.00)^4}{(4.00)(8.00)^2} = 64.0$$

Comparing Q_c and K_c: $Q_c > K_c$ $(64.0 > 0.036)$, so the reaction proceeds to the left. Therefore, concentrations of reactants increase and those of products decrease.
(b) Setting up a reaction table, with $x = [CS_2]$ that reacts, which equals $[CH_4]$ that forms:

Concentration (*M*)	$CH_4(g)$	+	$2H_2S(g)$	$\rightleftharpoons$	$CS_2(g)$	+	$4H_2(g)$
Initial	4.00		8.00		4.00		8.00
Change	$+x$		$+2x$		$-x$		$-4x$
Equilibrium	$4.00 + x$		$8.00 + 2x$		$4.00 - x$		$8.00 - 4x$

Solving for x: At equilibrium,

$$[CH_4] = 5.56\ M = 4.00\ M + x \qquad \text{so} \qquad x = 1.56\ M$$

Thus,

$$[H_2S] = 8.00\ M + 2x = 8.00\ M + 2(1.56\ M) = 11.12\ M$$

$$[CS_2] = 4.00\ M - x = 2.44\ M$$

$$[H_2] = 8.00\ M - 4x = 1.76\ M$$

Check The comparison of Q_c and K_c showed the reaction proceeding to the left. The given data from part (b) confirm this because $[CH_4]$ increases from 4.00 *M* to 5.56 *M* during the reaction. As always, you should check that the concentrations give the known K_c:

$$\frac{(2.44)(1.76)^4}{(5.56)(11.12)^2} = 0.0341, \text{ which is close to } 0.036$$

FOLLOW-UP PROBLEMS

17.11A An inorganic chemist studying the reactions of phosphorus halides mixes 0.1050 mol of PCl_5 with 0.0450 mol of Cl_2 and 0.0450 mol of PCl_3 in a 0.5000-L flask at 250°C:

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g) \qquad K_c = 4.2\times10^{-2}$$

(a) In which direction will the reaction proceed?
(b) If $[PCl_5] = 0.2065\ M$ at equilibrium, what are the equilibrium concentrations of the other components?

17.11B A chemist studying the production of nitrogen monoxide (NO) in the atmosphere adds 0.500 atm of N_2, 0.500 atm of O_2, and 0.750 atm of NO to a sealed container at 2500°C:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) \qquad K_p = 8.44\times10^{-3}$$

Determine the direction in which the reaction proceeds, and calculate the equilibrium pressures of all three gases.

SOME SIMILAR PROBLEMS 17.94 and 17.102

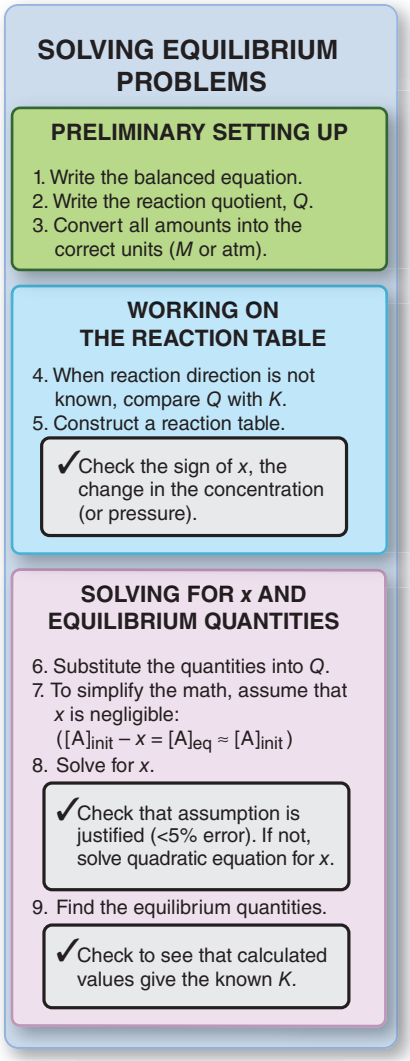


Figure 17.6 Steps in solving equilibrium problems.

Le Châtelier's principle applies to many systems.

Figure 17.6 groups the steps for solving equilibrium problems in which you know K and some initial quantities and must find the equilibrium quantities.

Summary of Section 17.5

- In equilibrium problems, we typically use quantities (concentrations or pressures) of reactants and products to find K, or we use K to find quantities.
- Reaction tables summarize the initial quantities, their changes during the reaction, and the equilibrium quantities.
- To simplify calculations, we assume that if K is small and the initial quantity of reactant is large, the unknown change in reactant (x) can be neglected. If this assumption is not justified (that is, if the error is greater than 5%), we use the quadratic formula to find x.
- For reactions that start with a mixture of reactants and products, we first determine reaction direction by comparing Q and K to decide on the sign of x.

17.6 REACTION CONDITIONS AND EQUILIBRIUM: LE CHÂTELIER'S PRINCIPLE

Change conditions so that a system is no longer at equilibrium and it has the remarkable ability to adjust itself and reattain equilibrium. This phenomenon is described by **Le Châtelier's principle:** when a chemical system at equilibrium is disturbed, it reattains equilibrium by undergoing a net reaction that reduces the effect of the disturbance.

Two phrases in this statement need further explanation:

1. How is a system "disturbed"? At equilibrium, Q equals K. The system is disturbed when a change in conditions forces it temporarily out of equilibrium ($Q \neq K$). Three common disturbances are a change in concentration, a change in pressure (caused by a change in volume), or a change in temperature. We'll discuss each below.

2. What does a "net reaction" mean? This phrase refers to a shift in the *equilibrium position* to the right or left. The *equilibrium position* is defined by the specific equilibrium concentrations (or pressures). A shift to the right is a net reaction that converts reactant to product until equilibrium is reattained; a shift to the left is a net reaction that converts product to reactant. Thus, *concentrations (or pressures) change in a way that reduces the effect of the change in conditions, and the system attains a new equilibrium position.*

For the remainder of this section, we'll examine a system at equilibrium to see how it responds to changes in concentration, pressure (volume), or temperature; then, we'll see what happens when we add a catalyst. As our example, we use the gaseous reaction between phosphorus trichloride and chlorine to produce phosphorus pentachloride:

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$$

Le Châtelier's principle holds for many systems at equilibrium in both the natural and social sciences—the effects of disease or drought on populations of predators and prey on the African savannah *(see margin),* a change in the cost of petroleum based on a balance of supply and demand, and even the formation of certain elements in the core of a star.

The Effect of a Change in Concentration

When a system at equilibrium is disturbed by a change in concentration of one of the components, it reacts in the direction that reduces the change:

- If the concentration of A increases, the system reacts to consume some of it.
- If the concentration of A decreases, the system reacts to produce some of it.

Only components that appear in Q can have an effect, so changes in the amounts of pure liquids and solids cannot.

A Qualitative View of a Concentration Change At 523 K, the PCl_3-Cl_2-PCl_5 system reaches equilibrium when

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g) \qquad Q_c = \frac{[PCl_5]}{[PCl_3][Cl_2]} = 24.0 = K_c$$

Starting with Q_c equal to K_c, let's think through some changes in concentration:

1. *Adding a reactant.* What happens if we disturb the system by adding some Cl_2 gas? To reduce the disturbance, the system will consume some of the added Cl_2 by shifting toward product. With regard to the reaction quotient, when the $[Cl_2]$ term increases, the value of Q_c decreases; thus, $Q_c \neq K_c$. As some of the added Cl_2 reacts with some of the PCl_3 to form more PCl_5, the denominator becomes smaller again and the numerator larger, until eventually $Q_c = K_c$ again. Notice the changes in the new equilibrium concentrations: $[Cl_2]$ and $[PCl_5]$ are higher than in the original equilibrium position, and $[PCl_3]$ is lower. Nevertheless, the ratio of values gives the same K_c. Thus, *the equilibrium position shifts to the right when a component on the left is added:*

$$PCl_3 + Cl_2(\text{added}) \longrightarrow PCl_5$$

2. *Removing a reactant.* What happens if we disturb the system by removing some PCl_3? To reduce this disturbance, the system will replace the PCl_3 by consuming some PCl_5 and proceeding toward reactants. With regard to Q_c, when the $[PCl_3]$ term decreases, Q_c increases, so $Q_c \neq K_c$. As some PCl_5 decomposes to PCl_3 and Cl_2, the numerator decreases and the denominator increases until $Q_c = K_c$ again. Once again, the new and old equilibrium concentrations are different, but the value of K_c is not. Thus, *the equilibrium position shifts to the left when a component on the left is removed:*

$$PCl_3(\text{removed}) + Cl_2 \longleftarrow PCl_5$$

3. *Adding or removing a product.* The same points we just made for a reactant hold for a product. If we add PCl_5, the equilibrium position shifts to the left to consume PCl_5; if we remove some PCl_5, the equilibrium position shifts to the right to produce PCl_5.

In other words, no matter how the disturbance in concentration comes about, *the system reacts to consume some of the added substance or produce some of the removed substance* to make $Q_c = K_c$ again (Figure 17.7):

- The equilibrium position shifts to the *right* if a reactant is added or a product is removed: [reactant] increases or [product] decreases.
- The equilibrium position shifts to the *left* if a reactant is removed or a product is added: [reactant] decreases or [product] increases.

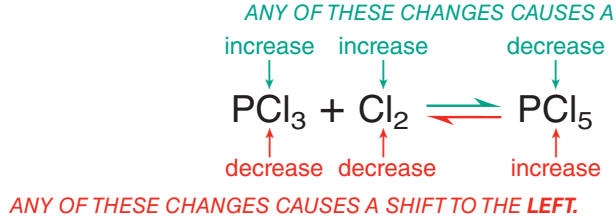

Figure 17.7 The effect of a change in concentration on a system at equilibrium.

A Quantitative View of a Concentration Change As you saw, the system "reduces the effect of the disturbance." But the effect is not completely eliminated, as we can see from a quantitative comparison of original and new equilibrium positions.

Consider what happens when we add Cl_2 to a system whose original equilibrium position was established with $[PCl_3] = 0.200\,M$, $[Cl_2] = 0.125\,M$, and $[PCl_5] = 0.600\,M$. That is,

$$Q_c = \frac{[PCl_5]}{[PCl_3][Cl_2]} = \frac{0.600}{(0.200)(0.125)} = 24.0 = K_c$$

Table 17.3 The Effect of Added Cl_2 on the PCl_3-Cl_2-PCl_5 System

Concentration (*M*)	$PCl_3(g)$	+	$Cl_2(g)$	⇌	$PCl_5(g)$
Original equilibrium	0.200		0.125		0.600
Disturbance			+0.075		
New initial	0.200		0.200		0.600
Change	$-x$		$-x$		$+x$
New equilibrium	$0.200 - x$		$0.200 - x$		$0.600 + x$ (0.637)*

*Experimentally determined value.

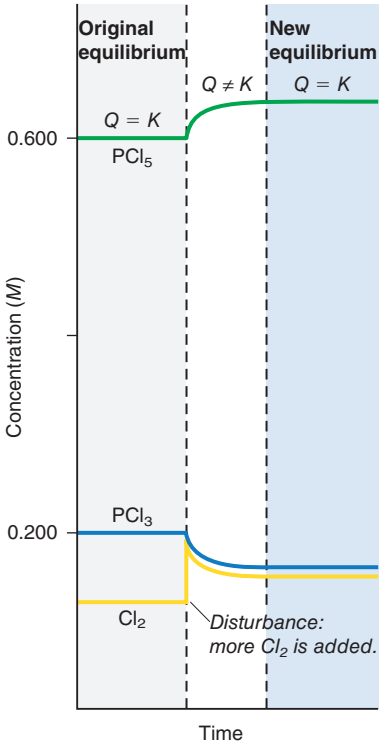

Figure 17.8 The effect of added Cl_2 on the PCl_3-Cl_2-PCl_5 system. The original equilibrium concentrations are shown at left *(gray region)*. When Cl_2 *(yellow curve)* is added, its concentration increases instantly *(vertical part of yellow curve)* and then falls gradually as it reacts with PCl_3 to form more PCl_5. Soon, equilibrium is re-established at new concentrations *(blue region)* but with the same *K*.

Now we add enough Cl_2 to increase its concentration by 0.075 *M* to a new $[Cl_2]_{init}$ of 0.200 *M*. The reaction proceeds, and the system comes to a new equilibrium position. From Le Châtelier's principle, we predict that adding more reactant will shift the equilibrium position to the right. Experimental measurement shows that the new $[PCl_5]_{eq}$ is 0.637 *M*.

Table 17.3 shows a reaction table of the entire process: the original equilibrium position, the disturbance, the (new) initial concentrations, the direction of *x* (the change needed to reattain equilibrium), and the new equilibrium position. Figure 17.8 depicts the process.

Let's determine the new equilibrium concentrations. From Table 17.3,

$$[PCl_5] = 0.600\ M + x = 0.637\ M \qquad \text{so} \qquad x = 0.037\ M$$

Thus, $$[PCl_3] = [Cl_2] = 0.200\ M - x = 0.200\ M - 0.037\ M = 0.163\ M$$

Therefore, at equilibrium,

$$K_{c(original)} = \frac{0.600}{(0.200)(0.125)} = 24.0$$

$$K_{c(new)} = \frac{0.637}{(0.163)(0.163)} = 24.0$$

There are several key points to notice about the new equilibrium concentrations:

- As we predicted, $[PCl_5]$ (0.637 *M*) is higher than the original concentration (0.600 *M*).
- $[Cl_2]$ (0.163 *M*) is higher than the *original* equilibrium concentration (0.125 *M*), but lower than the new initial concentration (0.200 *M*); thus, the disturbance is *reduced but not eliminated.*
- $[PCl_3]$ (0.163 *M*), the other reactant, is lower than the original equilibrium concentration (0.200 *M*) because some reacted with the added Cl_2.
- Most importantly, although the position of equilibrium shifted to the right, *at a given temperature, K_c does **not** change with a change in concentration.*

SAMPLE PROBLEM 17.12 Predicting the Effect of a Change in Concentration on the Equilibrium Position

Problem To improve air quality and obtain a useful product, chemists often remove sulfur from coal and natural gas by treating the contaminant hydrogen sulfide with O_2:

$$2H_2S(g) + O_2(g) \rightleftharpoons 2S(s) + 2H_2O(g)$$

What happens to

(a) $[H_2O]$ if O_2 is added? **(b)** $[H_2S]$ if O_2 is added?

(c) $[O_2]$ if H_2S is removed? **(d)** $[H_2S]$ if sulfur is added?

Plan We write the reaction quotient to see how Q_c is affected by each disturbance, relative to K_c. This effect tells us the direction in which the reaction proceeds for the system to reattain equilibrium and how each concentration changes.

Solution Writing the reaction quotient: $Q_c = \dfrac{[H_2O]^2}{[H_2S]^2[O_2]}$

(a) When O_2 is added, the denominator of Q_c increases, so $Q_c < K_c$. The reaction proceeds to the right until $Q_c = K_c$ again, so $[H_2O]$ increases.

(b) As in part (a), when O_2 is added, $Q_c < K_c$. Some H_2S reacts with the added O_2 as the reaction proceeds to the right, so $[H_2S]$ decreases.
(c) When H_2S is removed, the denominator of Q_c decreases, so $Q_c > K_c$. As the reaction proceeds to the left to re-form H_2S, more O_2 forms as well, so $[O_2]$ increases.
(d) The *concentration* of solid S does not change, so it does not appear in the reaction quotient. As long as some S is present, adding more S has no effect, so $[H_2S]$ is unchanged (but see Comment 2 below).

Check Apply Le Châtelier's principle to see that the reaction proceeds in the direction that lowers the increased concentration or raises the decreased concentration.

Comment **1.** As you know, sulfur exists most commonly as S_8. How would this change in formula affect the answers? The balanced equation and Q_c would be

$$8H_2S(g) + 4O_2(g) \rightleftharpoons S_8(s) + 8H_2O(g) \qquad Q_c = \frac{[H_2O]^8}{[H_2S]^8[O_2]^4}$$

The value of K_c is different for this equation, but the changes described in the problem have the same effects. Thus, shifts in equilibrium position predicted by Le Châtelier's principle are not affected by a change in the balancing coefficients.
2. In (d), you saw that adding a solid has no effect on the concentrations of other components: because *the* ***concentration*** *of the solid cannot change,* it does not appear in Q. But *the* ***amount*** *of solid can change*. Adding H_2S shifts the reaction to the right, so more S forms.

FOLLOW-UP PROBLEMS

17.12A In a study of glass etching, a chemist examines the reaction between sand (SiO_2) and hydrogen fluoride at 150°C:

$$SiO_2(s) + 4HF(g) \rightleftharpoons SiF_4(g) + 2H_2O(g)$$

Predict the effect on $[SiF_4]$ when **(a)** $H_2O(g)$ is removed; **(b)** some liquid water is added; **(c)** HF is removed; **(d)** some sand is removed.

17.12B Water gas, a fuel mixture of carbon monoxide and hydrogen, is produced by passing steam over hot carbon:

$$C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g)$$

For each of the following changes, what happens to [CO]?
(a) Carbon is added. **(b)** $H_2O(g)$ is removed.
(c) $H_2(g)$ is removed. **(d)** $H_2O(g)$ is added.

SOME SIMILAR PROBLEMS 17.63 and 17.64

The Effect of a Change in Pressure (Volume)

Changes in pressure can have a large effect on equilibrium systems containing gaseous components. (A change in pressure has a negligible effect on liquids and solids because they are nearly incompressible.) Pressure changes can occur in three ways:

- *Changing the concentration of a gaseous component*. We just considered the effect of changing the concentration of a component, and that reasoning applies here.
- *Adding an inert gas (one that does not take part in the reaction)*. As long as the volume of the system is constant, adding an inert gas has no effect on the equilibrium position because *all concentrations, and thus partial pressures, remain the same*. Moreover, the inert gas does not appear in Q, so it cannot have an effect.
- *Changing the volume of the reaction vessel*. This change can cause a large shift in equilibrium position, but only for reactions in which the number of moles of gas, n_{gas}, changes.

Let's consider the two possible situations for the third way: changing the volume of the reaction vessel.

1. *Reactions in which n_{gas} changes*. Suppose the PCl_3-Cl_2-PCl_5 system is in a piston-cylinder assembly. We press down on the piston to halve the volume, so the gas pressure doubles (recall that pressure and volume are inversely proportional—Boyle's law). To reduce this disturbance, the system responds by *reducing the number of gas*

molecules in order to reduce the pressure. And the only way to do that is through a net reaction toward the side with *fewer moles of gas,* in this case, toward product:

$$PCl_3(g) + Cl_2(g) \longrightarrow PCl_5(g)$$
$$2 \text{ mol gas} \longrightarrow 1 \text{ mol gas}$$

Recall that $Q_c = \dfrac{[PCl_5]}{[PCl_3][Cl_2]}$. When the volume is halved, the concentrations double, but the denominator of Q_c is the product of two concentrations, so it quadruples while the numerator only doubles. Thus, Q_c becomes less than K_c. As a result, the system forms more PCl_5 and a new equilibrium position is reached.

Thus, for a system that consists of gases at equilibrium, in which the amount (mol) of gas, n_{gas}, changes during the reaction (Figure 17.9):

- If the volume becomes smaller (pressure is higher), the reaction shifts so that the total number of gas molecules decreases.
- If the volume becomes larger (pressure is lower), the reaction shifts so that the total number of gas molecules increases.

2. *Reactions in which n_{gas} does **not** change*. For the formation of hydrogen iodide from its elements, we have the same amount (mol) of gas on both sides:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$
$$2 \text{ mol gas} \longrightarrow 2 \text{ mol gas}$$

Therefore, Q_c has the same number of terms in the numerator and denominator:

$$Q_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{[HI][HI]}{[H_2][I_2]}$$

Because a change in volume has the same effect on the numerator and denominator, *there is **no** effect on the equilibrium position.*

In terms of the equilibrium constant, *a change in volume is, in effect, a change in concentration:* a decrease in volume raises the concentration, and vice versa. Therefore, like other changes in concentration, *a change in pressure due to a change in volume does **not** alter K_c.*

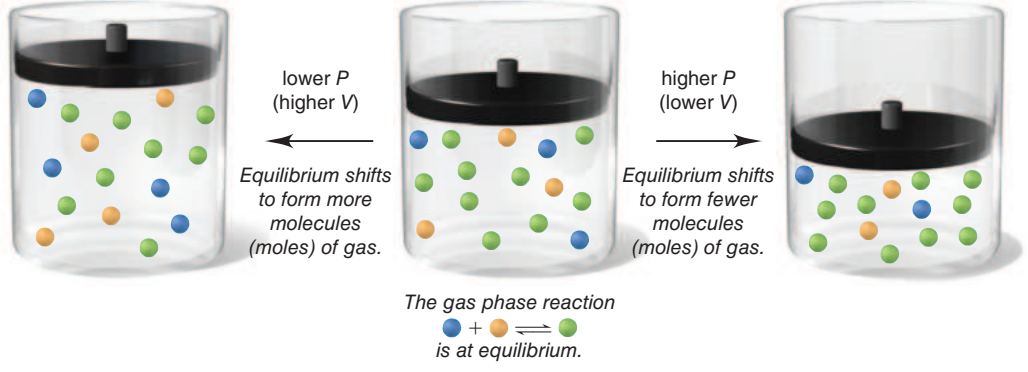

Figure 17.9 The effect of a change in pressure (volume) on a system at equilibrium.

SAMPLE PROBLEM 17.13 Predicting the Effect of a Change in Volume (Pressure) on the Equilibrium Position

Problem How would you change the volume for each of the following reactions to *increase* the yield of the products?

(a) $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$

(b) $S(s) + 3F_2(g) \rightleftharpoons SF_6(g)$

(c) $Cl_2(g) + I_2(g) \rightleftharpoons 2ICl(g)$

Plan Whenever gases are present, a change in volume causes a change in concentration. For reactions in which the number of moles of gas changes, if the volume decreases (pressure increases), the equilibrium position shifts to lower the pressure by reducing the number of moles of gas. A volume increase (pressure decrease) has the opposite effect.

Solution **(a)** The only gas is the product CO_2. To make the system produce more molecules of gas, that is, more CO_2, we increase the volume (decrease the pressure).
(b) With 3 mol of gas on the left and only 1 mol on the right, we decrease the volume (increase the pressure) to form fewer molecules of gas and, thus, more SF_6.
(c) The number of moles of gas is the same on both sides of the equation, so a change in volume (pressure) will have no effect on the yield of ICl.

Check Let's predict the relative values of Q_c and K_c.
(a) $Q_c = [CO_2]$, so increasing the volume will make $Q_c < K_c$, and the system will yield more CO_2.
(b) $Q_c = [SF_6]/[F_2]^3$. Lowering the volume increases $[F_2]$ and $[SF_6]$ proportionately, but Q_c decreases because of the exponent 3 in the denominator. To make $Q_c = K_c$ again, $[SF_6]$ must increase.
(c) $Q_c = [ICl]^2/[Cl_2][I_2]$. A change in volume (pressure) affects the numerator (2 mol) and denominator (2 mol) equally, so it will have no effect.

FOLLOW-UP PROBLEMS

17.13A Would you increase or decrease the pressure (via a volume change) of each of the following reaction mixtures to *decrease* the yield of products?
(a) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$
(b) $4NH_3(g) + 5O_2(g) \rightleftharpoons 4NO(g) + 6H_2O(g)$
(c) $CaC_2O_4(s) \rightleftharpoons CaCO_3(s) + CO(g)$

17.13B Predict the effect of an increase in container volume (decrease in P) on the yield of products in each of the following:
(a) $CH_4(g) + CO_2(g) \rightleftharpoons 2CO(g) + 2H_2(g)$
(b) $NO(g) + CO_2(g) \rightleftharpoons NO_2(g) + CO(g)$
(c) $2H_2S(g) + SO_2(g) \rightleftharpoons 3S(s) + 2H_2O(g)$

SOME SIMILAR PROBLEMS 17.65–17.70

The Effect of a Change in Temperature

Of the three types of disturbances that may occur—a change in concentration, pressure, or temperature—*only temperature changes alter the value of K*. To see why, let's focus on the sign of ΔH°_{rxn}:

$$PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g) \qquad \Delta H^\circ_{rxn} = -111\ kJ$$

The forward reaction is exothermic (releases heat; $\Delta H^\circ_{rxn} < 0$), so the reverse reaction is endothermic (absorbs heat; $\Delta H^\circ_{rxn} > 0$):

$$PCl_3(g) + Cl_2(g) \longrightarrow PCl_5(g) + \textbf{\textit{heat}}\ (\text{exothermic})$$
$$PCl_3(g) + Cl_2(g) \longleftarrow PCl_5(g) + \textbf{\textit{heat}}\ (\text{endothermic})$$

If we consider *heat as a component of the equilibrium system,* a rise in temperature occurs when heat is "added" to the system and a drop in temperature occurs when heat is "removed" from the system. As with a change in any other component, the system shifts to reduce the effect of the change. Therefore, *a temperature increase (adding heat) favors the endothermic (heat-absorbing) direction, and a temperature decrease (removing heat) favors the exothermic (heat-releasing) direction.*

If we start with the system at equilibrium, Q_c equals K_c. Increase the temperature, and the system absorbs the added heat by decomposing some PCl_5 to PCl_3 and Cl_2. The denominator of Q_c becomes larger and the numerator smaller, so the system reaches a new equilibrium position at a smaller ratio of concentration terms, that is, a lower K_c. Similarly, if the temperature drops, the system releases more heat by forming more PCl_5 from some PCl_3 and Cl_2. The numerator of Q_c becomes larger, the denominator smaller, and the new equilibrium position has a higher K_c. Thus,

- *A temperature rise will increase K_c for a system with a positive ΔH°_{rxn}.*
- *A temperature rise will decrease K_c for a system with a negative ΔH°_{rxn}.*

Let's review these ideas with a sample problem.

SAMPLE PROBLEM 17.14 **Predicting the Effect of a Change in Temperature on the Equilibrium Position**

Problem How does an *increase* in temperature affect the equilibrium concentration of the underlined substance and K for each of the following reactions?

(a) $CaO(s) + H_2O(l) \rightleftharpoons \underline{Ca(OH)_2}(aq) \quad \Delta H° = -82\ kJ$

(b) $CaCO_3(s) \rightleftharpoons CaO(s) + \underline{CO_2}(g) \quad \Delta H° = 178\ kJ$

(c) $\underline{SO_2}(g) \rightleftharpoons S(s) + O_2(g) \quad \Delta H° = 297\ kJ$

Plan We write each equation to show heat as a reactant or product. The temperature increases when we add heat, so the system shifts to absorb the heat; that is, the endothermic reaction occurs. Thus, K will increase if the forward reaction is endothermic and decrease if it is exothermic.

Solution **(a)** $CaO(s) + H_2O(l) \rightleftharpoons Ca(OH)_2(aq) + \textbf{\textit{heat}}$

Adding heat shifts the system to the left: $[Ca(OH)_2]$ and K will decrease.

(b) $CaCO_3(s) + \textbf{\textit{heat}} \rightleftharpoons CaO(s) + CO_2(g)$

Adding heat shifts the system to the right: $[CO_2]$ and K will increase.

(c) $SO_2(g) + \textbf{\textit{heat}} \rightleftharpoons S(s) + O_2(g)$

Adding heat shifts the system to the right: $[SO_2]$ will decrease and K will increase.

Check Check your answers by reasoning through a *decrease* in temperature: heat is removed and the exothermic direction is favored. All the answers should be opposite.

Comment Note that in (a) these ideas hold for solutions as well.

FOLLOW-UP PROBLEMS

17.14A How does a *decrease* in T affect the partial pressure of the underlined substance and the value of K for each of the following reactions?

(a) $C(\text{graphite}) + \underline{2H_2}(g) \rightleftharpoons CH_4(g) \quad \Delta H° = -75\ kJ$

(b) $\underline{N_2}(g) + O_2(g) \rightleftharpoons 2NO(g) \quad \Delta H° = 181\ kJ$

(c) $P_4(s) + 10Cl_2(g) \rightleftharpoons \underline{4PCl_5}(g) \quad \Delta H° = -1528\ kJ$

17.14B Should T be increased or decreased to yield more product in each of the following reactions? What effect does the change in T have on the value of K for each reaction?

(a) $2Cl_2(g) + 2H_2O(g) \rightleftharpoons 4HCl(g) + O_2(g) \quad \Delta H° = 114\ kJ$

(b) $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g) \quad \Delta H° = -77.2\ kJ$

(c) $2HgO(s) \rightleftharpoons 2Hg(l) + O_2(g) \quad \Delta H° = 182\ kJ$

SOME SIMILAR PROBLEMS 17.71 and 17.72

The van't Hoff Equation: The Effect of *T* on *K* The *van't Hoff equation* shows quantitatively how the equilibrium constant is affected by changes in temperature:

$$\ln\frac{K_2}{K_1} = -\frac{\Delta H°_{rxn}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) \qquad \textbf{(17.10)}$$

where K_1 is the equilibrium constant at T_1, K_2 is the equilibrium constant at T_2, and R is the universal gas constant (8.314 J/mol·K). If we know $\Delta H°_{rxn}$ and K at one temperature, the van't Hoff equation allows us to find K at any other temperature (or to find $\Delta H°_{rxn}$, given the two K's at two T's).

Equation 17.10 confirms the qualitative prediction from Le Châtelier's principle: for a temperature rise, we have

$$T_2 > T_1 \quad \text{and} \quad 1/T_2 < 1/T_1$$

so

$$1/T_2 - 1/T_1 < 0$$

Therefore,

- For an endothermic reaction ($\Delta H°_{rxn} > 0$), the $-(\Delta H°_{rxn}/R)$ term is <0. With $1/T_2 - 1/T_1 < 0$, the right side of the equation is >0. Thus, $\ln(K_2/K_1) > 0$, so $K_2 > K_1$. An increase in temperature results in a shift to the right and an increase in K.

- For an exothermic reaction ($\Delta H^\circ_{rxn} < 0$), the $-(\Delta H^\circ_{rxn}/R)$ term is >0. With $1/T_2 - 1/T_1 < 0$, the right side of the equation is <0. Thus, $\ln (K_2/K_1) < 0$, so $K_2 < K_1$. An increase in temperature results in a shift to the left and a decrease in K.

Here's a typical problem that requires the van't Hoff equation. Many coal gasification processes begin with the formation of syngas from carbon and steam:

$$C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g) \qquad \Delta H^\circ_{rxn} = 131 \text{ kJ/mol}$$

An engineer knows that K_p is only 9.36×10^{-17} at 25°C and therefore wants to find a temperature that allows a much higher yield. Calculate K_p at 700.°C.

$$\ln \frac{K_2}{K_1} = -\frac{\Delta H^\circ_{rxn}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

The temperatures must be in kelvins, and the units of ΔH° and R must be made consistent:

$$\ln\left(\frac{K_{p2}}{9.36\times10^{-17}}\right) = -\frac{131\times10^3 \text{ J/mol}}{8.314 \text{ J/mol·K}}\left(\frac{1}{973 \text{ K}} - \frac{1}{298 \text{ K}}\right)$$

$$\frac{K_{p2}}{9.36\times10^{-17}} = 8.51\times10^{15}$$

$$K_{p2} = 0.797 \qquad \text{(a much higher yield)}$$

(For further practice with the van't Hoff equation, see Problems 17.73 and 17.74.)

The Lack of Effect of a Catalyst

Let's briefly consider what effect, if any, adding a catalyst would have on the system. Recall from Chapter 16 that a catalyst speeds up a reaction by lowering the activation energy, thereby increasing the forward *and* reverse rates to the same extent. Thus, *a catalyst shortens the time it takes to reach equilibrium but has* ***no*** *effect on the equilibrium position.* That is, if we add a catalyst to a mixture of PCl_3 and Cl_2 at 523 K, the system attains the *same* equilibrium concentrations of PCl_3, Cl_2, and PCl_5 *more quickly* than it does without the catalyst. As you'll see in a moment, however, catalysts play key roles in optimizing reaction systems.

Table 17.4 summarizes the effects of changing conditions. Many changes alter the equilibrium *position*, but only temperature changes alter the equilibrium *constant*. Sample Problem 17.15 shows how to visualize equilibrium at the molecular level.

Table 17.4 Effects of Various Disturbances on a System at Equilibrium

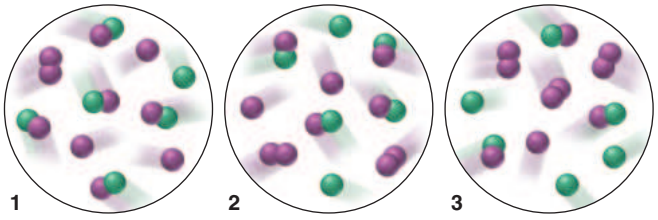
Disturbance	Effect on Equilibrium Position	Effect on Value of *K*
Concentration		
Increase [reactant]	Toward formation of product	None
Decrease [reactant]	Toward formation of reactant	None
Increase [product]	Toward formation of reactant	None
Decrease [product]	Toward formation of product	None
Pressure		
Increase P (decrease V)	Toward formation of fewer moles of gas	None
Decrease P (increase V)	Toward formation of more moles of gas	None
Increase P (add inert gas, no change in V)	None; concentrations unchanged	None
Temperature		
Increase T	Toward absorption of heat	Increases if $\Delta H^\circ_{rxn} > 0$ Decreases if $\Delta H^\circ_{rxn} < 0$
Decrease T	Toward release of heat	Increases if $\Delta H^\circ_{rxn} < 0$ Decreases if $\Delta H^\circ_{rxn} > 0$
Catalyst added	None; forward and reverse rates increase equally; equilibrium attained sooner	None

SAMPLE PROBLEM 17.15 Determining Equilibrium Parameters from Molecular Scenes

Problem For the reaction,

$$X(g) + Y_2(g) \rightleftharpoons XY(g) + Y(g) \qquad \Delta H > 0$$

the following molecular scenes depict different reaction mixtures (X is *green,* Y is *purple*):



(a) If $K = 2$ at the temperature of the reaction, which scene represents the mixture at equilibrium? **(b)** Will the reaction mixtures in the other two scenes proceed toward reactants or toward products to reach equilibrium? **(c)** For the mixture at equilibrium, how will a rise in temperature affect $[Y_2]$?

Plan **(a)** We are given the balanced equation and K and must choose the scene that represents the mixture at equilibrium. We write Q, and for each scene, count particles and find the value of Q. Whichever scene gives a Q equal to K (2) represents the mixture at equilibrium. **(b)** For each of the other two reaction mixtures, we compare the value of Q with 2. If $Q > K$, the numerator (product side) is too high, so the reaction proceeds toward reactants; if $Q < K$, the reaction proceeds toward products. **(c)** We are given that $\Delta H > 0$, so we must see whether a rise in T increases or decreases $[Y_2]$, one of the reactants.

Solution **(a)** For the reaction, we have $Q = \dfrac{[XY][Y]}{[X][Y_2]}$. Thus,

$$\text{scene 1: } Q = \frac{5 \times 3}{1 \times 1} = 15 \qquad \text{scene 2: } Q = \frac{4 \times 2}{2 \times 2} = 2 \qquad \text{scene 3: } Q = \frac{3 \times 1}{3 \times 3} = \frac{1}{3}$$

For scene 2, $Q = K$, so scene 2 represents the mixture at equilibrium.

(b) For scene 1, Q (15) $> K$ (2), so the reaction proceeds toward reactants.

For scene 3, Q ($\frac{1}{3}$) $< K$ (2), so the reaction proceeds toward products.

(c) The reaction is endothermic, so heat acts as a reactant:

$$X(g) + Y_2(g) + \textit{heat} \rightleftharpoons XY(g) + Y(g)$$

Therefore, adding heat to the left shifts the reaction to the right, so $[Y_2]$ decreases.

Check **(a)** Remember that quantities in the numerator (or denominator) of Q are multiplied, not added. For example, the denominator for scene 1 is $1 \times 1 = 1$, not $1 + 1 = 2$.

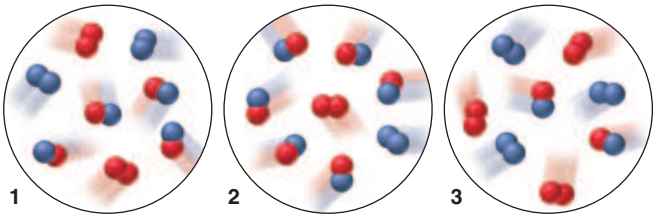
(c) A good check is to imagine that $\Delta H < 0$ and see if you get the opposite result:

$$X(g) + Y_2(g) \rightleftharpoons XY(g) + Y(g) + \textit{heat}$$

If $\Delta H < 0$, adding heat would shift the reaction to the left and increase $[Y_2]$.

FOLLOW-UP PROBLEMS

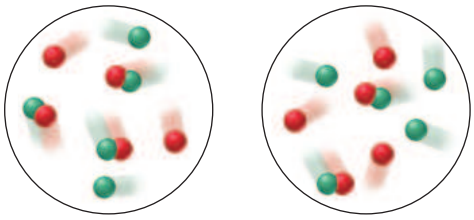
17.15A For the reaction $C_2(g) + D_2(g) \rightleftharpoons 2CD(g)$; $\Delta H < 0$, these molecular scenes depict different reaction mixtures (C is *red,* D is *blue*):



At equilibrium

(a) Calculate the value of K_p. **(b)** In which direction will the reaction proceed for the mixtures *not* at equilibrium? **(c)** For the mixture at equilibrium, what effect will a rise in T have on the total amount (mol) of gas (increase, decrease, no effect)? Explain.

17.15B For the reaction $A(g) + B(g) \rightleftharpoons AB(g)$, these molecular scenes depict reaction mixtures at two different temperatures (A is *red,* B is *green*):



At equilibrium at T_1 At equilibrium at T_2

(a) Calculate the value of K at T_1. **(b)** If $T_2 < T_1$, what is the sign of ΔH for the reaction? **(c)** Calculate K at T_2.

A SIMILAR PROBLEM 17.59

Applying Le Châtelier's Principle to the Synthesis of Ammonia

Le Châtelier's principle has countless applications in natural systems and in the chemical industry. As a case study, we'll look at the synthesis of ammonia, which, on a mole basis, is produced industrially in greater amount than any other compound. Then, a Chemical Connections essay applies the principle to cellular metabolism.

Even though four of every five molecules in the atmosphere are N_2, the supply of *usable* nitrogen is limited because the strong triple bond in N_2 lowers its reactivity. Thus, the N atom is very difficult to "fix," that is, to combine with other atoms into useful compounds. Natural nitrogen fixation occurs through the fine-tuned activity of enzymes found in bacteria that live on plant roots, or through the brute force of lightning. But, nearly 13% of nitrogen fixation is done industrially via the **Haber process:**

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) \qquad \Delta H^\circ_{rxn} = -91.8 \text{ kJ}$$

Developed by the German chemist Fritz Haber in 1913 and first used in a plant making 12,000 tons of ammonia a year, the process now yields over 110 million tons a year. Over 80% of this is used as fertilizer, with most of the remainder used to make explosives and nylons and other polymers, and smaller amounts going into production of refrigerants, rubber stabilizers, household cleaners, and pharmaceuticals.

Optimizing Reaction Conditions: Yield vs. Rate The Haber process applies equilibrium *and* kinetics principles to achieve a compromise that makes the process economical. From the balanced equation, we see three ways to maximize NH_3 yield:

1. *Decrease [NH_3].* Removing NH_3 as it forms will make the system shift toward producing more to reattain equilibrium.
2. *Decrease volume (increase pressure).* Because 4 mol of gas reacts to form 2 mol of gas, decreasing the volume will shift the system toward making fewer moles of gas.
3. *Decrease temperature.* Because the formation of NH_3 is exothermic, decreasing the temperature (removing heat) will shift the equilibrium position toward product, thereby increasing K_c (Table 17.5).

Therefore, the conditions for maximizing the yield of product are continual removal of NH_3, high pressure, and low temperature. Figure 17.10 on the next page shows the percent yield of NH_3 at various combinations of pressure and temperature. Note the almost complete conversion (98.3%) to product at 1000 atm and 473 K (200.°C).

Although the *yield* is favored at this relatively low temperature, the *rate* of formation is so low that the process is uneconomical. In practice, a compromise optimizes yield *and* rate. High pressure and continuous removal are used to increase yield, but the temperature is raised to a moderate level and *a catalyst is used to increase the rate*. Achieving the same rate without a catalyst would require much higher temperatures and, thus, result in a much lower yield.

Table 17.5 Effect of Temperature on K_c for Ammonia Synthesis

T (K)	K_c
200.	7.17×10^{15}
300.	2.69×10^{8}
400.	3.94×10^{4}
500.	1.72×10^{2}
600.	4.53×10^{0}
700.	2.96×10^{-1}
800.	3.96×10^{-2}

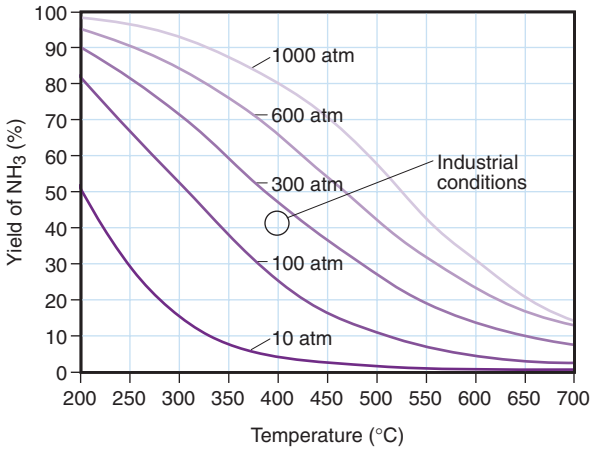


Figure 17.10 **Percent yield of ammonia vs. temperature at five different pressures.** At very high *P* and low *T (top left),* the yield is high, but the rate is low. Industrial conditions *(circle)* are between 200 and 300 atm at about 400°C.

The Industrial Process Stages in the industrial production of NH_3 are shown in Figure 17.11. To extend equipment life and minimize cost, modern plants operate at about 200 to 300 atm and around 673 K (400.°C). The stoichiometric ratio of reactant gases (N_2/H_2 = 1/3 by volume) is injected into the heated, pressurized reaction chamber. Some of the needed heat is supplied by ΔH°_{rxn}. The gases flow over catalyst beds that consist of 5-mm to 10-mm chunks of iron crystals embedded in a fused mixture of MgO, Al_2O_3, and SiO_2. The emerging equilibrium mixture contains about 35% NH_3 and is cooled by refrigeration until the NH_3 (bp −33.4°C) condenses; it is then removed and stored. Because N_2 and H_2 have much lower boiling points, they are recycled as gases by pumping them back into the reaction chamber.

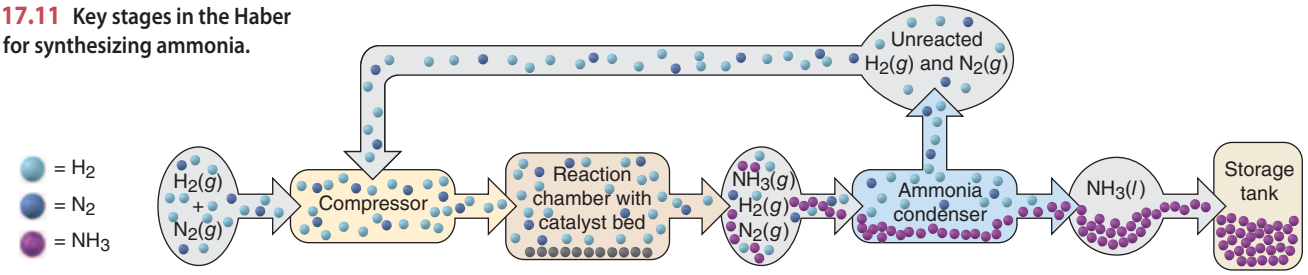

Figure 17.11 **Key stages in the Haber process for synthesizing ammonia.**

Summary of Section 17.6

- If a system at equilibrium is disturbed, it undergoes a net reaction that reduces the disturbance and returns the system to equilibrium.
- Changes in concentration cause a net reaction to consume the added component or to produce the removed component.
- For a reaction that involves a change in amount (mol) of gas, an increase in pressure (decrease in volume) causes a net reaction toward fewer moles of gas, and a decrease in pressure causes the opposite change.
- Although the equilibrium position changes as a result of a concentration or volume change, *K* does not.
- A temperature change affects *K*: higher *T* increases *K* for an endothermic reaction (positive ΔH°_{rxn}) and decreases *K* for an exothermic reaction (negative ΔH°_{rxn}).
- A catalyst causes the system to reach equilibrium more quickly by speeding forward and reverse reactions equally, but it does not affect the equilibrium position.
- Ammonia is produced in a process favored by high pressure, low temperature, and continual removal of product. To make the process economical, intermediate temperature and pressure and a catalyst are used.
- A metabolic pathway is a cellular reaction sequence with each step shifted completely toward product. Its overall yield is controlled by a feedback system that inhibits the activity of certain key enzymes.

Design and Control of a Metabolic Pathway

From the simplest bacterium to the most specialized neuron, every cell performs thousands of reactions that allow it to grow and reproduce, feed and excrete, move and communicate. Taken together, these myriad feats of breakdown, synthesis, and energy flow constitute the cell's *metabolism* and are organized into reaction sequences called **metabolic pathways.**

Continual Shift Toward Product

In principle, each step in a metabolic pathway is a reversible reaction catalyzed by a specific enzyme (Section 16.7). However, equilibrium is never reached in a pathway, because the product of each reaction becomes the reactant of the next. Consider the five-step pathway by which the amino acid threonine is converted into the amino acid isoleucine (Figure B17.1). Threonine, supplied from a different region of the cell, forms ketobutyrate through the catalytic action of enzyme 1. The equilibrium position of reaction 1 shifts to the right because the product, ketobutyrate, is the reactant in reaction 2. Similarly, reaction 2 shifts to the right as its product, acetohydroxybutyrate, is used up in reaction 3. In this way, each subsequent reaction shifts the previous reaction to the right. The final product, isoleucine, is removed to make proteins elsewhere in the cell. Thus, the entire pathway operates in one direction.

Creation of a Steady State

This continuous shift in equilibrium position has two consequences for metabolic pathways:

1. *Each step proceeds with nearly 100% yield:* Virtually every molecule of threonine that enters this region of the cell eventually changes to ketobutyrate, every molecule of ketobutyrate to the next product, and so on.
2. *Reactant and product concentrations remain nearly constant,* because they reach a *steady state*.
   - In an equilibrium system, equal rates in *opposing* directions create constant concentrations of reactants and products.
   - In a steady-state system, the rates of reactions in *one* direction—into, through, and out of the system—create constant concentrations of intermediates.

Ketobutyrate, for example, is formed in reaction 1 as fast as it is consumed in reaction 2, so its concentration is constant. (A steady-state amount of water results if you fill a sink and then adjust the flow of faucet and drain so that water enters as fast as it leaves.)

Regulation by Feedback Inhibition

Recall from Chapter 16 that substrate concentrations are *much* higher than enzyme concentrations. If the active sites on all the enzyme molecules were always occupied, all cellular reactions would occur at their maximum rates. This might be ideal for an industrial process, but an organism needs to control amounts carefully. To regulate product formation, certain key steps are catalyzed by *regulatory enzymes,* which contain an *inhibitor site* (Figure B17.2A) in addition to an active site: when the inhibitor site is occupied, the shape of the active site is deformed and the reaction is not catalyzed (Figure B17.2B).

In the simplest case of metabolic regulation (Figure B17.1), *the final product of a pathway is the inhibitor, and the regulatory enzyme catalyzes the first step.* Suppose, for instance, that a cell is temporarily making less protein, so isoleucine is not being removed as quickly. As its concentration rises, isoleucine lands more often on the inhibitor site of threonine dehydratase, the first enzyme in the pathway, thereby inhibiting its own production. This process is called *end-product feedback inhibition.* More complex pathways have more elaborate regulatory schemes.

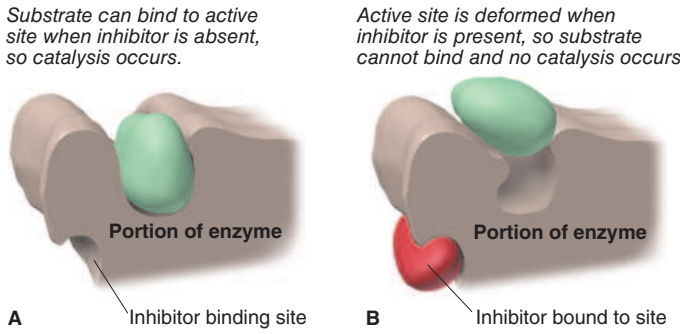

Figure B17.2 **Effect of inhibitor binding on shape of active site.**

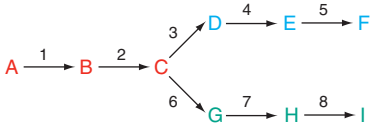
Problem

B17.1 Many metabolites are products in branched pathways. In the one below, letters are compounds, and numbers are enzymes:



One method of control of these pathways occurs through inhibition of the first enzyme specific for a branch. (a) Which enzyme is inhibited by F? (b) Which enzyme is inhibited by I? (c) What is the disadvantage if F inhibited enzyme 1? (d) What would be the disadvantage if F inhibited enzyme 6?

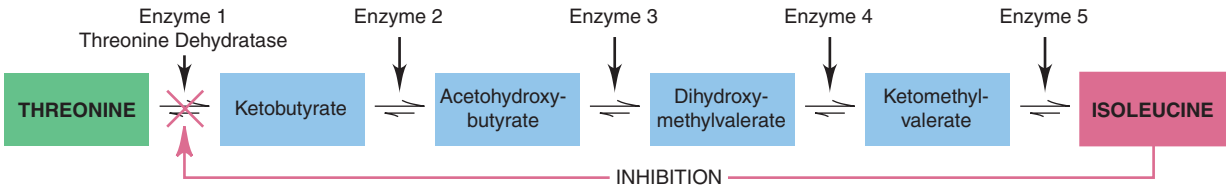


Figure B17.1 **The biosynthesis of isoleucine from threonine.** Isoleucine is synthesized from threonine in a sequence of five enzyme-catalyzed reactions. Once enough isoleucine is present, its concentration builds up and inhibits threonine dehydratase, the first enzyme in the pathway.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The distinction between the speed (rate) and the extent of a reaction (Introduction)
2. Why a system attains dynamic equilibrium when forward and reverse reaction rates are equal (§17.1)
3. The equilibrium constant as a number that is equal to a particular ratio of rate constants and of concentration terms (§17.1)
4. How the magnitude of K is related to the extent of the reaction (§17.1)
5. Why the same equilibrium state is reached no matter what the starting concentrations of the reacting system (§17.2)
6. How the reaction quotient (Q) changes continuously until the system reaches equilibrium, at which point $Q = K$ (§17.2)
7. Why the form of Q is based exactly on the balanced equation *as written* (§17.2)
8. Why terms for pure solids and liquids do not appear in Q (§17.2)
9. How the *sum* of reaction steps gives the overall reaction, and the *product* of Q's (or K's) gives the overall Q (or K) (§17.2)
10. How the interconversion of K_c and K_p is based on the ideal gas law and Δn_{gas} (§17.3)
11. How the reaction direction depends on the relative values of Q and K (§17.4)
12. How a reaction table is used to find an unknown quantity (concentration or pressure) (§17.5)
13. How assuming that the change in [reactant] is relatively small simplifies finding equilibrium quantities (§17.5)
14. How Le Châtelier's principle explains the effects of a change in concentration, pressure (volume), or temperature on a system at equilibrium and on K (§17.6)
15. Why a change in temperature *does* affect K (§17.6)
16. Why the addition of a catalyst does *not* affect K (§17.6)
17. How adjusting reaction conditions and using a catalyst optimizes the synthesis of ammonia (§17.6)

Master These Skills

1. Writing a reaction quotient (Q) from a balanced equation (SP 17.1)
2. Writing Q and finding K for a reaction consisting of more than one step (SP 17.2)
3. Writing Q and finding K for an equation multiplied by a common factor (SP 17.3)
4. Writing Q for heterogeneous equilibria (§17.2)
5. Converting between K_c and K_p (SP 17.4)
6. Comparing Q and K to determine reaction direction (SPs 17.5, 17.6)
7. Substituting quantities (concentrations or pressures) into Q to find K (§17.5)
8. Using a reaction table to determine quantities and find K (SP 17.7)
9. Finding one equilibrium quantity from other equilibrium quantities and K (SP 17.8)
10. Finding an equilibrium quantity from initial quantities and K (SP 17.9)
11. Solving a quadratic equation for an unknown equilibrium quantity (§17.5)
12. Assuming that the change in [reactant] is relatively small to find equilibrium quantities and checking the assumption (SP 17.10)
13. Comparing the values of Q and K to find reaction direction and x, the unknown change in a quantity (SP 17.11)
14. Using the relative values of Q and K to predict the effect of a change in concentration on the equilibrium position and on K (SP 17.12)
15. Using Le Châtelier's principle and Δn_{gas} to predict the effect of a change in pressure (volume) on the equilibrium position (SP 17.13)
16. Using Le Châtelier's principle and $\Delta H°$ to predict the effect of a change in temperature on the equilibrium position and on K (SP 17.14)
17. Using the van't Hoff equation to calculate K at one temperature given K at another temperature (§17.6)
18. Using molecular scenes to find equilibrium parameters (SP 17.15)

Key Terms

Page numbers appear in parentheses.

equilibrium constant (K) (733)

Section 17.2
law of chemical equilibrium (law of mass action) (734)
reaction quotient (Q) (734)

Section 17.6
Le Châtelier's principle (754)
Haber process (763)
metabolic pathway (765)

Key Equations and Relationships

Page numbers appear in parentheses.

17.1 Defining equilibrium in terms of reaction rates (732):

$$\text{At equilibrium: } \text{rate}_{fwd} = \text{rate}_{rev}$$

17.2 Defining the equilibrium constant for the reaction $A \rightleftharpoons 2B$ (733):

$$K = \frac{k_{fwd}}{k_{rev}} = \frac{[B]_{eq}^2}{[A]_{eq}}$$

17.3 Defining the equilibrium constant in terms of the reaction quotient (734):

$$\text{At equilibrium: } Q = K$$

17.4 Expressing Q_c for the reaction $aA + bB \rightleftharpoons cC + dD$ (735):

$$Q_c = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

17.5 Finding the overall K for a reaction sequence (737):

$$K_{\text{overall}} = K_1 \times K_2 \times K_3 \times \cdots$$

17.6 Finding K of a reaction from K of the reverse reaction (738):

$$K_{\text{fwd}} = \frac{1}{K_{\text{rev}}}$$

17.7 Finding Q and K of a reaction multiplied by a factor n (739):

$$Q' = Q^n = \left(\frac{[\text{C}]^c[\text{D}]^d}{[\text{A}]^a[\text{B}]^b}\right)^n \qquad \text{and} \qquad K' = K^n$$

17.8 Relating K based on pressures to K based on concentrations (741):

$$K_p = K_c(RT)^{\Delta n_{\text{gas}}}$$

17.9 Assuming that ignoring the concentration that reacts introduces no significant error (750):

$$[\text{A}]_{\text{init}} - [\text{A}]_{\text{reacting}} = [\text{A}]_{\text{eq}} \approx [\text{A}]_{\text{init}}$$

17.10 Finding K at one temperature given K at another (van't Hoff equation) (760):

$$\ln\frac{K_2}{K_1} = -\frac{\Delta H^\circ_{\text{rxn}}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

17.1A (a) $Q_c = \dfrac{[\text{NO}]^4[\text{H}_2\text{O}]^6}{[\text{NH}_3]^4[\text{O}_2]^5}$ (b) $Q_c = \dfrac{[\text{NH}_3]^2}{[\text{NO}_2]^2[\text{H}_2]^7}$

(c) $Q_c = [\text{O}_2]^3$

17.1B (a) $Q_c = \dfrac{[\text{CO}]^2[\text{H}_2]^2}{[\text{CH}_4][\text{CO}_2]}$ (b) $Q_c = \dfrac{[\text{H}_2\text{O}]^2}{[\text{H}_2\text{S}]^2[\text{SO}_2]}$

(c) $Q_c = \dfrac{[\text{NaCN}]}{[\text{HCN}][\text{NaOH}]}$

17.2A $\text{H}_2(g) + \text{Br}_2(g) \rightleftharpoons 2\text{HBr}(g)$

$$Q_{c(\text{overall})} = \frac{[\text{HBr}]^2}{[\text{H}_2][\text{Br}_2]}$$

$$Q_{c(\text{overall})} = Q_{c1} \times Q_{c2} \times Q_{c3} = \frac{\cancel{[\text{Br}]^2}}{[\text{Br}_2]} \times \frac{[\text{HBr}]\cancel{[\text{H}]}}{\cancel{[\text{Br}]}[\text{H}_2]} \times \frac{[\text{HBr}]}{\cancel{[\text{H}]}\cancel{[\text{Br}]}} = \frac{[\text{HBr}]^2}{[\text{H}_2][\text{Br}_2]}$$

17.2B $\text{H}_2(g) + 2\text{ICl}(g) \rightleftharpoons \text{I}_2(g) + 2\text{HCl}(g)$

$$Q_{c(\text{overall})} = \frac{[\text{I}_2][\text{HCl}]^2}{[\text{H}_2][\text{ICl}]^2}$$

$$Q_{c(\text{overall})} = Q_{c1} \times Q_{c2} = \frac{\cancel{[\text{HI}]^2}[\text{HCl}]}{[\text{H}_2][\text{ICl}]} \times \frac{[\text{I}_2][\text{HCl}]}{\cancel{[\text{HI}]^2}[\text{ICl}]} = \frac{[\text{I}_2][\text{HCl}]^2}{[\text{H}_2][\text{ICl}]^2}$$

17.3A (a) $K_c = K_{c(\text{ref})}^{1/2} = 2.8\times10^4$

(b) $K_c = \left(\dfrac{1}{K_{c(\text{ref})}}\right)^{2/3} = 1.2\times10^{-6}$

17.3B (a) $K_c = \left(\dfrac{1}{K_{c(\text{ref})}}\right)^2 = 5.9\times10^3$

(b) $K_c = K_{c(\text{ref})}^{1/4} = 0.34$

17.4A $K_p = K_c(RT)^{-1} = 1.67\left(0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 500.\ \text{K}\right)^{-1} = 4.07\times10^{-2}$

17.4B $K_c = K_p(RT)^2 = 3.0\times10^{-5}\left(0.0821\ \dfrac{\text{atm·L}}{\text{mol·K}} \times 1173\ \text{K}\right)^2 = 0.28$

17.5A $K_c = \dfrac{[\text{Y}]}{[\text{X}]} = 1.4$

1. $Q = 0.33$, right 2. $Q = 1.4$, no net change 3. $Q = 2.0$, left

17.5B $K_c = \dfrac{[\text{D}]}{[\text{C}]^2} = \dfrac{5}{3^2} = 0.56$

2. $Q = 0.67$, left 3. $Q = 0.44$, right

17.6A $Q_p = \dfrac{(P_{\text{CH}_3\text{Cl}})(P_{\text{HCl}})}{(P_{\text{CH}_4})(P_{\text{Cl}_2})} = \dfrac{(0.24)(0.47)}{(0.13)(0.035)} = 25$

$Q_p < K_p$, so CH_3Cl is forming.

17.6B $Q_c = \dfrac{[\text{SO}_3]^2}{[\text{SO}_2]^2[\text{O}_2]} = \dfrac{[0.60]^2}{[1.7]^2[0.75]} = 0.17$

$Q_c > K_c$, so the system is not at equilibrium, and the reaction will proceed toward the left.

17.7A From the reaction table for $2\text{NO} + \text{O}_2 \rightleftharpoons 2\text{NO}_2$,

$P_{\text{O}_2} = 1.000\ \text{atm} - x = 0.506\ \text{atm} \qquad x = 0.494\ \text{atm}$

Also, $P_{\text{NO}} = 0.012$ atm and $P_{\text{NO}_2} = 0.988$ atm, so

$$K_p = \frac{0.988^2}{(0.012)^2(0.506)} = 1.3\times10^4$$

17.7B From the reaction table, at equilibrium,

$[\text{N}_2\text{O}_4] = 0 + 2x = 0.134\ M \qquad x = 0.0670\ M$

$[\text{NH}_3] = 2.13\ M$, $[\text{O}_2] = 1.93\ M$, $[\text{H}_2\text{O}] = 0.402\ M$, so

$$K_c = \frac{(0.134)^2(0.402)^6}{(2.13)^4(1.93)^7} = 3.69\times10^{-8}$$

17.8A Since $\Delta n_{\text{gas}} = 0$, $K_p = K_c = 2.3\times10^{30} = \dfrac{(0.781)(0.209)}{P_{\text{NO}}^2}$

Thus, $P_{\text{NO}} = 2.7\times10^{-16}$ atm

17.8B $19.6 = \dfrac{0.215(P_{\text{H}_2}^3)}{(0.112)^2}$

$P_{\text{H}_2} = 1.05$ atm

17.9A From the reaction table, $[\text{H}_2] = [\text{I}_2] = x$;

$[\text{HI}] = 0.242 - 2x$. Thus,

$$K_c = 1.26\times10^{-3} = \frac{x^2}{(0.242 - 2x)^2}$$

Taking the square root of both sides, ignoring the negative root, and solving gives $x = [\text{H}_2] = 8.02\times10^{-3}\ M$.

17.9B From the reaction table, $[\text{H}_2\text{O}] = [\text{Cl}_2\text{O}] = 1.23 - x$;

$[\text{HClO}] = 2x$. Thus,

$$K_c = 0.18 = \frac{(2x)^2}{(1.23 - x)^2}$$

Taking the square root of both sides, ignoring the negative root, and solving gives $x = 0.21$.

$[\text{H}_2\text{O}] = [\text{Cl}_2\text{O}] = 1.23 - x = 1.23 - 0.21 = 1.02\ M$

$[\text{HClO}] = 2x = 2(0.21) = 0.42\ M$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

17.10A (a) Based on the reaction table, and assuming that $0.20\ M - x \approx 0.20\ M$,

$$K_c = 2.94\times10^{-10} \approx \frac{4x^2}{0.20} \qquad x \approx 3.8\times10^{-6}$$

Error $= 1.9\times10^{-3}\%$, so assumption is justified; therefore, at equilibrium, $[I_2] = 0.20\ M$ and $[I] = 7.6\times10^{-6}\ M$.
(b) Based on the same reaction table and assumption, $x \approx 0.10$; error is 50%, so assumption is *not* justified. Solve equation:
$4x^2 + 0.209x - 0.042 = 0 \qquad x = 0.080\ M$
Therefore, at equilibrium, $[I_2] = 0.12\ M$ and $[I] = 0.16\ M$.

17.10B (a) Based on the reaction table, and assuming that $0.18\ \text{atm} - x \approx 0.18\ \text{atm}$,

$$K_p = 3.4\times10^{-4} \approx \frac{x^2}{0.18} \qquad x \approx 7.8\times10^{-3}$$

Error $= 4.3\%$, so assumption is justified; therefore, at equilibrium, $P_{PCl_5} = 0.18 - x = 0.18 - (7.8\times10^{-3}) = 0.17$ atm.
(b) Based on the reaction table, and assuming that $0.025\ \text{atm} - x \approx 0.025\ \text{atm}$,

$$K_p = 3.4\times10^{-4} \approx \frac{x^2}{0.025} \qquad x \approx 2.9\times10^{-3}$$

Error $= 12\%$, so assumption is *not* justified. Solving the quadratic equation:
$x^2 + 3.4\times10^{-4}x - 8.5\times10^{-6} \qquad x = 0.0028$
Therefore, at equilibrium, $P_{PCl_5} = 0.022$ atm.

17.11A (a) $$Q_c = \frac{(0.0900)(0.0900)}{0.2100} = 3.86\times10^{-2}$$

$Q_c < K_c$, so reaction proceeds to the right.
(b) From the reaction table,
$[PCl_5] = 0.2100\ M - x = 0.2065\ M \qquad \text{so} \qquad x = 0.0035\ M$
Thus, $[Cl_2] = [PCl_3] = 0.0900\ M + x = 0.0935\ M$.

17.11B $$Q_p = \frac{(0.750)^2}{(0.500)(0.500)} = 2.25$$

$Q_p > K_p$, so reaction proceeds to the left.

From the reaction table, $P_{N_2} = P_{O_2} = 0.500 + x$; $P_{NO} = 0.750 - 2x$.

Thus, $$K_p = 8.44\times10^{-3} = \frac{(0.750 - 2x)^2}{(0.500 + x)^2}$$

Taking the square root of both sides and solving gives $x = 0.337$, so
$P_{N_2} = P_{O_2} = 0.500 + 0.337 = 0.837$ atm
$P_{NO} = 0.750 - 2(0.337) = 0.076$ atm

17.12A (a) $[SiF_4]$ increases; (b) decreases; (c) decreases; (d) no effect.

17.12B (a) [CO] does not change; (b) decreases; (c) increases; (d) increases.

17.13A (a) Decrease P; (b) increase P; (c) increase P.

17.13B (a) More CO and H_2; (b) no change; (c) less S and H_2O.

17.14A (a) P_{H_2} will decrease; K will increase; (b) P_{N_2} will increase; K will decrease; (c) P_{PCl_5} will increase; K will increase.

17.14B (a) Increase T, and K increases; (b) decrease T, and K increases; (c) increase T, and K increases.

17.15A (a) Since $P = \frac{n}{V}RT$ and, in this case, V, R, and T cancel,

$$K_p = \frac{n_{CD}^2}{n_{C_2}\times n_{D_2}} = \frac{16}{(2)(2)} = 4$$

(b) Scene 2, to the left; scene 3, to the right. (c) There are 2 mol of gas on each side of the balanced equation, so increasing T has no effect on total moles of gas.

17.15B (a) $$K = \frac{[AB]}{[A][B]} = \frac{3}{2\times2} = 0.75$$

(b) $\Delta H > 0$

(c) $$K = \frac{2}{3\times3} = 0.22$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

The Equilibrium State and the Equilibrium Constant

Concept Review Questions

17.1 A change in reaction conditions increases the rate of a certain forward reaction more than that of the reverse reaction. What is the effect on the equilibrium constant and on the concentrations of reactants and products at equilibrium?

17.2 When a chemical company employs a new reaction to manufacture a product, the chemists consider its rate (kinetics) and yield (equilibrium). How do each of these affect the usefulness of a manufacturing process?

17.3 If there is no change in concentrations, why is the equilibrium state considered dynamic?

17.4 Is K very large or very small for a reaction that goes essentially to completion? Explain.

17.5 White phosphorus, P_4, is produced by the reduction of phosphate rock, $Ca_3(PO_4)_2$. If exposed to oxygen, the waxy, white solid smokes, bursts into flames, and releases a large quantity of heat:

$$P_4(g) + 5O_2(g) \rightleftharpoons P_4O_{10}(s) + \textit{heat}$$

Does this reaction have a large or small equilibrium constant? Explain.

The Reaction Quotient and the Equilibrium Constant

(Sample Problems 17.1 to 17.3)

Concept Review Questions

17.6 For a given reaction at a given temperature, the value of K is constant. Is the value of Q also constant? Explain.

17.7 In a study of the thermal decomposition of lithium peroxide,

$$2Li_2O_2(s) \rightleftharpoons 2Li_2O(s) + O_2(g)$$

a chemist finds that, as long as some Li_2O_2 is present at the end of the experiment, the amount of O_2 obtained in a given container at a given T is the same. Explain.

17.8 In a study of the formation of HI from its elements,

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

equal amounts of H_2 and I_2 were placed in a container, which was then sealed and heated.
(a) On one set of axes, sketch concentration vs. time curves for H_2 and HI, and explain how Q changes as a function of time.
(b) Is the value of Q different if $[I_2]$ is plotted instead of $[H_2]$?

17.9 Explain the difference between a heterogeneous and a homogeneous equilibrium. Give an example of each.

17.10 Does Q for the formation of 1 mol of NO from its elements differ from Q for the decomposition of 1 mol of NO to its elements? Explain and give the relationship between the two Q's.

17.11 Does Q for the formation of 1 mol of NH_3 from H_2 and N_2 differ from Q for the formation of NH_3 from H_2 and 1 mol of N_2? Explain and give the relationship between the two Q's.

Skill-Building Exercises (grouped in similar pairs)

17.12 Balance each reaction and write its reaction quotient, Q_c:
(a) $NO(g) + O_2(g) \rightleftharpoons N_2O_3(g)$
(b) $SF_6(g) + SO_3(g) \rightleftharpoons SO_2F_2(g)$
(c) $SClF_5(g) + H_2(g) \rightleftharpoons S_2F_{10}(g) + HCl(g)$

17.13 Balance each reaction and write its reaction quotient, Q_c:
(a) $C_2H_6(g) + O_2(g) \rightleftharpoons CO_2(g) + H_2O(g)$
(b) $CH_4(g) + F_2(g) \rightleftharpoons CF_4(g) + HF(g)$
(c) $SO_3(g) \rightleftharpoons SO_2(g) + O_2(g)$

17.14 Balance each reaction and write its reaction quotient, Q_c:
(a) $NO_2Cl(g) \rightleftharpoons NO_2(g) + Cl_2(g)$
(b) $POCl_3(g) \rightleftharpoons PCl_3(g) + O_2(g)$
(c) $NH_3(g) + O_2(g) \rightleftharpoons N_2(g) + H_2O(g)$

17.15 Balance each reaction and write its reaction quotient, Q_c:
(a) $O_2(g) \rightleftharpoons O_3(g)$
(b) $NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g)$
(c) $N_2O(g) + H_2(g) \rightleftharpoons NH_3(g) + H_2O(g)$

17.16 At a particular temperature, $K_c = 1.6\times10^{-2}$ for

$$2H_2S(g) \rightleftharpoons 2H_2(g) + S_2(g)$$

Calculate K_c for each of the following reactions:
(a) $\frac{1}{2}S_2(g) + H_2(g) \rightleftharpoons H_2S(g)$
(b) $5H_2S(g) \rightleftharpoons 5H_2(g) + \frac{5}{2}S_2(g)$

17.17 At a particular temperature, $K_c = 6.5\times10^{2}$ for

$$2NO(g) + 2H_2(g) \rightleftharpoons N_2(g) + 2H_2O(g)$$

Calculate K_c for each of the following reactions:
(a) $NO(g) + H_2(g) \rightleftharpoons \frac{1}{2}N_2(g) + H_2O(g)$
(b) $2N_2(g) + 4H_2O(g) \rightleftharpoons 4NO(g) + 4H_2(g)$

17.18 Balance each of the following examples of heterogeneous equilibria and write each reaction quotient, Q_c:
(a) $Na_2O_2(s) + CO_2(g) \rightleftharpoons Na_2CO_3(s) + O_2(g)$
(b) $H_2O(l) \rightleftharpoons H_2O(g)$
(c) $NH_4Cl(s) \rightleftharpoons NH_3(g) + HCl(g)$

17.19 Balance each of the following examples of heterogeneous equilibria and write each reaction quotient, Q_c:
(a) $H_2O(l) + SO_3(g) \rightleftharpoons H_2SO_4(aq)$
(b) $KNO_3(s) \rightleftharpoons KNO_2(s) + O_2(g)$
(c) $S_8(s) + F_2(g) \rightleftharpoons SF_6(g)$

17.20 Balance each of the following examples of heterogeneous equilibria and write each reaction quotient, Q_c:
(a) $NaHCO_3(s) \rightleftharpoons Na_2CO_3(s) + CO_2(g) + H_2O(g)$
(b) $SnO_2(s) + H_2(g) \rightleftharpoons Sn(s) + H_2O(g)$
(c) $H_2SO_4(l) + SO_3(g) \rightleftharpoons H_2S_2O_7(l)$

17.21 Balance each of the following examples of heterogeneous equilibria and write each reaction quotient, Q_c:
(a) $Al(s) + NaOH(aq) + H_2O(l) \rightleftharpoons Na[Al(OH)_4](aq) + H_2(g)$
(b) $CO_2(s) \rightleftharpoons CO_2(g)$
(c) $N_2O_5(s) \rightleftharpoons NO_2(g) + O_2(g)$

Problems in Context

17.22 Write Q_c for each of the following:
(a) Hydrogen chloride gas reacts with oxygen gas to produce chlorine gas and water vapor.
(b) Solid diarsenic trioxide reacts with fluorine gas to produce liquid arsenic pentafluoride and oxygen gas.
(c) Gaseous sulfur tetrafluoride reacts with liquid water to produce gaseous sulfur dioxide and hydrogen fluoride gas.
(d) Solid molybdenum(VI) oxide reacts with gaseous xenon difluoride to form liquid molybdenum(VI) fluoride, xenon gas, and oxygen gas.

17.23 The interhalogen ClF_3 is prepared in a two-step fluorination of chlorine gas:

$$Cl_2(g) + F_2(g) \rightleftharpoons ClF(g)$$
$$ClF(g) + F_2(g) \rightleftharpoons ClF_3(g)$$

(a) Balance each step and write the overall equation.
(b) Show that the overall Q_c equals the product of the Q_c's for the individual steps.

Expressing Equilibria with Pressure Terms: Relation Between K_c and K_p

(Sample Problem 17.4)

Concept Review Questions

17.24 Guldberg and Waage proposed the definition of the equilibrium constant as a certain ratio of *concentrations*. What relationship allows us to use a particular ratio of *partial pressures* (for a gaseous reaction) to express an equilibrium constant? Explain.

17.25 When are K_c and K_p equal, and when are they not?

17.26 A certain reaction at equilibrium has more moles of gaseous products than of gaseous reactants.
(a) Is K_c larger or smaller than K_p?
(b) Write a statement about the relative sizes of K_c and K_p for any gaseous equilibrium.

Skill-Building Exercises (grouped in similar pairs)

17.27 Determine Δn_{gas} for each of the following reactions:
(a) $2KClO_3(s) \rightleftharpoons 2KCl(s) + 3O_2(g)$
(b) $2PbO(s) + O_2(g) \rightleftharpoons 2PbO_2(s)$
(c) $I_2(s) + 3XeF_2(s) \rightleftharpoons 2IF_3(s) + 3Xe(g)$

17.28 Determine Δn_{gas} for each of the following reactions:
(a) $MgCO_3(s) \rightleftharpoons MgO(s) + CO_2(g)$
(b) $2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(l)$
(c) $HNO_3(l) + ClF(g) \rightleftharpoons ClONO_2(g) + HF(g)$

17.29 Calculate K_c for each of the following equilibria:
(a) $CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$; $K_p = 3.9\times10^{-2}$ at 1000. K
(b) $S_2(g) + C(s) \rightleftharpoons CS_2(g)$; $K_p = 28.5$ at 500. K

17.30 Calculate K_c for each of the following equilibria:
(a) $H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$; $K_p = 49$ at 730. K
(b) $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$; $K_p = 2.5\times10^{10}$ at 500. K

17.31 Calculate K_p for each of the following equilibria:
(a) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$; $K_c = 6.1\times10^{-3}$ at 298 K
(b) $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$; $K_c = 2.4\times10^{-3}$ at 1000. K

17.32 Calculate K_p for each of the following equilibria:
(a) $H_2(g) + CO_2(g) \rightleftharpoons H_2O(g) + CO(g)$; $K_c = 0.77$ at 1020. K
(b) $3O_2(g) \rightleftharpoons 2O_3(g)$; $K_c = 1.8\times10^{-56}$ at 570. K

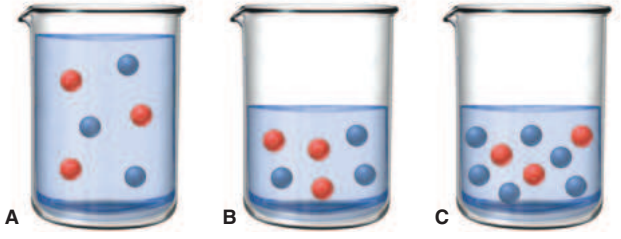
Comparing *Q* and *K* to Determine Reaction Direction

(Sample Problems 17.5 and 17.6)

Concept Review Questions

17.33 When the numerical value of Q is less than K, in which direction does the reaction proceed to reach equilibrium? Explain.

17.34 The following molecular scenes depict the aqueous reaction 2D $\rightleftharpoons$ E, with D *red* and E *blue*. Each sphere represents 0.0100 mol, but the volume is 1.00 L in scene A, whereas in scenes B and C, it is 0.500 L.



(a) If the reaction in scene A is at equilibrium, calculate K_c.
(b) Are the reactions in scenes B and C at equilibrium? Which, if either, is not, and in which direction will it proceed?

Skill-Building Exercises (grouped in similar pairs)

17.35 At 425°C, $K_p = 4.18\times10^{-9}$ for the reaction

$$2HBr(g) \rightleftharpoons H_2(g) + Br_2(g)$$

In one experiment, 0.20 atm of HBr(*g*), 0.010 atm of $H_2(g)$, and 0.010 atm of $Br_2(g)$ are introduced into a container. Is the reaction at equilibrium? If not, in which direction will it proceed?

17.36 At 100°C, $K_p = 60.6$ for the reaction

$$2NOBr(g) \rightleftharpoons 2NO(g) + Br_2(g)$$

In a given experiment, 0.10 atm of each component is placed in a container. Is the system at equilibrium? If not, in which direction will the reaction proceed?

Problems in Context

17.37 The water-gas shift reaction plays a central role in the chemical methods for obtaining cleaner fuels from coal:

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g)$$

At a given temperature, $K_p = 2.7$. If 0.13 mol of CO, 0.56 mol of H_2O, 0.62 mol of CO_2, and 0.43 mol of H_2 are put in a 2.0-L flask, in which direction does the reaction proceed?

How to Solve Equilibrium Problems

(Sample Problems 17.7 to 17.11)

Concept Review Questions

17.38 In the 1980s, CFC-11 was one of the most heavily produced chlorofluorocarbons. The last step in its formation is

$$CCl_4(g) + HF(g) \rightleftharpoons CFCl_3(g) + HCl(g)$$

If you start the reaction with equal concentrations of CCl_4 and HF, you obtain equal concentrations of $CFCl_3$ and HCl at equilibrium. Are the final concentrations of $CFCl_3$ and HCl equal if you start with unequal concentrations of CCl_4 and HF? Explain.

17.39 For a problem involving the catalyzed reaction of methane and steam, the following reaction table was prepared:

Pressure (atm)	$CH_4(g)$	+	$2H_2O(g)$	$\rightleftharpoons$	$CO_2(g)$	+	$4H_2(g)$
Initial	0.30		0.40		0		0
Change	$-x$		$-2x$		$+x$		$+4x$
Equilibrium	$0.30 - x$		$0.40 - 2x$		x		$4x$

Explain the entries in the "Change" and "Equilibrium" rows.

17.40 (a) What is the basis of the approximation that avoids using the quadratic formula to find an equilibrium concentration?
(b) When should this approximation *not* be made?

Skill-Building Exercises (grouped in similar pairs)

17.41 In an experiment to study the formation of HI(*g*),

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

$H_2(g)$ and $I_2(g)$ were placed in a sealed container at a certain temperature. At equilibrium, $[H_2] = 6.50\times10^{-5}$ *M*, $[I_2] = 1.06\times10^{-3}$ *M*, and $[HI] = 1.87\times10^{-3}$ *M*. Calculate K_c for the reaction at this temperature.

17.42 Gaseous ammonia was introduced into a sealed container and heated to a certain temperature:

$$2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$$

At equilibrium, $[NH_3] = 0.0225$ *M*, $[N_2] = 0.114$ *M*, and $[H_2] = 0.342$ *M*. Calculate K_c for the reaction at this temperature.

17.43 Gaseous PCl_5 decomposes according to the reaction

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

In one experiment, 0.15 mol of $PCl_5(g)$ was introduced into a 2.0-L container. Construct the reaction table for this process.

17.44 Hydrogen fluoride, HF, can be made from the reaction

$$H_2(g) + F_2(g) \rightleftharpoons 2HF(g)$$

In one experiment, 0.10 mol of $H_2(g)$ and 0.050 mol of $F_2(g)$ are added to a 0.50-L flask. Write a reaction table for this process.

17.45 For the following reaction, $K_p = 6.5\times10^4$ at 308 K:

$$2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$$

At equilibrium, $P_{NO} = 0.35$ atm and $P_{Cl_2} = 0.10$ atm. What is the equilibrium partial pressure of NOCl(*g*)?

17.46 For the following reaction, $K_p = 0.262$ at 1000°C:

$$C(s) + 2H_2(g) \rightleftharpoons CH_4(g)$$

At equilibrium, P_{H_2} is 1.22 atm. What is the equilibrium partial pressure of $CH_4(g)$?

17.47 Ammonium hydrogen sulfide decomposes according to the following reaction, for which $K_p = 0.11$ at 250°C:

$$NH_4HS(s) \rightleftharpoons H_2S(g) + NH_3(g)$$

If 55.0 g of $NH_4HS(s)$ is placed in a sealed 5.0-L container, what is the partial pressure of $NH_3(g)$ at equilibrium?

17.48 Hydrogen sulfide decomposes according to the following reaction, for which $K_c = 9.30\times10^{-8}$ at 700°C:

$$2H_2S(g) \rightleftharpoons 2H_2(g) + S_2(g)$$

If 0.45 mol of H_2S is placed in a 3.0-L container, what is the equilibrium concentration of $H_2(g)$ at 700°C?

17.49 Even at high T, the formation of NO is not favored:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) \quad K_c = 4.10\times10^{-4} \text{ at } 2000°C$$

What is [NO] when a mixture of 0.20 mol of $N_2(g)$ and 0.15 mol of $O_2(g)$ reach equilibrium in a 1.0-L container at 2000°C?

17.50 Nitrogen dioxide decomposes according to the reaction

$$2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$$

where $K_p = 4.48\times10^{-13}$ at a certain temperature. If 0.75 atm of NO_2 is added to a container and allowed to come to equilibrium, what are the equilibrium partial pressures of $NO(g)$ and $O_2(g)$?

17.51 Hydrogen iodide decomposes according to the reaction

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

A sealed 1.50-L container initially holds 0.00623 mol of H_2, 0.00414 mol of I_2, and 0.0244 mol of HI at 703 K. When equilibrium is reached, the concentration of $H_2(g)$ is 0.00467 M. What are the concentrations of $HI(g)$ and $I_2(g)$?

17.52 Compound A decomposes according to the equation

$$A(g) \rightleftharpoons 2B(g) + C(g)$$

A sealed 1.00-L container initially contains 1.75×10^{-3} mol of $A(g)$, 1.25×10^{-3} mol of $B(g)$, and 6.50×10^{-4} mol of $C(g)$ at 100°C. At equilibrium, [A] is 2.15×10^{-3} M. Find [B] and [C].

Problems in Context

17.53 In an analysis of interhalogen reactivity, 0.500 mol of ICl was placed in a 5.00-L flask, where it decomposed at a high T: $2ICl(g) \rightleftharpoons I_2(g) + Cl_2(g)$. Calculate the equilibrium concentrations of I_2, Cl_2, and ICl ($K_c = 0.110$ at this temperature).

17.54 A toxicologist studying mustard gas, $S(CH_2CH_2Cl)_2$, a blistering agent, prepares a mixture of 0.675 M SCl_2 and 0.973 M C_2H_4 and allows it to react at room temperature (20.0°C):

$$SCl_2(g) + 2C_2H_4(g) \rightleftharpoons S(CH_2CH_2Cl)_2(g)$$

At equilibrium, $[S(CH_2CH_2Cl)_2] = 0.350$ M. Calculate K_p.

17.55 The first step in HNO_3 production is the catalyzed oxidation of NH_3. Without a catalyst, a different reaction predominates:

$$4NH_3(g) + 3O_2(g) \rightleftharpoons 2N_2(g) + 6H_2O(g)$$

When 0.0150 mol of $NH_3(g)$ and 0.0150 mol of $O_2(g)$ are placed in a 1.00-L container at a certain temperature, the N_2 concentration at equilibrium is 1.96×10^{-3} M. Calculate K_c.

17.56 A key step in the extraction of iron from its ore is

$$FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g) \quad K_p = 0.403 \text{ at } 1000°C$$

This step occurs in the 700°C to 1200°C zone within a blast furnace. What are the equilibrium partial pressures of $CO(g)$ and $CO_2(g)$ when 1.00 atm of $CO(g)$ and excess $FeO(s)$ react in a sealed container at 1000°C?

Reaction Conditions and Equilibrium: Le Châtelier's Principle

(Sample Problems 17.12 to 17.15)

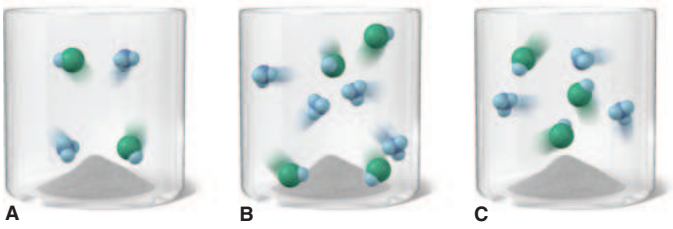
Concept Review Questions

17.57 What does "disturbance" mean in Le Châtelier's principle?

17.58 What is the difference between the equilibrium position and the equilibrium constant of a reaction? Which changes as a result of a change in reactant concentration?

17.59 Scenes A, B, and C below depict the following reaction at three temperatures:

$$NH_4Cl(s) \rightleftharpoons NH_3(g) + HCl(g) \qquad \Delta H°_{rxn} = 176 \text{ kJ}$$

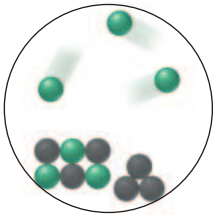


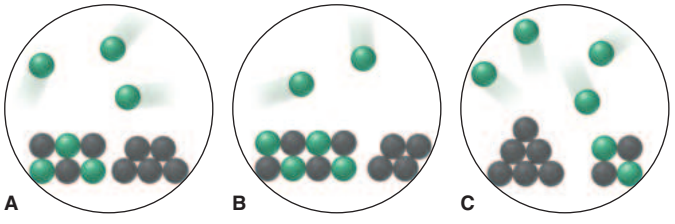
(a) Which best represents the reaction mixture at the highest temperature? Explain. (b) Which best represents the reaction mixture at the lowest temperature? Explain.

17.60 What is implied by the word "constant" in the term *equilibrium constant?* Give two reaction parameters that can be changed without changing the value of an equilibrium constant.

17.61 Le Châtelier's principle is related ultimately to the rates of the forward and reverse steps in a reaction. Explain (a) why an increase in reactant concentration shifts the equilibrium position to the right but does not change K; (b) why a decrease in V shifts the equilibrium position toward fewer moles of gas but does not change K; (c) why a rise in T shifts the equilibrium position of an exothermic reaction toward reactants and also changes K; and (d) why a rise in temperature of an endothermic reaction from T_1 to T_2 results in K_2 being larger than K_1.

17.62 An equilibrium mixture of two solids and a gas, in the reaction $XY(s) \rightleftharpoons X(g) + Y(s)$, is depicted at right (X is *green* and Y is *black*). Does scene A, B, or C best represent the system at equilibrium after two formula units of $Y(s)$ is added? Explain.





Skill-Building Exercises (grouped in similar pairs)

17.63 Consider this equilibrium system:

$$CO(g) + Fe_3O_4(s) \rightleftharpoons CO_2(g) + 3FeO(s)$$

How does the equilibrium position shift as a result of each of the following disturbances? (a) CO is added. (b) CO_2 is removed by adding solid NaOH. (c) Additional $Fe_3O_4(s)$ is added to the system. (d) Dry ice is added at constant temperature.

17.64 Sodium bicarbonate undergoes thermal decomposition according to the reaction

$$2NaHCO_3(s) \rightleftharpoons Na_2CO_3(s) + CO_2(g) + H_2O(g)$$

How does the equilibrium position shift as a result of each of the following disturbances? (a) 0.20 atm of argon gas is added. (b) $NaHCO_3(s)$ is added. (c) $Mg(ClO_4)_2(s)$ is added as a drying agent to remove H_2O. (d) Dry ice is added at constant T.

17.65 Predict the effect of *increasing* the container volume on the amounts of each reactant and product in the following reactions:
(a) $F_2(g) \rightleftharpoons 2F(g)$
(b) $2CH_4(g) \rightleftharpoons C_2H_2(g) + 3H_2(g)$

17.66 Predict the effect of *increasing* the container volume on the amounts of each reactant and product in the following reactions:
(a) $CH_3OH(l) \rightleftharpoons CH_3OH(g)$
(b) $CH_4(g) + NH_3(g) \rightleftharpoons HCN(g) + 3H_2(g)$

17.67 Predict the effect of *decreasing* the container volume on the amounts of each reactant and product in the following reactions:
(a) $H_2(g) + Cl_2(g) \rightleftharpoons 2HCl(g)$
(b) $2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(l)$

17.68 Predict the effect of *decreasing* the container volume on the amounts of each reactant and product in the following reactions:
(a) $C_3H_8(g) + 5O_2(g) \rightleftharpoons 3CO_2(g) + 4H_2O(l)$
(b) $4NH_3(g) + 3O_2(g) \rightleftharpoons 2N_2(g) + 6H_2O(g)$

17.69 How would you adjust the *volume* of the container in order to maximize product yield in each of the following reactions?
(a) $Fe_3O_4(s) + 4H_2(g) \rightleftharpoons 3Fe(s) + 4H_2O(g)$
(b) $2C(s) + O_2(g) \rightleftharpoons 2CO(g)$

17.70 How would you adjust the *volume* of the container in order to maximize product yield in each of the following reactions?
(a) $Na_2O_2(s) \rightleftharpoons 2Na(l) + O_2(g)$
(b) $C_2H_2(g) + 2H_2(g) \rightleftharpoons C_2H_6(g)$

17.71 Predict the effect of *increasing* the temperature on the amounts of products in the following reactions:
(a) $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g) \quad \Delta H^\circ_{rxn} = -90.7$ kJ
(b) $C(s) + H_2O(g) \rightleftharpoons CO(g) + H_2(g) \quad \Delta H^\circ_{rxn} = 131$ kJ
(c) $2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$ (endothermic)
(d) $2C(s) + O_2(g) \rightleftharpoons 2CO(g)$ (exothermic)

17.72 Predict the effect of *decreasing* the temperature on the amounts of reactants in the following reactions:
(a) $C_2H_2(g) + H_2O(g) \rightleftharpoons CH_3CHO(g) \quad \Delta H^\circ_{rxn} = -151$ kJ
(b) $CH_3CH_2OH(l) + O_2(g) \rightleftharpoons CH_3CO_2H(l) + H_2O(g)$
$\Delta H^\circ_{rxn} = -451$ kJ
(c) $2C_2H_4(g) + O_2(g) \rightleftharpoons 2CH_3CHO(g)$ (exothermic)
(d) $N_2O_4(g) \rightleftharpoons 2NO_2(g)$ (endothermic)

17.73 The molecule D_2 (where D, deuterium, is ^2H) undergoes a reaction with ordinary H_2 that leads to isotopic equilibrium:

$$D_2(g) + H_2(g) \rightleftharpoons 2DH(g) \qquad K_p = 1.80 \text{ at } 298 \text{ K}$$

If ΔH°_{rxn} is 0.32 kJ/mol DH, calculate K_p at 500. K.

17.74 The formation of methanol is important to the processing of new fuels. At 298 K, $K_p = 2.25\times10^4$ for the reaction

$$CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(l)$$

If $\Delta H^\circ_{rxn} = -128$ kJ/mol CH_3OH, calculate K_p at 0°C.

Problems in Context

17.75 The minerals hematite (Fe_2O_3) and magnetite (Fe_3O_4) exist in equilibrium with atmospheric oxygen:

$$4Fe_3O_4(s) + O_2(g) \rightleftharpoons 6Fe_2O_3(s) \qquad K_p = 2.5\times10^{87} \text{ at } 298 \text{ K}$$

(a) Determine P_{O_2} at equilibrium. (b) Given that P_{O_2} in air is 0.21 atm, in which direction will the reaction proceed to reach equilibrium? (c) Calculate K_c at 298 K.

17.76 The oxidation of SO_2 is the key step in H_2SO_4 production:

$$SO_2(g) + \tfrac{1}{2}O_2(g) \rightleftharpoons SO_3(g) \qquad \Delta H^\circ_{rxn} = -99.2 \text{ kJ}$$

(a) What qualitative combination of T and P maximizes SO_3 yield?
(b) How does addition of O_2 affect Q? K?
(c) Why is catalysis used for this reaction?

17.77 A mixture of 3.00 volumes of H_2 and 1.00 volume of N_2 reacts at 344°C to form ammonia. The equilibrium mixture at 110. atm contains 41.49% NH_3 by volume. Calculate K_p for the reaction, assuming that the gases behave ideally.

17.78 You are a member of a research team of chemists discussing plans for a plant to produce ammonia:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

(a) The plant will operate at close to 700 K, at which K_p is 1.00×10^{-4}, and employs the stoichiometric 1/3 ratio of N_2/H_2. At equilibrium, the partial pressure of NH_3 is 50. atm. Calculate the partial pressures of each reactant and P_{total}.
(b) One member of the team suggests the following: since the partial pressure of H_2 is cubed in the reaction quotient, the plant could produce the same amount of NH_3 if the reactants were in a 1/6 ratio of N_2/H_2 and could do so at a lower pressure, which would cut operating costs. Calculate the partial pressure of each reactant and P_{total} under these conditions, assuming an unchanged partial pressure of 50. atm for NH_3. Is the suggestion valid?

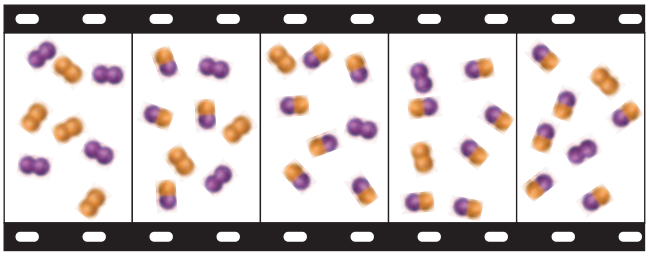
Comprehensive Problems

17.79 For the following equilibrium system, which of the changes will form more $CaCO_3$?

$$CO_2(g) + Ca(OH)_2(s) \rightleftharpoons CaCO_3(s) + H_2O(l) \qquad \Delta H^\circ = -113 \text{ kJ}$$

(a) Decrease temperature at constant pressure (no phase change)
(b) Increase volume at constant temperature
(c) Increase partial pressure of CO_2
(d) Remove one-half of the initial $CaCO_3$

17.80 The "filmstrip" represents five molecular scenes of a gaseous mixture as it reaches equilibrium over time:



X is *purple* and Y is *orange:* $X_2(g) + Y_2(g) \rightleftharpoons 2XY(g)$.
(a) Write the reaction quotient, Q, for this reaction.
(b) If each particle represents 0.1 mol, find Q for each scene.
(c) If $K > 1$, is time progressing to the right or to the left? Explain.
(d) Calculate K at this temperature.
(e) If $\Delta H^\circ_{rxn} < 0$, which scene, if any, best represents the mixture at a higher temperature? Explain.
(f) Which scene, if any, best represents the mixture at a higher pressure (lower volume)? Explain.

17.81 Ammonium carbamate (NH_2COONH_4) is a salt of carbamic acid that is found in the blood and urine of mammals. At 250.°C, $K_c = 1.58\times10^{-8}$ for the following equilibrium:

$$NH_2COONH_4(s) \rightleftharpoons 2NH_3(g) + CO_2(g)$$

If 7.80 g of NH_2COONH_4 is put into a 0.500-L evacuated container, what is the total pressure at equilibrium?

17.82 Isolation of Group 8B(10) elements, used as industrial catalysts, involves a series of steps. For nickel, the sulfide ore is roasted in air: $Ni_3S_2(s) + O_2(g) \rightleftharpoons NiO(s) + SO_2(g)$. The metal oxide is reduced by the H_2 in water gas ($CO + H_2$) to impure Ni: $NiO(s) + H_2(g) \rightleftharpoons Ni(s) + H_2O(g)$. The CO in water gas then reacts with the metal in the Mond process to form gaseous nickel carbonyl, $Ni(s) + CO(g) \rightleftharpoons Ni(CO)_4(g)$, which is subsequently decomposed to the metal. (a) Balance each of the three steps, and obtain an overall balanced equation for the conversion of Ni_3S_2 to $Ni(CO)_4$. (b) Show that the overall Q_c is the product of the Q_c's for the individual reactions.

17.83 Consider the formation of ammonia in two experiments.
(a) To a 1.00-L container at 727°C, 1.30 mol of N_2 and 1.65 mol of H_2 are added. At equilibrium, 0.100 mol of NH_3 is present. Calculate the equilibrium concentrations of N_2 and H_2, and find K_c for the reaction: $2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$.
(b) In a different 1.00-L container at the same temperature, equilibrium is established with 8.34×10^{-2} mol of NH_3, 1.50 mol of N_2, and 1.25 mol of H_2 present. Calculate K_c for the reaction:

$$NH_3(g) \rightleftharpoons \tfrac{1}{2}N_2(g) + \tfrac{3}{2}H_2(g)$$

(c) What is the relationship between the K_c values in parts (a) and (b)? Why aren't these values the same?

17.84 An important industrial source of ethanol is the reaction, catalyzed by H_3PO_4, of steam with ethylene derived from oil:

$$C_2H_4(g) + H_2O(g) \rightleftharpoons C_2H_5OH(g)$$
$$\Delta H^\circ_{rxn} = -47.8\text{ kJ} \qquad K_c = 9\times10^3 \text{ at } 600.\text{ K}$$

(a) At equilibrium, $P_{C_2H_5OH} = 200.$ atm and $P_{H_2O} = 400.$ atm. Calculate $P_{C_2H_4}$. (b) Is the highest yield of ethanol obtained at high or low P? High or low T? (c) Calculate K_c at 450. K. (d) In NH_3 manufacture, the yield is increased by condensing the NH_3 to a liquid and removing it. Would condensing the C_2H_5OH have the same effect in ethanol production? Explain.

17.85 An industrial chemist introduces 2.0 atm of H_2 and 2.0 atm of CO_2 into a 1.00-L container at 25.0°C and then raises the temperature to 700.°C, at which $K_c = 0.534$:

$$H_2(g) + CO_2(g) \rightleftharpoons H_2O(g) + CO(g)$$

How many grams of H_2 are present at equilibrium?

17.86 As an EPA scientist studying catalytic converters and urban smog, you want to find K_c for the following reaction:

$$2NO_2(g) \rightleftharpoons N_2(g) + 2O_2(g) \qquad K_c = ?$$

Use the following data to find the unknown K_c:

$$\tfrac{1}{2}N_2(g) + \tfrac{1}{2}O_2(g) \rightleftharpoons NO(g) \qquad K_c = 4.8\times10^{-10}$$
$$2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g) \qquad K_c = 1.1\times10^{-5}$$

17.87 An engineer examining the oxidation of SO_2 in the manufacture of sulfuric acid determines that $K_c = 1.7\times10^8$ at 600. K:

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

(a) At equilibrium, $P_{SO_3} = 300.$ atm and $P_{O_2} = 100.$ atm. Calculate P_{SO_2}. (b) The engineer places a mixture of 0.0040 mol of $SO_2(g)$ and 0.0028 mol of $O_2(g)$ in a 1.0-L container and raises the temperature to 1000 K. At equilibrium, 0.0020 mol of $SO_3(g)$ is present. Calculate K_c and P_{SO_2} for this reaction at 1000. K.

17.88 Phosgene ($COCl_2$) is a toxic substance that forms readily from carbon monoxide and chlorine at elevated temperatures:

$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

If 0.350 mol of each reactant is placed in a 0.500-L flask at 600 K, what are the concentrations of all three substances at equilibrium ($K_c = 4.95$ at this temperature)?

17.89 When 0.100 mol of $CaCO_3(s)$ and 0.100 mol of $CaO(s)$ are placed in an evacuated sealed 10.0-L container and heated to 385 K, $P_{CO_2} = 0.220$ atm after equilibrium is established:

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

An additional 0.300 atm of $CO_2(g)$ is pumped in. What is the total mass (in g) of $CaCO_3$ after equilibrium is re-established?

17.90 Use each of the following reaction quotients to write the balanced equation:

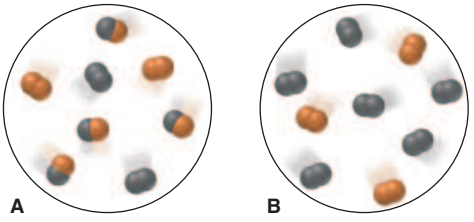
(a) $Q = \dfrac{[CO_2]^2[H_2O]^2}{[C_2H_4][O_2]^3}$ (b) $Q = \dfrac{[NH_3]^4[O_2]^7}{[NO_2]^4[H_2O]^6}$

17.91 Hydrogenation of carbon-carbon π bonds is important in the petroleum and food industries. The conversion of acetylene to ethylene is a simple example of the process:

$$C_2H_2(g) + H_2(g) \rightleftharpoons C_2H_4(g)$$

The calculated K_c at 2000. K is 2.9×10^8. But the process is run at lower temperatures with the aid of a catalyst to prevent decomposition. Use ΔH° values to calculate K_c at 300. K.

17.92 For the reaction $M_2 + N_2 \rightleftharpoons 2MN$, scene A represents the mixture at equilibrium, with M *black* and N *orange*. If each molecule represents 0.10 mol and the volume is 1.0 L, how many moles of each substance will be present in scene B when that mixture reaches equilibrium?



17.93 Highly toxic disulfur decafluoride decomposes by a free-radical process: $S_2F_{10}(g) \rightleftharpoons SF_4(g) + SF_6(g)$. In a study of the decomposition, S_2F_{10} was placed in a 2.0-L flask and heated to 100°C; $[S_2F_{10}]$ was 0.50 *M* at equilibrium. More S_2F_{10} was added, and when equilibrium was reattained, $[S_2F_{10}]$ was 2.5 *M*. How did $[SF_4]$ and $[SF_6]$ change from the original to the new equilibrium position after the addition of more S_2F_{10}?

17.94 A study of the water-gas shift reaction (see Problem 17.37) was made in which equilibrium was reached with $[CO] = [H_2O] = [H_2] = 0.10\ M$ and $[CO_2] = 0.40\ M$. After 0.60 mol of H_2 is added to the 2.0-L container and equilibrium is re-established, what are the new concentrations of all the components?

17.95 A gaseous mixture of 10.0 volumes of CO_2, 1.00 volume of unreacted O_2, and 50.0 volumes of unreacted N_2 leaves an engine at 4.0 atm and 800. K. Assuming that the mixture reaches equilibrium, what are (a) the partial pressure and (b) the concentration (in picograms per liter, pg/L) of CO in this exhaust gas?

$$2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g) \qquad K_p = 1.4\times10^{-28} \text{ at } 800.\text{ K}$$

(The actual concentration of CO in exhaust gas is much higher because the gases do *not* reach equilibrium in the short transit time through the engine and exhaust system.)

17.96 When ammonia is made industrially, the mixture of N_2, H_2, and NH_3 that emerges from the reaction chamber is far from equilibrium. Why does the plant supervisor use reaction conditions that produce less than the maximum yield of ammonia?

17.97 The following reaction can be used to make H_2 for the synthesis of ammonia from the greenhouse gases carbon dioxide and methane:

$$CH_4(g) + CO_2(g) \rightleftharpoons 2CO(g) + 2H_2(g)$$

(a) What is the percent yield of H_2 when an equimolar mixture of CH_4 and CO_2 with a total pressure of 20.0 atm reaches equilibrium at 1200. K, at which $K_p = 3.548\times10^6$?
(b) What is the percent yield of H_2 for this system at 1300. K, at which $K_p = 2.626\times10^7$?
(c) Use the van't Hoff equation to find ΔH°_{rxn}.

17.98 The methane used to obtain H_2 for NH_3 manufacture is impure and usually contains other hydrocarbons, such as propane, C_3H_8. Imagine the reaction of propane occurring in two steps:

$$C_3H_8(g) + 3H_2O(g) \rightleftharpoons 3CO(g) + 7H_2(g) \qquad K_p = 8.175\times10^{15} \text{ at 1200. K}$$

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g) \qquad K_p = 0.6944 \text{ at 1200. K}$$

(a) Write the overall equation for the reaction of propane and steam to produce carbon dioxide and hydrogen.
(b) Calculate K_p for the overall process at 1200. K.
(c) When 1.00 volume of C_3H_8 and 4.00 volumes of H_2O, each at 1200. K and 5.0 atm, are mixed in a container, what is the final pressure? Assume the total volume remains constant, that the reaction is essentially complete, and that the gases behave ideally.
(d) What percentage of the C_3H_8 remains unreacted?

17.99 Using CH_4 and steam as a source of H_2 for NH_3 synthesis requires high temperatures. Rather than burning CH_4 separately to heat the mixture, it is more efficient to inject some O_2 into the reaction mixture. All of the H_2 is thus released for the synthesis, and the heat of reaction for the combustion of CH_4 helps maintain the required temperature. Imagine the reaction occurring in two steps:

$$2CH_4(g) + O_2(g) \rightleftharpoons 2CO(g) + 4H_2(g) \qquad K_p = 9.34\times10^{28} \text{ at 1000. K}$$

$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g) \qquad K_p = 1.374 \text{ at 1000. K}$$

(a) Write the overall equation for the reaction of methane, steam, and oxygen to form carbon dioxide and hydrogen.
(b) What is K_p for the overall reaction?
(c) What is K_c for the overall reaction?
(d) A mixture of 2.0 mol of CH_4, 1.0 mol of O_2, and 2.0 mol of steam with a total pressure of 30. atm reacts at 1000. K at constant volume. Assuming that the reaction is complete and the ideal gas law is a valid approximation, what is the final pressure?

17.100 One mechanism for the synthesis of ammonia proposes that N_2 and H_2 molecules catalytically dissociate into atoms:

$$N_2(g) \rightleftharpoons 2N(g) \qquad \log K_p = -43.10$$

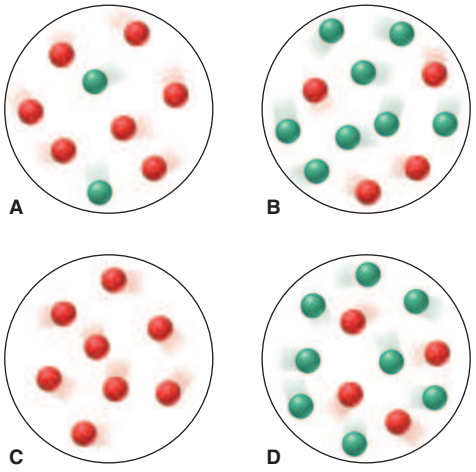
$$H_2(g) \rightleftharpoons 2H(g) \qquad \log K_p = -17.30$$

(a) Find the partial pressure of N in N_2 at 1000. K and 200. atm.
(b) Find the partial pressure of H in H_2 at 1000. K and 600. atm.
(c) How many N atoms and H atoms are present per liter?
(d) Based on these answers, which of the following is a more reasonable step to continue the mechanism after the catalytic dissociation? Explain.

$$N(g) + H(g) \longrightarrow NH(g)$$

$$N_2(g) + H(g) \longrightarrow NH(g) + N(g)$$

17.101 The molecular scenes below depict the reaction $Y \rightleftharpoons 2Z$ at four different times, out of sequence, as it reaches equilibrium. Each sphere (Y is *red* and Z is *green*) represents 0.025 mol, and the volume is 0.40 L. (a) Which scene(s) represent(s) equilibrium? (b) List the scenes in the correct sequence. (c) Calculate K_c.



17.102 For the equilibrium

$$H_2S(g) \rightleftharpoons 2H_2(g) + S_2(g) \qquad K_c = 9.0\times10^{-8} \text{ at 700°C}$$

the initial concentrations of the three gases are 0.300 *M* H_2S, 0.300 *M* H_2, and 0.150 *M* S_2. Determine the equilibrium concentrations of the gases.

17.103 The two most abundant atmospheric gases react to a tiny extent at 298 K in the presence of a catalyst:

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g) \qquad K_p = 4.35\times10^{-31}$$

(a) What are the equilibrium pressures of the three gases when the atmospheric partial pressures of O_2 (0.210 atm) and of N_2 (0.780 atm) are put into an evacuated 1.00-L flask at 298 K with the catalyst? (b) What is P_{total} in the container? (c) Find K_c at 298 K.

17.104 The oxidation of nitrogen monoxide is favored at 457 K:

$$2NO(g) + O_2(g) \rightleftharpoons 2NO_2(g) \qquad K_p = 1.3\times10^4$$

(a) Calculate K_c at 457 K. (b) Find ΔH°_{rxn} from standard heats of formation. (c) At what temperature does $K_c = 6.4\times10^9$?

17.105 The kinetics and equilibrium of the decomposition of hydrogen iodide have been studied extensively:

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

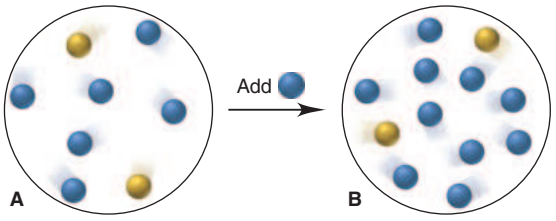
(a) At 298 K, $K_c = 1.26\times10^{-3}$ for this reaction. Calculate K_p.
(b) Calculate K_c for the *formation* of HI at 298 K.
(c) Calculate ΔH°_{rxn} for HI decomposition from ΔH°_f values.
(d) At 729 K, $K_c = 2.0\times10^{-2}$ for HI decomposition. Calculate ΔH_{rxn} for this reaction from the van't Hoff equation.

17.106 Isopentyl alcohol reacts with pure acetic acid to form isopentyl acetate, the essence of banana oil:

$$C_5H_{11}OH + CH_3COOH \rightleftharpoons CH_3COOC_5H_{11} + H_2O$$

A student adds a drying agent to remove H_2O and thus increase the yield of banana oil. Is this approach reasonable? Explain.

17.107 Isomers Q *(blue)* and R *(yellow)* interconvert. They are depicted in an equilibrium mixture in scene A. Scene B represents the mixture after addition of more Q. How many molecules of each isomer are present when the mixture in scene B attains equilibrium again?



17.108 Glauber's salt, $Na_2SO_4 \cdot 10H_2O$, was used by J. R. Glauber in the 17th century as a medicinal agent. At 25°C, $K_p = 4.08 \times 10^{-25}$ for the loss of waters of hydration from Glauber's salt:

$$Na_2SO_4 \cdot 10H_2O(s) \rightleftharpoons Na_2SO_4(s) + 10H_2O(g)$$

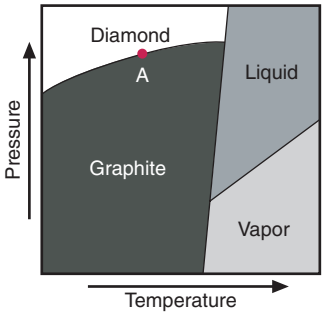
(a) What is the vapor pressure of water at 25°C in a closed container holding a sample of $Na_2SO_4 \cdot 10H_2O(s)$?

(b) How do the following changes affect the ratio (higher, lower, same) of hydrated form to anhydrous form for the system above?

(1) Add more $Na_2SO_4(s)$
(2) Reduce the container volume
(3) Add more water vapor
(4) Add N_2 gas

17.109 In a study of synthetic fuels, 0.100 mol of CO and 0.100 mol of water vapor are added to a 20.00-L container at 900.°C, and they react to form CO_2 and H_2. At equilibrium, [CO] is 2.24×10^{-3} *M*. (a) Calculate K_c at this temperature. (b) Calculate P_{total} in the flask at equilibrium. (c) How many moles of CO must be added to double this pressure? (d) After P_{total} is doubled and the system reattains equilibrium, what is $[CO]_{eq}$?

17.110 Synthetic diamonds are made under conditions of high temperature (2000 K) and high pressure (10^{10} Pa; 10^5 atm) in the presence of catalysts. Carbon's phase diagram is useful for finding the conditions for formation of natural and synthetic diamonds. Along the diamond-graphite line, the two allotropes are in equilibrium.



(a) At point A, what is the sign of ΔH for the formation of diamond from graphite? Explain. (b) Which allotrope is denser? Explain.

Concepts and Skills to Review Before You Study This Chapter

- role of water as solvent (Section 4.1)
- writing ionic equations (Section 4.2)
- acids, bases, and acid-base reactions (Section 4.4)
- proton transfer in acid-base reactions (Section 4.4)
- properties of an equilibrium constant (Section 17.2)
- solving equilibrium problems (Section 17.5)

Acids and bases played a central role in the alchemists' labs, and they remain indispensable, not only in modern academic and industrial research, but in many consumer products (Table 18.1), including delectable muffins! Baked goods require leavening, a process that produces bubbles of carbon dioxide gas in the dough resulting in a springy texture. Chemical leavening is accomplished by a reaction between an acid, such as lemon juice or vinegar, and a base, usually the sodium bicarbonate in baking soda or baking powder.

The acids in lemon juice and vinegar give these substances a sour taste. In fact, sourness was a defining property since the 17th century: an acid was any substance that had a sour taste; reacted with active metals, such as aluminum and zinc, to produce hydrogen gas; and turned certain organic compounds specific colors. (We discuss *indicators* in this chapter and Chapter 19.) Similarly, a base was any substance that had a bitter taste and slippery feel and turned the same organic compounds different colors. Moreover, it was known that *when an acid and a base react, each cancels the properties of the other in a process called neutralization.* Although these early definitions described distinctive properties, they gave way to others based on molecular behavior. As science progresses, limited definitions are replaced by broader ones that explain more phenomena.

Table 18.1 Some Common Acids and Bases and Their Household Uses

Substance	Use
Acids	
Acetic acid, CH_3COOH	Flavoring, preservative (vinegar)
Citric acid, $H_3C_6H_5O_7$	Flavoring (lemon juice)
Ascorbic acid, $H_2C_6H_6O_6$	Vitamin C; nutritional supplement
Aluminum salts, $NaAl(SO_4)_2 \cdot 12H_2O$	In baking powder, with sodium hydrogen carbonate
Bases	
Sodium hydroxide (lye), NaOH	Oven and drain cleaners
Ammonia, NH_3	Household cleaner
Sodium carbonate, Na_2CO_3	Water softener, grease remover
Sodium hydrogen carbonate, $NaHCO_3$	Fire extinguisher, rising agent in cake mixes (baking soda), mild antacid
Sodium phosphate, Na_3PO_4	Cleaner for surfaces before painting or wallpapering

IN THIS CHAPTER . . . *We develop three definitions of acids and bases that explain an expanded range of reactions, and we apply equilibrium principles to understand acid-base behavior.*

- We begin with the *Arrhenius* acid-base definition, which relies on formulas and behavior in water.
- We examine acid dissociation to see how variation in acid strength is expressed by a new equilibrium constant.
- We introduce the pH scale to measure the acidity of aqueous solutions.
- We discuss proton transfer in the *Brønsted-Lowry* acid-base definition, which expands the meaning of "base," along with the scope of acid-base reactions.
- We apply a systematic approach to solving acid-base equilibrium problems.
- We examine the molecular structures of acids to rationalize their relative strengths.

- We examine weak bases and their interdependence with weak acids.
- We determine the relative acidity of salt solutions from the reactions of the salts' cations and anions with water.
- We see that the designations "acid" and "base" depend on the substances' relative strengths *and* on the solvent.
- We discuss the *Lewis* acid-base definition, which greatly expands the meanings of "acid" and "acid-base reaction."

18.1 ACIDS AND BASES IN WATER

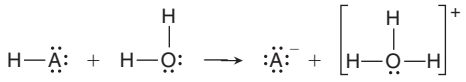
Most laboratory work with acids and bases involves water, as do most environmental, biological, and industrial applications. Recall from our discussion in Chapter 4 that *water is **the** product in all reactions between strong acids and strong bases,* which the net ionic equation for any such reaction shows:

$$\begin{aligned} HX(aq) + MOH(aq) &\longrightarrow MX(aq) + H_2O(l) && \text{[molecular]} \\ H^+(aq) + X^-(aq) + M^+(aq) + OH^-(aq) &\longrightarrow M^+(aq) + X^-(aq) + H_2O(l) && \text{[total ionic]} \\ H^+(aq) + OH^-(aq) &\longrightarrow H_2O(l) && \text{[net ionic]} \end{aligned}$$

where M^+ is a metal ion and X^- is a nonmetal ion.

Furthermore, whenever an acid dissociates in water, solvent molecules participate in the reaction:

$$HA(g \text{ or } l) + H_2O(l) \longrightarrow A^-(aq) + H_3O^+(aq)$$



Water molecules surround the proton to form H-bonded species with the general formula $H(H_2O)_n^+$. The proton's charge density is so high that it attracts water molecules especially strongly, covalently bonding to one of the lone electron pairs of a water molecule's O atom to form a **hydronium ion, H_3O^+,** which forms H bonds to several other water molecules (see Figure 4.11, p. 159). To emphasize the active role of water and the proton-water interaction, the hydrated proton is usually shown in the text as $H_3O^+(aq)$ [although, for simplicity, we sometimes show it as $H^+(aq)$].

Release of H^+ or OH^- and the Arrhenius Acid-Base Definition

The earliest definition that highlighted the molecular nature of acids and bases is the **Arrhenius acid-base definition,** which classifies these substances in terms of their formulas and behavior *in water:*

- An *acid* is a substance with H in its formula that dissociates in water to yield H_3O^+.
- A *base* is a substance with OH in its formula that dissociates in water to yield OH^-.

Some typical Arrhenius acids are HCl, HNO_3, and HCN, and some typical bases are NaOH, KOH, and $Ba(OH)_2$. Because they are ionic compounds, Arrhenius bases contain discrete OH^- ions in their structures, but Arrhenius acids *never* contain discrete H^+ ions. Instead, they contain *covalently bonded H atoms that ionize when molecules of the acid dissolve in water.*

When an acid and a base react, they undergo **neutralization.** The meaning of this term has changed, as we'll see, but in the Arrhenius sense, neutralization occurs when *the H^+ from the acid and the OH^- from the base form H_2O.* A key point about neutralization that Arrhenius was able to explain is that no matter which strong acid and strong base react, and no matter which salt results, ΔH°_{rxn} is -55.9 kJ per mole of water formed. Arrhenius suggested that the enthalpy change is always the same because the reaction is always the same—a hydrogen ion and a hydroxide ion form water:

$$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l) \qquad \Delta H^\circ_{rxn} = -55.9 \text{ kJ}$$

The dissolved salt that is present, for example, NaCl in the reaction of sodium hydroxide with hydrochloric acid,

$$Na^+(aq) + OH^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow Na^+(aq) + Cl^-(aq) + H_2O(l)$$

exists as hydrated spectator ions and does not affect ΔH°_{rxn}.

Despite its importance at the time, limitations in the Arrhenius definition soon became apparent. Arrhenius and many others realized that even though some substances do *not* have discrete OH^- ions, they still behave as bases. For example, NH_3 and K_2CO_3 also yield OH^- in water. As you'll see shortly, broader acid-base definitions are required to include species that do not have OH in their formula.

Variation in Acid Strength: The Acid-Dissociation Constant (K_a)

Acids (and bases) are classified by their *strength,* the amount of H_3O^+ (or OH^-) produced per mole of substance dissolved, in other words, by the extent of their dissociation into ions (see Table 4.2, p. 159). Because acids and bases are electrolytes, their strength correlates with electrolyte strength: *strong electrolytes dissociate completely, and weak electrolytes dissociate slightly.*

1. *Strong acids dissociate* ***completely*** *into ions in water* (Figure 18.1A):

$$HA(g \text{ or } l) + H_2O(l) \longrightarrow H_3O^+(aq) + A^-(aq)$$

In a dilute solution of a strong acid, *HA molecules are no longer present:* $[H_3O^+] = [A^-] \approx [HA]_{init}$. In other words, $[HA]_{eq} \approx 0$, so the value of K_c is extremely large:

$$Q_c = \frac{[H_3O^+][A^-]}{[HA][H_2O]} \qquad \text{(at equilibrium, } Q_c = K_c >> 1\text{)}$$

Because the reaction is essentially complete, we usually don't express it as an equilibrium process. In dilute aqueous nitric acid, for example, there are virtually no undissociated nitric acid molecules:

$$HNO_3(l) + H_2O(l) \longrightarrow H_3O^+(aq) + NO_3^-(aq)$$

2. *Weak acids dissociate* ***slightly*** *into ions in water* (Figure 18.1B):

$$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq)$$

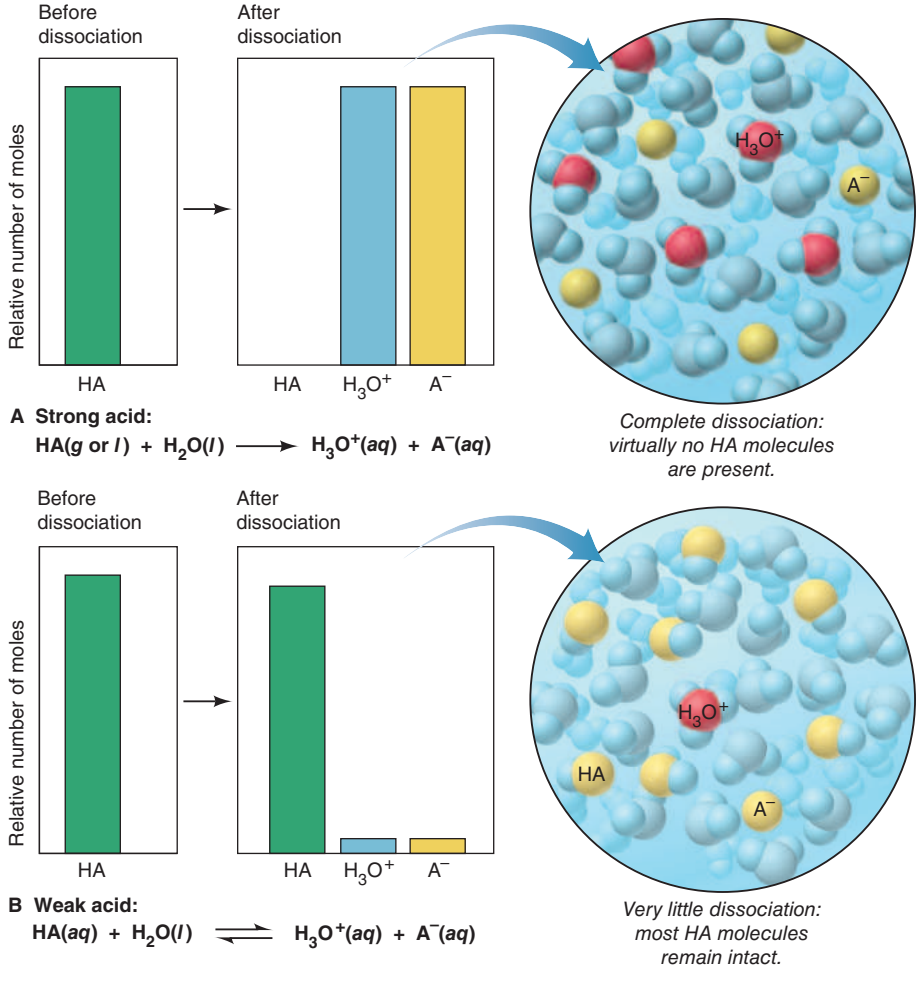


Figure 18.1 The extent of dissociation for strong acids and weak acids. The bar graphs show the relative numbers of moles of species before *(left)* and after *(right)* acid dissociation.

In a dilute solution of a weak acid, *the great majority of HA molecules are undissociated.* Thus, $[H_3O^+] = [A^-] << [HA]_{init}$, and $[HA]_{eq} \approx [HA]_{init}$, so K_c is very small. Hydrocyanic acid is an example of a weak acid:

$$HCN(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CN^-(aq)$$

$$Q_c = \frac{[H_3O^+][CN^-]}{[HCN][H_2O]} \qquad \text{(at equilibrium, } Q_c = K_c << 1\text{)}$$

(As in Chapter 17, brackets with no subscript mean molar concentration *at equilibrium;* that is, [X] means $[X]_{eq}$. In this chapter, we are dealing with systems *at equilibrium,* so instead of writing Q and stating that Q equals K at equilibrium, we'll express K directly as a collection of equilibrium concentration terms.)

The difference in $[H_3O^+]$ causes a much higher rate for the reaction of a strong acid with an active metal like zinc than for the same reaction of a weak acid (Figure 18.2):

$$Zn(s) + 2H_3O^+(aq) \longrightarrow Zn^{2+}(aq) + 2H_2O(l) + H_2(g)$$

In a strong acid, with its much higher $[H_3O^+]$, zinc reacts rapidly, forming bubbles of H_2 vigorously. In a weak acid, $[H_3O^+]$ is much lower, so zinc reacts slowly.

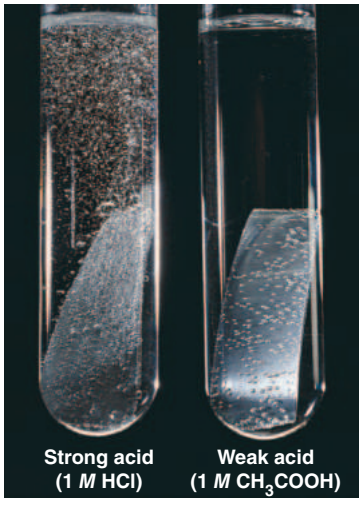

Figure 18.2 Reaction of zinc with a strong acid *(left)* and a weak acid *(right)*.

The Meaning of K_a We write a *specific* equilibrium constant for acid dissociation that only includes species whose concentrations change to any significant extent. For the dissociation of a general *weak acid,* HA,

$$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq)$$

the equilibrium expression is

$$K_c = \frac{[H_3O^+][A^-]}{[HA][H_2O]}$$

The concentration of water ($[H_2O] = \dfrac{1000\text{ g}}{18.02\text{ g/mol}} = 55.5\ M$) is typically several orders of magnitude larger than [HA]. Therefore, $[H_2O]$ is essentially constant when HA dissociates, and so it can be considered a pure liquid. As we discussed in Section 17.2, the concentration terms for pure liquids and solids are equal to 1 and do not appear in the equilibrium expression. Thus, we can define a new equilibrium constant, the **acid-dissociation constant** (or **acid-ionization constant**), K_a**:**

$$K_c(1) = K_a = \frac{[H_3O^+][A^-]}{[HA]} \qquad \textbf{(18.1)}$$

Like any equilibrium constant, K_a is a number whose magnitude is temperature dependent and tells how far to the right the reaction has proceeded to reach equilibrium. Thus, *the stronger the acid, the higher $[H_3O^+]$ is at equilibrium, and the larger the value of K_a:*

Stronger acid $\Longrightarrow$ higher $[H_3O^+]$ $\Longrightarrow$ larger K_a

The Range of K_a Values Acid-dissociation constants of weak acids range over many orders of magnitude. Some benchmark K_a values for typical weak acids give an idea of the fraction of HA molecules that dissociate into ions:

- For a weak acid with a relatively high K_a ($\sim 10^{-2}$), a 1 *M* solution has ~10% of the HA molecules dissociated. The K_a of chlorous acid ($HClO_2$) is 1.1×10^{-2}, and 1 *M* $HClO_2$ is 10.% dissociated.
- For a weak acid with a moderate K_a ($\sim 10^{-5}$), a 1 *M* solution has ~0.3% of the HA molecules dissociated. The K_a of acetic acid (CH_3COOH) is 1.8×10^{-5}, and 1 *M* CH_3COOH is 0.42% dissociated.
- For a weak acid with a relatively low K_a ($\sim 10^{-10}$), a 1 *M* solution has ~0.001% of the HA molecules dissociated. The K_a of HCN is 6.2×10^{-10}, and 1 *M* HCN is 0.0025% dissociated.

Thus, for solutions of the same initial HA concentration, *the smaller the K_a, the lower the percent dissociation of HA:*

Weaker acid $\Longrightarrow$ lower % dissociation of HA $\Longrightarrow$ smaller K_a

Table 18.2 K_a Values for Some Monoprotic Acids at 25°C

Name (Formula)*	Lewis Structure*	Dissociation Reaction	K_a
Chlorous acid ($HClO_2$)		$HClO_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + ClO_2^-(aq)$	1.1×10^{-2}
Nitrous acid (HNO_2)		$HNO_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + NO_2^-(aq)$	7.1×10^{-4}
Hydrofluoric acid (HF)		$HF(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + F^-(aq)$	6.8×10^{-4}
Formic acid (HCOOH)		$HCOOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HCOO^-(aq)$	1.8×10^{-4}
Acetic acid (CH_3COOH)		$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3COO^-(aq)$	1.8×10^{-5}
Propanoic acid (CH_3CH_2COOH)		$CH_3CH_2COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3CH_2COO^-(aq)$	1.3×10^{-5}
Hypochlorous acid (HClO)		$HClO(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + ClO^-(aq)$	2.9×10^{-8}
Hydrocyanic acid (HCN)		$HCN(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CN^-(aq)$	6.2×10^{-10}

ACID STRENGTH

* Red type indicates the ionizable proton; all atoms have zero formal charge.

Table 18.2 lists K_a values of some weak *monoprotic* acids, those with one ionizable proton. (A more extensive list is in Appendix C.) Note that the ionizable proton in organic acids is bound to the O in —COOH; H atoms bonded to C do *not* ionize.

Classifying the Relative Strengths of Acids and Bases

Using a table of K_a values is the surest way to quantify strengths of weak acids, but you can classify acids and bases qualitatively as strong or weak from their formulas:

- *Strong acids.* Two types of strong acids, with examples *you should memorize,* are
  1. The hydrohalic acids HCl, HBr, and HI
  2. Oxoacids in which the number of O atoms exceeds the number of ionizable protons by two or more, such as HNO_3, H_2SO_4, and $HClO_4$; for example, in the case of H_2SO_4, 4 O's − 2 H's = 2
- *Weak acids.* There are many *more* weak acids than strong ones. Four types are
  1. The hydrohalic acid HF
  2. Acids in which H is not bonded to O or to a halogen, such as HCN and H_2S
  3. Oxoacids in which the number of O atoms equals or exceeds by one the number of ionizable protons, such as HClO, HNO_2, and H_3PO_4
  4. Carboxylic acids (general formula RCOOH, with the ionizable proton shown in red), such as CH_3COOH and C_6H_5COOH
- *Strong bases.* Water-soluble compounds containing O^{2-} or OH^- ions are strong bases. The cations are usually those of the most active metals:
  1. M_2O or MOH, where M = Group 1A(1) metal (Li, Na, K, Rb, Cs)
  2. MO or $M(OH)_2$, where M = Group 2A(2) metal (Ca, Sr, Ba)
     [MgO and $Mg(OH)_2$ are only slightly soluble in water, but the soluble portion dissociates completely.]
- *Weak bases.* Many compounds with an electron-rich nitrogen atom are weak bases (none is an Arrhenius base). The common structural feature is an N atom with a lone electron pair (shown in blue):
  1. Ammonia ($\ddot{N}H_3$)
  2. Amines (general formula $R\ddot{N}H_2$, $R_2\ddot{N}H$, or $R_3\ddot{N}$), such as $CH_3CH_2\ddot{N}H_2$, $(CH_3)_2\ddot{N}H$, and $(C_3H_7)_3\ddot{N}$

SAMPLE PROBLEM 18.1 Classifying Acid and Base Strength from the Chemical Formula

Problem Classify each of the following compounds as a strong acid, weak acid, strong base, or weak base, and write the K_a expression for any weak acid:
(a) KOH **(b)** $(CH_3)_2CHCOOH$ **(c)** H_2SeO_4 **(d)** $(CH_3)_2CHNH_2$

Plan We examine the formula and classify each compound as acid or base, using the text descriptions. Particular points to note for acids are the numbers of O atoms relative to ionizable H atoms and the presence of the —COOH group. For bases, we note the nature of the cation or the presence of an N atom that has a lone pair.

Solution **(a)** Strong base: KOH is one of the Group 1A(1) hydroxides.
(b) Weak acid: $(CH_3)_2CHCOOH$ is a carboxylic acid, as indicated by the —COOH group;

$$K_a = \frac{[H_3O^+][(CH_3)_2CHCOO^-]}{[(CH_3)_2CHCOOH]}$$

(c) Strong acid: H_2SeO_4 is an oxoacid in which the number of O atoms exceeds the number of ionizable protons by two.
(d) Weak base: $(CH_3)_2CHNH_2$ has a lone electron pair on the N and is an amine.

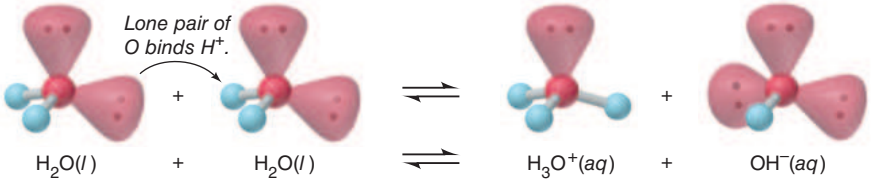
FOLLOW-UP PROBLEMS
Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*
18.1A Which member of each pair is the stronger acid or base?
(a) HClO or $HClO_3$ **(b)** HCl or CH_3COOH **(c)** NaOH or CH_3NH_2
18.1B Classify each of the following compounds as a strong acid, weak acid, strong base, or weak base, and write the K_a expression for any weak acid:
(a) $(CH_3)_3N$ **(b)** HI **(c)** HBrO **(d)** $Ca(OH)_2$
SOME SIMILAR PROBLEMS 18.15–18.18

Summary of Section 18.1

- In aqueous solution, water binds the proton released from an acid to form a hydrated species represented by $H_3O^+(aq)$.
- By the Arrhenius definition, acids contain H and yield H_3O^+ in water, bases contain OH and yield OH^- in water, and an acid-base reaction (neutralization) is the reaction of H^+ and OH^- to form H_2O.
- Acid strength depends on $[H_3O^+]$ relative to [HA] in aqueous solution. Strong acids dissociate completely and weak acids slightly.
- The extent of dissociation is expressed by the acid-dissociation constant, K_a. Most weak acids have K_a values ranging from about 10^{-2} to 10^{-10}.
- Many acids and bases can be classified as strong or weak based on their formulas.

18.2 AUTOIONIZATION OF WATER AND THE pH SCALE

Before we discuss the next major acid-base definition, let's examine a crucial property of water that enables us to quantify $[H_3O^+]$: *water dissociates very slightly into ions* in an equilibrium process known as **autoionization** (or self-ionization):



The Equilibrium Nature of Autoionization: The Ion-Product Constant for Water (K_w)

Like any equilibrium process, the autoionization of water is described quantitatively by an equilibrium constant:

$$K_c = \frac{[H_3O^+][OH^-]}{[H_2O]^2}$$

Because the concentration of H_2O (55.5 *M*) remains essentially constant, it is considered a pure liquid and is eliminated from the equilibrium expression. Thus, we obtain the **ion-product constant for water, K_w:**

$$K_c(1)^2 = K_w = [H_3O^+][OH^-] = 1.0\times10^{-14} \text{ (at 25°C)} \qquad \textbf{(18.2)}$$

Notice that *one H_3O^+ ion and one OH^- ion form for each H_2O molecule that dissociates.* Therefore, in pure water, we find that

$$[H_3O^+] = [OH^-] = \sqrt{1.0\times10^{-14}} = 1.0\times10^{-7}\ M \text{ (at 25°C)}$$

Since pure water has a concentration of about 55.5 *M*, these equilibrium concentrations are attained when only 1 in 555 million water molecules dissociates reversibly into ions!

Autoionization of water affects aqueous acid-base chemistry in two major ways:

1. *A change in $[H_3O^+]$ causes an inverse change in $[OH^-]$,* and vice versa:

Higher $[H_3O^+] \Longrightarrow$ lower $[OH^-]$ and Higher $[OH^-] \Longrightarrow$ lower $[H_3O^+]$

Recall from Le Châtelier's principle (Section 17.6) that a change in concentration shifts the equilibrium position but does *not* change the equilibrium constant. Therefore, if some acid is added, $[H_3O^+]$ increases and $[OH^-]$ decreases as the ions react to form water; similarly, if some base is added, $[OH^-]$ increases and $[H_3O^+]$ decreases. In both cases, as long as the temperature is constant, the value of K_w is constant.

2. *Both ions are present in all aqueous systems.* Thus, all acidic solutions contain a low $[OH^-]$, and all basic solutions contain a low $[H_3O^+]$. The equilibrium nature of autoionization allows us to define "acidic" and "basic" solutions in terms of relative magnitudes of $[H_3O^+]$ and $[OH^-]$:

In an *acidic* solution, $[H_3O^+] > [OH^-]$
In a *neutral* solution, $[H_3O^+] = [OH^-]$
In a *basic* solution, $[H_3O^+] < [OH^-]$

Figure 18.3 summarizes these relationships. Moreover, if you know the value of K_w at a particular temperature and the concentration of one of the two ions, you can find the concentration of the other:

$$[H_3O^+] = \frac{K_w}{[OH^-]} \quad \text{or} \quad [OH^-] = \frac{K_w}{[H_3O^+]}$$

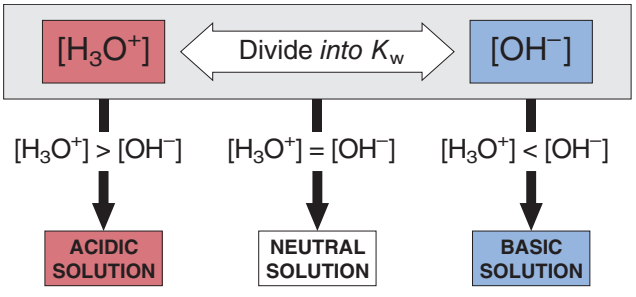


Figure 18.3 The relationship between $[H_3O^+]$ and $[OH^-]$ and the relative acidity of solutions.

SAMPLE PROBLEM 18.2 **Calculating $[H_3O^+]$ or $[OH^-]$ in Aqueous Solution**

Problem A research chemist adds a measured amount of HCl gas to pure water at 25°C and obtains a solution with $[H_3O^+] = 3.0\times10^{-4}\ M$. Calculate $[OH^-]$. Is the solution neutral, acidic, or basic?

Plan We use the known value of K_w at 25°C (1.0×10^{-14}) and the given $[H_3O^+]$ ($3.0\times10^{-4}\ M$) to solve for $[OH^-]$. Then we compare $[H_3O^+]$ with $[OH^-]$ to determine whether the solution is acidic, basic, or neutral (see Figure 18.3).

Solution Calculating $[OH^-]$:

$$[OH^-] = \frac{K_w}{[H_3O^+]} = \frac{1.0\times10^{-14}}{3.0\times10^{-4}} = 3.3\times10^{-11}\ M$$

Because $[H_3O^+] > [OH^-]$, the solution is acidic.

Check It makes sense that adding an acid to water results in an acidic solution. Also, since $[H_3O^+]$ is greater than $10^{-7}\ M$, $[OH^-]$ must be less than $10^{-7}\ M$ to give a constant K_w.

FOLLOW-UP PROBLEMS

18.2A Calculate $[H_3O^+]$ in a solution that has $[OH^-] = 6.7\times10^{-2}\ M$ at 25°C. Is the solution neutral, acidic, or basic?

18.2B An aqueous solution of window cleaner has $[H_3O^+] = 1.8\times10^{-10}\ M$ at 25°C. Calculate $[OH^-]$. Is the solution neutral, acidic, or basic?

SOME SIMILAR PROBLEMS 18.27–18.30

Expressing the Hydronium Ion Concentration: The pH Scale

In aqueous solutions, $[H_3O^+]$ can vary from about 10 M to $10^{-15}\ M$. To handle numbers with negative exponents more conveniently in calculations, we convert them to positive numbers using a numerical system called a *p-scale,* the negative of the common (base-10) logarithm of the number. Applying this numerical system to $[H_3O^+]$ gives **pH,** the negative logarithm of $[H^+]$ (or $[H_3O^+]$):

$$pH = -\log[H_3O^+] \qquad (18.3)$$

What is the pH of a $10^{-12}\ M$ H_3O^+ solution?

$$pH = -\log[H_3O^+] = -\log 10^{-12} = (-1)(-12) = 12$$

Similarly, a $10^{-3}\ M$ H_3O^+ solution has a pH of 3, and a $5.4\times10^{-4}\ M$ H_3O^+ solution has a pH of 3.27:

$$pH = -\log[H_3O^+] = (-1)(\log 5.4 + \log 10^{-4}) = 3.27$$

As with any measurement, the number of significant figures in a pH value reflects the precision with which the concentration is known. However, a pH value is a logarithm, so the number of significant figures in the concentration equals the number of digits *to the right of the decimal point in the pH value* (see Appendix A). In the preceding example, $5.4\times10^{-4}\ M$ has two significant figures, so its negative logarithm, 3.27, has two digits to the right of the decimal point.

Note in particular that *the higher the pH, the lower the $[H_3O^+]$.* Therefore, *an acidic solution has a lower pH (higher $[H_3O^+]$) than a basic solution.* At 25°C in pure water, $[H_3O^+]$ is $1.0\times10^{-7}\ M$, so

pH of an acidic solution $<$ 7.00
pH of a neutral solution $=$ 7.00
pH of a basic solution $>$ 7.00

Figure 18.4 shows that the pH values of some familiar aqueous solutions fall within a range of 0 to 14.

Because the pH scale is logarithmic, a solution of pH 1.0 has an $[H_3O^+]$ that is 10 times higher than that of a pH 2.0 solution, 100 times higher than that of a pH 3.0 solution, and so forth. To find the $[H_3O^+]$ from the pH, you perform the opposite arithmetic process; that is, you find the negative antilog of pH:

$$[H_3O^+] = 10^{-pH}$$

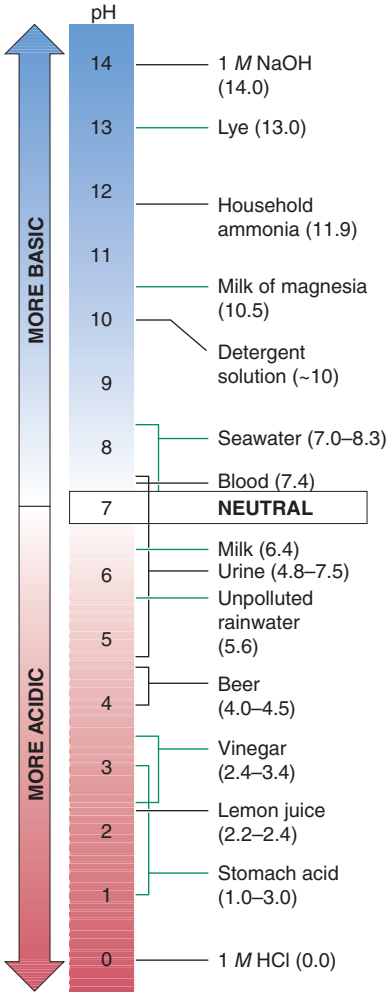

Figure 18.4 The pH values of some familiar aqueous solutions.

Table 18.3 The Relationship Between K_a and pK_a

Acid Name (Formula)	K_a at 25°C	pK_a
Hydrogen sulfate ion (HSO_4^-)	1.0×10^{-2}	1.99
Nitrous acid (HNO_2)	7.1×10^{-4}	3.15
Acetic acid (CH_3COOH)	1.8×10^{-5}	4.75
Hypobromous acid (HBrO)	2.3×10^{-9}	8.64
Phenol (C_6H_5OH)	1.0×10^{-10}	10.00

ACID STRENGTH

A p-scale is used to express other quantities as well:

- Hydroxide ion concentration can be expressed as pOH:

$$\text{pOH} = -\log[\text{OH}^-]$$

Acidic solutions have a higher pOH (lower $[OH^-]$) than basic solutions.

- Equilibrium constants can be expressed as pK:

$$pK = -\log K$$

Specifically for weak acids:

$$pK_a = -\log K_a \qquad \text{and} \qquad K_a = 10^{-pK_a}$$

A low pK corresponds to a high K. A reaction that reaches equilibrium with mostly products present (proceeds far to the right) has a low pK (high K), whereas one that has mostly reactants present at equilibrium has a high pK (low K). Table 18.3 shows this relationship for aqueous equilibria of some weak acids.

The Relationships Among pH, pOH, and pK_w Taking the negative log of both sides of the K_w expression gives a useful relationship among pK_w, pH, and pOH:

$$K_w = [H_3O^+][OH^-] = 1.0\times10^{-14} \text{ (at 25°C)}$$

$$-\log K_w = (-\log[H_3O^+]) + (-\log[OH^-]) = -\log(1.0\times10^{-14})$$

$$pK_w = \text{pH} + \text{pOH} = 14.00 \qquad \text{(at 25°C)} \qquad \textbf{(18.4)}$$

Note these important points:

1. The sum of pH and pOH is pK_w for any aqueous solution at any temperature, and pK_w equals 14.00 at 25°C.
2. Because K_w is constant, pH, pOH, $[H_3O^+]$, and $[OH^-]$ are interrelated:
   - $[H_3O^+]$ and $[OH^-]$ change in opposite directions.
   - pH and pOH also change in opposite directions.
   - At 25°C, the product of $[H_3O^+]$ and $[OH^-]$ is 1.0×10^{-14}, and the sum of pH and pOH is 14.00 (Figure 18.5).

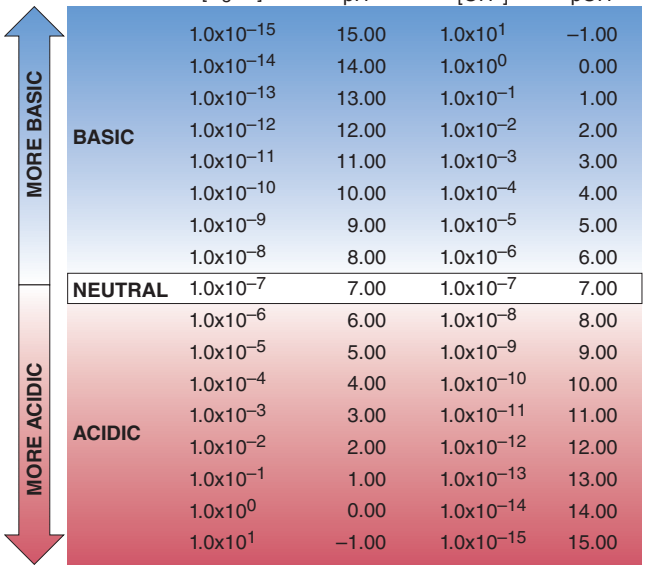

Figure 18.5 The relationships among $[H_3O^+]$, pH, $[OH^-]$, and pOH.

Calculating pH for Strong Acids and Bases Since strong acids and bases dissociate completely, calculating pH, $[H_3O^+]$, $[OH^-]$, and pOH for these substances is straightforward:

- The equilibrium concentration of H_3O^+ is equal to the initial concentration of a strong acid: 0.200 *M* HCl dissociates to produce 0.200 *M* H_3O^+.
- The equilibrium concentration of OH^- is equal to the initial concentration of a Group 1A(1) hydroxide: 0.200 *M* KOH dissociates to produce 0.200 *M* OH^-.
- The equilibrium concentration of OH^- is equal to twice the initial concentration of a Group 2A(2) hydroxide: 0.200 *M* $Ba(OH)_2$ dissociates to produce 2(0.200 *M*) = 0.400 *M* OH^- since there are two moles of OH^- in every mole of $Ba(OH)_2$.

SAMPLE PROBLEM 18.3 Calculating $[H_3O^+]$, pH, $[OH^-]$, and pOH for Strong Acids and Bases

Problem Calculate $[H_3O^+]$, pH, $[OH^-]$, and pOH for each solution at 25°C:
(a) 0.30 *M* HNO_3, used for etching copper metal
(b) 0.0042 *M* $Ca(OH)_2$, used in leather tanning to remove hair from hides

Plan We know that HNO_3 is a strong acid and dissociates completely; thus, $[H_3O^+] = [HNO_3]_{init}$. Similarly, $Ca(OH)_2$ is a strong base and dissociates completely, $[OH^-] = 2[Ca(OH)_2]_{init}$. We use these concentrations and the value of K_w at 25°C (1.0×10^{-14}) to find $[OH^-]$ or $[H_3O^+]$, which we then use to calculate pH and pOH.

Solution **(a)** For 0.30 *M* HNO_3:

$$[H_3O^+] = 0.30\ M$$
$$\text{pH} = -\log[H_3O^+] = -\log 0.30 = 0.52$$
$$[OH^-] = \frac{K_w}{[H_3O^+]} = \frac{1.0\times10^{-14}}{0.30} = 3.3\times10^{-14}\ M$$
$$\text{pOH} = -\log[OH^-] = -\log(3.3\times10^{-14}) = 13.48$$

(b) For 0.0042 *M* $Ca(OH)_2$:

$$[OH^-] = 2(0.0042\ M) = 0.0084\ M$$
$$\text{pOH} = -\log[OH^-] = -\log 0.0084 = 2.08$$
$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0\times10^{-14}}{0.0084} = 1.2\times10^{-12}\ M$$
$$\text{pH} = -\log[H_3O^+] = -\log(1.2\times10^{-12}) = 11.92$$

Check The strong acid has pH < 7 and the strong base has a pH > 7, as expected. In each case, pH + pOH = 14, so the arithmetic seems correct.

FOLLOW-UP PROBLEMS

18.3A Sodium hydroxide is used to clear clogged drains. A solution of NaOH has a pH of 9.52 at 25°C. What are its pOH, $[H_3O^+]$, and $[OH^-]$?

18.3B Hydrochloric acid is sold commercially under the name *muriatic acid* and is used to clean concrete masonry. A dilute solution of HCl has a pH of 2.28 at 25°C. Calculate its pOH, $[H_3O^+]$, and $[OH^-]$.

SOME SIMILAR PROBLEMS 18.23–18.30

Measuring pH In the laboratory, pH values are usually obtained in two ways:

1. **Acid-base indicators** are organic molecules whose colors depend on the acidity of the solution in which they are dissolved. A pH can be estimated quickly with *pH paper,* a paper strip impregnated with one or a mixture of indicators. A drop of solution is placed on the strip, and the color is compared with a chart (Figure 18.6A).

2. A *pH meter* measures $[H_3O^+]$ by means of two electrodes immersed in the test solution. One electrode supplies a reference system; the other consists of a very

thin glass membrane that separates a known internal $[H_3O^+]$ from the unknown external $[H_3O^+]$. The difference in $[H_3O^+]$ creates a voltage difference across the membrane, which is displayed in pH units (Figure 18.6B). We examine this device in Chapter 21.

Summary of Section 18.2

- Pure water has a low conductivity because it autoionizes to a small extent in a process whose equilibrium constant is the ion-product constant for water, K_w (1.0×10^{-14} at 25°C).
- $[H_3O^+]$ and $[OH^-]$ are inversely related: in acidic solution, $[H_3O^+]$ is greater than $[OH^-]$; the reverse is true in basic solution; and the two are equal in neutral solution.
- To express small values of $[H_3O^+]$, we use the pH scale: pH = −log $[H_3O^+]$. Similarly, pOH = −log $[OH^-]$, and pK = −log K.
- A high pH corresponds to a low $[H_3O^+]$. In acidic solutions, pH < 7.00; in basic solutions, pH > 7.00; and in neutral solutions, pH = 7.00. The sum of pH and pOH equals pK_w (14.00 at 25°C).
- A pH is typically measured with either an acid-base indicator or a pH meter.

18.3 PROTON TRANSFER AND THE BRØNSTED-LOWRY ACID-BASE DEFINITION

Earlier we noted a key limitation of the Arrhenius definition: many substances that yield OH^- ions in water do not contain OH in their formulas. Examples include ammonia, the amines, and many salts of weak acids, such as NaF. Another limitation is that water had to be the solvent for acid-base reactions. In the early 20th century, J. N. Brønsted and T. M. Lowry suggested definitions that remove these limitations. (We introduced some of these ideas in Section 4.4.)

According to the **Brønsted-Lowry acid-base definition,**

- *An acid is a* ***proton donor,*** *any species that donates an H^+ ion.* An acid must contain H in its formula; HNO_3 and $H_2PO_4^-$ are two of many examples. All Arrhenius acids are Brønsted-Lowry acids.
- *A base is a* ***proton acceptor,*** *any species that accepts an H^+ ion.* A base must contain a lone pair of electrons to bind H^+; a few examples are NH_3, CO_3^{2-}, and F^-, as well as OH^- itself. Brønsted-Lowry bases are not Arrhenius bases, but all Arrhenius bases contain the Brønsted-Lowry base OH^-.

From this perspective, an acid-base reaction occurs when *one species donates a proton and another species simultaneously accepts it: an acid-base reaction is thus a proton-transfer process.* Acid-base reactions can occur between gases, in nonaqueous solutions, and in heterogeneous mixtures, as well as in aqueous solutions.

According to this definition, an acid-base reaction occurs even when an acid (or a base) just dissolves in water, because water acts as the proton acceptor (or donor):

1. *Acid donates a proton to water* (Figure 18.7A, *next page*). When HCl dissolves in water, an H^+ ion (a proton) is transferred from HCl to H_2O, where it becomes attached to a lone pair of electrons on the O atom, forming H_3O^+. Thus, HCl (the acid) has *donated* the H^+, and H_2O (the base) has *accepted* it:

$$HCl(g) + H_2\ddot{O}(l) \longrightarrow Cl^-(aq) + H_3\ddot{O}^+(aq)$$

2. *Base accepts a proton from water* (Figure 18.7B, *next page*). When ammonia dissolves in water, an H^+ from H_2O is transferred to the lone pair of N, forming NH_4^+, and the H_2O becomes an OH^- ion:

$$\ddot{N}H_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

In this case, H_2O (the acid) has *donated* the H^+, and NH_3 (the base) has *accepted* it.

Note that H_2O is *amphiprotic:* it acts as a base (accepts an H^+) in one case and as an acid (donates an H^+) in the other. Many other species are amphiprotic as well.

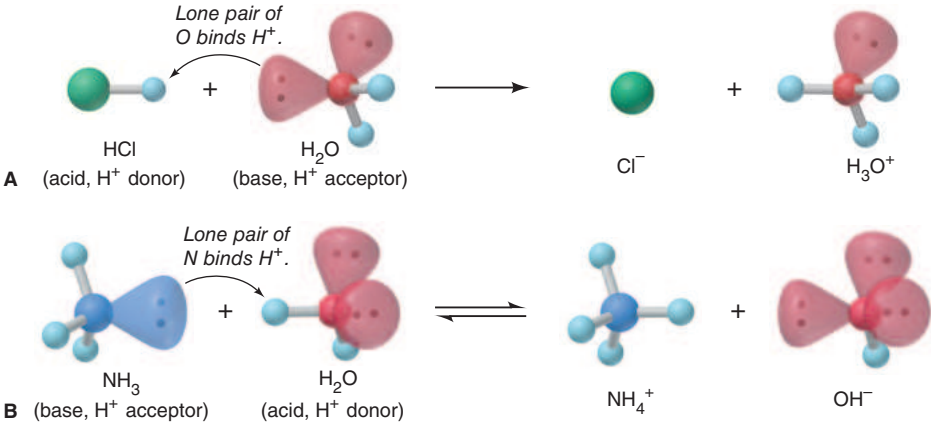

Figure 18.7 **Dissolving of an acid or base in water as a Brønsted-Lowry acid-base reaction. A,** The acid HCl dissolving in the base water. **B,** The base NH_3 dissolving in the acid water.

Conjugate Acid-Base Pairs

The Brønsted-Lowry definition provides a new way to look at acid-base reactions because it focuses on the reactants *and* the products as acids and bases. For example, let's examine the reaction between hydrogen sulfide and ammonia:

$$H_2S + NH_3 \rightleftharpoons HS^- + NH_4^+$$

In the forward reaction, H_2S acts as an acid by donating an H^+ to NH_3, which acts as a base by accepting it. In the reverse reaction, the ammonium ion, NH_4^+, acts as an acid by donating an H^+ to the hydrogen sulfide ion, HS^-, which acts as a base. Notice that the acid, H_2S, becomes a base, HS^-, and the base, NH_3, becomes an acid, NH_4^+.

In Brønsted-Lowry terminology, H_2S and HS^- are a **conjugate acid-base pair:** HS^- is the conjugate base of the acid H_2S. Similarly, NH_3 and NH_4^+ are a conjugate acid-base pair: NH_4^+ is the conjugate acid of the base NH_3. *Every acid has a conjugate base, and every base has a conjugate acid.* For any conjugate acid-base pair,

- The conjugate base has one *fewer* H and one *more* minus charge than the acid.
- The conjugate acid has one *more* H and one *fewer* minus charge than the base.

A Brønsted-Lowry acid-base reaction occurs when *an acid and a base react to form their conjugate base and conjugate acid, respectively:*

$$\text{acid}_1 + \text{base}_2 \rightleftharpoons \text{base}_1 + \text{acid}_2$$

Table 18.4 shows some Brønsted-Lowry acid-base reactions. Note these points:

- Each reaction has an acid and a base as reactants *and* as products, comprising two conjugate acid-base pairs.
- Acids and bases can be neutral molecules, cations, or anions.
- The same species can be an acid or a base (amphiprotic), depending on the other species reacting. Water behaves this way in reactions 1 and 4 in Table 18.4 and HPO_4^{2-} does so in reactions 4 and 6.

Table 18.4 **The Conjugate Pairs in Some Acid-Base Reactions**

	Conjugate Pair: Acid	+	Base	⇌	Base	+	Acid: Conjugate Pair
Reaction 1	HF	+	H_2O	⇌	F^-	+	H_3O^+
Reaction 2	HCOOH	+	CN^-	⇌	$HCOO^-$	+	HCN
Reaction 3	NH_4^+	+	CO_3^{2-}	⇌	NH_3	+	HCO_3^-
Reaction 4	$H_2PO_4^-$	+	OH^-	⇌	HPO_4^{2-}	+	H_2O
Reaction 5	H_2SO_4	+	$N_2H_5^+$	⇌	HSO_4^-	+	$N_2H_6^{2+}$
Reaction 6	HPO_4^{2-}	+	SO_3^{2-}	⇌	PO_4^{3-}	+	HSO_3^-

SAMPLE PROBLEM 18.4 **Identifying Conjugate Acid-Base Pairs**

Problem The following reactions are important environmental processes. Identify the conjugate acid-base pairs.

(a) $H_2PO_4^-(aq) + CO_3^{2-}(aq) \rightleftharpoons HCO_3^-(aq) + HPO_4^{2-}(aq)$

(b) $H_2O(l) + SO_3^{2-}(aq) \rightleftharpoons OH^-(aq) + HSO_3^-(aq)$

Plan To find the conjugate pairs, we find the species that donated an H^+ (acid) and the species that accepted it (base). The acid (or base) on the left becomes its conjugate base (or conjugate acid) on the right. Remember, the conjugate acid has one more H and one fewer minus charge than its conjugate base.

Solution **(a)** $H_2PO_4^-$ has one more H^+ than HPO_4^{2-}; CO_3^{2-} has one fewer H^+ than HCO_3^-. Therefore, $H_2PO_4^-$ and HCO_3^- are the acids, and HPO_4^{2-} and CO_3^{2-} are the bases. The conjugate acid-base pairs are $H_2PO_4^-/HPO_4^{2-}$ and HCO_3^-/CO_3^{2-}.

(b) H_2O has one more H^+ than OH^-; SO_3^{2-} has one fewer H^+ than HSO_3^-. The acids are H_2O and HSO_3^-; the bases are OH^- and SO_3^{2-}. The conjugate acid-base pairs are H_2O/OH^- and HSO_3^-/SO_3^{2-}.

FOLLOW-UP PROBLEMS

18.4A Identify the conjugate acid-base pairs:

(a) $CH_3COOH(aq) + H_2O(l) \rightleftharpoons CH_3COO^-(aq) + H_3O^+(aq)$

(b) $H_2O(l) + F^-(aq) \rightleftharpoons OH^-(aq) + HF(aq)$

18.4B Give the formula of each of the following:

(a) The conjugate acid of HSO_3^-

(b) The conjugate base of $C_5H_5NH^+$

(c) The conjugate acid of CO_3^{2-}

(d) The conjugate base of HCN

SOME SIMILAR PROBLEMS 18.43–18.52

Relative Acid-Base Strength and the Net Direction of Reaction

The *net* direction of an acid-base reaction depends on relative acid and base strengths: *A reaction proceeds to the greater extent in the direction in which a stronger acid and stronger base form a weaker acid and weaker base.*

Competition for the Proton The net direction of the reaction of H_2S and NH_3 is to the right ($K_c > 1$) because H_2S is a stronger acid than NH_4^+, the other acid present, and NH_3 is a stronger base than HS^-, the other base:

$$\underset{\text{stronger acid}}{H_2S} + \underset{\text{stronger base}}{NH_3} \rightleftharpoons \underset{\text{weaker base}}{HS^-} + \underset{\text{weaker acid}}{NH_4^+}$$

You might think of the process as *a competition for the proton between the two bases,* NH_3 and HS^-, in which NH_3 wins.

In effect, the extent of acid (HA) dissociation in water can be viewed as the result of a competition for the proton between the two bases, A^- and H_2O. Strong and weak acids give different results:

1. *Strong acids.* When the strong acid HNO_3 dissolves, it completely transfers an H^+ to the base, H_2O, forming the conjugate base NO_3^- and the conjugate acid H_3O^+:

$$\underset{\text{stronger acid}}{HNO_3} + \underset{\text{stronger base}}{H_2O} \rightleftharpoons \underset{\text{weaker base}}{NO_3^-} + \underset{\text{weaker acid}}{H_3O^+}$$

Even though we show an equilibrium arrow here, the net direction is so far to the right that $K_c >> 1$ and the reaction is essentially complete. HNO_3 is a stronger acid than H_3O^+, and H_2O is a stronger base than NO_3^-. Thus, with a strong HA, H_2O wins the competition for the proton because A^- is a *much* weaker base. In fact, *the only acidic species that remains in strong-acid solutions is* H_3O^+.

2. *Weak acids*. On the other hand, with weak acids such as HF, the A^- (F^-) wins the competition because it is a stronger base than H_2O and the net direction is to the left ($K_c < 1$):

$$\underset{\text{weaker acid}}{HF} + \underset{\text{weaker base}}{H_2O} \rightleftharpoons \underset{\text{stronger base}}{F^-} + \underset{\text{stronger acid}}{H_3O^+}$$

Ranking Conjugate Pairs Based on evidence from many such reactions, we can rank conjugate pairs in terms of the ability of the acid to transfer its proton (Figure 18.8). Note that *a weaker acid has a stronger conjugate base:* the acid can't give up its proton very readily because its conjugate base attracts the proton too strongly.

We use Figure 18.8 to predict the net direction of a reaction between any two pairs, that is, whether the equilibrium position lies to the right ($K_c > 1$) or to the left ($K_c < 1$). *A reaction proceeds to the right if an acid reacts with a base lower on the list*. Here are two sample problems that demonstrate this key idea.

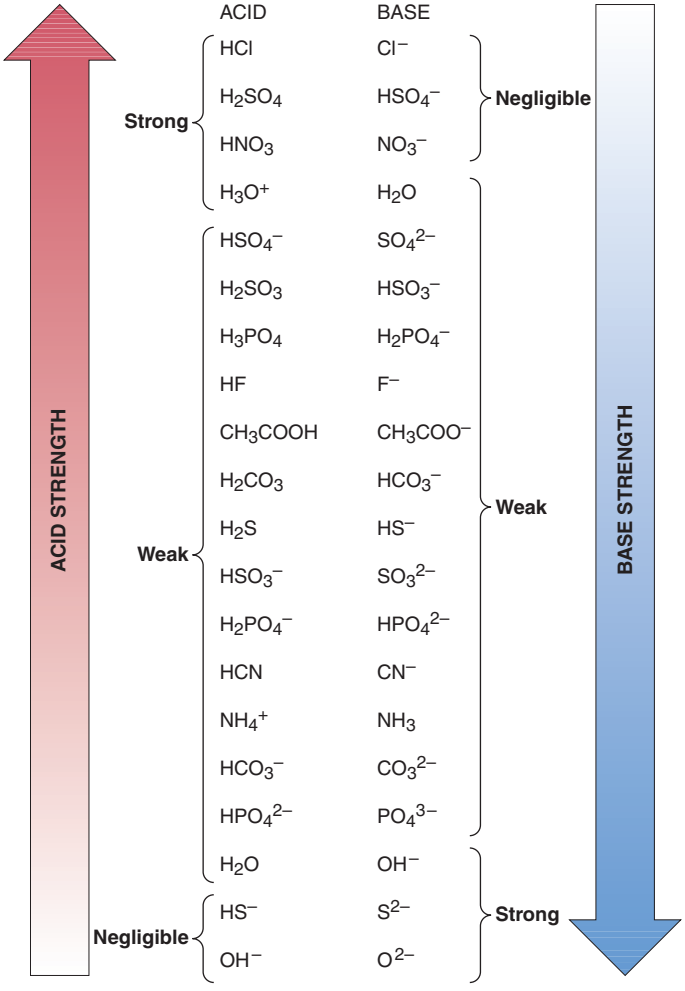

Figure 18.8 Strengths of conjugate acid-base pairs. The stronger the acid is, the weaker its conjugate base. The strongest acid is at top left and the strongest base at bottom right. When an acid reacts with a base farther down the list, the reaction proceeds to the right ($K_c > 1$).

SAMPLE PROBLEM 18.5 Predicting the Net Direction of an Acid-Base Reaction

Problem Predict the net direction and whether K_c is greater or less than 1 for each of the following reactions (assume equal initial concentrations of all species):

(a) $H_2PO_4^-(aq) + NH_3(aq) \rightleftharpoons NH_4^+(aq) + HPO_4^{2-}(aq)$

(b) $H_2O(l) + HS^-(aq) \rightleftharpoons OH^-(aq) + H_2S(aq)$

Plan We identify the conjugate acid-base pairs and consult Figure 18.8 to see which acid and base are stronger. The reaction proceeds in the direction in which the stronger acid and base form the weaker acid and base. If the reaction *as written* proceeds to the right, then [products] is higher than [reactants], so $K_c > 1$.

Solution **(a)** The conjugate pairs are $H_2PO_4^-/HPO_4^{2-}$ and NH_4^+/NH_3. Since $H_2PO_4^-$ is higher on the list of acids, it is stronger than NH_4^+; since NH_3 is lower on the list of bases, it is stronger than HPO_4^{2-}. Therefore,

$$\underset{\text{stronger acid}}{H_2PO_4^-(aq)} + \underset{\text{stronger base}}{NH_3(aq)} \rightleftharpoons \underset{\text{weaker base}}{HPO_4^{2-}(aq)} + \underset{\text{weaker acid}}{NH_4^+(aq)}$$

The net direction is to the right, so $K_c > 1$.

(b) The conjugate pairs are H_2O/OH^- and H_2S/HS^-. Since H_2S is higher on the list of acids, and OH^- is lower on the list of bases, we have

$$\underset{\text{weaker acid}}{H_2O(l)} + \underset{\text{weaker base}}{HS^-(aq)} \rightleftharpoons \underset{\text{stronger base}}{OH^-(aq)} + \underset{\text{stronger acid}}{H_2S(aq)}$$

The net direction is to the left, so $K_c < 1$.

FOLLOW-UP PROBLEMS

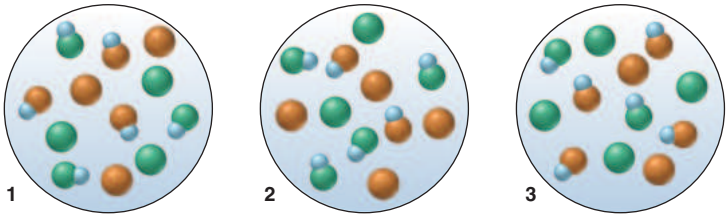
18.5A Use the following conjugate acid-base pairs and Figure 18.8 to write acid-base reactions with K_c values as specified:
(a) H_2SO_3/HSO_3^- and HCO_3^-/CO_3^{2-}, $K_c > 1$ **(b)** HF/F^- and HCN/CN^-, $K_c < 1$

18.5B Use balanced equations that show the net direction of the reaction to explain each of the following observations:
(a) You smell ammonia when NH_3 dissolves in water.
(b) The odor goes away when you add an excess of HCl to the solution in part (a).
(c) The odor returns when you add an excess of NaOH to the solution in part (b).

SOME SIMILAR PROBLEMS 18.53–18.58

SAMPLE PROBLEM 18.6 Using Molecular Scenes to Predict the Net Direction of an Acid-Base Reaction

Problem Given that 0.10 *M* HX *(blue and green)* has a pH of 2.88, and 0.10 *M* HY *(blue and orange)* has a pH of 3.52, which scene best represents the final mixture after equimolar solutions of HX and Y^- are mixed?



Plan A stronger acid and base yield a weaker acid and base, so we have to determine the relative acid strengths of HX and HY in order to choose the correct molecular scene. The concentrations of the acid solutions are equal, so we can pick the stronger acid directly from the pH values of the two acid solutions. Because the stronger acid reacts to a greater extent, fewer molecules of it will be in the scene than molecules of the weaker acid.

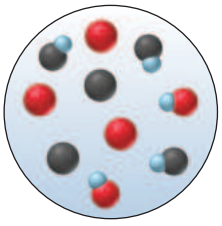
Solution The HX solution has a lower pH (2.88) than the HY solution (3.52), so we know right away that HX is the stronger acid and Y^- is the stronger base. Therefore, the reaction of HX and Y^- has a $K_c > 1$, which means the equilibrium mixture will have more HY than HX. Scene 1 has equal numbers of HX and HY, which would occur if the acids were of equal strength, and scene 2 shows fewer HY than HX, which would occur if HY were stronger. Therefore, only scene 3 is consistent with the relative acid strengths.

FOLLOW-UP PROBLEMS

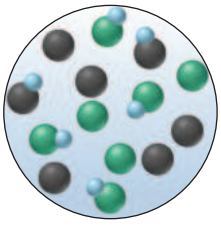
18.6A The left-hand scene in the margin represents the equilibrium mixture after 0.10 *M* solutions of HA *(blue and red)* and B^- *(black)* react: Does this reaction have a K_c greater or less than 1? Which acid is stronger, HA or HB?

18.6B The right-hand scene depicts an aqueous solution of two conjugate acid-base pairs: HC/C^- and HD/D^-. HD is a stronger acid than HC. What colors represent the base C^- and the base D^-? Does the reaction between HC and D^- have a K_c greater or less than 1?

A SIMILAR PROBLEM 18.39



18.6A



18.6B

Summary of Section 18.3

- The Brønsted-Lowry acid-base definition does not require that bases contain OH in their formula or that acid-base reactions occur in aqueous solution.
- An acid is a species that donates a proton and a base is one that accepts it, so an acid-base reaction is a proton-transfer process.
- When an acid donates a proton, it becomes the conjugate base; when a base accepts a proton, it becomes the conjugate acid. In an acid-base reaction, acids and bases form their conjugates. A stronger acid has a weaker conjugate base, and vice versa.
- An acid-base reaction proceeds to the greater extent ($K > 1$) in the direction in which a stronger acid and base form a weaker base and acid.

18.4 SOLVING PROBLEMS INVOLVING WEAK-ACID EQUILIBRIA

Just as you saw in Chapter 17 for equilibrium problems in general, there are two general types of equilibrium problems involving weak acids and their conjugate bases:

1. Given equilibrium concentrations, find K_a.
2. Given K_a and some concentrations, find other equilibrium concentrations.

For all of these problems, we'll apply the same problem-solving approach, notation system, and assumptions:

- *The problem-solving approach.* Start with what is given in the problem and move toward what you want to find. Make a habit of applying the following steps:
  1. Write the balanced equation and K_a expression; these tell you what to find.
  2. Define x as the unknown change in concentration that occurs during the reaction. Frequently, $x = [HA]_{dissoc}$, the concentration of HA that dissociates, which, through the use of certain assumptions, also equals $[H_3O^+]$ and $[A^-]$ at equilibrium.
  3. Construct a reaction table (for most problems) that incorporates x.
  4. Make assumptions (usually that x is very small relative to the initial concentration) that simplify the calculations.
  5. Substitute the values into the K_a expression, and solve for x.
  6. Check that the assumptions are justified with the 5% test first used in Sample Problem 17.10, pp. 750–752. If they are not justified, use the quadratic formula to find x.

- *The notation system.* As always, molar concentration is indicated with brackets. A subscript refers to where the species comes from or when it occurs in the reaction process. For example, $[H_3O^+]_{from\ HA}$ is the molar concentration of H_3O^+ that comes from the dissociation of HA; $[HA]_{init}$ is the initial molar concentration of HA, that is, before dissociation; $[HA]_{dissoc}$ is the molar concentration of HA that dissociates; and so forth. A bracketed formula with *no* subscript represents the molar concentration of the species *at equilibrium.*

- *The assumptions.* We make two assumptions to simplify the arithmetic:
  1. $[H_3O^+]$ from the autoionization of water is negligible. It is so much smaller than the $[H_3O^+]$ from the dissociation of HA that we can neglect it in these problems:
  $$[H_3O^+] = [H_3O^+]_{from\ HA} + [H_3O^+]_{from\ H_2O} \approx [H_3O^+]_{from\ HA}$$
  Note that each molecule of HA that dissociates forms one H_3O^+ and one A^-:
  $$[HA]_{dissoc} = [H_3O^+] = [A^-]$$
  2. A weak acid has a small K_a. Therefore, it dissociates to such a small extent that we can neglect the change in its concentration to find its equilibrium concentration:
  $$[HA] = [HA]_{init} - [HA]_{dissoc} \approx [HA]_{init}$$

Finding K_a Given Concentrations

This type of problem involves finding K_a of a weak acid from the concentration of one of the species in solution, usually $[H_3O^+]$ from a given pH:

$$HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq)$$

$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

You prepare an aqueous solution of HA and measure its pH. Thus, you know $[HA]_{init}$, can calculate $[H_3O^+]$ from the pH, and then determine $[A^-]$ and $[HA]$ at equilibrium. You substitute these values into the K_a expression and solve for K_a. Let's go through the approach in Sample Problem 18.7.

SAMPLE PROBLEM 18.7 Finding K_a of a Weak Acid from the Solution pH

Problem Phenylacetic acid ($C_6H_5CH_2COOH$, simplified here to HPAc; *see model*) builds up in the blood of persons with phenylketonuria, an inherited disorder that, if untreated, causes mental retardation and death. A study of the acid shows that the pH of 0.12 *M* HPAc is 2.62. What is the K_a of phenylacetic acid?

Phenylalanine, one of the amino acids that make up aspartame, is metabolized to phenylacetic acid (model).

Plan We are given $[HPAc]_{init}$ (0.12 *M*) and the pH (2.62) and must find K_a. As always, we first write the equation for HPAc dissociation and the expression for K_a to see which values we need. We set up a reaction table and use the given pH to find $[H_3O^+]$, which equals $[PAc^-]$ and $[HPAc]_{dissoc}$ (we assume that $[H_3O^+]_{from\ H_2O}$ is negligible). To find [HPAc], we assume that, because it is a weak acid, very little dissociates, so $[HPAc]_{init} - [HPAc]_{dissoc} = [HPAc] \approx [HPAc]_{init}$. We make these assumptions, substitute the equilibrium values, solve for K_a, and then check the assumptions using the 5% rule (Sample Problem 17.10).

Solution Writing the dissociation equation and K_a expression:

$$HPAc(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + PAc^-(aq) \qquad K_a = \frac{[H_3O^+][PAc^-]}{[HPAc]}$$

Setting up a reaction table, with $x = [HPAc]_{dissoc} = [H_3O^+]_{from\ HPAc} = [PAc^-]$:

Concentration (*M*)	HPAc(*aq*)	+	$H_2O(l)$	$\rightleftharpoons$	$H_3O^+(aq)$	+	$PAc^-(aq)$
Initial	0.12		—		0		0
Change	$-x$		—		$+x$		$+x$
Equilibrium	$0.12 - x$		—		x		x

Calculating $[H_3O^+]$:

$$[H_3O^+] = 10^{-pH} = 10^{-2.62} = 2.4\times10^{-3}\ M$$

Making the assumptions:

1. The calculated $[H_3O^+]$ ($2.4\times10^{-3}\ M$) >> $[H_3O^+]_{from\ H_2O}$ ($1.0\times10^{-7}\ M$), so we assume that $[H_3O^+] \approx [H_3O^+]_{from\ HPAc} = [PAc^-] = x$ (the change in [HPAc], or $[HPAc]_{dissoc}$).
2. HPAc is a weak acid, so we assume that $[HPAc] = 0.12\ M - x \approx 0.12\ M$.

Solving for the equilibrium concentrations:

$$x \approx [H_3O^+] = [PAc^-] = 2.4\times10^{-3}\ M$$

$$[HPAc] = 0.12\ M - x = 0.12\ M - (2.4\times10^{-3}\ M) \approx 0.12\ M \text{ (to 2 sf)}$$

Substituting these values into K_a:

$$K_a = \frac{[H_3O^+][PAc^-]}{[HPAc]} \approx \frac{(2.4\times10^{-3})(2.4\times10^{-3})}{0.12} = 4.8\times10^{-5}$$

Checking the assumptions by finding the percent error in concentration:

1. For $[H_3O^+]_{from\ H_2O}$: $\dfrac{1\times10^{-7}\ M}{2.4\times10^{-3}\ M} \times 100 = 4\times10^{-3}\%$ (<5%; assumption is justified).
2. For $[HPAc]_{dissoc}$: $\dfrac{2.4\times10^{-3}\ M}{0.12\ M} \times 100 = 2.0\%$ (<5%; assumption is justified).

Check The $[H_3O^+]$ makes sense: pH 2.62 should give $[H_3O^+]$ between 10^{-2} and 10^{-3} *M*. The K_a calculation also seems in the correct range: $(10^{-3})^2/10^{-1} = 10^{-5}$, and this value seems reasonable for a weak acid.

FOLLOW-UP PROBLEMS

18.7A The conjugate acid of ammonia is the weak acid NH_4^+. If a 0.2 *M* NH_4Cl solution has a pH of 5.0, what is the K_a of NH_4^+?

18.7B Over a million tons of acrylic acid ($H_2C{=}CHCOOH$) are produced each year for manufacturing plastics, adhesives, and paint. A 0.30 *M* solution of the acid has a pH of 2.43. What is K_a for this acid?

SOME SIMILAR PROBLEMS 18.64, 18.65, 18.72, and 18.73

Finding Concentrations Given K_a

The second type of equilibrium problem gives some concentration data and K_a and asks for the equilibrium concentration of some component. Such problems are very similar to those we solved in Chapter 17 in which a substance with a given initial concentration reacted to an unknown extent (see Sample Problems 17.9 to 17.11). We will use a reaction table in these problems to find the values, and, as we just found, $[H_3O^+]_{from\ H_2O}$ is so small relative to $[H_3O^+]_{from\ HA}$ that we will neglect it and enter the initial $[H_3O^+]$ in all reaction tables as zero.

SAMPLE PROBLEM 18.8 Determining Concentration and pH from K_a and Initial [HA]

Problem Propanoic acid (CH_3CH_2COOH, which we simplify as HPr) is a carboxylic acid whose salts are used to retard mold growth in foods. What are the $[H_3O^+]$ and the pH of 0.10 *M* HPr ($K_a = 1.3\times10^{-5}$)?

Plan We know the initial concentration (0.10 *M*) and K_a (1.3×10^{-5}) of HPr, and we need to find $[H_3O^+]$ and pH. First, we write the balanced equation and the expression for K_a. We know $[HPr]_{init}$ but not [HPr] (that is, the concentration at equilibrium). If we let $x = [HPr]_{dissoc}$, x is also $[H_3O^+]_{from\ HPr}$ and $[Pr^-]$ because each HPr dissociates into one H_3O^+ and one Pr^-. With this information, we set up a reaction table. We assume that, because HPr has a small K_a, it dissociates very little. After solving for x, which is $[H_3O^+]$, we check the assumption. Then we use the value for $[H_3O^+]$ to find the pH.

Solution Writing the balanced equation and expression for K_a:

$$HPr(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + Pr^-(aq) \qquad K_a = \frac{[H_3O^+][Pr^-]}{[HPr]} = 1.3\times10^{-5}$$

Setting up a reaction table, with $x = [HPr]_{dissoc} = [H_3O^+]_{from\ HPr} = [Pr^-] = [H_3O^+]$:

Concentration (*M*)	HPr(*aq*)	+	$H_2O(l)$	$\rightleftharpoons$	$H_3O^+(aq)$	+	$Pr^-(aq)$
Initial	0.10		—		0		0
Change	$-x$		—		$+x$		$+x$
Equilibrium	$0.10 - x$		—		x		x

Making the assumption: K_a is small, so x is small compared with $[HPr]_{init}$; therefore, $[HPr]_{init} - x = [HPr] \approx [HPr]_{init}$, or $0.10\ M - x \approx 0.10\ M$. Substituting into the K_a expression and solving for x:

$$K_a = \frac{[H_3O^+][Pr^-]}{[HPr]} = 1.3\times10^{-5} \approx \frac{(x)(x)}{0.10}$$

$$x \approx \sqrt{(0.10)(1.3\times10^{-5})} = 1.1\times10^{-3}\ M = [H_3O^+]$$

Checking the assumption for $[HPr]_{dissoc}$:

$$\frac{1.1\times10^{-3}\ M}{0.10\ M} \times 100 = 1.1\%\ (<5\%;\ \text{assumption is justified})$$

Finding the pH:

$$\text{pH} = -\log [H_3O^+] = -\log (1.1\times10^{-3}) = 2.96$$

Check The $[H_3O^+]$ and pH seem reasonable for a dilute solution of a weak acid with a moderate K_a. By reversing the calculation, we can check the math: $(1.1\times10^{-3})^2/0.10 = 1.2\times10^{-5}$, which is within rounding of the given K_a.

Comment In Chapter 17 we introduced a benchmark, aside from the 5% rule, to see if the assumption is justified (see the discussion following Sample Problem 17.10):

- If $\dfrac{[HA]_{init}}{K_a} > 400$, the assumption is justified: neglecting x introduces an error <5%.
- If $\dfrac{[HA]_{init}}{K_a} < 400$, the assumption is *not* justified; neglecting x introduces an error >5%, so we solve a quadratic equation to find x.

In this sample problem, we have $\dfrac{0.10}{1.3\times10^{-5}} = 7.7\times10^3$, which is greater than 400. The alternative situation occurs in Follow-up Problem 18.8A.

FOLLOW-UP PROBLEMS

18.8A Cyanic acid (HOCN) is an extremely acrid, unstable substance. What are the $[H_3O^+]$ and the pH of 0.10 *M* HOCN ($K_a = 3.5\times10^{-4}$)?

18.8B Benzoic acid (C_6H_5COOH) is used as a food preservative. What are the $[H_3O^+]$ and the pH of 0.25 *M* C_6H_5COOH ($pK_a = 4.20$)?

SOME SIMILAR PROBLEMS 18.66–18.69 and 18.74–18.77

The Effect of Concentration on the Extent of Acid Dissociation

If we repeat the calculation in Sample Problem 18.8, but start with a lower [HPr], we observe a very interesting fact about the extent of dissociation of a weak acid. Suppose the initial concentration of HPr is one-tenth as much, 0.010 *M* rather than 0.10 *M*. After filling in the reaction table and making the same assumptions, we find that

$$x = [H_3O^+] = [HPr]_{dissoc} = 3.6\times10^{-4}\ M$$

Now, let's compare the percentages of HPr molecules dissociated at the two different initial acid concentrations, using the relationship

$$\text{Percent HA dissociated} = \frac{[HA]_{dissoc}}{[HA]_{init}}\times 100 \qquad (18.5)$$

Case 1: $[HPr]_{init} = 0.10\ M$

$$\text{Percent HPr dissociated} = \frac{1.1\times10^{-3}\ M}{1.0\times10^{-1}\ M}\times 100 = 1.1\%$$

Case 2: $[HPr]_{init} = 0.010\ M$

$$\text{Percent HPr dissociated} = \frac{3.6\times10^{-4}\ M}{1.0\times10^{-2}\ M}\times 100 = 3.6\%$$

As the initial acid concentration decreases, the percent dissociation of the acid increases. Don't confuse the *concentration* of HA dissociated with the *percent* HA dissociated. The concentration, $[HA]_{dissoc}$, is lower in the diluted HA solution because the actual *number* of dissociated HA molecules is smaller. It is the *fraction* (or the *percent*) of dissociated HA molecules that increases with dilution.

This phenomenon is analogous to a change in container volume (pressure) for a reaction involving gases at equilibrium (Section 17.6). In the case of gases, an increase in volume shifts the equilibrium position to favor more moles of gas. In the case of HA dissociation, a lower HA concentration, which is the same as an increase in volume, shifts the equilibrium position to favor more moles of ions.

SAMPLE PROBLEM 18.9 Finding the Percent Dissociation of a Weak Acid

Problem In 2011, researchers showed that hypochlorous acid (HClO) generated by white blood cells kills bacteria. Calculate the percent dissociation of **(a)** 0.40 *M* HClO; **(b)** 0.035 *M* HClO ($K_a = 2.9\times10^{-8}$).

Plan We know the K_a of HClO and need $[HClO]_{dissoc}$ to find the percent dissociation at two different initial concentrations. We write the balanced equation and the expression for K_a and then set up a reaction table, with $x = [HClO]_{dissoc} = [ClO^-] = [H_3O^+]$. We assume that because HClO has a small K_a, it dissociates very little. Once $[HClO]_{dissoc}$ is known, we use Equation 18.5 to find the percent dissociation and check the assumption.

Solution **(a)** Writing the balanced equation and the expression for K_a:

$$HClO(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + ClO^-(aq) \qquad K_a = \frac{[ClO^-][H_3O^+]}{[HClO]} = 2.9\times10^{-8}$$

Setting up a reaction table with $x = [HClO]_{dissoc} = [ClO^-] = [H_3O^+]$:

Concentration (*M*)	HClO(*aq*)	+	$H_2O(l)$	$\rightleftharpoons$	$H_3O^+(aq)$	+	$ClO^-(aq)$
Initial	0.40		—		0		0
Change	$-x$		—		$+x$		$+x$
Equilibrium	$0.40 - x$		—		x		x

Making the assumption: K_a is small, so x is small compared with $[HClO]_{init}$; therefore, $[HClO]_{init} - x \approx [HClO]_{init}$, or $0.40\ M - x \approx 0.40\ M$. Substituting into the K_a expression and solving for x:

$$K_a = \frac{[ClO^-][H_3O^+]}{[HClO]} = 2.9\times10^{-8} \approx \frac{(x)(x)}{0.40}$$

Thus,

$$x^2 = (0.40)(2.9\times10^{-8})$$
$$x = \sqrt{(0.40)(2.9\times10^{-8})} = 1.1\times10^{-4}\ M = [HClO]_{dissoc}$$

Finding the percent dissociation:

$$\text{Percent dissociation} = \frac{[HClO]_{dissoc}}{[HClO]_{init}} \times 100 = \frac{1.1\times10^{-4}\ M}{0.40\ M} \times 100 = \boxed{0.028\%}$$

Since the percent dissociation is <5%, the assumption is justified.

(b) Performing the same calculations using $[HClO]_{init} = 0.035\ M$:

$$K_a = \frac{[ClO^-][H_3O^+]}{[HClO]} = 2.9\times10^{-8} \approx \frac{(x)(x)}{0.035}$$
$$x = \sqrt{(0.035)(2.9\times10^{-8})} = 3.2\times10^{-5}\ M = [HClO]_{dissoc}$$

Finding the percent dissociation:

$$\text{Percent dissociation} = \frac{[HClO]_{dissoc}}{[HClO]_{init}} \times 100 = \frac{3.2\times10^{-5}\ M}{0.035\ M} \times 100 = \boxed{0.091\%}$$

Since the percent dissociation is <5%, the assumption is justified.

Check The percent dissociation is very small as we expect for an acid with such a low K_a. Note, however, that the percent dissociation is larger for the lower initial concentration, as we also expect.

FOLLOW-UP PROBLEMS

18.9A Calculate the percent dissociation of 0.75 *M* HCN, an extremely poisonous acid that can be obtained from the pits of fruits such as cherries and apples ($K_a = 6.2\times10^{-10}$).

18.9B A weak acid is 3.16% dissociated in a 1.5 *M* solution. What is the K_a of the acid?

SOME SIMILAR PROBLEMS 18.70, 18.71, 18.78, and 18.79

The Behavior of Polyprotic Acids

Acids with more than one ionizable proton are **polyprotic acids.** In solution, each dissociation step has a different K_a. For example, phosphoric acid is a triprotic acid (three ionizable protons), so it has three K_a values:

$$H_3PO_4(aq) + H_2O(l) \rightleftharpoons H_2PO_4^-(aq) + H_3O^+(aq)$$

$$K_{a1} = \frac{[H_2PO_4^-][H_3O^+]}{[H_3PO_4]} = 7.2\times10^{-3}$$

$$H_2PO_4^-(aq) + H_2O(l) \rightleftharpoons HPO_4^{2-}(aq) + H_3O^+(aq)$$

$$K_{a2} = \frac{[HPO_4^{2-}][H_3O^+]}{[H_2PO_4^-]} = 6.3\times10^{-8}$$

$$HPO_4^{2-}(aq) + H_2O(l) \rightleftharpoons PO_4^{3-}(aq) + H_3O^+(aq)$$

$$K_{a3} = \frac{[PO_4^{3-}][H_3O^+]}{[HPO_4^{2-}]} = 4.2\times10^{-13}$$

The relative K_a values show that H_3PO_4 is a much stronger acid than $H_2PO_4^-$, which is much stronger than HPO_4^{2-}.

Table 18.5 lists some common polyprotic acids and their K_a values. (More are listed in Appendix C.) Note that the general pattern seen for H_3PO_4 occurs for all polyprotic acids:

$$K_{a1} >> K_{a2} >> K_{a3}$$

This trend occurs because it is more difficult for the positively charged H^+ ion to leave a singly charged anion (such as $H_2PO_4^-$) than to leave a neutral molecule (such as H_3PO_4), and more difficult still for it to leave a doubly charged anion (such as HPO_4^{2-}). Successive K_a values typically differ by several orders of magnitude. This fact simplifies calculations because *we usually neglect the H_3O^+ coming from the subsequent dissociations.*

Table 18.5 Successive K_a Values for Some Polyprotic Acids at 25°C

Name (Formula)	Lewis Structure*	K_{a1}	K_{a2}	K_{a3}
Oxalic acid ($H_2C_2O_4$)		5.6×10^{-2}	5.4×10^{-5}	
Sulfurous acid (H_2SO_3)		1.4×10^{-2}	6.5×10^{-8}	
Phosphoric acid (H_3PO_4)		7.2×10^{-3}	6.3×10^{-8}	4.2×10^{-13}
Arsenic acid (H_3AsO_4)		6×10^{-3}	1.1×10^{-7}	3×10^{-12}
Carbonic acid (H_2CO_3)		4.5×10^{-7}	4.7×10^{-11}	
Hydrosulfuric acid (H_2S)		9×10^{-8}	1×10^{-17}	

ACID STRENGTH

*Red type indicates the ionizable protons.

SAMPLE PROBLEM 18.10 Calculating Equilibrium Concentrations for a Polyprotic Acid

Problem Ascorbic acid ($H_2C_6H_6O_6$; H_2Asc for this problem), known as vitamin C, is a diprotic acid ($K_{a1} = 1.0\times10^{-5}$ and $K_{a2} = 5\times10^{-12}$) found in citrus fruit. Calculate $[HAsc^-]$, $[Asc^{2-}]$, and the pH of 0.050 M H_2Asc.

Plan We know the initial concentration (0.050 M) and both K_a's for H_2Asc, and we have to calculate the equilibrium concentrations of all species and convert $[H_3O^+]$ to pH. We first write the equations and K_a expressions. Because $K_{a1} >> K_{a2}$, we can assume that the first dissociation produces almost all the H_3O^+: $[H_3O^+]_{from\ H_2Asc} >> [H_3O^+]_{from\ HAsc^-}$. Also, because K_{a1} is small, the amount of H_2Asc that dissociates can be neglected. We set up a reaction table for the first dissociation, with $x = [H_2Asc]_{dissoc}$, and then we solve for $[H_3O^+]$ and $[HAsc^-]$. Because the second dissociation occurs to a much lesser extent, we can substitute values from the first dissociation directly to find $[Asc^{2-}]$ from the second.

Solution Writing the equations and K_a expressions:

$$H_2Asc(aq) + H_2O(l) \rightleftharpoons HAsc^-(aq) + H_3O^+(aq)$$

$$K_{a1} = \frac{[HAsc^-][H_3O^+]}{[H_2Asc]} = 1.0\times10^{-5}$$

$$HAsc^-(aq) + H_2O(l) \rightleftharpoons Asc^{2-}(aq) + H_3O^+(aq)$$

$$K_{a2} = \frac{[Asc^{2-}][H_3O^+]}{[HAsc^-]} = 5\times10^{-12}$$

Setting up a reaction table with $x = [H_2Asc]_{dissoc} = [HAsc^-] \approx [H_3O^+]$:

Concentration (M)	$H_2Asc(aq)$	+	$H_2O(l)$	$\rightleftharpoons$	$H_3O^+(aq)$	+	$HAsc^-(aq)$
Initial	0.050		—		0		0
Change	$-x$		—		$+x$		$+x$
Equilibrium	$0.050 - x$		—		x		x

Making the assumptions:

1. Because $K_{a2} << K_{a1}$, $[H_3O^+]_{from\ HAsc^-} << [H_3O^+]_{from\ H_2Asc}$. Therefore,
$$[H_3O^+]_{from\ H_2Asc} \approx [H_3O^+]$$
2. Because K_{a1} is small, $[H_2Asc]_{init} - x = [H_2Asc] \approx [H_2Asc]_{init}$. Thus,
$$[H_2Asc] = 0.050\ M - x \approx 0.050\ M$$

Substituting into the expression for K_{a1} and solving for x:

$$K_{a1} = \frac{[H_3O^+][HAsc^-]}{[H_2Asc]} = 1.0\times10^{-5} = \frac{x^2}{0.050 - x} \approx \frac{x^2}{0.050}$$

$$x = [HAsc^-] \approx [H_3O^+] \approx 7.1\times10^{-4}\ M$$

$$pH = -\log[H_3O^+] = -\log(7.1\times10^{-4}) = 3.15$$

Checking the assumptions:

1. $[H_3O^+]_{from\ HAsc^-} << [H_3O^+]_{from\ H_2Asc}$: For any second dissociation that does occur,
$$K_{a2} = \frac{[Asc^-][H_3O^+]}{[HAsc^-]} = 5\times10^{-12} = \frac{(x)(x)}{7.1\times10^{-4}}$$
$$x = [H_3O^+]_{from\ HAsc^-} = 6\times10^{-8}\ M$$
This is even less than $[H_3O^+]_{from\ H_2O}$, so the assumption is justified.
2. $[H_2Asc]_{dissoc} << [H_2Asc]_{init}$: $\frac{7.1\times10^{-4}\ M}{0.050\ M} \times 100 = 1.4\%$ (<5%; assumption is justified).

Also, note that

$$\frac{[H_2Asc]_{init}}{K_{a1}} = \frac{0.050}{1.0\times10^{-5}} = 5000 > 400$$

Using the equilibrium concentrations from the first dissociation to calculate $[Asc^{2-}]$:

$$K_{a2} = \frac{[H_3O^+][Asc^{2-}]}{[HAsc^-]} \quad \text{and} \quad [Asc^{2-}] = \frac{(K_{a2})[HAsc^-]}{[H_3O^+]}$$

$$[Asc^{2-}] = \frac{(5\times10^{-12})(7.1\times10^{-4})}{7.1\times10^{-4}} = 5\times10^{-12}\ M$$

Check $K_{a1} >> K_{a2}$, so it makes sense that $[HAsc^-] >> [Asc^{2-}]$ because Asc^{2-} is produced only in the second (much weaker) dissociation. Both K_a's are small, so all concentrations except $[H_2Asc]$ should be much lower than the original 0.050 *M*.

FOLLOW-UP PROBLEMS

18.10A Oxalic acid (HOOC—COOH, or $H_2C_2O_4$) is the simplest diprotic carboxylic acid. Its commercial uses include bleaching straw and leather and removing rust and ink stains. Calculate the equilibrium values of $[H_2C_2O_4]$, $[HC_2O_4^-]$, and $[C_2O_4^{2-}]$, and find the pH of a 0.150 *M* $H_2C_2O_4$ solution. Use K_a values from Appendix C. (*Hint:* First check whether you need the quadratic equation to find *x*.)

18.10B Carbonic acid (H_2CO_3) plays a role in blood chemistry, cave formation, and ocean acidification. Using its K_a values from Appendix C, calculate the equilibrium values of $[H_2CO_3]$, $[HCO_3^-]$, and $[CO_3^{2-}]$, and find the pH of a 0.075 *M* H_2CO_3 solution.

SOME SIMILAR PROBLEMS 18.80 and 18.81

Summary of Section 18.4

- Two common types of weak-acid equilibrium problems involve finding K_a from a given concentration and finding a concentration from a given K_a.
- We simplify the arithmetic by assuming (1) that $[H_3O^+]_{from\ H_2O}$ is much smaller than $[H_3O^+]_{from\ HA}$ and can be neglected and (2) that weak acids dissociate so little that $[HA]_{init} \approx [HA]$ at equilibrium.
- The *fraction* of weak acid molecules that dissociates is greater in a more dilute solution, even though the total $[H_3O^+]$ is lower.
- Polyprotic acids have more than one ionizable proton, but we assume that the first dissociation provides virtually all the H_3O^+.

18.5 MOLECULAR PROPERTIES AND ACID STRENGTH

The strength of an acid depends on its ability to donate a proton, which depends in turn on the strength of the bond to the acidic proton. In this section, we apply trends in atomic and bond properties to determine the trends in acid strength of nonmetal hydrides and oxoacids and then discuss the acidity of hydrated metal ions.

Acid Strength of Nonmetal Hydrides

Two factors determine how easily a proton is released from a nonmetal hydride:

- The electronegativity of the central nonmetal (E)
- The strength of the E—H bond

Figure 18.9 displays two periodic trends among the nonmetal hydrides:

1. *Across a period, acid strength increases.* The electronegativity of the nonmetal E determines this horizontal trend. From left to right, as E becomes more electronegative, it withdraws electron density from H, and the E—H bond becomes more polar. As a result, H^+ is pulled away more easily by an O atom of a water molecule. In aqueous solution, the hydrides of Groups 3A(13) to 5A(15) do not behave as acids, but an increase in acid strength is seen from Group 6A(16) to 7A(17).

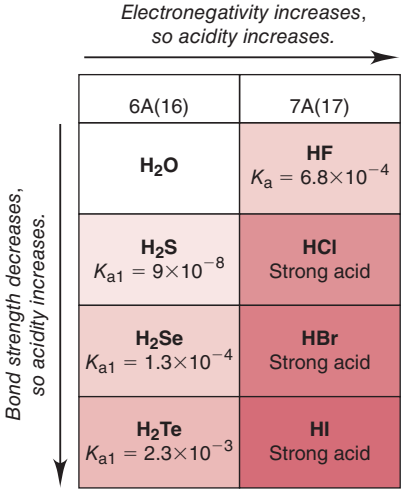


Figure 18.9 The effect of atomic and molecular properties on nonmetal hydride acidity.

2. *Down a group, acid strength increases.* E—H bond strength determines this vertical trend. As E becomes larger, the E—H bond becomes longer and weaker, so H^+ comes off more easily.* For example, the hydrohalic acid strength increases down the group:

Acid strength:	HF	<<	HCl	<	HBr	<	HI
Bond length (pm):	92		127		141		161
Bond energy (kJ/mol):	565		427		363		295

(This trend is not seen in aqueous solution, where HCl, HBr, and HI are all equally strong; we discuss how it *is* observed in Section 18.8.)

Acid Strength of Oxoacids

All oxoacids have the acidic H atom bonded to an O atom, so bond length is not involved. As we mentioned for the halogen oxoacids (Section 14.9), two other factors determine the acid strength of oxoacids:

- The electronegativity of the central nonmetal (E)
- The number of O atoms around E (O.N. of E)

Figure 18.10 summarizes these trends:

1. *For oxoacids with the **same** number of O atoms, acid strength increases with the electronegativity of E.* Consider the hypohalous acids (HOE, where E is a halogen atom). The more electronegative E is, the more polar the O—H bond becomes and the more easily H^+ is lost (Figure 18.10A). Electronegativity decreases down a group, as does acid strength:

K_a of HOCl $= 2.9\times10^{-8}$ K_a of HOBr $= 2.3\times10^{-9}$ K_a of HOI $= 2.3\times10^{-11}$

Similarly, in Group 6A(16), H_2SO_4 is stronger than H_2SeO_4; in Group 5A(15), H_3PO_4 is stronger than H_3AsO_4, and so forth.

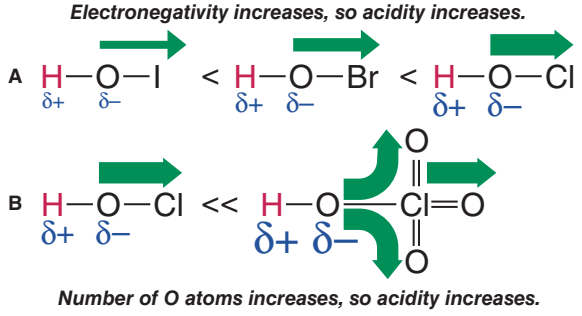

Figure 18.10 The relative strengths of oxoacids. A, Cl withdraws electron density (thickness of green arrow) from the O—H bond most effectively, making that bond most polar (relative size of δ symbols). **B,** Additional O atoms pull more electron density from the O—H bond.

2. *For oxoacids with **different** numbers of O atoms, acid strength increases with number of O atoms (or O.N. of central nonmetal).* The electronegative O atoms pull electron density away from E, which makes the O—H bond more polar. The more O atoms present, the greater the shift in electron density, and the more easily the H^+ ion comes off (Figure 18.10B). Therefore, the chlorine oxoacids ($HOClO_n$, with n from 0 to 3) increase in strength with the number of O atoms (and O.N. of Cl):

$$\overset{+1}{K_a \text{ of HOCl}} = 2.9\times10^{-8} \qquad \overset{+3}{K_a \text{ of HOClO}} = 1.12\times10^{-2} \qquad \overset{+5}{K_a \text{ of HOClO}_2} \approx 1 \qquad \overset{+7}{K_a \text{ of HOClO}_3} > 10^7$$

Similarly, HNO_3 is stronger than HNO_2, H_2SO_4 is stronger than H_2SO_3, and so forth.

*Actually, bond energy refers to bond breakage that forms an H atom, whereas acidity refers to bond breakage that forms an H^+ ion. Although these two types of bond breakage are not the same, the trends in bond energy and acid strength are opposites.

Acidity of Hydrated Metal Ions

The aqueous solutions of certain metal ions are acidic because the *hydrated* metal ion transfers an H^+ ion to water. Consider a general metal nitrate, $M(NO_3)_n$, as it dissolves in water. The ions separate and the metal ion becomes bonded to some number of H_2O molecules. This equation shows the hydration of the cation (M^{n+}) with H_2O molecules and (*aq*); hydration of the anion (NO_3^-) is indicated by just (*aq*):

$$M(NO_3)_n(s) + xH_2O(l) \longrightarrow M(H_2O)_x^{n+}(aq) + nNO_3^-(aq)$$

If the metal ion, M^{n+}, is *small and highly charged,* its high charge density withdraws sufficient electron density from the O—H bonds of the bound water molecules for an H^+ to be released. Thus, the hydrated cation, $M(H_2O)_x^{n+}$, is a typical Brønsted-Lowry acid. The bound H_2O that releases the H^+ becomes a bound OH^- ion:

$$M(H_2O)_x^{n+}(aq) + H_2O(l) \rightleftharpoons M(H_2O)_{x-1}OH^{(n-1)+}(aq) + H_3O^+(aq)$$

Salts of most M^{2+} and M^{3+} ions yield acidic aqueous solutions. The K_a values for some acidic hydrated metal ions appear in Appendix C.

Consider the small, highly charged Al^{3+} ion. When an aluminum salt, such as $Al(NO_3)_3$, dissolves in water, the following steps occur:

$$Al(NO_3)_3(s) + 6H_2O(l) \longrightarrow Al(H_2O)_6^{3+}(aq) + 3NO_3^-(aq)$$

[dissolution and hydration]

$$Al(H_2O)_6^{3+}(aq) + H_2O(l) \rightleftharpoons Al(H_2O)_5OH^{2+}(aq) + H_3O^+(aq) \qquad K_a = 1\times10^{-5}$$

[dissociation of weak acid]

Note the formulas of the hydrated metal ions in the last step. When H^+ is released, the number of bound H_2O molecules decreases by 1 (from 6 to 5) and the number of bound OH^- ions increases by 1 (from 0 to 1), which reduces the ion's positive charge by 1 (from 3 to 2) (Figure 18.11). This pattern of changes in the formula of the hydrated metal ion before and after it loses a proton appears for any highly charged metal ion in water.

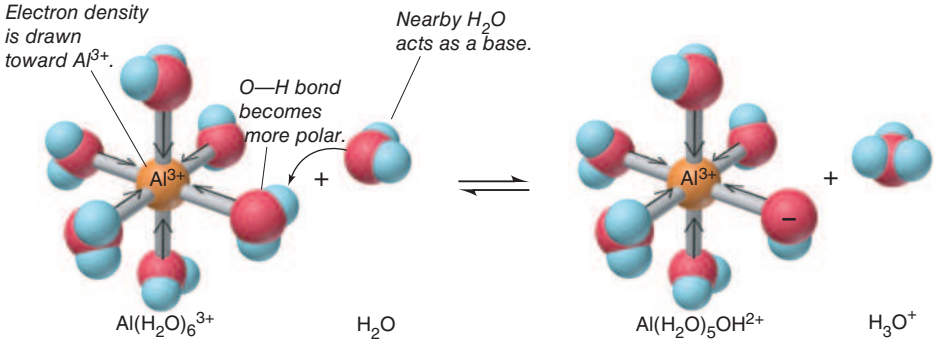

Figure 18.11 The acidic behavior of the hydrated Al^{3+} ion. The hydrated Al^{3+} ion is small and highly charged and pulls electron density from the O—H bonds, so an H^+ ion can be transferred to a nearby water molecule.

Summary of Section 18.5

- For nonmetal hydrides, acid strength increases across a period, with the electronegativity of the nonmetal (E), and down a group, with the length of the E—H bond.
- For oxoacids with the same number of O atoms, acid strength increases with electronegativity of E; for oxoacids with the same E, acid strength increases with number of O atoms (or O.N. of E).
- Small, highly charged metal ions are acidic in water because they withdraw electron density from the O—H bonds of bound H_2O molecules, releasing an H^+ ion to the solution.

18.6 WEAK BASES AND THEIR RELATION TO WEAK ACIDS

The Brønsted-Lowry concept expands the definition of a base to encompass a host of species that the Arrhenius definition excludes: *to accept a proton, a base needs only a lone electron pair.*

Let's examine the equilibrium system of a weak base (B) as it dissolves in water: B accepts a proton from H_2O, which acts as an acid, leaving behind an OH^- ion:

$$B(aq) + H_2O(l) \rightleftharpoons BH^+(aq) + OH^-(aq)$$

This general reaction for a base in water is described by the equilibrium expression

$$K_c = \frac{[BH^+][OH^-]}{[B][H_2O]}$$

Based on our earlier reasoning, we eliminate $[H_2O]$ from the equilibrium expression and obtain the **base-dissociation constant** (or **base-ionization constant**), K_b**:**

$$K_b = \frac{[BH^+][OH^-]}{[B]} \qquad (18.6)$$

Despite the name "base-dissociation constant," *no base dissociates in the process.*

Base-dissociation constants can be expressed as pK_b values:

$$pK_b = -\log K_b \qquad \text{and} \qquad 10^{-pK_b} = K_b$$

The larger the value of K_b, the smaller the value of pK_b and the stronger the base, producing a higher $[OH^-]$ at equilibrium:

$$\text{Stronger base} \Longrightarrow \text{higher } [OH^-] \Longrightarrow \text{larger } K_b \text{ (lower } pK_b)$$

In aqueous solution, the two large classes of weak bases are (1) the molecular species ammonia and the amines and (2) the anions of weak acids.

Molecules as Weak Bases: Ammonia and the Amines

Ammonia is the simplest N-containing compound that acts as a weak base in water:

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq) \qquad K_b = 1.76\times10^{-5} \text{ (at 25°C)}$$

Despite labels on reagent bottles that read "ammonium hydroxide," an aqueous solution of ammonia consists largely of water and *unprotonated* NH_3 molecules, as its small K_b indicates. In a 1.0 *M* NH_3 solution, for example, $[OH^-] = [NH_4^+] = 4.2\times10^{-3}$ *M*, so about 99.6% of the NH_3 is not protonated. Table 18.6 shows the K_b values for a few molecular bases. (A more extensive list appears in Appendix C.)

If one or more of the H atoms in ammonia is replaced by an organic group (designated as R), an *amine* results: RNH_2, R_2NH, or R_3N (Section 15.4; see Figure 15.17). The key structural feature of these organic compounds, as in all Brønsted-Lowry bases, is *a lone pair of electrons that can bind the proton donated by the acid.* Figure 18.12 depicts this process for methylamine, the simplest amine.

To find the pH of a solution of a molecular weak base, we use an approach very similar to that for a weak acid: write the equilibrium expression, set up a reaction table to find $[B]_{reacting}$, make the usual assumptions, and then solve for $[OH^-]$. The only additional step is to convert $[OH^-]$ to $[H_3O^+]$ in order to calculate pH.

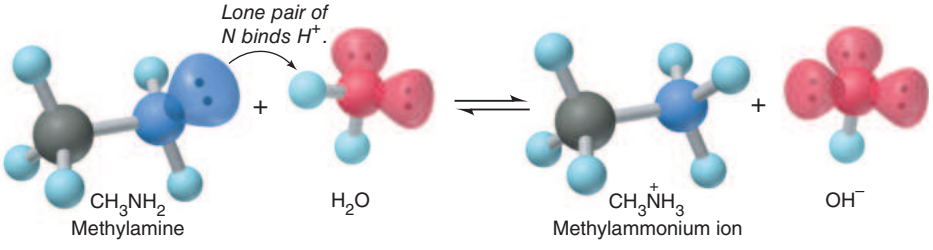

Figure 18.12 **Abstraction of a proton from water by the base methylamine.**

Table 18.6 K_b Values for Some Molecular (Amine) Bases at 25°C

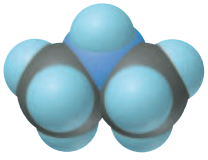
Name (Formula)	Lewis Structure*	Reaction	K_b	pK_b
Diethylamine [$(CH_3CH_2)_2NH$]		$(CH_3CH_2)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3CH_2)_2NH_2^+(aq) + OH^-(aq)$	8.6×10^{-4}	3.07
Dimethylamine [$(CH_3)_2NH$]		$(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) + OH^-(aq)$	5.9×10^{-4}	3.23
Methylamine (CH_3NH_2)		$CH_3NH_2(aq) + H_2O(l) \rightleftharpoons CH_3NH_3^+(aq) + OH^-(aq)$	4.4×10^{-4}	3.36
Ammonia (NH_3)		$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$	1.76×10^{-5}	4.75
Pyridine (C_5H_5N)		$C_5H_5N(aq) + H_2O(l) \rightleftharpoons C_5H_5NH^+(aq) + OH^-(aq)$	1.7×10^{-9}	8.77
Aniline ($C_6H_5NH_2$)		$C_6H_5NH_2(aq) + H_2O(l) \rightleftharpoons C_6H_5NH_3^+(aq) + OH^-(aq)$	4.0×10^{-10}	9.40

BASE STRENGTH

*Blue type indicates the basic nitrogen and its lone pair.

SAMPLE PROBLEM 18.11 Determining pH from K_b and Initial [B]

Problem Dimethylamine, $(CH_3)_2NH$ *(see margin)*, a key intermediate in detergent manufacture, has a K_b of 5.9×10^{-4}. What is the pH of 1.5 *M* $(CH_3)_2NH$?



Dimethylamine

Plan We know the initial concentration (1.5 *M*) and K_b (5.9×10^{-4}) of $(CH_3)_2NH$ and have to find the pH. The amine reacts with water to form OH^-, so we have to find $[OH^-]$ and then calculate $[H_3O^+]$ and pH. We first write the balanced equation and K_b expression. Because $K_b >> K_w$, the $[OH^-]$ from the autoionization of water is negligible, so we disregard it and assume that all the $[OH^-]$ comes from the base reacting with water. Because K_b is small, we assume that the amount of amine reacting, $[(CH_3)_2NH]_{reacting}$, can be neglected. We set up a reaction table, make the assumption, and solve for x. Then we check the assumption and convert $[OH^-]$ to $[H_3O^+]$ using K_w; finally, we calculate pH.

Solution Writing the balanced equation and K_b expression:

$$(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) + OH^-(aq)$$

$$K_b = \frac{[(CH_3)_2NH_2^+][OH^-]}{[(CH_3)_2NH]}$$

Setting up the reaction table, with $x = [(CH_3)_2NH]_{reacting} = [(CH_3)_2NH_2^+] = [OH^-]$:

Concentration (*M*)	$(CH_3)_2NH(aq)$	+ $H_2O(l)$ $\rightleftharpoons$	$(CH_3)_2NH_2^+(aq)$	+ $OH^-(aq)$
Initial	1.5	—	0	0
Change	$-x$	—	$+x$	$+x$
Equilibrium	$1.5 - x$	—	x	x

Making the assumption: K_b is small, so

$$[(CH_3)_2NH]_{init} - [(CH_3)_2NH]_{reacting} = [(CH_3)_2NH] \approx [(CH_3)_2NH]_{init}$$

thus, $1.5\ M - x \approx 1.5\ M$.

Substituting into the K_b expression and solving for x:

$$K_b = \frac{[(CH_3)_2NH_2^+][OH^-]}{[(CH_3)_2NH]} = 5.9\times10^{-4} \approx \frac{x^2}{1.5}$$

$$x = [OH^-] \approx 3.0\times10^{-2}\ M$$

Checking the assumption:

$$\frac{3.0\times10^{-2}\ M}{1.5\ M} \times 100 = 2.0\%\ (<5\%;\ \text{assumption is justified})$$

Note that the Comment in Sample Problem 18.8 applies in these cases as well:

$$\frac{[B]_{init}}{K_b} = \frac{1.5}{5.9\times10^{-4}} = 2.5\times10^3 > 400$$

Calculating pH:

$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0\times10^{-14}}{3.0\times10^{-2}} = 3.3\times10^{-13}\ M$$

$$pH = -\log(3.3\times10^{-13}) = 12.48$$

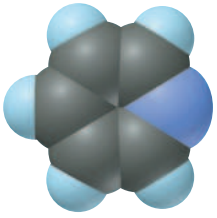
Check The value of x seems reasonable: $\sqrt{(\sim6\times10^{-4})(1.5)} = \sqrt{9\times10^{-4}} = 3\times10^{-2}$. Because $(CH_3)_2NH$ is a weak base, the pH should be several pH units above 7.

FOLLOW-UP PROBLEMS

18.11A Pyridine (C_5H_5N, *see margin*) serves as a solvent *and* a base in many organic syntheses. It has a pK_b of 8.77. What is the pH of 0.10 M pyridine?

18.11B The weak base amphetamine, $C_6H_5CH_2CH(CH_3)NH_2$, is a stimulant used to treat narcolepsy and attention deficit disorder. What is the pH of 0.075 M amphetamine ($K_b = 6.3\times10^{-5}$)?

SOME SIMILAR PROBLEMS 18.103–18.106



Pyridine

Anions of Weak Acids as Weak Bases

The other large group of Brønsted-Lowry bases consists of anions of weak acids:*

$$A^-(aq) + H_2O(l) \rightleftharpoons HA(aq) + OH^-(aq) \qquad K_b = \frac{[HA][OH^-]}{[A^-]}$$

For example, F^-, the anion of the weak acid HF, is a weak base:

$$F^-(aq) + H_2O(l) \rightleftharpoons HF(aq) + OH^-(aq) \qquad K_b = \frac{[HF][OH^-]}{[F^-]}$$

Why is a solution of HA acidic and a solution of A^- basic? We'll find the answer from relative concentrations of species in 1 M HF and in 1 M NaF:

1. *The acidity of HA(aq).* HF is a weak acid, so the equilibrium position of the acid dissolving in water lies far to the left:

$$HF(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + F^-(aq)$$

Water also contributes H_3O^+ and OH^-, but their concentrations are extremely small:

$$2H_2O(l) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$$

Of all the species present—HF, H_2O, H_3O^+, F^-, and OH^-—the two that can influence the acidity of the solution are H_3O^+, predominantly from HF, and OH^- from water. Thus, the HF solution is acidic because $[H_3O^+]_{\text{from HF}} >> [OH^-]_{\text{from } H_2O}$.

*This equation and equilibrium expression are sometimes referred to as a *hydrolysis reaction* and a *hydrolysis constant*, K_h, because water is dissociated (hydrolyzed). Actually, except for the charge on the base, this process is the same as the proton-abstraction process by ammonia and amines. That is, K_h is just another symbol for K_b, so we'll use K_b throughout.

2. *The basicity of $A^-(aq)$.* Now, consider the species present in 1 *M* NaF. The salt dissociates completely to yield 1 *M* Na^+ and 1 *M* F^-. The Na^+ behaves as a spectator ion, while some F^- reacts as a weak base to produce small amounts of HF and OH^-:

$$F^-(aq) + H_2O(l) \rightleftharpoons HF(aq) + OH^-(aq)$$

As before, water dissociation contributes minute amounts of H_3O^+ and OH^-. Thus, in addition to the Na^+ ion, the species present are the same as in the HF solution: HF, H_2O, H_3O^+, F^-, and OH^-. The two species that affect the acidity are OH^-, predominantly from F^- reacting with water, and H_3O^+ from water. In this case, $[OH^-]_{\text{from } F^-} >> [H_3O^+]_{\text{from } H_2O}$, so the solution is basic.

To summarize,

- In an HA solution, $[HA] >> [A^-]$ and $[H_3O^+]_{\text{from HA}} >> [OH^-]_{\text{from } H_2O}$, so the solution is acidic.
- In an A^- solution, $[A^-] >> [HA]$ and $[OH^-]_{\text{from } A^-} >> [H_3O^+]_{\text{from } H_2O}$, so the solution is basic.

The Relation Between K_a and K_b of a Conjugate Acid-Base Pair

A key relationship exists between the K_a of HA and the K_b of its conjugate base, A^-, which we can see by writing the two reactions as a reaction sequence and adding them:

$$\begin{array}{rl} HA + H_2O & \rightleftharpoons H_3O^+ + A^- \\ A^- + H_2O & \rightleftharpoons HA + OH^- \\ \hline 2H_2O & \rightleftharpoons H_3O^+ + OH^- \end{array}$$

The sum of the two dissociation reactions is the autoionization of water. Recall from Chapter 17 that, for a reaction that is the *sum* of two or more reactions, the overall equilibrium constant is the *product* of the individual equilibrium constants. Therefore, writing the equilibrium expressions for each reaction gives

$$\frac{[H_3O^+][A^-]}{[HA]} \times \frac{[HA][OH^-]}{[A^-]} = [H_3O^+][OH^-]$$

or

$$K_a \times K_b = K_w \qquad (18.7)$$

This relationship allows us to find K_a of the acid in a conjugate pair given K_b of the base, and vice versa. Reference tables typically have K_a and K_b values for *molecular species only*. The K_b for F^- and the K_a for $CH_3NH_3^+$, for example, do not appear in standard tables, but you can calculate them by looking up the value for the molecular conjugate species and relating it to K_w. To find the K_b value for F^-, for instance, we look up the K_a value for HF and apply Equation 18.7:

$$K_a \text{ of HF} = 6.8 \times 10^{-4} \text{ (from Appendix C)}$$

So, we have

$$K_a \text{ of HF} \times K_b \text{ of } F^- = K_w$$

or

$$K_b \text{ of } F^- = \frac{K_w}{K_a \text{ of HF}} = \frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}} = 1.5 \times 10^{-11}$$

SAMPLE PROBLEM 18.12 Determining the pH of a Solution of A^-

Problem Sodium acetate (CH_3COONa, or NaAc for this problem) is used in textile dyeing. What is the pH of 0.25 *M* NaAc at 25°C? The K_a of acetic acid (HAc) is 1.8×10^{-5}.

Plan We know the initial concentration of Ac^- (0.25 *M*) and the K_a of HAc (1.8×10^{-5}), and we have to find the pH of the Ac^- solution, which acts as a base in water. We write the base dissociation equation and K_b expression. If we can find $[OH^-]$, we can use K_w to find $[H_3O^+]$ and convert it to pH. To solve for $[OH^-]$, we

need the K_b of Ac^-, which we obtain from the K_a of HAc by applying Equation 18.7. We set up a reaction table to find $[OH^-]$ and make the usual assumption that K_b is small, so $[Ac^-]_{init} \approx [Ac^-]$.

Solution Writing the base dissociation equation and K_b expression:

$$Ac^-(aq) + H_2O(l) \rightleftharpoons HAc(aq) + OH^-(aq) \qquad K_b = \frac{[HAc][OH^-]}{[Ac^-]}$$

Setting up the reaction table, with $x = [Ac^-]_{reacting} = [HAc] = [OH^-]$:

Concentration (*M*)	$Ac^-(aq)$	+	$H_2O(l)$	$\rightleftharpoons$	$HAc(aq)$	+	$OH^-(aq)$
Initial	0.25		—		0		0
Change	$-x$		—		$+x$		$+x$
Equilibrium	$0.25 - x$		—		x		x

Solving for K_b of Ac^-:

$$K_b = \frac{K_w}{K_a} = \frac{1.0\times10^{-14}}{1.8\times10^{-5}} = 5.6\times10^{-10}$$

Making the assumption: Because K_b is small, $0.25\ M - x \approx 0.25\ M$.
Substituting into the expression for K_b and solving for x:

$$K_b = \frac{[HAc][OH^-]}{[Ac^-]} = 5.6\times10^{-10} \approx \frac{x^2}{0.25} \qquad x = [OH^-] \approx 1.2\times10^{-5}\ M$$

Checking the assumption:

$$\frac{1.2\times10^{-5}\ M}{0.25\ M} \times 100 = 4.8\times10^{-3}\%\ (<5\%;\ \text{assumption is justified})$$

Also note that

$$\frac{0.25}{5.6\times10^{-10}} = 4.5\times10^{8} > 400$$

Solving for pH:

$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0\times10^{-14}}{1.2\times10^{-5}} = 8.3\times10^{-10}\ M$$

$$pH = -\log(8.3\times10^{-10}) = 9.08$$

Check The K_b calculation seems reasonable: $\sim 10\times10^{-15}/2\times10^{-5} = 5\times10^{-10}$. Because Ac^- is a weak base, $[OH^-] > [H_3O^+]$; thus, pH > 7, which makes sense.

FOLLOW-UP PROBLEMS

18.12A Sodium hypochlorite (NaClO) is the active ingredient in household laundry bleach. What is the pH of 0.20 *M* NaClO?

18.12B Sodium nitrite ($NaNO_2$) is added to cured meats such as bacon to prevent growth of bacteria. What is the pH of 0.80 *M* $NaNO_2$?

SOME SIMILAR PROBLEMS 18.111–18.114

Summary of Section 18.6

- The extent to which a weak base accepts a proton from water to form OH^- is expressed by a base-dissociation constant, K_b.
- Brønsted-Lowry bases include NH_3 and amines and the anions of weak acids. All produce basic solutions by accepting H^+ from water, which yields OH^-, thus making $[H_3O^+] < [OH^-]$.
- A solution of HA is acidic because $[HA] >> [A^-]$, so $[H_3O^+] > [OH^-]$. A solution of A^- is basic because $[A^-] >> [HA]$, so $[OH^-] > [H_3O^+]$.
- By multiplying the expressions for K_a of HA and K_b of A^-, we obtain K_w. This relationship allows us to calculate either K_a of BH^+ or K_b of A^-.

18.7 ACID-BASE PROPERTIES OF SALT SOLUTIONS

In many cases, when a salt dissolves, one or both of its ions may react with water and affect the pH of the solution. You've seen that cations of weak bases (such as NH_4^+) are acidic, anions of weak acids (such as CN^-) are basic, and small, highly charged metal cations (such as Al^{3+}) are acidic. In addition, certain ions (such as $H_2PO_4^-$ and HCO_3^-) can act as an acid or a base. In this section, we classify the acid-base behavior of the various types of salt solutions.

Salts That Yield Neutral Solutions

A salt consisting of the anion of a strong acid and the cation of a strong base yields a neutral solution because the ions do not react with water. When a strong acid such as HNO_3 dissolves, the reaction goes essentially to completion because *the anion of a strong acid is a much weaker base than water.* The anion is hydrated, but *it does not react with water:*

$$HNO_3(l) + H_2O(l) \longrightarrow NO_3^-(aq) + H_3O^+(aq) \qquad \text{[dissolution and hydration]}$$

Similarly, a strong base, such as NaOH, dissolves completely. The cation, in this case Na^+, is hydrated, but *it is not small and charged enough to react with water:*

$$NaOH(s) \xrightarrow{H_2O} Na^+(aq) + OH^-(aq) \qquad \text{[dissolution and hydration]}$$

The anions of strong acids are the halide ions (except F^-) and the ions of strong oxoacids, such as NO_3^- and ClO_4^-. The cations of strong bases are the Group 1A(1) ions and Ca^{2+}, Sr^{2+}, and Ba^{2+} in Group 2A(2). *Salts containing only these anions and cations yield neutral solutions.* The salts $LiNO_3$ and $CaCl_2$ are two examples.

Salts That Yield Acidic Solutions

There are two types of salts that yield acidic solutions; in both types, the cation is responsible for the acidity:

1. *A salt consisting of the cation of a weak base and the anion of a strong acid yields an acidic solution because the cation acts as a weak acid,* and the anion does not react. For example, NH_4Cl yields an acidic solution because NH_4^+, the cation of the weak base NH_3, is a weak acid; Cl^-, the anion of the strong HCl, does not react:

$$NH_4Cl(s) \xrightarrow{H_2O} NH_4^+(aq) + Cl^-(aq) \qquad \text{[dissolution and hydration]}$$
$$NH_4^+(aq) + H_2O(l) \rightleftharpoons NH_3(aq) + H_3O^+(aq) \qquad \text{[dissociation of weak acid]}$$

2. *A salt consisting of a small, highly charged metal cation and the anion of a strong acid yields an acidic solution because the cation acts as a weak acid,* and the anion does not react. For example, $Fe(NO_3)_3$ yields an acidic solution because the hydrated Fe^{3+} ion is a weak acid; NO_3^-, the anion of the strong HNO_3, does not react:

$$Fe(NO_3)_3(s) + 6H_2O(l) \xrightarrow{H_2O} Fe(H_2O)_6^{3+}(aq) + 3NO_3^-(aq) \qquad \text{[dissolution and hydration]}$$
$$Fe(H_2O)_6^{3+}(aq) + H_2O(l) \rightleftharpoons Fe(H_2O)_5OH^{2+}(aq) + H_3O^+(aq) \qquad \text{[dissociation of weak acid]}$$

Salts That Yield Basic Solutions

A salt consisting of the anion of a weak acid and the cation of a strong base yields a basic solution because the anion acts as a weak base, and the cation does not react. Sodium acetate, for example, yields a basic solution because the CH_3COO^- ion, the anion of the weak acid CH_3COOH, acts as a weak base; Na^+, the cation of the strong base NaOH, does not react:

$$CH_3COONa(s) \xrightarrow{H_2O} Na^+(aq) + CH_3COO^-(aq) \qquad \text{[dissolution and hydration]}$$
$$CH_3COO^-(aq) + H_2O(l) \rightleftharpoons CH_3COOH(aq) + OH^-(aq) \qquad \text{[reaction of weak base]}$$

SAMPLE PROBLEM 18.13 Predicting Relative Acidity of Salt Solutions from Reactions of the Ions with Water

Problem Predict whether aqueous solutions of the following salts are acidic, basic, or neutral, and write an equation for the reaction of any ion with water:
(a) Potassium perchlorate, $KClO_4$
(b) Sodium benzoate, C_6H_5COONa
(c) Chromium(III) nitrate, $Cr(NO_3)_3$

Plan The formula shows the cation and the anion. Depending on an ion's ability to react with water, the solution will be neutral (strong-acid anion and strong-base cation), acidic (weak-base cation or highly charged metal cation with strong-acid anion), or basic (weak-acid anion and strong-base cation).

Solution **(a)** Neutral. The ions are K^+ and ClO_4^-. The K^+ is from the strong base KOH, and the ClO_4^- is from the strong acid $HClO_4$. Neither ion reacts with water.
(b) Basic. The ions are Na^+ and $C_6H_5COO^-$. The Na^+ is the cation of the strong base NaOH, so it does not react with water. The benzoate ion, $C_6H_5COO^-$, is the anion of the weak acid benzoic acid, so it reacts with water to produce OH^- ion:

$$C_6H_5COO^-(aq) + H_2O(l) \rightleftharpoons C_6H_5COOH(aq) + OH^-(aq)$$

(c) Acidic. The ions are Cr^{3+} and NO_3^-. The NO_3^- is the anion of the strong acid HNO_3, so it does not react with water. The Cr^{3+} ion is small and highly charged, so the hydrated ion, $Cr(H_2O)_6^{3+}$, reacts with water to produce H_3O^+:

$$Cr(H_2O)_6^{3+}(aq) + H_2O(l) \rightleftharpoons Cr(H_2O)_5OH^{2+}(aq) + H_3O^+(aq)$$

FOLLOW-UP PROBLEMS

18.13A Write equations to predict whether solutions of the following salts are acidic, basic, or neutral: **(a)** $KClO_2$; **(b)** $CH_3NH_3NO_3$; **(c)** RbBr.

18.13B Write equations to predict whether solutions of the following salts are acidic, basic, or neutral: **(a)** $FeBr_3$; **(b)** $Ca(NO_2)_2$; **(c)** $C_6H_5NH_3I$.

SOME SIMILAR PROBLEMS 18.120, 18.121(a), 18.122, 18.123(a), 18.123(b), 18.124, 18.125(c), 18.126(c), and 18.127(c)

Salts of Weakly Acidic Cations and Weakly Basic Anions

If a salt consists of a cation that is a weak acid *and* an anion that is a weak base, the overall acidity of the solution depends on the relative acid strength (K_a) and base strength (K_b) of the separated ions. Consider a solution of ammonium cyanide, NH_4CN, and the reactions that occur between the separated ions and water. Ammonium ion is the conjugate acid of a weak base, so it is a weak acid:

$$NH_4^+(aq) + H_2O(l) \rightleftharpoons NH_3(aq) + H_3O^+(aq)$$

Cyanide ion is the anion of a weak acid, so it is a weak base:

$$CN^-(aq) + H_2O(l) \rightleftharpoons HCN(aq) + OH^-(aq)$$

The reaction that goes farther to the right determines the pH of the solution, so we compare the K_a of NH_4^+ with the K_b of CN^-. Only molecular compounds are listed in K_a and K_b tables, so we use Equation 18.7 to calculate these values for the two ions:

$$K_a \text{ of } NH_4^+ = \frac{K_w}{K_b \text{ of } NH_3} = \frac{1.0\times10^{-14}}{1.76\times10^{-5}} = 5.7\times10^{-10}$$

$$K_b \text{ of } CN^- = \frac{K_w}{K_a \text{ of HCN}} = \frac{1.0\times10^{-14}}{6.2\times10^{-10}} = 1.6\times10^{-5}$$

Because K_b of CN^- > K_a of NH_4^+, we know that CN^- is a stronger base than NH_4^+ is an acid. Thus, more OH^- than H_3O^+ is produced, and the NH_4CN solution is basic.

Salts of Amphiprotic Anions

The only salts left to consider are those in which the cation comes from a strong base and therefore does not react with water, and the anion comes from a polyprotic acid with one or more ionizable protons still attached. These anions are amphiprotic—they can act as an acid and release a proton *to* water or as a base and abstract a proton *from* water. As in the previous case, to determine the overall acidity of their solutions, we compare the magnitudes of K_a and K_b, but here we compare the K_a and K_b of the *same* species, the anion.

For example, Na_2HPO_4 consists of Na^+, the cation of a strong base, which does not react with water, and HPO_4^{2-}, the second anion of the weak polyprotic acid H_3PO_4. In water, the salt undergoes three steps:

1. $Na_2HPO_4(s) \xrightarrow{H_2O} 2Na^+(aq) + HPO_4^{2-}(aq)$ [dissolution and hydration]
2. $HPO_4^{2-}(aq) + H_2O(l) \rightleftharpoons PO_4^{3-}(aq) + H_3O^+(aq)$ [acting as a weak acid]
3. $HPO_4^{2-}(aq) + H_2O(l) \rightleftharpoons H_2PO_4^-(aq) + OH^-(aq)$ [acting as a weak base]

We must decide whether step 2 or step 3 goes farther to the right. Appendix C lists the K_a of HPO_4^{2-} as 4.2×10^{-13}, but the K_b of HPO_4^{2-} is not given, so we find it from the K_a of its conjugate acid, $H_2PO_4^{2-}$, using Equation 18.7:

$$K_b \text{ of } HPO_4^{2-} = \frac{K_w}{K_a \text{ of } H_2PO_4^-} = \frac{1.0\times10^{-14}}{6.3\times10^{-8}} = 1.6\times10^{-7}$$

Because K_b $(1.6\times10^{-7}) > K_a$ (4.2×10^{-13}), HPO_4^{2-} is stronger as a base than as an acid, so a solution of Na_2HPO_4 is basic.

Table 18.7 displays the acid-base behavior of the various types of salts in water.

Table 18.7 The Acid-Base Behavior of Salts in Water

Nature of Ions	Examples	Ion That Reacts with Water: Example(s)	pH
Neutral			
Cation of strong base Anion of strong acid	NaCl, KBr, $Ba(NO_3)_2$	None	7.0
Acidic			
Cation of weak base Anion of strong acid	NH_4Cl, NH_4NO_3, CH_3NH_3Br	Cation: $NH_4^+ + H_2O \rightleftharpoons NH_3 + H_3O^+$	<7.0
Small, highly charged metal cation Anion of strong acid	$Al(NO_3)_3$, $CrBr_3$, $FeCl_3$	Cation: $Al(H_2O)_6^{3+} + H_2O \rightleftharpoons Al(H_2O)_5OH^{2+} + H_3O^+$	<7.0
Basic			
Cation of strong base Anion of weak acid	KNO_2, NaClO, Na_2CO_3	Anion: $NO_2^- + H_2O \rightleftharpoons HNO_2 + OH^-$	>7.0
Acidic/Basic			
Cation of weak base or small, highly charged metal cation Anion of weak acid	NH_4ClO_2, NH_4CN, $Pb(CH_3COO)_2$	Cation *and* anion: $NH_4^+ + H_2O \rightleftharpoons NH_3 + H_3O^+$ $ClO_2^- + H_2O \rightleftharpoons HClO_2 + OH^-$	<7.0 if $K_{a(cation)} > K_{b(anion)}$ >7.0 if $K_{b(anion)} > K_{a(cation)}$
Cation of strong base Anion of polyprotic acid	NaH_2PO_4, $KHCO_3$, $NaHSO_3$	Anion: $HSO_3^- + H_2O \rightleftharpoons SO_3^{2-} + H_3O^+$ $HSO_3^- + H_2O \rightleftharpoons H_2SO_3 + OH^-$	<7.0 if $K_{a(anion)} > K_{b(anion)}$ >7.0 if $K_{b(anion)} > K_{a(anion)}$

SAMPLE PROBLEM 18.14 Predicting the Relative Acidity of a Salt Solution from K_a and K_b of the Ions

Problem Determine whether an aqueous solution of zinc formate, $Zn(HCOO)_2$, at 25°C is acidic, basic, or neutral.

Plan The formula consists of the small, highly charged, and therefore weakly acidic, Zn^{2+} cation and the weakly basic $HCOO^-$ anion of the weak acid HCOOH. To determine the relative acidity of the solution, we write equations that show the reactions of the ions with water, and then find K_a of Zn^{2+} (from Appendix C) and calculate K_b of $HCOO^-$ (from K_a of HCOOH in Appendix C) to see which ion reacts with water to a greater extent.

Solution Writing the reactions with water:

$$Zn(H_2O)_6^{2+}(aq) + H_2O(l) \rightleftharpoons Zn(H_2O)_5OH^+(aq) + H_3O^+(aq)$$
$$HCOO^-(aq) + H_2O(l) \rightleftharpoons HCOOH(aq) + OH^-(aq)$$

Obtaining K_a and K_b of the ions: From Appendix C, the K_a of $Zn(H_2O)_6^{2+}(aq)$ is 1×10^{-9}. We obtain K_a of HCOOH and solve for K_b of $HCOO^-$:

$$K_b \text{ of } HCOO^- = \frac{K_w}{K_a \text{ of HCOOH}} = \frac{1.0\times10^{-14}}{1.8\times10^{-4}} = 5.6\times10^{-11}$$

K_a of $Zn(H_2O)_6^{2+}$ > K_b of $HCOO^-$, so the solution is acidic.

FOLLOW-UP PROBLEMS

18.14A Determine whether solutions of the following salts are acidic, basic, or neutral at 25°C: **(a)** $Cu(CH_3COO)_2$; **(b)** NH_4F; **(c)** $KHSO_3$.

18.14B Determine whether solutions of the following salts are acidic, basic, or neutral at 25°C: **(a)** $NaHCO_3$; **(b)** $C_6H_5NH_3NO_2$; **(c)** NaH_2PO_4.

SOME SIMILAR PROBLEMS 18.121(b), 18.121(c), 18.123(c), 18.125(a), 18.125(b), 18.126(a), 18.127(a), and 18.127(b)

Summary of Section 18.7

- Salts that yield a neutral solution consist of ions that do not react with water.
- Salts that yield an acidic solution contain an unreactive anion (from a strong acid) and a cation that releases a proton to water.
- Salts that yield a basic solution contain an unreactive cation (from a strong base) and an anion that accepts a proton from water.
- If both cation and anion react with water, the ion that reacts to the greater extent (higher K) determines the acidity or basicity of the salt solution.
- If the anion is amphiprotic (from a polyprotic acid), the strength of the anion as an acid (K_a) or as a base (K_b) determines the acidity of the salt.

18.8 GENERALIZING THE BRØNSTED-LOWRY CONCEPT: THE LEVELING EFFECT

In general, *an acid yields the cation and a base yields the anion of solvent autoionization.* For example, in H_2O, all Brønsted-Lowry acids yield H_3O^+ and all Brønsted-Lowry bases yield OH^-, which are the ions that form when water autoionizes.

This idea lets us examine a key question: Why are all strong acids and strong bases *equally* strong in water? The answer is that *in water, the strongest acid possible is H_3O^+ and the strongest base possible is OH^-:*

- *For strong acids.* The moment we put gaseous HCl in water, it reacts with the base H_2O to form H_3O^+. The same holds for any strong acid because it dissociates *completely* to form H_3O^+. Thus, we are actually observing the acid strength of H_3O^+.
- *For strong bases.* A strong base, such as $Ba(OH)_2$, dissociates completely in water to yield OH^-. Even strong bases that do not contain hydroxide ions in the solid, such as K_2O, do so. The oxide ion, which is a stronger base than OH^-, immediately takes a proton from water to form OH^-:

$$O^{2-}(aq) + H_2O(l) \longrightarrow 2OH^-(aq)$$

Thus, water exerts a **leveling effect** on any strong acid or base by reacting with it to form the products of water's autoionization. Acting as a base, water levels the strength of all strong acids by making them appear equally strong, and acting as an acid, it levels the strength of all strong bases.

Therefore, to rank the relative strengths of strong acids, we must dissolve them in a solvent that is a *weaker* base than water, so it accepts their protons less readily. For example, the hydrohalic acids increase in strength as the halogen becomes larger, as a result of the longer, weaker H—X bond (see Figure 18.9). But, in water, HF is weak, and HCl, HBr, and HI appear equally strong because they dissociate completely. When we dissolve them in pure acetic acid, however, *the acetic acid acts as the base* and accepts a proton:

$$\begin{aligned} \overset{\text{acid}}{HCl}(g) + \overset{\text{base}}{CH_3COOH}(l) &\rightleftharpoons \overset{\text{base}}{Cl^-}(acet) + \overset{\text{acid}}{CH_3COOH_2^+}(acet) \\ HBr(g) + CH_3COOH(l) &\rightleftharpoons Br^-(acet) + CH_3COOH_2^+(acet) \\ HI(g) + CH_3COOH(l) &\rightleftharpoons I^-(acet) + CH_3COOH_2^+(acet) \end{aligned}$$

[The use of (*acet*) instead of (*aq*) indicates solvation by CH_3COOH.] Because acetic acid is a *weaker base* than water, the three acids donate their protons to *different* extents. Measurements show that HI protonates the solvent to a greater extent than HBr, and HBr does so more than HCl; that is, in pure acetic acid, $K_{HI} > K_{HBr} > K_{HCl}$. Similarly, the relative strengths of strong bases are determined in a solvent that is a weaker acid than H_2O, such as pure liquid NH_3.

Summary of Section 18.8

- Strong acids (or strong bases) dissociate completely to yield H_3O^+ (or OH^-) in water; in effect, water equalizes (levels) their strengths.
- Strong acids show differences in strength when dissolved in a weaker base than water, such as acetic acid.

18.9 ELECTRON-PAIR DONATION AND THE LEWIS ACID-BASE DEFINITION

The final acid-base concept we consider was developed by Gilbert N. Lewis, whose contribution to understanding valence electron pairs in bonding we discussed in Chapter 9. Whereas the Brønsted-Lowry concept focuses on the proton in defining a species as an acid or a base, the Lewis concept highlights the role of the *electron pair*. The **Lewis acid-base definition** holds that

- A *base* is any species that *donates* an electron pair to form a bond.
- An *acid* is any species that *accepts* an electron pair to form a bond.

The Lewis definition, like the Brønsted-Lowry definition, requires that a base have an electron pair to donate, so it does not expand the classes of bases. However, *it greatly expands the classes of acids*. Many species, such as CO_2 and Cu^{2+}, that do not contain H in their formula (and thus cannot be Brønsted-Lowry acids) are Lewis acids because they accept an electron pair in reactions. In fact, the proton itself is a Lewis acid because it accepts the electron pair donated by a base:

$$B: + H^+ \rightleftharpoons B{-}H^+$$

Thus, *all Brønsted-Lowry acids donate H^+, a Lewis acid.*

The product of a Lewis acid-base reaction is an **adduct,** *a single species that contains a* ***new*** *covalent bond:*

$$A + :B \rightleftharpoons A{-}B \text{ (adduct)}$$

Thus, the Lewis concept radically broadens the idea of an acid-base reaction:

- To Arrhenius, it is the formation of H_2O from H^+ and OH^-.
- To Brønsted and Lowry, it is H^+ transfer from a stronger acid to a stronger base to form a weaker base and weaker acid.
- To Lewis, it is *the donation and acceptance of an electron pair to form a covalent bond in an adduct.*

By definition, then,

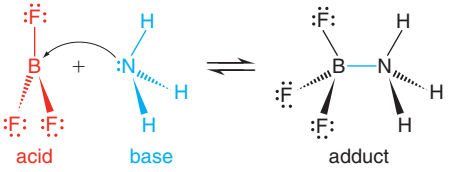
- *A Lewis base must have a lone pair of electrons to donate.*
- *A Lewis acid must have a vacant orbital* (or the ability to rearrange its bonds to form one) to accept a lone pair and form a new bond.

In this section, we discuss molecules and positive metal ions that act as Lewis acids.

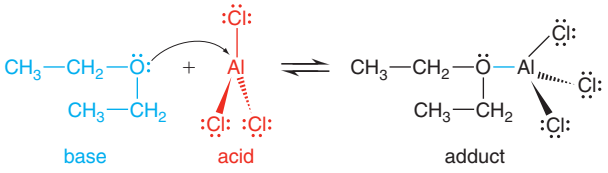
Molecules as Lewis Acids

Many molecules act as Lewis acids. In every case, the atom accepting the electron pair has *low electron density* due to either an electron deficiency or a polar multiple bond.

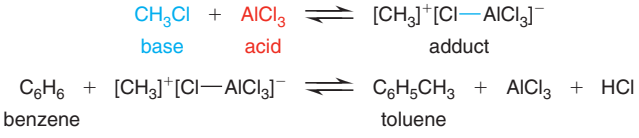
Lewis Acids with Electron-Deficient Atoms The most important of the *electron-deficient* Lewis acids are compounds of the Group 3A(13) elements boron and aluminum. Recall from Chapters 10 and 14 that these compounds have fewer than eight electrons around the central atom, so they react to complete that atom's octet. For example, boron trifluoride accepts an electron pair from ammonia to form a covalent bond:



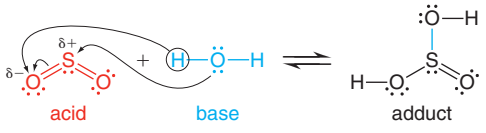
Aluminum chloride, a salt, dissolves freely in relatively nonpolar diethyl ether when the ether's O atom donates an electron pair to Al to form a covalent bond:



This acidic behavior of boron and aluminum halides is often used in organic syntheses. For example, a methyl group is added to the benzene ring by the action of CH_3Cl in the presence of $AlCl_3$. The Lewis acid $AlCl_3$ abstracts the Lewis base Cl^- from CH_3Cl to form an ionic adduct that has a reactive CH_3^+ group, which then attacks the electron-rich benzene ring:

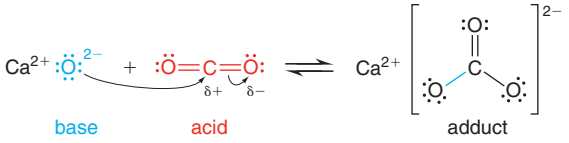


Lewis Acids with Polar Multiple Bonds Molecules with a polar double bond also function as Lewis acids. An electron pair on the Lewis base approaches the partially positive end of the double bond to form the new bond in the adduct, as the π bond breaks. For example, consider the reaction of SO_2 in water. The electronegative O atoms in SO_2 make the central S partially positive. The O atom of water donates a lone pair to the S, thus forming an S—O bond and breaking one of the π bonds. Then, a proton is transferred from water to the O that was part of the π bond. The resulting adduct is sulfurous acid:



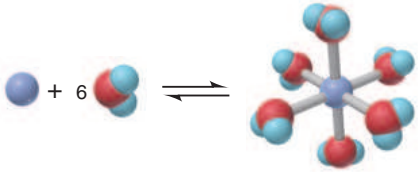
The analogous formation of a carbonate from a metal oxide and carbon dioxide occurs in a nonaqueous system. The O^{2-} ion (shown coming from CaO) donates an

electron pair to the partially positive C in CO_2, a π bond breaks, and the CO_3^{2-} ion (shown as part of $CaCO_3$) is the adduct:



Metal Cations as Lewis Acids

In the Lewis sense, hydration of a metal ion is itself an acid-base reaction. As electron pairs on the O atoms of H_2O molecules form covalent bonds, the hydrated cation is the adduct; thus, *a metal ion acts as a Lewis acid when it dissolves in water:*



Ammonia is a stronger Lewis base than water because, when it is added to the aqueous solution of the hydrated cation, it displaces H_2O, with $K >> 1$:

$$\underset{\text{hydrated adduct}}{Ni(H_2O)_6^{2+}(aq)} + 6NH_3(aq) \rightleftharpoons \underset{\text{ammoniated adduct}}{Ni(NH_3)_6^{2+}(aq)} + 6H_2O(l)$$

We discuss the equilibrium nature of these acid-base reactions in greater detail in Chapter 19, and we investigate the structures of these ions in Chapter 23.

Many biomolecules with central metal ions are Lewis adducts. Most often, O and N atoms of organic groups donate their lone pairs as the Lewis bases. Chlorophyll is a Lewis adduct of a central Mg^{2+} and the four N atoms of a tetrapyrrole (porphin) ring system (Figure 18.13). Vitamin B_{12} has a similar structure with a central Co^{3+}, and so does heme with a central Fe^{2+}. Several other metal ions, such as Zn^{2+}, Mo^{2+}, and Cu^{2+}, are bound at the active sites of enzymes and function as Lewis acids in the catalytic action (Section 23.4).

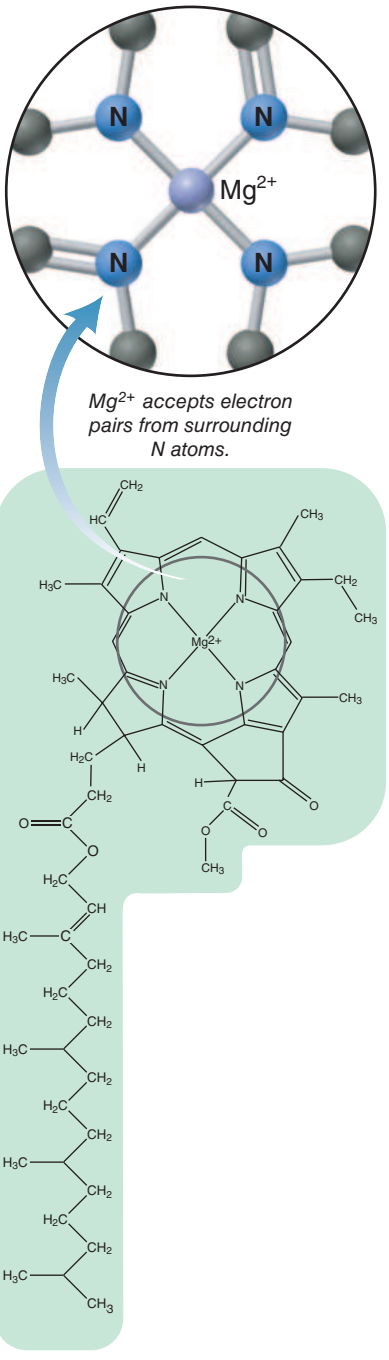


Figure 18.13 The Mg^{2+} ion as a Lewis acid in chlorophyll.

SAMPLE PROBLEM 18.15 Identifying Lewis Acids and Bases

Problem Identify the Lewis acids and Lewis bases in the following reactions:
(a) $H^+ + OH^- \rightleftharpoons H_2O$ **(b)** $Cl^- + BCl_3 \rightleftharpoons BCl_4^-$ **(c)** $K^+ + 6H_2O \rightleftharpoons K(H_2O)_6^+$

Plan We examine the formulas to see which species accepts the electron pair (Lewis acid) and which donates it (Lewis base) in forming the adduct.

Solution **(a)** The H^+ ion accepts an electron pair from the OH^- ion in forming a bond. H^+ is the acid and OH^- is the base.
(b) The Cl^- ion has four lone pairs and uses one to form a new bond to the central B. BCl_3 is the acid and Cl^- is the base.
(c) The K^+ ion does not have any valence electrons to provide, so the bond is formed when electron pairs from O atoms of water enter empty orbitals on K^+. K^+ is the acid and H_2O is the base.

Check The Lewis acids (H^+, BCl_3, and K^+) each have an unfilled valence shell that can accept an electron pair from the Lewis bases (OH^-, Cl^-, and H_2O).

FOLLOW-UP PROBLEMS

18.15A Identify the Lewis acids and Lewis bases:
(a) $OH^- + Al(OH)_3 \rightleftharpoons Al(OH)_4^-$
(b) $SO_3 + H_2O \rightleftharpoons H_2SO_4$
(c) $Co^{3+} + 6NH_3 \rightleftharpoons Co(NH_3)_6^{3+}$

18.15B Identify the Lewis acids and Lewis bases:
(a) $B(OH)_3 + H_2O \rightleftharpoons B(OH)_4^- + H^+$
(b) $Cd^{2+} + 4I^- \rightleftharpoons CdI_4^{2-}$
(c) $2F^- + SiF_4 \rightleftharpoons SiF_6^{2-}$
SOME SIMILAR PROBLEMS 18.142 and 18.143

An Overview of Acid-Base Definitions

From a broader chemical perspective, the diversity of acid-base reactions takes on more unity. Chemists see a common theme in reactions as diverse as a standardized base being used to analyze an unknown fatty acid, baking soda being used in bread-making, and even oxygen binding to hemoglobin in a blood cell. Let's see how the three acid-base definitions fit together.

1. The *Arrhenius definition,* which was the first attempt at describing acids and bases on the molecular level, is the most limited and narrow of the three. It applies only to species with an H atom or an OH group that is released as an ion when the species dissolves in water. Because relatively few species have these structural prerequisites, Arrhenius acid-base reactions are relatively few in number, and all occur in H_2O and result in the formation of H_2O.

2. The *Brønsted-Lowry definition* sees acid-base reactions as proton-transfer processes that need not occur in water. A Brønsted-Lowry acid, like an Arrhenius acid, must have an H, but a Brønsted-Lowry base is any species with an electron pair available to accept a proton. This definition includes many more species as bases, including OH^-. It defines the acid-base reaction in terms of conjugate acid-base pairs, with an acid and a base on both sides of the reaction. The system reaches equilibrium based on the relative strengths of the acid, the base, and their conjugates.

3. The *Lewis definition* has the widest scope and includes the other two. The defining event of a Lewis acid-base reaction is the donation and acceptance of an electron pair to form a new covalent bond in an adduct. Lewis bases still must have an electron pair to donate, but Lewis acids—the electron-pair acceptors—include many species not encompassed by the other definitions, including molecules with electron-deficient atoms or with polar double bonds, metal ions, and even H^+ itself.

Summary of Section 18.9

- The Lewis acid-base definition focuses on the donation or acceptance of an electron pair to form a new covalent bond in an adduct, the product of an acid-base reaction. Lewis bases donate the electron pair, and Lewis acids accept it.
- Thus, many species that do not contain H are Lewis acids. Molecules with polar double bonds act as Lewis acids, as do those with electron-deficient atoms.
- Metal ions act as Lewis acids when they dissolve in water, which acts as a Lewis base, to form a hydrated cation as the adduct.
- Many metal ions function as Lewis acids in biomolecules.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. Why the proton is bonded to a water molecule, as H_3O^+, in all aqueous acid-base systems (§18.1)
2. The Arrhenius definitions of an acid and a base (§18.1)
3. Why all reactions of a strong acid and a strong base have the same ΔH°_{rxn} (§18.1)
4. How the strength of an acid (or base) relates to the extent of its dissociation into ions in water (§18.1)
5. How relative acid strength is expressed by the acid-dissociation constant K_a (§18.1)
6. Why water is a very weak electrolyte and how its autoionization is expressed by K_w (§18.2)

7. Why $[H_3O^+]$ is inversely related to $[OH^-]$ in any aqueous solution (§18.2)
8. How the relative magnitudes of $[H_3O^+]$ and $[OH^-]$ define whether a solution is acidic, basic, or neutral (§18.2)
9. The Brønsted-Lowry definitions of an acid and a base and how an acid-base reaction can be viewed as a proton-transfer process (§18.3)
10. How water acts as a base (or as an acid) when an acid (or a base) dissolves in it (§18.3)
11. How a conjugate acid-base pair differs by one proton (§18.3)
12. How a Brønsted-Lowry acid-base reaction involves two conjugate acid-base pairs (§18.3)
13. Why a stronger acid and base react ($K_c > 1$) to form a weaker base and acid (§18.3)
14. How the percent dissociation of a weak acid increases as its concentration decreases (§18.4)
15. How a polyprotic acid dissociates in two or more steps and why only the first step supplies significant $[H_3O^+]$ (§18.4)
16. The effects of electronegativity, bond polarity, and bond strength on acid strength (§18.5)
17. Why aqueous solutions of small, highly charged metal ions are acidic (§18.5)
18. How weak bases in water accept a proton rather than dissociate; the meaning of K_b and pK_b (§18.6)
19. How ammonia, amines, and weak-acid anions act as weak bases in water (§18.6)
20. Why relative concentrations of HA and A^- determine the acidity or basicity of their solution (§18.6)
21. The relationship of the K_a and K_b of a conjugate acid-base pair to K_w (§18.6)
22. The various combinations of cations and anions that lead to acidic, basic, or neutral salt solutions (§18.7)
23. Why the strengths of strong acids are leveled in water but differentiated in a less basic solvent (§18.8)
24. The Lewis definitions of an acid and a base and how a Lewis acid-base reaction involves the donation and acceptance of an electron pair to form a covalent bond (§18.9)
25. How molecules with electron-deficient atoms, molecules with polar multiple bonds, and metal cations act as Lewis acids (§18.9)

Master These Skills

1. Classifying strong and weak acids and bases from their formulas (SP 18.1)
2. Using K_w to calculate $[H_3O^+]$ or $[OH^-]$ in an aqueous solution (SP 18.2)
3. Using p-scales to express $[H_3O^+]$, $[OH^-]$, and K (§18.2)
4. Calculating $[H_3O^+]$, pH, $[OH^-]$, and pOH (SP 18.3)
5. Identifying conjugate acid-base pairs (SP 18.4)
6. Using relative acid strengths to predict the net direction of an acid-base reaction (SPs 18.5, 18.6)
7. Calculating K_a of a weak acid from pH (SP 18.7)
8. Calculating $[H_3O^+]$ (and, thus, pH) from K_a and $[HA]_{init}$ (SP 18.8)
9. Applying the quadratic equation to find a concentration (Follow-Up Problem 18.8A)
10. Calculating the percent dissociation of a weak acid (§18.4 and SP 18.9)
11. Calculating $[H_3O^+]$ and other concentrations for a polyprotic acid (SP 18.10)
12. Predicting relative acid strengths of nonmetal hydrides and oxoacids (§18.5)
13. Calculating pH from K_b and $[B]_{init}$ (SP 18.11)
14. Finding K_b of A^- from K_a of HA and K_w (§18.6 and SP 18.12)
15. Calculating pH from K_b of A^- and $[A^-]_{init}$ (SP 18.12)
16. Predicting the relative acidity of a salt solution from the nature of the cation and anion (SPs 18.13, 18.14)
17. Identifying Lewis acids and bases (SP 18.15)

Key Equations and Relationships

Page numbers appear in parentheses.

18.1 Defining the acid-dissociation constant (780):

$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

18.2 Defining the ion-product constant for water (783):

$$K_w = [H_3O^+][OH^-] = 1.0 \times 10^{-14} \text{ (at 25°C)}$$

18.3 Defining pH (784):

$$pH = -\log [H_3O^+]$$

18.4 Relating pK_w to pH and pOH (785):

$$pK_w = pH + pOH = 14.00 \text{ (at 25°C)}$$

18.5 Finding the percent dissociation of HA (795):

$$\text{Percent HA dissociated} = \frac{[HA]_{dissoc}}{[HA]_{init}} \times 100$$

18.6 Defining the base-dissociation constant (802):

$$K_b = \frac{[BH^+][OH^-]}{[B]}$$

18.7 Expressing the relationship among K_a, K_b, and K_w (805):

$$K_a \times K_b = K_w$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

18.1A (a) $HClO_3$; (b) HCl; (c) NaOH

18.1B (a) Weak base; (b) strong acid; (c) weak acid, $K_a = \dfrac{[H_3O^+][BrO^-]}{[HBrO]}$; (d) strong base

18.2A $[H_3O^+] = \dfrac{1.0\times10^{-14}}{6.7\times10^{-2}} = 1.5\times10^{-13}\ M$; basic

18.2B $[OH^-] = \dfrac{1.0\times10^{-14}}{1.8\times10^{-10}} = 5.6\times10^{-5}\ M$; basic

18.3A $pOH = 14.00 - 9.52 = 4.48$

$[H_3O^+] = 10^{-9.52} = 3.0\times10^{-10}\ M$

$[OH^-] = \dfrac{1.0\times10^{-14}}{3.0\times10^{-10}} = 3.3\times10^{-5}\ M$

18.3B $pOH = 14.00 - 2.28 = 11.72$

$[H_3O^+] = 10^{-2.28} = 5.2\times10^{-3}\ M$

$[OH^-] = \dfrac{1.0\times10^{-14}}{5.2\times10^{-3}} = 1.9\times10^{-12}\ M$

18.4A (a) CH_3COOH/CH_3COO^- and H_3O^+/H_2O
(b) H_2O/OH^- and HF/F^-

18.4B (a) H_2SO_3; (b) C_5H_5N; (c) HCO_3^-; (d) CN^-

18.5A (a) $H_2SO_3(aq) + CO_3^{2-}(aq) \rightleftharpoons HSO_3^-(aq) + HCO_3^-(aq)$
(b) $HCN(aq) + F^-(aq) \rightleftharpoons CN^-(aq) + HF(aq)$

18.5B (a) $NH_3(g) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$
(b) $NH_3(g) + H_3O^+(aq;\ \text{from HCl}) \longrightarrow NH_4^+(aq) + H_2O(l)$
(c) $NH_4^+(aq) + OH^-(aq;\ \text{from NaOH}) \longrightarrow NH_3(g) + H_2O(l)$

18.6A There are more HB molecules than HA, so $K_c > 1$ and HA is the stronger acid.

18.6B Since HD is the stronger acid, there should be more D^- particles than C^- particles: thus, D^- is black and C^- is green. $K_c < 1$ for $HC(aq) + D^-(aq) \rightleftharpoons HD(aq) + C^-(aq)$.

18.7A $NH_4^+(aq) + H_2O(l) \rightleftharpoons NH_3(aq) + H_3O^+(aq)$

$[H_3O^+] = 10^{-pH} = 10^{-5.0} = 1\times10^{-5}\ M = [NH_3]$

And, $[NH_4^+] = 0.2\ M - (1\times10^{-5}\ M) \approx 0.2\ M$

$$K_a = \frac{[NH_3][H_3O^+]}{[NH_4^+]} \approx \frac{(1\times10^{-5})^2}{0.2} = 5\times10^{-10}$$

18.7B $CH_2CHCOOH(aq) + H_2O(l) \rightleftharpoons CH_2CHCOO^-(aq) + H_3O^+(aq)$

$[H_3O^+] = 10^{-pH} = 10^{-2.43} = 0.0037\ M = [CH_2CHCOO^-]$

$$K_a = \frac{[CH_2CHCOO^-][H_3O^+]}{[CH_2CHCOOH]} \approx \frac{(0.0037)^2}{0.30} = 4.6\times10^{-5}$$

18.8A $$K_a = \frac{[H_3O^+][OCN^-]}{[HOCN]} = \frac{(x)(x)}{0.10 - x} = 3.5\times10^{-4}$$

Since $\dfrac{[HOCN]_{init}}{K_a} = \dfrac{0.10}{3.5\times10^{-4}} = 286 < 400$, you must solve a quadratic equation: $x^2 + (3.5\times10^{-4})x - (3.5\times10^{-5}) = 0$

$x = [H_3O^+] = 5.7\times10^{-3}\ M$

$pH = -\log(5.7\times10^{-3}) = 2.24$

18.8B $K_a = 10^{-pK_a} = 10^{-4.20} = 6.3\times10^{-5}$

$$K_a = \frac{[H_3O^+][C_6H_5COO^-]}{[C_6H_5COOH]} = \frac{(x)(x)}{0.25 - x} \approx \frac{(x)(x)}{0.25} = 6.3\times10^{-5}$$

$x = [H_3O^+] = 4.0\times10^{-3}\ M$

Since $\dfrac{[C_6H_5COOH]_{init}}{K_a} = \dfrac{0.25}{6.3\times10^{-5}} = 3968 > 400$, you may assume that $0.25 - x = 0.25\ M$.

$pH = -\log[H_3O^+] = -\log[4.0\times10^{-3}] = 2.40$

18.9A $$K_a = \frac{[H_3O^+][CN^-]}{[HCN]} = \frac{x^2}{0.75 - x} \approx \frac{x^2}{0.75} = 6.2\times10^{-10}$$

Since $\dfrac{[HCN]_{init}}{K_a} > 400$, you may assume that $0.75 - x = 0.75$.

$x = 2.2\times10^{-5}\ M = [HCN]_{dissoc}$

$$\text{Percent dissociation} = \frac{2.2\times10^{-5}}{0.75}\times 100 = 0.0029\%$$

18.9B $$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

$$3.16\% = \frac{[HA]_{dissoc}}{[HA]_{init}}\times 100 = \frac{x}{1.5}\times 100$$

$x = 0.047\ M = [HA]_{dissoc} = [H_3O^+] = [A^-]$

$$K_a = \frac{(0.047)(0.047)}{1.5 - 0.047} = 1.5\times10^{-3}$$

18.10A $$K_{a1} = \frac{[HC_2O_4^-][H_3O^+]}{[H_2C_2O_4]} = \frac{x^2}{0.150 - x} = 5.6\times10^{-2}$$

Since $\dfrac{[H_2C_2O_4]_{init}}{K_{a1}} < 400$, you must solve a quadratic equation:

$x^2 + (5.6\times10^{-2})x - (8.4\times10^{-3}) = 0$

$x = [H_3O^+] = 0.068\ M$; $pH = 1.17$

$x = [HC_2O_4^-] = 0.068\ M$; $[H_2C_2O_4] = 0.150\ M - x = 0.082\ M$

$$[C_2O_4^{2-}] = \frac{(K_{a2})[HC_2O_4^-]}{[H_3O^+]} = \frac{(5.4\times10^{-5})(0.068)}{0.068} = 5.4\times10^{-5}\ M$$

18.10B $$K_{a1} = \frac{[HCO_3^-][H_3O^+]}{[H_2CO_3]} = \frac{x^2}{0.075 - x} = 4.5\times10^{-7}$$

Since $\dfrac{[H_2CO_3]_{init}}{K_{a1}} > 400$, $[H_2CO_3]_{dissoc} << [H_2CO_3]_{init}$,

$$4.5\times10^{-7} \approx \frac{x^2}{0.075}$$

$x = [H_3O^+] = 1.8\times10^{-4}\ M$; $pH = 3.74$

$x = [HCO_3^-] = 1.8\times10^{-4}\ M$; $[H_2CO_3] = 0.075 - x \approx 0.075\ M$

$$[CO_3^{2-}] = \frac{(K_{a2})[HCO_3^-]}{[H_3O^+]} = \frac{(4.7\times10^{-11})(1.8\times10^{-4})}{(1.8\times10^{-4})} = 4.7\times10^{-11}\ M$$

18.11A $$K_b = \frac{[C_5H_5NH^+][OH^-]}{[C_5H_5N]} = 10^{-8.77} = 1.7\times10^{-9}$$

Assuming $0.10\ M - x \approx 0.10\ M$, $K_b = 1.7\times10^{-9} \approx \dfrac{(x)(x)}{0.10}$;

$x = [OH^-] \approx 1.3\times10^{-5}\ M$; $[H_3O^+] = 7.7\times10^{-10}\ M$; $pH = 9.11$

18.11B $K_b = \dfrac{[C_6H_5CH_2CH(CH_3)NH_3^+][OH^-]}{[C_6H_5CH_2CH(CH_3)NH_2]} = 6.3\times10^{-5}$

Assuming $0.075\ M - x \approx 0.075\ M$, $K_b = 6.3\times10^{-5} \approx \dfrac{(x)(x)}{0.075}$;

$x = [OH^-] = 2.2\times10^{-3}\ M$; $[H_3O^+] = 4.5\times10^{-12}\ M$;
pH = 11.35

18.12A K_b of $ClO^- = \dfrac{K_w}{K_a \text{ of HClO}} = \dfrac{1.0\times10^{-14}}{2.9\times10^{-8}} = 3.4\times10^{-7}$

Assuming $0.20\ M - x \approx 0.20\ M$,

$K_b = 3.4\times10^{-7} = \dfrac{[HClO][OH^-]}{[ClO^-]} \approx \dfrac{x^2}{0.20}$;

$x = [OH^-] \approx 2.6\times10^{-4}\ M$; $[H_3O^+] = 3.8\times10^{-11}\ M$;
pH = 10.42

18.12B K_b of $NO_2^- = \dfrac{K_w}{K_a \text{ of HNO}_2} = \dfrac{1.0\times10^{-14}}{7.1\times10^{-4}} = 1.4\times10^{-11}$

Assuming $0.80\ M - x \approx 0.80\ M$,

$K_b = 1.4\times10^{-11} = \dfrac{[HNO_2][OH^-]}{[NO_2^-]} \approx \dfrac{x^2}{0.80}$;

$x = [OH^-] \approx 3.3\times10^{-6}\ M$; $[H_3O^+] = 3.0\times10^{-9}\ M$;
pH = 8.52

18.13A (a) Basic:

$$ClO_2^-(aq) + H_2O(l) \rightleftharpoons HClO(aq) + OH^-(aq)$$

K^+ is from the strong base KOH.
(b) Acidic:

$$CH_3NH_3^+(aq) + H_2O(l) \rightleftharpoons CH_3NH_2(aq) + H_3O^+(aq)$$

NO_3^- is from the strong acid HNO_3.
(c) Neutral: Rb^+ is from the strong base RbOH; Br^- is from the strong acid HBr.

18.13B (a) Acidic:

$$Fe(H_2O)_6^{3+}(aq) + H_2O(l) \rightleftharpoons Fe(H_2O)_5OH^{2+}(aq) + H_3O^+(aq)$$

Br^- is from the strong acid HBr.
(b) Basic:

$$NO_2^-(aq) + H_2O(l) \rightleftharpoons HNO_2(aq) + OH^-(aq)$$

Ca^{2+} is from the strong base $Ca(OH)_2$.

(c) Acidic:

$$C_6H_5NH_3^+(aq) + H_2O(l) \rightleftharpoons C_6H_5NH_2(aq) + H_3O^+(aq)$$

I^- is from the strong acid HI.

18.14A (a) K_a of $Cu(H_2O)_6^{2+} = 3\times10^{-8}$

K_b of $CH_3COO^- = \dfrac{K_w}{K_a \text{ of CH}_3\text{COOH}} = 5.6\times10^{-10}$

Since $K_a > K_b$, $Cu(CH_3COO)_2(aq)$ is acidic.

(b) K_a of $NH_4^+ = \dfrac{K_w}{K_b \text{ of NH}_3} = 5.7\times10^{-10}$

K_b of $F^- = \dfrac{K_w}{K_a \text{ of HF}} = 1.5\times10^{-11}$

Because $K_a > K_b$, $NH_4F(aq)$ is acidic.
(c) From Appendix C, K_a of $HSO_3^- = 6.5\times10^{-8}$

K_b of $HSO_3^- = \dfrac{K_w}{K_a \text{ of H}_2\text{SO}_3} = 7.1\times10^{-13}$

Because $K_a > K_b$, $KHSO_3(aq)$ is acidic.

18.14B (a) From Appendix C, K_a of $HCO_3^- = 4.7\times10^{-11}$

K_b of $HCO_3^- = \dfrac{K_w}{K_a \text{ of H}_2\text{CO}_3} = 2.2\times10^{-8}$

Because $K_b > K_a$, $NaHCO_3(aq)$ is basic.

(b) K_a of $C_6H_5NH_3^+ = \dfrac{K_w}{K_b \text{ of } C_6H_5NH_2} = 2.5\times10^{-5}$

K_b of $NO_2^- = \dfrac{K_w}{K_a \text{ of HNO}_2} = 1.4\times10^{-11}$

Because $K_a > K_b$, $C_6H_5NH_3NO_2(aq)$ is acidic.
(c) From Appendix C, K_a of $H_2PO_4^- = 6.3\times10^{-8}$

K_b of $H_2PO_4^- = \dfrac{K_w}{K_a \text{ of H}_3\text{PO}_4} = 1.4\times10^{-12}$

Because $K_a > K_b$, $NaH_2PO_4(aq)$ is acidic.

18.15A (a) OH^- is the Lewis base; $Al(OH)_3$ is the Lewis acid.
(b) H_2O is the Lewis base; SO_3 is the Lewis acid.
(c) NH_3 is the Lewis base; Co^{3+} is the Lewis acid.

18.15B (a) H_2O is the Lewis base; $B(OH)_3$ is the Lewis acid.
(b) I^- is the Lewis base; Cd^{2+} is the Lewis acid.
(c) F^- is the Lewis base; SiF_4 is the Lewis acid.

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Note: Unless stated otherwise, all problems refer to aqueous solutions at 298 K (25°C).

Acids and Bases in Water

(Sample Problem 18.1)

Concept Review Questions

18.1 What is the role of water in the Arrhenius acid-base definition?

18.2 What do Arrhenius acids have in common? What do Arrhenius bases have in common? Explain neutralization in terms of the Arrhenius acid-base definition. What data led Arrhenius to propose this idea of neutralization?

18.3 Why is the Arrhenius acid-base definition too limited? Give an example for which the Arrhenius definition does not apply.

18.4 What do "strong" and "weak" mean for acids and bases? K_a values of weak acids vary over more than 10 orders of magnitude. What do the acids have in common that makes them "weak"?

Skill-Building Exercises (grouped in similar pairs)

18.5 Which of the following are Arrhenius acids?
(a) H_2O (b) $Ca(OH)_2$ (c) H_3PO_3 (d) HI

18.6 Which of the following are Arrhenius acids?
(a) $NaHSO_4$ (b) CH_4 (c) NaH (d) H_3N

18.7 Which of the following are Arrhenius bases?
(a) H_3AsO_4 (b) $Ba(OH)_2$ (c) HClO (d) KOH

18.8 Which of the following are Arrhenius bases?
(a) CH_3COOH (b) HOH (c) CH_3OH (d) H_2NNH_2

18.9 Write the K_a expression for each of the following in water:
(a) HCN (b) HCO_3^- (c) HCOOH

18.10 Write the K_a expression for each of the following in water:
(a) $CH_3NH_3^+$ (b) HClO (c) H_2S

18.11 Write the K_a expression for each of the following in water:
(a) HNO_2 (b) CH_3COOH (c) $HBrO_2$

18.12 Write the K_a expression for each of the following in water:
(a) $H_2PO_4^-$ (b) H_3PO_2 (c) HSO_4^-

18.13 Use Appendix C to rank the following in order of *increasing* acid strength: HIO_3, HI, CH_3COOH, HF.

18.14 Use Appendix C to rank the following in order of *decreasing* acid strength: HClO, HCl, HCN, HNO_2.

18.15 Classify each as a strong or weak acid or base:
(a) H_3AsO_4 (b) $Sr(OH)_2$ (c) HIO (d) $HClO_4$

18.16 Classify each as a strong or weak acid or base:
(a) CH_3NH_2 (b) K_2O (c) HI (d) HCOOH

18.17 Classify each as a strong or weak acid or base:
(a) RbOH (b) HBr (c) H_2Te (d) HClO

18.18 Classify each as a strong or weak acid or base:
(a) $HOCH_2CH_2NH_2$ (b) H_2SeO_4 (c) HS^- (d) $B(OH)_3$

Autoionization of Water and the pH Scale

(Sample Problems 18.2 and 18.3)

Concept Review Questions

18.19 What is an autoionization reaction? Write equations for the autoionization reactions of H_2O and of H_2SO_4.

18.20 What is the difference between K_c and K_w for the autoionization of water?

18.21 (a) What is the change in pH when $[OH^-]$ increases by a factor of 10? (b) What is the change in $[H_3O^+]$ when the pH decreases by 3 units?

18.22 Which solution has the higher pH? Explain.
(a) A 0.1 *M* solution of an acid with $K_a = 1\times10^{-4}$ or one with $K_a = 4\times10^{-5}$
(b) A 0.1 *M* solution of an acid with $pK_a = 3.0$ or one with $pK_a = 3.5$
(c) A 0.1 *M* solution or a 0.01 *M* solution of a weak acid
(d) A 0.1 *M* solution of a weak acid or a 0.1 *M* solution of a strong acid
(e) A 0.1 *M* solution of an acid or a 0.01 *M* solution of a base
(f) A solution of pOH 6.0 or one of pOH 8.0

Skill-Building Exercises (grouped in similar pairs)

18.23 (a) What is the pH of 0.0111 *M* NaOH? Is the solution neutral, acidic, or basic? (b) What is the pOH of 1.35×10^{-3} *M* HCl? Is the solution neutral, acidic, or basic?

18.24 (a) What is the pH of 0.0333 *M* HNO_3? Is the solution neutral, acidic, or basic? (b) What is the pOH of 0.0347 *M* KOH? Is the solution neutral, acidic, or basic?

18.25 (a) What is the pH of 6.14×10^{-3} *M* HI? Is the solution neutral, acidic, or basic? (b) What is the pOH of 2.55 *M* $Ba(OH)_2$? Is the solution neutral, acidic, or basic?

18.26 (a) What is the pH of 7.52×10^{-4} *M* CsOH? Is the solution neutral, acidic, or basic? (b) What is the pOH of 1.59×10^{-3} *M* $HClO_4$? Is the solution neutral, acidic, or basic?

18.27 (a) What are $[H_3O^+]$, $[OH^-]$, and pOH in a solution with a pH of 9.85? (b) What are $[H_3O^+]$, $[OH^-]$, and pH in a solution with a pOH of 9.43?

18.28 (a) What are $[H_3O^+]$, $[OH^-]$, and pOH in a solution with a pH of 3.47? (b) What are $[H_3O^+]$, $[OH^-]$, and pH in a solution with a pOH of 4.33?

18.29 (a) What are $[H_3O^+]$, $[OH^-]$, and pOH in a solution with a pH of 4.77? (b) What are $[H_3O^+]$, $[OH^-]$, and pH in a solution with a pOH of 5.65?

18.30 (a) What are $[H_3O^+]$, $[OH^-]$, and pOH in a solution with a pH of 8.97? (b) What are $[H_3O^+]$, $[OH^-]$, and pH in a solution with a pOH of 11.27?

18.31 How many moles of H_3O^+ or OH^- must you add to a liter of HA solution to adjust its pH from 3.15 to 3.65? Assume a negligible volume change.

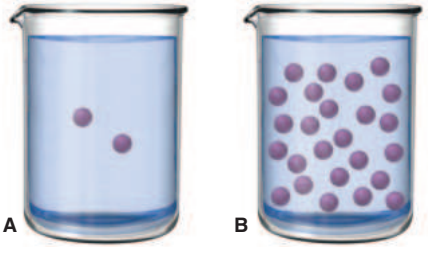
18.32 How many moles of H_3O^+ or OH^- must you add to a liter of HA solution to adjust its pH from 9.33 to 9.07? Assume a negligible volume change.

18.33 How many moles of H_3O^+ or OH^- must you add to 5.6 L of HA solution to adjust its pH from 4.52 to 5.25? Assume a negligible volume change.

18.34 How many moles of H_3O^+ or OH^- must you add to 87.5 mL of HA solution to adjust its pH from 8.92 to 6.33? Assume a negligible volume change.

Problems in Context

18.35 The two molecular scenes below depict the relative concentrations of H_3O^+ *(purple)* in solutions of the same volume (with counter ions and solvent molecules omitted for clarity). If the pH in scene A is 4.8, what is the pH in scene B?



18.36 Like any equilibrium constant, K_w changes with temperature. (a) Given that autoionization is endothermic, how does K_w change with rising T? Explain with a reaction that includes heat as reactant or product. (b) In many medical applications, the value of K_w at 37°C (body temperature) may be more appropriate than the value at 25°C, 1.0×10^{-14}. The pH of pure water at 37°C is 6.80. Calculate K_w, pOH, and $[OH^-]$ at this temperature.

Proton Transfer and the Brønsted-Lowry Acid-Base Definition

(Sample Problems 18.4 to 18.6)

Concept Review Questions

18.37 How are the Arrhenius and Brønsted-Lowry acid-base definitions different? How are they similar? Name two Brønsted-Lowry bases that are not Arrhenius bases. Can you do the same for acids? Explain.

18.38 What is a conjugate acid-base pair? What is the relationship between the two members of the pair?

18.39 (a) A Brønsted-Lowry acid-base reaction proceeds in the net direction in which a stronger acid and stronger base form a weaker acid and weaker base. Explain.

(b) The molecular scene at right depicts an aqueous solution of two conjugate acid-base pairs: HA/A^- and HB/B^-. The base in the first pair is represented by red spheres, and the base in the second pair by green spheres; solvent molecules are omitted for clarity. Which is the stronger acid? Stronger base? Explain.

18.40 What is an amphiprotic species? Name one and write balanced equations that show why it is amphiprotic.

Skill-Building Exercises (grouped in similar pairs)

18.41 Write balanced equations and K_a expressions for these Brønsted-Lowry acids in water:
(a) H_3PO_4 (b) C_6H_5COOH (c) HSO_4^-

18.42 Write balanced equations and K_a expressions for these Brønsted-Lowry acids in water:
(a) HCOOH (b) $HClO_3$ (c) $H_2AsO_4^-$

18.43 Give the formula of the conjugate base:
(a) HCl (b) H_2CO_3 (c) H_2O

18.44 Give the formula of the conjugate base:
(a) HPO_4^{2-} (b) NH_4^+ (c) HS^-

18.45 Give the formula of the conjugate acid:
(a) NH_3 (b) NH_2^- (c) nicotine, $C_{10}H_{14}N_2$

18.46 Give the formula of the conjugate acid:
(a) O^{2-} (b) SO_4^{2-} (c) H_2O

18.47 In each equation, label the acids, bases, and conjugate pairs:
(a) $HCl + H_2O \rightleftharpoons Cl^- + H_3O^+$
(b) $HClO_4 + H_2SO_4 \rightleftharpoons ClO_4^- + H_3SO_4^+$
(c) $HPO_4^{2-} + H_2SO_4 \rightleftharpoons H_2PO_4^- + HSO_4^-$

18.48 In each equation, label the acids, bases, and conjugate pairs:
(a) $NH_3 + HNO_3 \rightleftharpoons NH_4^+ + NO_3^-$
(b) $O^{2-} + H_2O \rightleftharpoons OH^- + OH^-$
(c) $NH_4^+ + BrO_3^- \rightleftharpoons NH_3 + HBrO_3$

18.49 In each equation, label the acids, bases, and conjugate pairs:
(a) $NH_3 + H_3PO_4 \rightleftharpoons NH_4^+ + H_2PO_4^-$
(b) $CH_3O^- + NH_3 \rightleftharpoons CH_3OH + NH_2^-$
(c) $HPO_4^{2-} + HSO_4^- \rightleftharpoons H_2PO_4^- + SO_4^{2-}$

18.50 In each equation, label the acids, bases, and conjugate pairs:
(a) $NH_4^+ + CN^- \rightleftharpoons NH_3 + HCN$
(b) $H_2O + HS^- \rightleftharpoons OH^- + H_2S$
(c) $HSO_3^- + CH_3NH_2 \rightleftharpoons SO_3^{2-} + CH_3NH_3^+$

18.51 Write balanced net ionic equations for the following reactions, and label the conjugate acid-base pairs:
(a) $NaOH(aq) + NaH_2PO_4(aq) \rightleftharpoons H_2O(l) + Na_2HPO_4(aq)$
(b) $KHSO_4(aq) + K_2CO_3(aq) \rightleftharpoons K_2SO_4(aq) + KHCO_3(aq)$

18.52 Write balanced net ionic equations for the following reactions, and label the conjugate acid-base pairs:
(a) $HNO_3(aq) + Li_2CO_3(aq) \rightleftharpoons LiNO_3(aq) + LiHCO_3(aq)$
(b) $2NH_4Cl(aq) + Ba(OH)_2(aq) \rightleftharpoons 2H_2O(l) + BaCl_2(aq) + 2NH_3(aq)$

18.53 The following aqueous species constitute two conjugate acid-base pairs. Use them to write one acid-base reaction with $K_c > 1$ and another with $K_c < 1$: HS^-, Cl^-, HCl, H_2S.

18.54 The following aqueous species constitute two conjugate acid-base pairs. Use them to write one acid-base reaction with $K_c > 1$ and another with $K_c < 1$: NO_3^-, F^-, HF, HNO_3.

18.55 Use Figure 18.8 (p. 790) to determine whether $K_c > 1$ for
(a) $HCl + NH_3 \rightleftharpoons NH_4^+ + Cl^-$
(b) $H_2SO_3 + NH_3 \rightleftharpoons HSO_3^- + NH_4^+$

18.56 Use Figure 18.8 (p. 790) to determine whether $K_c > 1$ for
(a) $OH^- + HS^- \rightleftharpoons H_2O + S^{2-}$
(b) $HCN + HCO_3^- \rightleftharpoons H_2CO_3 + CN^-$

18.57 Use Figure 18.8 (p. 790) to determine whether $K_c < 1$ for
(a) $NH_4^+ + HPO_4^{2-} \rightleftharpoons NH_3 + H_2PO_4^-$
(b) $HSO_3^- + HS^- \rightleftharpoons H_2SO_3 + S^{2-}$

18.58 Use Figure 18.8 (p. 790) to determine whether $K_c < 1$ for
(a) $H_2PO_4^- + F^- \rightleftharpoons HPO_4^{2-} + HF$
(b) $CH_3COO^- + HSO_4^- \rightleftharpoons CH_3COOH + SO_4^{2-}$

Solving Problems Involving Weak-Acid Equilibria

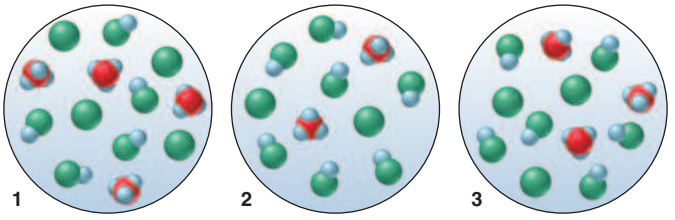
(Sample Problems 18.7 to 18.10)

Concept Review Questions

18.59 In each of the following cases, is the concentration of acid before and after dissociation nearly the same or very different? Explain your reasoning: (a) a concentrated solution of a strong acid; (b) a concentrated solution of a weak acid; (c) a dilute solution of a weak acid; (d) a dilute solution of a strong acid.

18.60 A sample of 0.0001 *M* HCl has $[H_3O^+]$ close to that of a sample of 0.1 *M* CH_3COOH. Are acetic acid and hydrochloric acid equally strong in these samples? Explain.

18.61 A 0.15 *M* solution of HA *(blue and green)* is 33% dissociated. Which of the scenes below represents a sample of that solution after it is diluted with water? (A real weak acid does not have a percent dissociation this high.)



18.62 In which of the following solutions will $[H_3O^+]$ be approximately equal to $[CH_3COO^-]$: (a) 0.1 *M* CH_3COOH; (b) 1×10^{-7} *M* CH_3COOH; (c) a solution containing both 0.1 *M* CH_3COOH and 0.1 *M* CH_3COONa? Explain.

18.63 Why do successive K_a's decrease for all polyprotic acids?

Skill-Building Exercises (grouped in similar pairs)

18.64 A 0.15 *M* solution of butanoic acid, $CH_3CH_2CH_2COOH$, contains 1.51×10^{-3} *M* H_3O^+. What is the K_a of butanoic acid?

18.65 A 0.035 *M* solution of a weak acid (HA) has a pH of 4.88. What is the K_a of the acid?

18.66 Nitrous acid, HNO_2, has a K_a of 7.1×10^{-4}. What are $[H_3O^+]$, $[NO_2^-]$, and $[OH^-]$ in 0.60 *M* HNO_2?

18.67 Hydrofluoric acid, HF, has a K_a of 6.8×10^{-4}. What are $[H_3O^+]$, $[F^-]$, and $[OH^-]$ in 0.75 *M* HF?

18.68 Chloroacetic acid, $ClCH_2COOH$, has a pK_a of 2.87. What are $[H_3O^+]$, pH, $[ClCH_2COO^-]$, and $[ClCH_2COOH]$ in 1.25 *M* $ClCH_2COOH$?

18.69 Hypochlorous acid, HClO, has a pK_a of 7.54. What are $[H_3O^+]$, pH, $[ClO^-]$, and [HClO] in 0.115 *M* HClO?

18.70 In a 0.20 *M* solution, a weak acid is 3.0% dissociated.
(a) Calculate the $[H_3O^+]$, pH, $[OH^-]$, and pOH of the solution.
(b) Calculate K_a of the acid.

18.71 In a 0.735 *M* solution, a weak acid is 12.5% dissociated.
(a) Calculate the $[H_3O^+]$, pH, $[OH^-]$, and pOH of the solution.
(b) Calculate K_a of the acid.

18.72 A 0.250-mol sample of HX is dissolved in enough H_2O to form 655 mL of solution. If the pH of the solution is 3.54, what is the K_a of HX?

18.73 A 4.85×10^{-3}-mol sample of HY is dissolved in enough H_2O to form 0.095 L of solution. If the pH of the solution is 2.68, what is the K_a of HY?

18.74 The weak acid HZ has a K_a of 2.55×10^{-4}.
(a) Calculate the pH of 0.075 *M* HZ.
(b) Calculate the pOH of 0.045 *M* HZ.

18.75 The weak acid HQ has a pK_a of 4.89.
(a) Calculate the $[H_3O^+]$ of 3.5×10^{-2} *M* HQ.
(b) Calculate the $[OH^-]$ of 0.65 *M* HQ.

18.76 (a) Calculate the pH of 0.175 *M* HY, if $K_a = 1.50\times10^{-4}$.
(b) Calculate the pOH of 0.175 *M* HX, if $K_a = 2.00\times10^{-2}$.

18.77 (a) Calculate the pH of 0.55 *M* HCN, if $K_a = 6.2\times10^{-10}$.
(b) Calculate the pOH of 0.044 *M* HIO_3, if $K_a = 0.16$.

18.78 Use Appendix C to calculate the percent dissociation of 0.55 *M* benzoic acid, C_6H_5COOH.

18.79 Use Appendix C to calculate the percent dissociation of 0.050 *M* CH_3COOH.

18.80 Use Appendix C to calculate $[H_2S]$, $[HS^-]$, $[S^{2-}]$, $[H_3O^+]$, pH, $[OH^-]$, and pOH in a 0.10 *M* solution of the diprotic acid hydrosulfuric acid.

18.81 Use Appendix C to calculate $[H_2C_3H_2O_4]$, $[HC_3H_2O_4^-]$, $[C_3H_2O_4^{2-}]$, $[H_3O^+]$, pH, $[OH^-]$, and pOH in a 0.200 *M* solution of the diprotic acid malonic acid.

Problems in Context

18.82 Acetylsalicylic acid (aspirin), $HC_9H_7O_4$, is the most widely used pain reliever and fever reducer. Find the pH of 0.018 *M* aqueous aspirin at body temperature (K_a at 37°C = 3.6×10^{-4}).

18.83 Formic acid, HCOOH, the simplest carboxylic acid, is used in the textile and rubber industries and is secreted as a defense by many species of ants (family *Formicidae*). Calculate the percent dissociation of 0.75 *M* HCOOH.

Molecular Properties and Acid Strength

Concept Review Questions

18.84 Across a period, how does the electronegativity of a nonmetal affect the acidity of its binary hydride?

18.85 How does the atomic size of a nonmetal affect the acidity of its binary hydride?

18.86 A strong acid has a weak bond to its acidic proton, whereas a weak acid has a strong bond to its acidic proton. Explain.

18.87 Perchloric acid, $HClO_4$, is the strongest of the halogen oxoacids, and hypoiodous acid, HIO, is the weakest. What two factors govern this difference in acid strength?

Skill-Building Exercises (grouped in similar pairs)

18.88 Choose the *stronger* acid in each of the following pairs:
(a) H_2SeO_3 or H_2SeO_4 (b) H_3PO_4 or H_3AsO_4 (c) H_2S or H_2Te

18.89 Choose the *weaker* acid in each of the following pairs:
(a) HBr or H_2Se (b) $HClO_4$ or H_2SO_4 (c) H_2SO_3 or H_2SO_4

18.90 Choose the *stronger* acid in each of the following pairs:
(a) H_2Se or H_3As (b) $B(OH)_3$ or $Al(OH)_3$ (c) $HBrO_2$ or HBrO

18.91 Choose the *weaker* acid in each of the following pairs:
(a) HI or HBr (b) H_3AsO_4 or H_2SeO_4 (c) HNO_3 or HNO_2

18.92 Use Appendix C to choose the solution with the *lower* pH:
(a) 0.5 *M* $CuBr_2$ or 0.5 *M* $AlBr_3$
(b) 0.3 *M* $ZnCl_2$ or 0.3 *M* $SnCl_2$

18.93 Use Appendix C to choose the solution with the *lower* pH:
(a) 0.1 *M* $FeCl_3$ or 0.1 *M* $AlCl_3$
(b) 0.1 *M* $BeCl_2$ or 0.1 *M* $CaCl_2$

18.94 Use Appendix C to choose the solution with the *higher* pH:
(a) 0.2 *M* $Ni(NO_3)_2$ or 0.2 *M* $Co(NO_3)_2$
(b) 0.35 *M* $Al(NO_3)_3$ or 0.35 *M* $Cr(NO_3)_3$

18.95 Use Appendix C to choose the solution with the *higher* pH:
(a) 0.1 *M* $NiCl_2$ or 0.1 *M* NaCl
(b) 0.1 *M* $Sn(NO_3)_2$ or 0.1 *M* $Co(NO_3)_2$

Weak Bases and Their Relation to Weak Acids

(Sample Problems 18.11 and 18.12)

Concept Review Questions

18.96 What is the key structural feature of all Brønsted-Lowry bases? How does this feature function in an acid-base reaction?

18.97 Why are most anions basic in H_2O? Give formulas of four anions that are not basic.

18.98 Except for the Na^+ spectator ion, aqueous solutions of CH_3COOH and CH_3COONa contain the same species. (a) What are the species (other than H_2O)? (b) Why is 0.1 *M* CH_3COOH acidic and 0.1 *M* CH_3COONa basic?

Skill-Building Exercises (grouped in similar pairs)

18.99 Write balanced equations and K_b expressions for these Brønsted-Lowry bases in water:
(a) Pyridine, C_5H_5N (b) CO_3^{2-}

18.100 Write balanced equations and K_b expressions for these Brønsted-Lowry bases in water:
(a) Benzoate ion, $C_6H_5COO^-$ (b) $(CH_3)_3N$

18.101 Write balanced equations and K_b expressions for these Brønsted-Lowry bases in water:
(a) Hydroxylamine, HO—NH_2 (b) HPO_4^{2-}

18.102 Write balanced equations and K_b expressions for these Brønsted-Lowry bases in water:
(a) Guanidine, $(H_2N)_2C{=}NH$ (double-bonded N is most basic)
(b) Acetylide ion, $HC{\equiv}C^-$

18.103 What is the pH of 0.070 *M* dimethylamine?

18.104 What is the pH of 0.12 *M* diethylamine?

18.105 What is the pH of 0.25 *M* ethanolamine?

18.106 What is the pH of 0.26 *M* aniline?

18.107 (a) What is the K_b of the acetate ion?
(b) What is the K_a of the anilinium ion, $C_6H_5NH_3^+$?

18.108 (a) What is the K_b of the benzoate ion, $C_6H_5COO^-$?
(b) What is the K_a of the 2-hydroxyethylammonium ion, $HOCH_2CH_2NH_3^+$ (pK_b of $HOCH_2CH_2NH_2 = 4.49$)?

18.109 (a) What is the pK_b of ClO_2^-?
(b) What is the pK_a of the dimethylammonium ion, $(CH_3)_2NH_2^+$?

18.110 (a) What is the pK_b of NO_2^-?
(b) What is the pK_a of the hydrazinium ion, $H_2N{-}NH_3^+$ (K_b of hydrazine $= 8.5\times10^{-7}$)?

18.111 (a) What is the pH of 0.150 *M* KCN?
(b) What is the pH of 0.40 *M* triethylammonium chloride, $(CH_3CH_2)_3NHCl$?

18.112 (a) What is the pH of 0.100 *M* sodium phenolate, C_6H_5ONa, the sodium salt of phenol?
(b) What is the pH of 0.15 *M* methylammonium bromide, CH_3NH_3Br (K_b of $CH_3NH_2 = 4.4\times10^{-4}$)?

18.113 (a) What is the pH of 0.65 *M* potassium formate, HCOOK?
(b) What is the pH of 0.85 *M* NH_4Br?

18.114 (a) What is the pH of 0.75 *M* NaF?
(b) What is the pH of 0.88 *M* pyridinium chloride, C_5H_5NHCl?

Problems in Context

18.115 Sodium hypochlorite solution, sold as chlorine bleach, is potentially dangerous because of the basicity of ClO^-, the active bleaching ingredient. What is $[OH^-]$ in an aqueous solution that is 6.5% NaClO by mass? What is the pH of the solution? (Assume that *d* of the solution is 1.0 g/mL.)

18.116 Codeine ($C_{18}H_{21}NO_3$) is a narcotic pain reliever that forms a salt with HCl. What is the pH of 0.050 *M* codeine hydrochloride (pK_b of codeine $= 5.80$)?

Acid-Base Properties of Salt Solutions

(Sample Problems 18.13 and 18.14)

Concept Review Questions

18.117 What determines whether an aqueous solution of a salt will be acidic, basic, or neutral? Give an example of each type of salt.

18.118 Why is aqueous NaF basic but aqueous NaCl neutral?

18.119 The NH_4^+ ion forms acidic solutions, and the CH_3COO^- ion forms basic solutions. However, a solution of ammonium acetate is almost neutral. Do all of the ammonium salts of weak acids form neutral solutions? Explain your answer.

Skill-Building Exercises (grouped in similar pairs)

18.120 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) KBr; (b) NH_4I; (c) KCN.

18.121 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $SnCl_2$; (b) NaHS; (c) $Zn(CH_3COO)_2$.

18.122 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) Na_2CO_3; (b) $CaCl_2$; (c) $Cu(NO_3)_2$.

18.123 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) CH_3NH_3Cl; (b) $LiClO_4$; (c) CoF_2.

18.124 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $SrBr_2$; (b) $Ba(CH_3COO)_2$; (c) $(CH_3)_2NH_2Br$.

18.125 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $Fe(HCOO)_3$; (b) $KHCO_3$; (c) K_2S.

18.126 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $(NH_4)_3PO_4$; (b) Na_2SO_4; (c) LiClO.

18.127 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $Pb(CH_3COO)_2$; (b) $Cr(NO_2)_3$; (c) CsI.

18.128 Rank the following salts in order of *increasing* pH of their 0.1 *M* aqueous solutions:
(a) KNO_3, K_2SO_3, K_2S, $Fe(NO_3)_2$
(b) NH_4NO_3, $NaHSO_4$, $NaHCO_3$, Na_2CO_3

18.129 Rank the following salts in order of *decreasing* pH of their 0.1 *M* aqueous solutions:
(a) $FeCl_2$, $FeCl_3$, $MgCl_2$, $KClO_2$
(b) NH_4Br, $NaBrO_2$, NaBr, $NaClO_2$

Generalizing the Brønsted-Lowry Concept: The Leveling Effect

Concept Review Questions

18.130 Methoxide ion, CH_3O^-, and amide ion, NH_2^-, are very strong bases that are "leveled" by water. What does this mean? Write the reactions that occur in the leveling process. What species do the two leveled solutions have in common?

18.131 Explain the differing extents of dissociation of H_2SO_4 in CH_3COOH, H_2O, and NH_3.

18.132 In H_2O, HF is weak and the other hydrohalic acids are equally strong. In NH_3, however, all the hydrohalic acids are equally strong. Explain.

Electron-Pair Donation and the Lewis Acid-Base Definition

(Sample Problem 18.15)

Concept Review Questions

18.133 What feature must a molecule or ion have in order to act as a Lewis base? A Lewis acid? Explain the roles of these features.

18.134 How do Lewis acids differ from Brønsted-Lowry acids? How are they similar? Do Lewis bases differ from Brønsted-Lowry bases? Explain.

18.135 (a) Is a weak Brønsted-Lowry base necessarily a weak Lewis base? Explain with an example.
(b) Identify the Lewis bases in the following reaction:
$Cu(H_2O)_4^{2+}(aq) + 4CN^-(aq) \rightleftharpoons Cu(CN)_4^{2-}(aq) + 4H_2O(l)$
(c) Given that $K_c > 1$ for the reaction in part (b), which Lewis base is stronger?

18.136 In which of the three acid-base concepts can water be a product of an acid-base reaction? In which is it the only product?

18.137 (a) Give an example of a *substance* that is a base in two of the three acid-base definitions, but not in the third.
(b) Give an example of a *substance* that is an acid in one of the three acid-base definitions, but not in the other two.

Skill-Building Exercises (grouped in similar pairs)

18.138 Which are Lewis acids and which are Lewis bases?
(a) Cu^{2+} (b) Cl^- (c) $SnCl_2$ (d) OF_2

18.139 Which are Lewis acids and which are Lewis bases?
(a) Na^+ (b) NH_3 (c) CN^- (d) BF_3

18.140 Which are Lewis acids and which are Lewis bases?
(a) BF_3 (b) S^{2-} (c) SO_3^{2-} (d) SO_3

18.141 Which are Lewis acids and which are Lewis bases?
(a) Mg^{2+} (b) OH^- (c) SiF_4 (d) $BeCl_2$

18.142 Identify the Lewis acid and Lewis base in each reaction:
(a) $Na^+ + 6H_2O \rightleftharpoons Na(H_2O)_6^+$
(b) $CO_2 + H_2O \rightleftharpoons H_2CO_3$
(c) $F^- + BF_3 \rightleftharpoons BF_4^-$

18.143 Identify the Lewis acid and Lewis base in each reaction:
(a) $Fe^{3+} + 2H_2O \rightleftharpoons FeOH^{2+} + H_3O^+$
(b) $H_2O + H^- \rightleftharpoons OH^- + H_2$
(c) $4CO + Ni \rightleftharpoons Ni(CO)_4$

18.144 Classify the following as Arrhenius, Brønsted-Lowry, or Lewis acid-base reactions. A reaction may fit all, two, one, or none of the categories:
(a) $Ag^+ + 2NH_3 \rightleftharpoons Ag(NH_3)_2^+$
(b) $H_2SO_4 + NH_3 \rightleftharpoons HSO_4^- + NH_4^+$
(c) $2HCl \rightleftharpoons H_2 + Cl_2$
(d) $AlCl_3 + Cl^- \rightleftharpoons AlCl_4^-$

18.145 Classify the following as Arrhenius, Brønsted-Lowry, or Lewis acid-base reactions. A reaction may fit all, two, one, or none of the categories:
(a) $Cu^{2+} + 4Cl^- \rightleftharpoons CuCl_4^{2-}$
(b) $Al(OH)_3 + 3HNO_3 \rightleftharpoons Al^{3+} + 3H_2O + 3NO_3^-$
(c) $N_2 + 3H_2 \rightleftharpoons 2NH_3$
(d) $CN^- + H_2O \rightleftharpoons HCN + OH^-$

Comprehensive Problems

18.146 Chloral ($Cl_3C—CH=O$) forms a monohydrate, chloral hydrate, the sleep-inducing depressant called "knockout drops" in old movies. (a) Write two possible structures for chloral hydrate, one involving hydrogen bonding and one that is a Lewis adduct. (b) What spectroscopic method could be used to identify the real structure? Explain.

18.147 In humans, blood pH is maintained within a narrow range: *acidosis* occurs if the blood pH is below 7.35, and *alkalosis* occurs if the pH is above 7.45. Given that the pK_w of blood is 13.63 at 37°C (body temperature), what is the normal range of $[H_3O^+]$ and of $[OH^-]$ in blood?

18.148 The disinfectant phenol, C_6H_5OH, has a pK_a of 10.0 in water, but 14.4 in methanol.
(a) Why are the values different?
(b) Is methanol a stronger or weaker base than water?
(c) Write the dissociation reaction of phenol in methanol.
(d) Write an expression for the autoionization constant of methanol.

18.149 When carbon dioxide dissolves in water, it undergoes a multistep equilibrium process, with $K_{overall} = 4.5\times10^{-7}$, which is simplified to the following:

$$CO_2(g) + H_2O(l) \rightleftharpoons H_2CO_3(aq)$$
$$H_2CO_3(aq) + H_2O(l) \rightleftharpoons HCO_3^-(aq) + H_3O^+(aq)$$

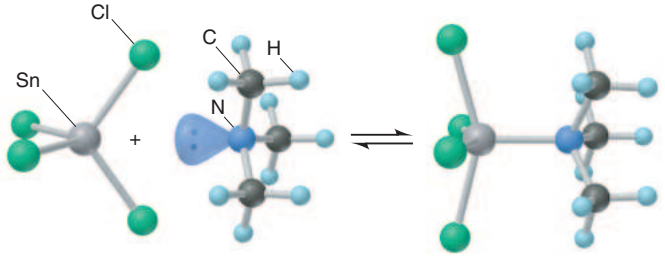
(a) Classify each step as a Lewis or a Brønsted-Lowry reaction.
(b) What is the pH of nonpolluted rainwater in equilibrium with clean air (P_{CO_2} in clean air $= 4\times10^{-4}$ atm; Henry's law constant for CO_2 at 25°C is 0.033 mol/L·atm)?
(c) What is $[CO_3^{2-}]$ in rainwater (K_a of $HCO_3^- = 4.7\times10^{-11}$)?
(d) If the partial pressure of CO_2 in clean air doubles in the next few decades, what will the pH of rainwater become?

18.150 Seashells are mostly calcium carbonate, which reacts with H_3O^+ according to the equation

$$CaCO_3(s) + H_3O^+(aq) \rightleftharpoons Ca^{2+}(aq) + HCO_3^-(aq) + H_2O(l)$$

If K_w increases at higher pressure, will seashells dissolve more rapidly near the surface of the ocean or at great depths? Explain.

18.151 Many molecules with central atoms from Period 3 or higher take part in Lewis acid-base reactions in which the central atom expands its valence shell. $SnCl_4$ reacts with $(CH_3)_3N$ as follows:

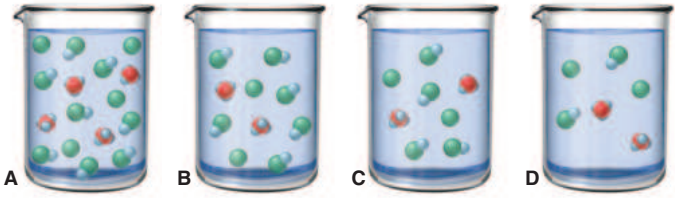


(a) Identify the Lewis acid and the Lewis base in the reaction.
(b) Give the *nl* designation of the sublevel of the central atom in the acid before it accepts the lone pair.

18.152 A chemist makes four successive ten-fold dilutions of 1.0×10^{-5} *M* HCl. Calculate the pH of the original solution and of each diluted solution (through 1.0×10^{-9} *M* HCl).

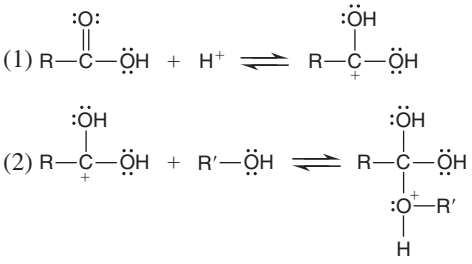
18.153 Chlorobenzene, C_6H_5Cl, is a key intermediate in the manufacture of dyes and pesticides. It is made by the chlorination of benzene, catalyzed by $FeCl_3$, in this series of steps:
(1) $Cl_2 + FeCl_3 \rightleftharpoons FeCl_5$ (or $Cl^+FeCl_4^-$)
(2) $C_6H_6 + Cl^+FeCl_4^- \rightleftharpoons C_6H_6Cl^+ + FeCl_4^-$
(3) $C_6H_6Cl^+ \rightleftharpoons C_6H_5Cl + H^+$
(4) $H^+ + FeCl_4^- \rightleftharpoons HCl + FeCl_3$
(a) Which of the step(s) is (are) Lewis acid-base reactions?
(b) Identify the Lewis acids and bases in each of those steps.

18.154 The beakers shown contain 0.300 L of aqueous solutions of a moderately weak acid HY. Each particle represents 0.010 mol; solvent molecules are omitted for clarity. (a) The reaction in beaker A is at equilibrium. Calculate Q for B, C, and D to determine which, if any, is also at equilibrium. (b) For any not at equilibrium, in which direction does the reaction proceed? (c) Does dilution affect the extent of dissociation of a weak acid? Explain.



18.155 The strength of an acid or base is related to its strength as an electrolyte. (a) Is the electrical conductivity of 0.1 M HCl higher, lower, or the same as that of 0.1 M CH_3COOH? Explain. (b) Is the electrical conductivity of 1×10^{-7} M HCl higher, lower, or the same as that of 1×10^{-7} M CH_3COOH? Explain.

18.156 Esters, RCOOR′, are formed by the reaction of carboxylic acids, RCOOH, and alcohols, R′OH, where R and R′ are hydrocarbon groups. Many esters are responsible for the odors of fruit and, thus, have important uses in the food and cosmetics industries. The first two steps in the mechanism of ester formation are



Identify the Lewis acids and Lewis bases in these two steps.

18.157 Three beakers contain 100. mL of 0.10 M HCl, $HClO_2$, and HClO, respectively. (a) Find the pH of each. (b) Describe quantitatively how to make the pH equal in the beakers through the addition of water only.

18.158 Human urine has a normal pH of 6.2. If a person eliminates an average of 1250. mL of urine per day, how many H^+ ions are eliminated per week?

18.159 Liquid ammonia autoionizes like water:

$$2NH_3(l) \longrightarrow NH_4^+(am) + NH_2^-(am)$$

where (am) represents solvation by NH_3.
(a) Write the ion-product constant expression, K_{am}.
(b) What are the strongest acid and base that can exist in $NH_3(l)$?
(c) HNO_3 and HCOOH are leveled in $NH_3(l)$. Explain with equations.
(d) At the boiling point (−33°C), $K_{am} = 5.1\times10^{-27}$. Calculate $[NH_4^+]$ at this temperature.
(e) Pure sulfuric acid also autoionizes. Write the ion-product constant expression, K_{sulf}, and find the concentration of the conjugate base at 20°C ($K_{sulf} = 2.7\times10^{-4}$ at 20°C).

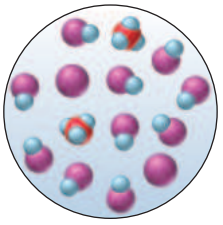
18.160 Thiamine hydrochloride ($C_{12}H_{18}ON_4SCl_2$) is a water-soluble form of thiamine (vitamin B_1; $K_a = 3.37\times10^{-7}$). How many grams of the hydrochloride must be dissolved in 10.00 mL of water to give a pH of 3.50?

18.161 Tris(hydroxymethyl)aminomethane, known as TRIS or THAM, is a water-soluble base used in synthesizing surfactants and pharmaceuticals, as an emulsifying agent in cosmetics, and in cleaning mixtures for textiles and leather. In biomedical research, solutions of TRIS are used to maintain nearly constant pH for the study of enzymes and other cellular components. Given that the pK_b is 5.91, calculate the pH of 0.075 M TRIS.

18.162 When an Fe^{3+} salt is dissolved in water, the solution becomes acidic due to formation of $Fe(H_2O)_5OH^{2+}$ and H_3O^+. The overall process involves both Lewis and Brønsted-Lowry acid-base reactions. Write the equations for the process.

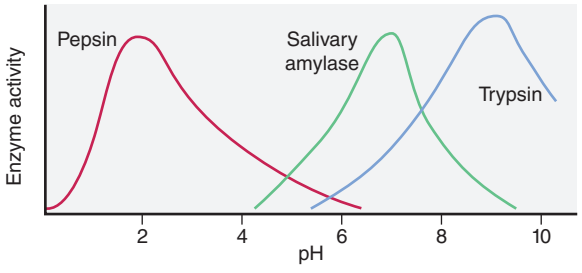
18.163 What is the pH of a vinegar with 5.0% (w/v) acetic acid in water?

18.164 The scene below represents a sample of a weak acid HB *(blue and purple)* dissolved in water. Draw a scene that represents the same volume after the solution has been diluted with water.



18.165 How would you differentiate between a strong and a weak monoprotic acid from the results of the following procedures? (a) Electrical conductivity of an equimolar solution of each acid is measured. (b) Equal molarities of each are tested with pH paper. (c) Zinc metal is added to solutions of equal concentration.

18.166 The catalytic efficiency of an enzyme is called its *activity* and refers to the rate at which it catalyzes the reaction. Most enzymes have optimum activity over a relatively narrow pH range, which is related to the pH of the local cellular fluid. The pH profiles of three digestive enzymes are shown.



Salivary amylase begins digestion of starches in the mouth and has optimum activity at a pH of 6.8; pepsin begins protein digestion in the stomach and has optimum activity at a pH of 2.0; and trypsin, released in pancreatic juices, continues protein digestion in the small intestine and has optimum activity at a pH of 9.5. Calculate $[H_3O^+]$ in the local cellular fluid for each enzyme.

18.167 Acetic acid has a K_a of 1.8×10^{-5}, and ammonia has a K_b of 1.8×10^{-5}. Find $[H_3O^+]$, $[OH^-]$, pH, and pOH for (a) 0.240 M acetic acid and (b) 0.240 M ammonia.

18.168 The uses of sodium phosphate include clarifying crude sugar, manufacturing paper, removing boiler scale, and washing concrete. What is the pH of a solution containing 33 g of Na_3PO_4 per liter? What is $[OH^-]$ of this solution?

18.169 The Group 5A(15) hydrides react with boron trihalides in a reversible Lewis acid-base reaction. When 0.15 mol of $PH_3BCl_3(s)$ is introduced into a 3.0-L container at a certain temperature, 8.4×10^{-3} mol of PH_3 is present at equilibrium: $PH_3BCl_3(s) \rightleftharpoons PH_3(g) + BCl_3(g)$. (a) Find K_c for the reaction at this temperature. (b) Draw a Lewis structure for the reactant.

18.170 A 1.000 *m* solution of chloroacetic acid ($ClCH_2COOH$) freezes at −1.93°C. Find the K_a of chloroacetic acid. (Assume that the molarities equal the molalities.)

18.171 Sodium stearate ($C_{17}H_{35}COONa$) is a major component of bar soap. The K_a of the stearic acid is 1.3×10^{-5}. What is the pH of 10.0 mL of a solution containing 0.42 g of sodium stearate?

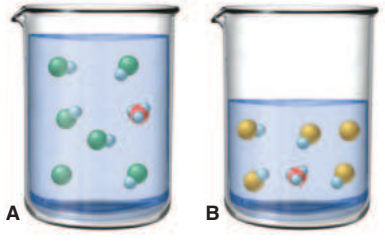
18.172 Calcium propionate [$Ca(CH_3CH_2COO)_2$; calcium propanoate] is a mold inhibitor used in food, tobacco, and pharmaceuticals. (a) Use balanced equations to show whether aqueous calcium propionate is acidic, basic, or neutral. (b) Use Appendix C to find the resulting pH when 8.75 g of $Ca(CH_3CH_2COO)_2$ dissolves in enough water to give 0.500 L of solution.

18.173 A site in Pennsylvania receives a total annual deposition of 2.688 g/m^2 of sulfate from fertilizer and acid rain. The ratio by mass of ammonium sulfate/ammonium bisulfate/sulfuric acid is 3.0/5.5/1.0. (a) How much acid, expressed as kg of sulfuric acid, is deposited over an area of 10. km^2? (b) How many pounds of $CaCO_3$ are needed to neutralize this acid? (c) If 10. km^2 is the area of an unpolluted lake 3 m deep and there is no loss of acid, what pH will the lake water attain by the end of the year? (Assume constant volume.)

18.174 (a) If $K_w = 1.139\times10^{-15}$ at 0°C and 5.474×10^{-14} at 50°C, find $[H_3O^+]$ and pH of water at 0°C and 50°C.
(b) The autoionization constant for heavy water (deuterium oxide, D_2O) is 3.64×10^{-16} at 0°C and 7.89×10^{-15} at 50°C. Find $[D_3O^+]$ and pD of heavy water at 0°C and 50°C.
(c) Suggest a reason for these differences.

18.175 HX ($\mathcal{M}$ = 150. g/mol) and HY ($\mathcal{M}$ = 50.0 g/mol) are weak acids. A solution of 12.0 g/L of HX has the same pH as one containing 6.00 g/L of HY. Which is the stronger acid? Why?

18.176 The beakers below depict the aqueous dissociations of weak acids HA *(blue and green)* and HB *(blue and yellow);* solvent molecules are omitted for clarity. If the HA solution is 0.50 L, and the HB solution is 0.25 L, and each particle represents 0.010 mol, find the K_a of each acid. Which acid, if either, is stronger?



18.177 In his acid-base studies, Arrhenius discovered an important fact involving reactions like the following:

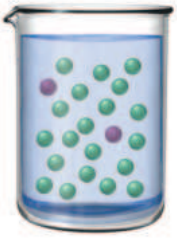
$$KOH(aq) + HNO_3(aq) \longrightarrow ?$$
$$NaOH(aq) + HCl(aq) \longrightarrow ?$$

(a) Complete the reactions and use the data for the individual ions in Appendix B to calculate each ΔH°_{rxn}.
(b) Explain your results and use them to predict ΔH°_{rxn} for

$$KOH(aq) + HCl(aq) \longrightarrow ?$$

18.178 Putrescine [$NH_2(CH_2)_4NH_2$], found in rotting animal tissue, is now known to be in all cells and essential for normal and abnormal (cancerous) growth. It also plays a key role in the formation of GABA, a neurotransmitter. A 0.10 *M* aqueous solution of putrescine has $[OH^-] = 2.1\times10^{-3}$. What is the K_b?

18.179 The molecular scene depicts the relative concentrations of H_3O^+ *(purple)* and OH^- *(green)* in an aqueous solution at 25°C. (Counter ions and solvent molecules are omitted for clarity.) (a) Calculate the pH. (b) How many H_3O^+ ions would you have to draw for every OH^- ion to depict a solution of pH 4?



18.180 Polymers are not very soluble in water, but their solubility increases if they have charged groups. (a) Casein, a milk protein, contains many —COO^- groups on its side chains. How does the solubility of casein vary with pH? (b) Histones are proteins essential to the function of DNA. They are weakly basic due to the presence of side chains with —NH_2 and =NH groups. How does the solubility of a histone vary with pH?

18.181 Hemoglobin (Hb) transports oxygen in the blood:

$$HbH^+(aq) + O_2(aq) + H_2O(l) \longrightarrow HbO_2(aq) + H_3O^+(aq)$$

In blood, $[H_3O^+]$ is held nearly constant at 4×10^{-8} *M*.
(a) How does the equilibrium position change in the lungs?
(b) How does it change in O_2-deficient cells?
(c) Excessive vomiting may lead to metabolic *alkalosis,* in which $[H_3O^+]$ in blood *decreases*. How does this condition affect the ability of Hb to transport O_2?
(d) Diabetes mellitus may lead to metabolic *acidosis,* in which $[H_3O^+]$ in blood *increases*. How does this condition affect the ability of Hb to transport O_2?

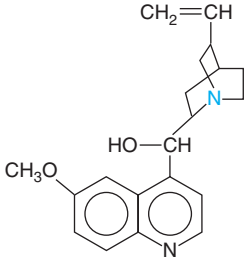
18.182 Nitrogen is discharged from wastewater treatment facilities into rivers and streams, usually as NH_3 and NH_4^+:

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq) \qquad K_b = 1.76\times10^{-5}$$

One strategy for removing it is to raise the pH and "strip" the NH_3 from solution by bubbling air through the water. (a) At pH 7.00, what fraction of the total nitrogen in solution is NH_3, defined as $[NH_3]/([NH_3] + [NH_4^+])$? (b) What is the fraction at pH 10.00? (c) Explain the basis of ammonia stripping.

18.183 A solution of propanoic acid (CH_3CH_2COOH), made by dissolving 7.500 g in sufficient water to make 100.0 mL, has a freezing point of −1.890°C.
(a) Calculate the molarity of the solution.
(b) Calculate the molarity of the propanoate ion. (Assume the molarity of the solution equals the molality.)
(c) Calculate the percent dissociation of propanoic acid.

18.184 The antimalarial properties of quinine ($C_{20}H_{24}N_2O_2$) saved thousands of lives during construction of the Panama Canal. This substance is a classic example of the medicinal wealth of tropical forests. Both N atoms are basic, but the N (colored) of the 3° amine group is far more basic (pK_b = 5.1) than the N within the aromatic ring system (pK_b = 9.7).



(a) A saturated solution of quinine in water is only 1.6×10^{-3} *M*. What is the pH of this solution?
(b) Show that the aromatic N contributes negligibly to the pH of the solution.
(c) Because of its low solubility, quinine is given as the salt quinine hydrochloride ($C_{20}H_{24}N_2O_2\cdot HCl$), which is 120 times more soluble than quinine. What is the pH of 0.33 *M* quinine hydrochloride?
(d) An antimalarial concentration in water is 1.5% quinine hydrochloride by mass ($d = 1.0$ g/mL). What is the pH?

18.185 Drinking water is often disinfected with Cl_2, which hydrolyzes to form HClO, a weak acid but powerful disinfectant:

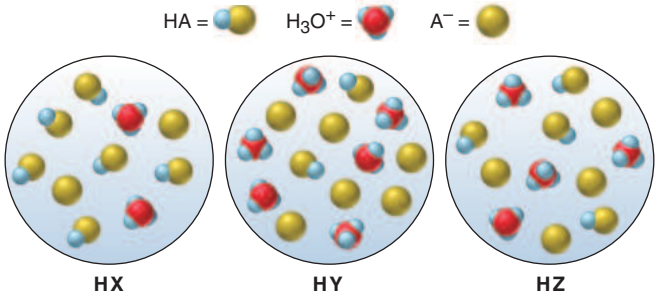
$$Cl_2(aq) + 2H_2O(l) \longrightarrow HClO(aq) + H_3O^+(aq) + Cl^-(aq)$$

The fraction of HClO in solution is defined as

$$\frac{[HClO]}{[HClO] + [ClO^-]}$$

(a) What is the fraction of HClO at pH 7.00 (K_a of HClO = 2.9×10^{-8})? (b) What is the fraction at pH 10.00?

18.186 The following scenes represent three weak acids HA (where A = X, Y, or Z) dissolved in water (H_2O is not shown):



(a) Rank the acids in order of increasing K_a. (b) Rank the acids in order of increasing pK_a. (c) Rank the conjugate bases in order of increasing pK_b. (d) What is the percent dissociation of HX? (e) If equimolar amounts of the sodium salts of the acids (NaX, NaY, and NaZ) were dissolved in water, which solution would have the highest pOH? The lowest pH?

19 Ionic Equilibria in Aqueous Systems

19.1 Equilibria of Acid-Base Buffers

Concepts and Skills to Review Before You Study This Chapter

- solubility rules for ionic compounds (Section 4.3)
- equilibrium nature of a saturated solution (Section 13.4)
- effect of concentration on equilibrium position (Section 17.6)
- conjugate acid-base pairs (Section 18.3)
- calculations for weak-acid and weak-base equilibria (Sections 18.4 and 18.6)
- acid-base properties of salt solutions (Section 18.7)
- Lewis acids and bases (Section 18.9)

Continuing our exploration of the universal nature of equilibrium, we now examine aqueous ionic systems. Marine organisms such as sea urchins, starfish, and coral *(see photo)* are affected by acid-base and carbonate solubility equilibria, which are also responsible for the unique formations in limestone caves. Organisms survive by maintaining cellular pH within narrow limits through complex carbonate and phosphate equilibria. In soils, equilibria involving clays control the availability of ionic nutrients for plants. In industrial settings, the same principles govern the softening of water and the purification of products by precipitation of unwanted ions. And they even explain how the weak acids in wine and vinegar influence the delicate taste of a fine sauce.

IN THIS CHAPTER . . . *We define and quantify three aqueous ionic equilibrium systems—acid-base buffers, slightly soluble salts, and complex ions.*

- We introduce the common-ion effect to explain how buffers work, and see why buffers are important and how to prepare them.
- We describe several types of acid-base titrations and the role buffers play in them.
- We see that slightly soluble salts have their own equilibrium constant and learn how a common ion and pH influence the solubility of these compounds.
- We use concepts of aqueous ionic equilibria to understand how a cave forms.
- We investigate how complex ions form and change from one type to another.

19.1 EQUILIBRIA OF ACID-BASE BUFFERS

Why do some lakes become acidic when showered by acid rain, while others remain unaffected? How does blood maintain a constant pH in contact with countless cellular acid-base reactions? How can a chemist sustain a nearly constant $[H_3O^+]$ in reactions that consume or produce H_3O^+ or OH^-? The answer in each case depends on the action of a buffer, and in this section we discuss how buffers work and how to prepare them.

What a Buffer Is and How It Works: The Common-Ion Effect

In everyday language, a buffer is something that lessens the impact of an external force. An **acid-base buffer** is a solution that *lessens the impact on pH of the addition of acid or base*. Add a small amount of H_3O^+ or OH^- to an *un*buffered solution, and the pH changes by several units; thus, $[H_3O^+]$ changes by *several orders of magnitude* (Figure 19.1).

Figure 19.1 The effect of adding acid or base to an unbuffered solution. **A,** A 100-mL sample of dilute HCl is adjusted to pH 5.00 *(left)*. **B,** Adding 1 mL of strong acid *(left)* or of strong base *(right)* changes the pH by several units.

Figure 19.2 The effect of adding acid or base to a buffered solution. **A,** A 100-mL sample of an acetate buffer, which was made by mixing 1 *M* CH_3COOH with 1 *M* CH_3COONa, is adjusted to pH 5.00. **B,** Adding 1 mL of strong acid *(left)* or of strong base *(right)* changes the pH negligibly.

The same addition of strong acid or strong base to a buffered solution causes only a minor change in pH (Figure 19.2). To withstand these additions, a buffer must have an acidic component that reacts with the added OH^- *and* a basic component that reacts with the added H_3O^+. However, these components can't be any acid and base because they would neutralize each other. Most often, *the components of a buffer are a conjugate acid-base pair* (weak acid and conjugate base or weak base and conjugate acid). The buffer in Figure 19.2, for example, is a mixture of acetic acid (CH_3COOH) and acetate ion (CH_3COO^-).

Presence of a Common Ion Buffers work through the **common-ion effect.** When you dissolve acetic acid in water, the acid dissociates slightly:

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3COO^-(aq)$$

What happens if you now introduce acetate ion by adding the soluble salt sodium acetate? From Le Châtelier's principle (Section 17.6), we know that adding CH_3COO^- ion will shift the equilibrium position to the left; thus, $[H_3O^+]$ decreases, in effect lowering the extent of acid dissociation:

$$CH_3COOH(aq) + H_2O(l) \overset{\leftarrow}{\rightleftharpoons} H_3O^+(aq) + CH_3COO^-(aq;\ \text{added})$$

We get the same result when we add acetic acid to a sodium acetate solution instead of water. The acetate ion already present suppresses the acid from dissociating as much as it does in water, thus keeping the $[H_3O^+]$ lower (and pH higher). In either case, the effect is less acid dissociation. Acetate ion is called *the common ion* because it is "common" to both the acetic acid and sodium acetate solutions. *The common-ion effect occurs when a given ion is added to an equilibrium mixture that already contains that ion, and the position of equilibrium shifts away from forming it.*

Table 19.1 shows that the percent dissociation (and the $[H_3O^+]$) of an acetic acid solution decreases as the concentration of acetate ion (supplied by dissolving sodium acetate) increases. Thus, the *common ion, A^-, suppresses the dissociation of HA,* which makes the solution less acidic (higher pH).

Table 19.1 The Effect of Added Acetate Ion on the Dissociation of Acetic Acid

$[CH_3COOH]_{init}$	$[CH_3COO^-]_{added}$	% Dissociation*	H_3O^+	pH
0.10	0.00	1.3	1.3×10^{-3}	2.89
0.10	0.050	0.036	3.6×10^{-5}	4.44
0.10	0.10	0.018	1.8×10^{-5}	4.74
0.10	0.15	0.012	1.2×10^{-5}	4.92

$$*\%\ \text{Dissociation} = \frac{[CH_3COOH]_{dissoc}}{[CH_3COOH]_{init}} \times 100$$

Relative Concentrations of Buffer Components A buffer works because *large amounts of the acidic (HA) and basic (A^-) components consume small amounts of added OH^- or H_3O^+, respectively.* Consider what happens in a solution containing high $[CH_3COOH]$ and high $[CH_3COO^-]$ when we add small amounts of strong acid or base. The equilibrium expression for HA dissociation is

$$K_a = \frac{[CH_3COO^-][H_3O^+]}{[CH_3COOH]}$$

Solving for $[H_3O^+]$ gives

$$[H_3O^+] = K_a \times \frac{[CH_3COOH]}{[CH_3COO^-]}$$

Since K_a is constant, *the $[H_3O^+]$ of the solution depends on the buffer-component concentration ratio,* $\frac{[CH_3COOH]}{[CH_3COO^-]}$:

- If the ratio $[HA]/[A^-]$ goes up (more acid and less conjugate base), then $[H_3O^+]$ goes up.
- If the ratio $[HA]/[A^-]$ goes down (less acid and more conjugate base), then $[H_3O^+]$ goes down.

Let's track this ratio as we add strong acid or strong base to a buffer in which $[HA] = [A^-]$ (Figure 19.3, *middle*):

1. *Strong acid.* When we add a small amount of strong acid, the H_3O^+ ions react with an *equal (stoichiometric) amount* of acetate ion from the buffer to form more acetic acid:

$$H_3O^+(aq;\ \text{added}) + CH_3COO^-(aq;\ \text{from buffer}) \longrightarrow CH_3COOH(aq) + H_2O(l)$$

As a result, $[CH_3COO^-]$ goes down by that small amount and $[CH_3COOH]$ goes up by that amount, which increases the buffer-component concentration ratio (Figure 19.3, *to the left*). The $[H_3O^+]$ increases *very* slightly.

2. *Strong base.* The addition of a small amount of strong base produces the opposite result. The OH^- ions react with an *equal (stoichiometric) amount* of CH_3COOH from the buffer to form that much more CH_3COO^- (Figure 19.3, *to the right*):

$$CH_3COOH(aq;\ \text{from buffer}) + OH^-(aq;\ \text{added}) \longrightarrow CH_3COO^-(aq) + H_2O(l)$$

This time, the buffer-component concentration ratio decreases, which decreases $[H_3O^+]$ *very* slightly.

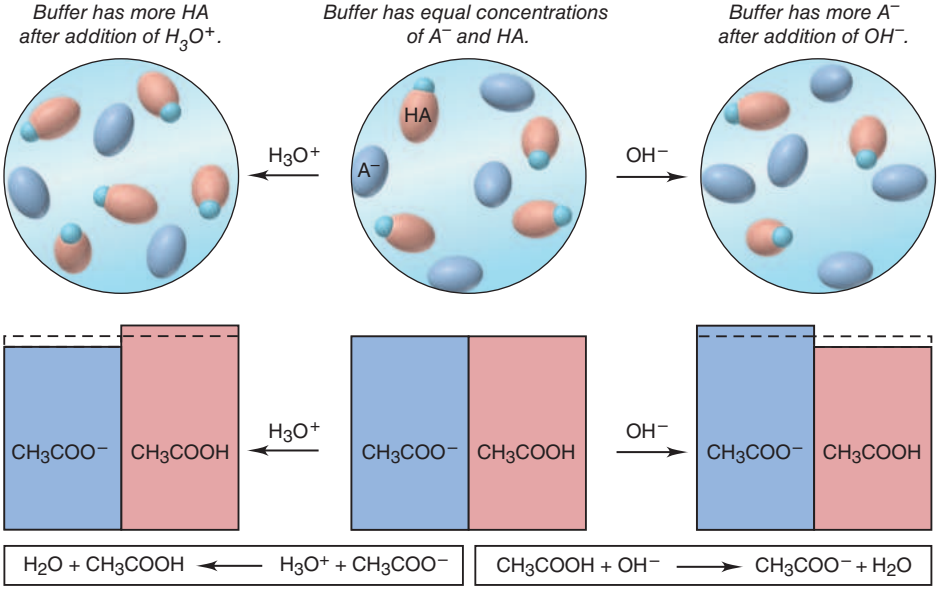

Figure 19.3 How a buffer works. The relative concentrations of the buffer components, acetic acid (CH_3COOH, *red*) and acetate ion (CH_3COO^-, *blue*) are indicated by the heights of the bars.

Thus, the buffer components consume *nearly all* the added H_3O^+ or OH^-. To reiterate, as long as the amount of added H_3O^+ or OH^- is small compared with the amounts of the buffer components, *the conversion of one component into the other produces a small change in the buffer-component concentration ratio and, consequently, a small change in* $[H_3O^+]$ *and in pH.* Sample Problem 19.1 demonstrates how small these pH changes typically are. Note that the latter two parts of the problem combine a stoichiometry portion, like the problems in Chapter 4, and a weak-acid dissociation portion, like those in Chapter 18.

SAMPLE PROBLEM 19.1 Calculating the Effect of Added H_3O^+ or OH^- on Buffer pH

Problem Calculate the pH: **(a)** of a buffer solution consisting of 0.50 *M* CH_3COOH ($K_a = 1.8\times10^{-5}$) and 0.50 *M* CH_3COONa; **(b)** after adding 0.020 mol of solid NaOH to 1.0 L of the buffer solution in part (a); **(c)** after adding 0.020 mol of HCl to 1.0 L of the buffer solution in part (a). (Assume that the additions cause negligible volume changes.)

Plan For each part, we know, or can find, $[CH_3COOH]_{init}$ and $[CH_3COO^-]_{init}$. We know the K_a of CH_3COOH (1.8×10^{-5}) and need to find $[H_3O^+]$ at equilibrium and convert it to pH. **(a)** We use the given concentrations of buffer components (each 0.50 *M*) as the initial values. As in earlier problems, we assume that *x*, the $[CH_3COOH]$ that dissociates, which equals $[H_3O^+]$, is so small relative to $[CH_3COOH]_{init}$ that it can be neglected. We set up a reaction table, solve for *x*, and check the assumption. **(b)** and **(c)** We assume that the added OH^- or H_3O^+ reacts completely with the buffer components to yield new $[CH_3COOH]_{init}$ and $[CH_3COO^-]_{init}$, and then the acid dissociates to an unknown extent. We set up two reaction tables. The first summarizes the stoichiometry of adding strong base (0.020 mol) or acid (0.020 mol). The second summarizes the dissociation of the new $[CH_3COOH]_{init}$, and we proceed as in part (a) to find the new $[H_3O^+]$.

Solution **(a)** The original pH: $[H_3O^+]$ in the original buffer. Setting up a reaction table with $x = [CH_3COOH]_{dissoc} = [H_3O^+]$ (as in Chapter 18, we assume that $[H_3O^+]$ from H_2O is negligible and disregard it):

Concentration (*M*)	$CH_3COOH(aq)$	+ $H_2O(l)$	⇌	$CH_3COO^-(aq)$	+ $H_3O^+(aq)$
Initial	0.50	—		0.50	0
Change	$-x$	—		$+x$	$+x$
Equilibrium	$0.50 - x$	—		$0.50 + x$	x

Making the assumption and finding the equilibrium $[CH_3COOH]$ and $[CH_3COO^-]$: With K_a small, *x* is small, so we assume

$$[CH_3COOH] = 0.50\,M - x \approx 0.50\,M \quad \text{and} \quad [CH_3COO^-] = 0.50\,M + x \approx 0.50\,M$$

Solving for *x* ($[H_3O^+]$ at equilibrium):

$$x = [H_3O^+] = K_a \times \frac{[CH_3COOH]}{[CH_3COO^-]} \approx (1.8\times10^{-5}) \times \frac{0.50}{0.50} = 1.8\times10^{-5}\,M$$

Checking the assumption:

$$\frac{1.8\times10^{-5}\,M}{0.50\,M} \times 100 = 3.6\times10^{-3}\% < 5\%$$

The assumption is justified, and we will use the same assumption in parts (b) and (c). Also, according to the other criterion (see Sample Problem 18.8),

$$\frac{[HA]_{init}}{K_a} = \frac{0.50}{1.8\times10^{-5}} = 2.8\times10^4 > 400$$

Calculating pH:

$$pH = -\log[H_3O^+] = -\log(1.8\times10^{-5}) = 4.74$$

(b) The pH after adding base (0.020 mol of NaOH to 1.0 L of buffer). Finding $[OH^-]_{added}$:

$$[OH^-]_{added} = \frac{0.020\text{ mol } OH^-}{1.0\text{ L soln}} = 0.020\,M\,OH^-$$

Setting up a reaction table for the *stoichiometry* of adding OH^- to CH_3COOH (notice that the reaction between weak acid and strong base goes to completion):

Concentration (*M*)	$CH_3COOH(aq)$	+ $OH^-(aq)$	⟶ $CH_3COO^-(aq)$	+ $H_2O(l)$
Initial	0.50	0.020	0.50	—
Change	−0.020	−0.020	+0.020	—
Final	0.48	0	0.52	—

Setting up a reaction table for the *acid dissociation,* using these new initial concentrations. As in part (a), $x = [CH_3COOH]_{dissoc} = [H_3O^+]$:

Concentration (*M*)	$CH_3COOH(aq)$	+ $H_2O(l)$	⇌ $CH_3COO^-(aq)$	+ $H_3O^+(aq)$
Initial	0.48	—	0.52	0
Change	$-x$	—	$+x$	$+x$
Equilibrium	$0.48 - x$	—	$0.52 + x$	x

Making the assumption that x is small, and solving for x:

$$[CH_3COOH] = 0.48\,M - x \approx 0.48\,M \quad \text{and} \quad [CH_3COO^-] = 0.52\,M + x \approx 0.52\,M$$

$$x = [H_3O^+] = K_a \times \frac{[CH_3COOH]}{[CH_3COO^-]} \approx (1.8\times10^{-5}) \times \frac{0.48}{0.52} = 1.7\times10^{-5}\,M$$

Calculating the pH:

$$\text{pH} = -\log [H_3O^+] = -\log (1.7\times10^{-5}) = \boxed{4.77}$$

The addition of strong base increased the concentration of the basic buffer component at the expense of the acidic buffer component. Note especially that the pH *increased only slightly,* from 4.74 to 4.77.

(c) The pH after adding acid (0.020 mol of HCl to 1.0 L of buffer). Finding $[H_3O^+]_{added}$:

$$[H_3O^+]_{added} = \frac{0.020 \text{ mol } H_3O^+}{1.0 \text{ L soln}} = 0.020\,M\,H_3O^+$$

Now we proceed as in part (b), by first setting up a reaction table for the *stoichiometry* of adding H_3O^+ to CH_3COO^- (notice that the reaction between strong acid and weak base goes to completion):

Concentration (*M*)	$CH_3COO^-(aq)$	+ $H_3O^+(aq)$	⟶ $CH_3COOH(aq)$	+ $H_2O(l)$
Initial	0.50	0.020	0.50	—
Change	−0.020	−0.020	+0.020	—
Final	0.48	0	0.52	—

The reaction table for the *acid dissociation,* with $x = [CH_3COOH]_{dissoc} = [H_3O^+]$ is

Concentration (*M*)	$CH_3COOH(aq)$	+ $H_2O(l)$	⇌ $CH_3COO^-(aq)$	+ $H_3O^+(aq)$
Initial	0.52	—	0.48	0
Change	$-x$	—	$+x$	$+x$
Equilibrium	$0.52 - x$	—	$0.48 + x$	x

Making the assumption that x is small, and solving for x:

$$[CH_3COOH] = 0.52\,M - x \approx 0.52\,M \quad \text{and} \quad [CH_3COO^-] = 0.48\,M + x \approx 0.48\,M$$

$$x = [H_3O^+] = K_a \times \frac{[CH_3COOH]}{[CH_3COO^-]} \approx (1.8\times10^{-5}) \times \frac{0.52}{0.48} = 2.0\times10^{-5}\,M$$

Calculating the pH:

$$\text{pH} = -\log [H_3O^+] = -\log (2.0\times10^{-5}) = \boxed{4.70}$$

The addition of strong acid increased the concentration of the acidic buffer component at the expense of the basic buffer component and *lowered* the pH only slightly, from 4.74 to 4.70.

Check The changes in $[CH_3COOH]$ and $[CH_3COO^-]$ occur in opposite directions in parts (b) and (c), which makes sense. The additions were of equal amounts, so the pH increase in (b) should equal the pH decrease in (c), within rounding.

Comment In part (a), we justified our assumption that x can be neglected. Therefore, in parts (b) and (c), we could have used the "Final" values from the last line of the stoichiometry reaction tables directly for the ratio of buffer components; that would have allowed us to dispense with a reaction table for the acid dissociation. In subsequent problems in this chapter, we will follow this more straightforward approach.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

19.1A Calculate the pH of a buffer consisting of 0.50 M HF and 0.45 M KF **(a)** before and **(b)** after addition of 0.40 g of NaOH to 1.0 L of the buffer (K_a of HF $= 6.8\times10^{-4}$).

19.1B Calculate the pH of a buffer consisting of 0.25 M $(CH_3)_2NH_2Cl$ and 0.30 M $(CH_3)_2NH$ **(a)** before and **(b)** after addition of 0.73 g of HCl to 1.0 L of the buffer [pK_b of $(CH_3)_2NH = 3.23$].

SOME SIMILAR PROBLEMS 19.11–19.20 and 19.27–19.30

Figure 19.4 summarizes the changes in concentrations of buffer components upon addition of strong acid or strong base.

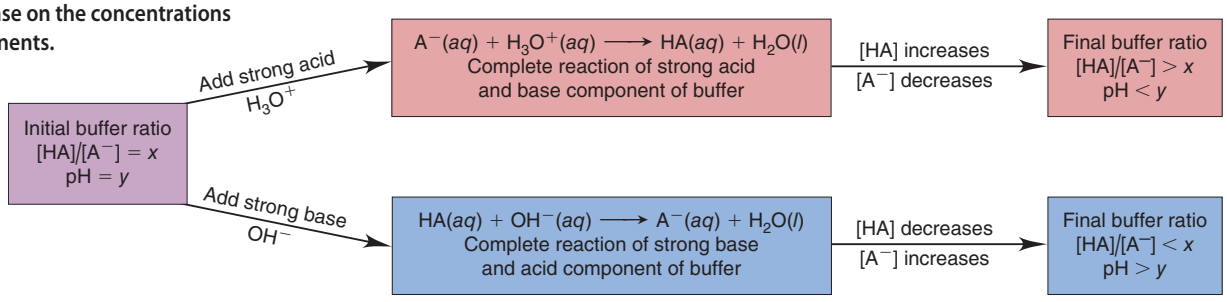

Figure 19.4 **Summary of the effect of added acid or base on the concentrations of buffer components.**

The Henderson-Hasselbalch Equation

For any weak acid, HA, the dissociation equation and K_a expression are

$$HA + H_2O \rightleftharpoons H_3O^+ + A^-$$

$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

The key variable that determines $[H_3O^+]$ is the concentration *ratio* of acid species to base species, so, as before, rearranging to isolate $[H_3O^+]$ gives

$$[H_3O^+] = K_a \times \frac{[HA]}{[A^-]}$$

Taking the negative common (base 10) logarithm of both sides gives

$$\underbrace{-\log [H_3O^+]}_{\text{pH}} = \underbrace{-\log K_a}_{\text{p}K_a} - \log\left(\frac{[HA]}{[A^-]}\right)$$

which, from definitions, is $\text{pH} = \text{p}K_a - \log \dfrac{[HA]}{[A^-]}$

Then, because of the nature of logarithms, when we invert the buffer-component concentration ratio, the sign of the logarithm changes, to give $\text{pH} = \text{p}K_a + \log\left(\dfrac{[A^-]}{[HA]}\right)$.

Generalizing the previous equation for any conjugate acid-base pair gives the **Henderson-Hasselbalch equation:**

$$\text{pH} = \text{p}K_a + \log\left(\frac{[\text{base}]}{[\text{acid}]}\right) \qquad (19.1)$$

This relationship allows us to solve directly for pH instead of having to calculate $[H_3O^+]$ first. For instance, using the Henderson-Hasselbalch equation in part (b) of Sample Problem 19.1, the pH of the buffer after the addition of NaOH is

$$\text{pH} = \text{p}K_a + \log\left(\frac{[CH_3COO^-]}{[CH_3COOH]}\right) = 4.74 + \log\left(\frac{0.52}{0.48}\right) = 4.77$$

Buffer Capacity and Buffer Range

Let's consider two key aspects of a buffer—its capacity and the closely related range.

Buffer Capacity **Buffer capacity** is a measure of the "strength" of the buffer, its ability to maintain the pH following addition of strong acid or base. Capacity depends ultimately on component concentrations, both the absolute and relative concentrations:

1. In terms of *absolute* concentrations, *the more concentrated the buffer components, the greater the capacity.* Thus, for a given amount of added H_3O^+ or OH^-, the pH of a higher capacity buffer changes less than the pH of a lower capacity buffer (Figure 19.5). Note that *buffer pH is independent of buffer capacity.* A buffer made of equal volumes of 1.0 *M* CH_3COOH and 1.0 *M* CH_3COO^- has the same pH (4.74) as a buffer made of equal volumes of 0.10 *M* CH_3COOH and 0.10 *M* CH_3COO^-, but the more concentrated buffer has a greater capacity.

2. In terms of *relative* concentrations, *the closer the component concentrations are to each other, the greater the capacity.* As a buffer functions, the concentration of one component increases relative to the other. Because the concentration ratio determines the pH, the less the ratio changes, the less the pH changes. Let's compare the percent change in component concentration ratio for a buffer at two different initial ratios:

- Add 0.010 mol of OH^- to 1.00 L of buffer with initial concentrations [HA] = $[A^-]$ = 1.000 *M*: $[A^-]$ becomes 1.010 *M* and [HA] becomes 0.990 *M*,

$$\frac{[A^-]_{init}}{[HA]_{init}} = \frac{1.000\ M}{1.000\ M} = 1.000 \qquad \frac{[A^-]_{final}}{[HA]_{final}} = \frac{1.010\ M}{0.990\ M} = 1.02$$

$$\text{Percent change} = \frac{1.02 - 1.000}{1.000} \times 100 = 2\%$$

- Add 0.010 mol of OH^- to 1.00 L of buffer with initial concentrations [HA] = 0.250 *M* and $[A^-]$ = 1.750 *M*: $[A^-]$ becomes 1.760 *M* and [HA] becomes 0.240 *M*,

$$\frac{[A^-]_{init}}{[HA]_{init}} = \frac{1.750\ M}{0.250\ M} = 7.00 \qquad \frac{[A^-]_{final}}{[HA]_{final}} = \frac{1.760\ M}{0.240\ M} = 7.33$$

$$\text{Percent change} = \frac{7.33 - 7.00}{7.00} \times 100 = 4.7\%$$

Note that the change in the concentration ratio is more than twice as large when the initial component concentrations are different than when they are the same. Thus, *a buffer has the highest capacity when the component concentrations are equal.* In the Henderson-Hasselbalch equation, when $[A^-]$ = [HA], their ratio is 1, the log term is 0, and so pH = $\text{p}K_a$:

$$\text{pH} = \text{p}K_a + \log\left(\frac{[A^-]}{[HA]}\right) = \text{p}K_a + \log 1 = \text{p}K_a + 0 = \text{p}K_a$$

Therefore, *a buffer whose pH is equal to or near the* $\text{p}K_a$ *of its acid component has the highest capacity* for a given concentration.

Buffer Range **Buffer range** is the pH range over which the buffer is effective and is also related to the *relative* buffer-component concentrations. The further the concentration ratio is from 1, the less effective the buffer (the lower the buffer capacity). In practice, if the $[A^-]/[HA]$ ratio is greater than 10 or less than 0.1—that is, if one component concentration is more than 10 times the other—buffering action is poor.

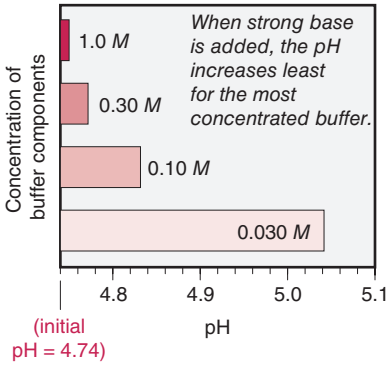

Figure 19.5 **The relation between buffer capacity and pH change.** The bars indicate the final pH values, after strong base was added, for four CH_3COOH/CH_3COO^- buffers with the same initial pH (4.74) and different component concentrations.

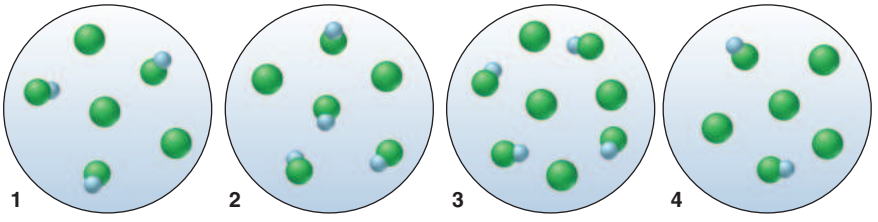
Since log 10 = +1 and log 0.1 = −1, *buffers have a usable range within ±1 pH unit of the* pK_a *of the acid component:*

$$pH = pK_a + \log\left(\frac{10}{1}\right) = pK_a + 1 \qquad \text{and} \qquad pH = pK_a + \log\left(\frac{1}{10}\right) = pK_a - 1$$

For example, a buffer consisting of CH_3COOH (pK_a = 4.74) and CH_3COO^- has a usable pH range from about 3.7 to 5.7.

SAMPLE PROBLEM 19.2 Using Molecular Scenes to Examine Buffers

Problem The molecular scenes below represent equal-volume samples of four HA/A^- buffers. (HA is *blue and green*, and A^- is *green*; other ions and water are not shown.)

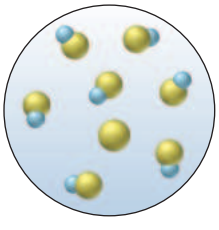


(a) Which buffer has the highest pH?
(b) Which buffer has the greatest capacity?
(c) Should you add a small amount of concentrated strong acid or strong base to convert sample 1 to sample 2 (assuming no volume change)?

Plan The molecular scenes show varying numbers of weak acid molecules (HA) and the conjugate base (A^-). Because the volumes are equal, the scenes represent molarities as well as numbers. **(a)** As the pH rises, more HA loses its H^+ and becomes A^-, so the $[A^-]/[HA]$ ratio will increase. We examine the scenes to see which has the highest ratio. **(b)** Buffer capacity depends on buffer-component concentration *and* ratio. We examine the scenes to see which has a high concentration and a ratio close to 1. **(c)** Adding strong acid converts some A^- to HA, and adding strong base does the opposite. Comparing the $[A^-]/[HA]$ ratios in samples 1 and 2 tells which to add.

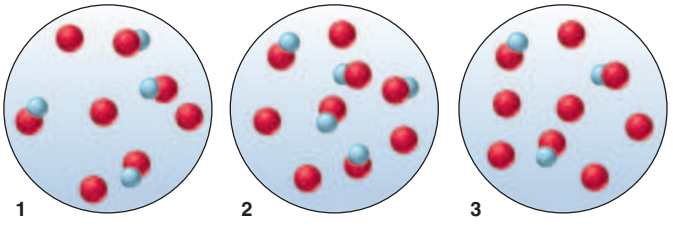
Solution **(a)** The $[A^-]/[HA]$ ratios are as follows: For sample 1, $[A^-]/[HA] = 3/3 = 1$. Similarly, sample 2 = 0.5; sample 3 = 1; sample 4 = 2. Sample 4 has the highest pH because it has the highest $[A^-]/[HA]$ ratio.
(b) Samples 1 and 3 have a $[A^-]/[HA]$ ratio of 1, but sample 3 has the greater capacity because it has a higher concentration.
(c) Sample 2 has a lower $[A^-]/[HA]$ ratio than sample 1, so you would add strong acid to sample 1 to convert some A^- to HA.

FOLLOW-UP PROBLEMS



19.2A The molecular scene *(see margin)* shows a sample of an HB/B^- buffer. (HB is *blue and yellow,* and B^- is *yellow;* other ions and water are not shown.)
(a) Would you add a small amount of concentrated strong acid or strong base to increase the buffer capacity?
(b) Assuming no volume change, draw a scene that represents the buffer with the highest possible capacity after the addition in part (a).

19.2B The molecular scenes below show three samples of a buffer consisting of HA (pK_a = 4.2) and A^-. (HA is *blue and red,* and A^- is *red;* other ions and water are not shown.)



(a) Which buffer has pH > pK_a?
(b) Which buffer can react with the largest amount of added strong base?
(c) Is this conjugate acid-base pair suitable for preparing a buffer with a pH of 6.1?

A SIMILAR PROBLEM 19.4

Preparing a Buffer

Even though chemical supply-houses offer buffers in a variety of pH values and concentrations, you may have to prepare a specific one, for example, in an environmental or biomedical application. Several steps are required to prepare a buffer:

1. *Choose the conjugate acid-base pair.* Deciding on the chemical composition is based to a large extent on the desired pH. Suppose that, for a biochemical experiment, you need a buffer whose pH is 3.90. Therefore, to maximize the capacity, the pK_a of the acid component should be close to 3.90; or $K_a = 10^{-3.90} = 1.3\times10^{-4}$. A table of K_a values (see Appendix C) shows that lactic acid (pK_a = 3.86), glycolic acid (pK_a = 3.83), and formic acid (pK_a = 3.74) are possibilities. To avoid substances that are common in biochemical systems, you choose formic acid, HCOOH, and formate ion, $HCOO^-$, supplied by a soluble salt, such as sodium formate, HCOONa, as the basic component.

2. *Calculate the ratio of buffer component concentrations.* To find the ratio $[A^-]/[HA]$ that gives the desired pH, you use Equation 19.1:

$$\text{pH} = \text{p}K_a + \log\left(\frac{[A^-]}{[HA]}\right) \qquad \text{or} \qquad 3.90 = 3.74 + \log\left(\frac{[HCOO^-]}{[HCOOH]}\right)$$

$$\log\left(\frac{[HCOO^-]}{[HCOOH]}\right) = 0.16 \qquad \text{so} \qquad \left(\frac{[HCOO^-]}{[HCOOH]}\right) = 10^{0.16} = 1.4$$

Thus, for every 1.0 mol of HCOOH in a given volume of solution, you need 1.4 mol of HCOONa.

3. *Determine the buffer concentration.* For most laboratory-scale applications, concentrations of about 0.5 *M* are suitable, but the decision is often based on availability of stock solutions. Suppose you have a large stock of 0.40 *M* HCOOH and you need approximately 1.0 L of final buffer. First, you find the amount (mol) of sodium formate that will give the needed 1.4/1.0 ratio, and then convert to mass (g):

$$\text{Amount (mol) of HCOOH} = 1.0\text{ L soln} \times \frac{0.40\text{ mol HCOOH}}{1.0\text{ L soln}} = 0.40\text{ mol HCOOH}$$

$$\text{Amount (mol) of HCOONa} = 0.40\text{ mol HCOOH} \times \frac{1.4\text{ mol HCOONa}}{1.0\text{ mol HCOOH}} = 0.56\text{ mol HCOONa}$$

$$\text{Mass (g) of HCOONa} = 0.56\text{ mol HCOONa} \times \frac{68.01\text{ g HCOONa}}{1\text{ mol HCOONa}} = 38\text{ g HCOONa}$$

4. *Mix the solution and correct the pH.* You dissolve 38 g of sodium formate in the stock 0.40 *M* HCOOH to a total volume of 1.0 L. Because of nonideal behavior (Section 13.6), the buffer may vary slightly from the desired pH, so you add strong acid or strong base dropwise, while monitoring the solution with a pH meter.

SAMPLE PROBLEM 19.3 Preparing a Buffer

Problem An environmental chemist needs a carbonate buffer of pH 10.00 to study the effects of acid rain on limestone-rich soils. How many grams of Na_2CO_3 must she add to 1.5 L of 0.20 *M* $NaHCO_3$ to make the buffer (K_a of HCO_3^- = 4.7×10^{-11})?

Plan The conjugate pair is HCO_3^- (acid) and CO_3^{2-} (base), and we know the buffer volume (1.5 L) and the concentration (0.20 *M*) of HCO_3^-, so we need the buffer-component concentration ratio that gives a pH of 10.00 and the mass of Na_2CO_3

to dissolve. We convert K_a to pK_a and use Equation 19.1 to find the ratio $[CO_3^{2-}]/[HCO_3^-]$ that gives a pH of 10.00. Multiplying the given molarity of HCO_3^- by the volume of solution gives the amount (mol) of HCO_3^- and the ratio of $[CO_3^{2-}]/[HCO_3^-]$ gives the amount (mol) of CO_3^{2-} needed, which we convert to mass (g) of Na_2CO_3.

Solution Calculating pK_a:

$$pK_a = -\log K_a = -\log (4.7\times10^{-11}) = 10.33$$

Solving for $[CO_3^{2-}]/[HCO_3^-]$:

$$pH = pK_a + \log\left(\frac{[CO_3^{2-}]}{[HCO_3^-]}\right) \qquad 10.00 = 10.33 + \log\left(\frac{[CO_3^{2-}]}{[HCO_3^-]}\right)$$

$$-0.33 = \log\left(\frac{[CO_3^{2-}]}{[HCO_3^-]}\right) \quad \text{and} \quad \left(\frac{[CO_3^{2-}]}{[HCO_3^-]}\right) = 10^{-0.33} = 0.47$$

Calculating the amount (mol) of CO_3^{2-} needed for the given volume of solution:

$$\text{Amount (mol) of } HCO_3^- = 1.5 \text{ L soln} \times \frac{0.20 \text{ mol } HCO_3^-}{1.0 \text{ L soln}} = 0.30 \text{ mol } HCO_3^-$$

$$\text{Amount (mol) of } CO_3^{2-} = 0.30 \text{ mol } HCO_3^- \times \frac{0.47 \text{ mol } CO_3^{2-}}{1.0 \text{ mol } HCO_3^-} = 0.14 \text{ mol } CO_3^{2-}$$

Calculating the mass (g) of Na_2CO_3 needed:

$$\text{Mass (g) of } Na_2CO_3 = 0.14 \text{ mol } Na_2CO_3 \times \frac{105.99 \text{ g } Na_2CO_3}{1 \text{ mol } Na_2CO_3} = 15 \text{ g } Na_2CO_3$$

The buffer is prepared by dissolving 15 g of Na_2CO_3 into about 1.3 L of 0.20 *M* $NaHCO_3$ and adding more 0.20 *M* $NaHCO_3$ to make 1.5 L. Then a pH meter is used to adjust the pH to 10.00 by dropwise addition of concentrated strong acid or base.

Check For a useful buffer range, the concentration of the acidic component, $[HCO_3^-]$ in this case, must be within a factor of 10 of the concentration of the basic component, $[CO_3^{2-}]$. And we have (1.5 L)(0.20 *M* HCO_3^-), or 0.30 mol of HCO_3^-, and 0.14 mol of CO_3^{2-}; 0.30/0.14 = 2.1. Make sure the relative amounts of components are reasonable: we want a pH below the pK_a of HCO_3^- (10.33), so we want more of the acidic than the basic species.

FOLLOW-UP PROBLEMS

19.3A How would you prepare a benzoic acid/benzoate buffer with a pH of 4.25, starting with 5.0 L of 0.050 *M* sodium benzoate (C_6H_5COONa) solution and adding the acidic component (K_a of benzoic acid (C_6H_5COOH) = 6.3×10^{-5})?

19.3B What mass of NH_4Cl must be added to 750 mL of 0.15 *M* NH_3 to prepare a buffer with a pH of 9.18 (K_b of NH_3 = 1.76×10^{-5})?

SOME SIMILAR PROBLEMS 19.23–19.26

Another way to prepare a buffer is to form one of the components by *partial neutralization* of the other. For example, you can prepare an $HCOOH/HCOO^-$ buffer by mixing aqueous solutions of HCOOH and NaOH. As OH^- reacts with HCOOH, neutralization of some of the HCOOH produces the $HCOO^-$ needed:

$$HCOOH \text{ (HA total)} + OH^- \text{(amt added)} \longrightarrow$$
$$HCOOH \text{ (HA total} - OH^- \text{ amt added)} + HCOO^- (OH^- \text{ amt added}) + H_2O$$

This method is based on the same chemical process that occurs when a weak acid is titrated with a strong base, as you'll see in Section 19.2.

Summary of Section 19.1

- The pH of a buffered solution changes much less than the pH of an unbuffered solution when H_3O^+ or OH^- is added.
- A buffer consists of a weak acid and its conjugate base (or a weak base and its conjugate acid). To be effective, the amounts of the components must be *much* greater than the amount of H_3O^+ or OH^- added.
- The buffer-component concentration ratio determines the pH; the ratio and the pH are related by the Henderson-Hasselbalch equation.

- When H_3O^+ or OH^- is added to a buffer, one component reacts to form the other; thus, $[H_3O^+]$ (and pH) changes only slightly.
- A concentrated (higher capacity) buffer undergoes smaller changes in pH than a dilute buffer. When the buffer pH equals the pK_a of the acid component, the buffer has its highest capacity.
- A buffer has an effective pH range of $pK_a \pm 1$ pH unit.
- To prepare a buffer, choose the conjugate acid-base pair, calculate the ratio of components, determine the buffer concentration, and adjust the final solution to the desired pH.

19.2 ACID-BASE TITRATION CURVES

In Chapter 4, we used titrations to quantify acid-base (and redox) reactions. In this section, we focus on the **acid-base titration curve,** a plot of pH vs. volume of titrant added. We discuss curves for strong acid–strong base, weak acid–strong base, weak base–strong acid, and polyprotic acid–strong base titrations. Running a titration is an exercise for the lab, but understanding the role of acid-base indicators and seeing how salt solutions (Section 18.7) and buffers are involved apply key principles of acid-base equilibria.

Monitoring pH with Acid-Base Indicators

An *acid-base indicator* is a weak organic acid (denoted as HIn) whose color (A) differs from the color (B) of its conjugate base (In^-) and whose color change occurs over a specific, narrow pH range. Typically, HIn and/or In^- are highly colored, so only a tiny amount of indicator is needed, far too little to affect the pH during the titration.

Figure 19.6 shows the color change(s) and pH range(s) of some acid-base indicators. To select an indicator, you must know the approximate pH of the titration end point, which means you know the ionic species present. Because the indicator is a weak acid, the $[HIn]/[In^-]$ ratio is governed by the $[H_3O^+]$ of the solution:

$$\underset{\text{color A}}{HIn(aq)} + H_2O(l) \rightleftharpoons H_3O^+(aq) + \underset{\text{color B}}{In^-(aq)} \qquad K_a \text{ of HIn} = \frac{[H_3O^+][In^-]}{[HIn]}$$

Therefore,

$$\frac{[HIn]}{[In^-]} = \frac{[H_3O^+]}{K_a}$$

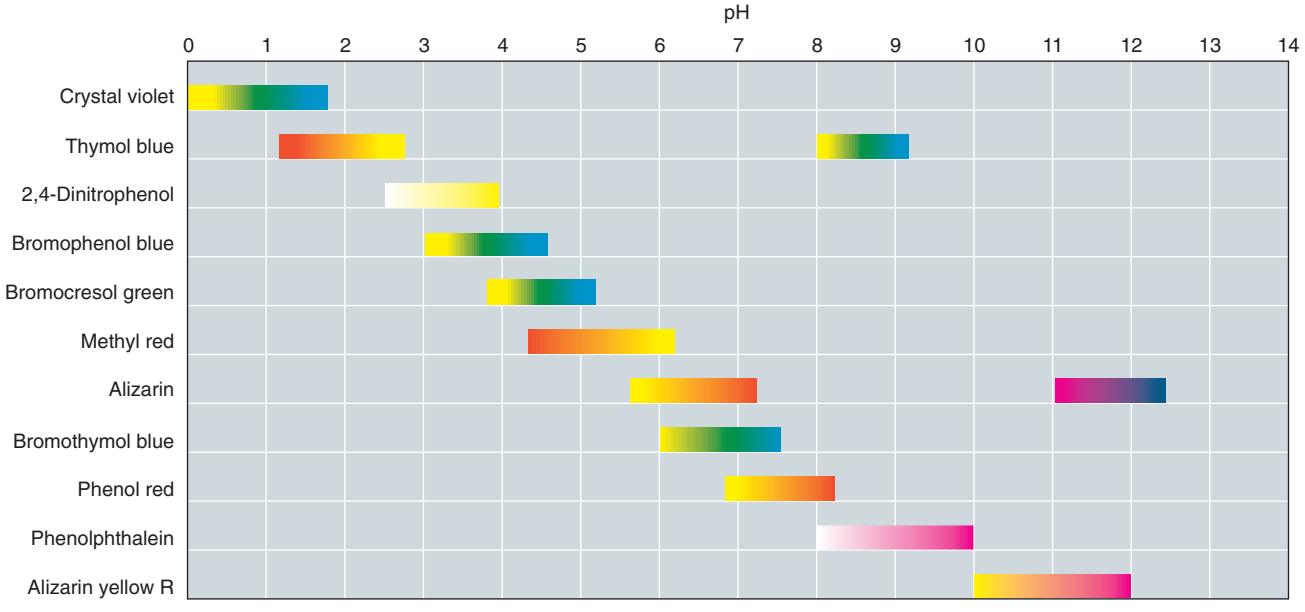


Figure 19.6 Colors and approximate pH ranges of some common acid-base indicators.

Figure 19.7 The color change of the indicator bromothymol blue.

The pH (or $[H_3O^+]$) of the solution being titrated determines the $[HIn]/[In^-]$ ratio, which determines the color of the indicator in the solution:

- We see the HIn color if the $[HIn]/[In^-]$ ratio is 10/1 or greater.
- We see the In^- color if the $[HIn]/[In^-]$ ratio is 1/10 or less.
- Between these extremes, the two colors merge into an intermediate hue.

Thus, an indicator has a *color range* equal to a 10^2-fold range in the [HIn]/[In] ratio: an *indicator changes color over a range of about 2 pH units.* For example, bromothymol blue has a pH range of about 6.0 to 7.6. As Figure 19.7 shows, it is yellow below a pH of 6.0 *(left),* blue above a pH of 7.6 *(right),* and greenish in between *(center).*

Strong Acid–Strong Base Titration Curves

Figure 19.8 shows a typical curve for the titration of a strong acid with a strong base, the data used to construct it, and molecular views of the key species in solution at various points during the titration.

Volume of NaOH added (mL)	pH
00.00	1.00
10.00	1.22
20.00	1.48
30.00	1.85
35.00	2.18
39.00	2.89
39.50	3.20
39.75	3.50
39.90	3.90
39.95	4.20
39.99	4.90
40.00	7.00
40.01	9.10
40.05	9.80
40.10	10.10
40.25	10.50
40.50	10.79
41.00	11.09
45.00	11.76
50.00	12.05
60.00	12.30
70.00	12.43
80.00	12.52

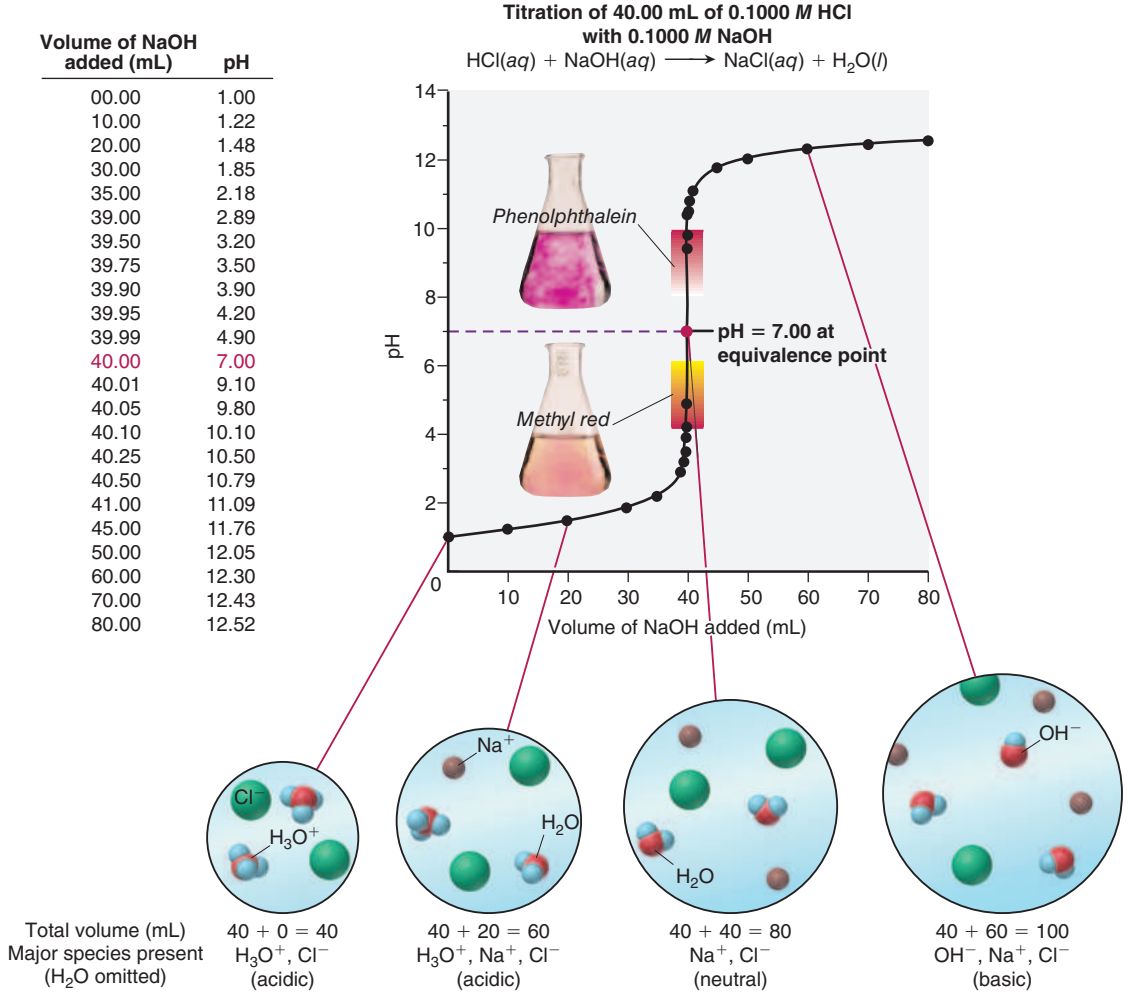

Figure 19.8 **Curve for a strong acid–strong base titration.** Data *(at left)* for the titration of 40.00 mL of 0.1000 *M* HCl with 0.1000 *M* NaOH. In the titration, pH increases gradually, then rapidly near and at the equivalence point, and then gradually again. In a strong acid–strong base titration, pH = 7.00 at the equivalence point. Each molecular-scale view shows the relative numbers of species, other than solvent, in a portion of the solution at one point during the titration. The circles increase in size in proportion to the solution's total volume.

Features of the Curve There are three distinct regions of the titration curve, which correspond to three major changes in slope:

1. *The pH starts out low,* reflecting the high $[H_3O^+]$ of the strong acid, and increases slowly as acid is gradually neutralized by the added base.
2. *The pH rises 6 to 8 units very rapidly.* This steep increase begins when the amount (mol) of OH^- added nearly equals the amount (mol) of H_3O^+ originally present in the acid. One or two more drops of base neutralize the remaining tiny excess of acid and introduce a tiny excess of base.
3. *The pH increases slowly* beyond the steep rise as more base is added.

Let's distinguish between the *equivalence point* and the *end point,* both of which occur on the steep portion of the curve:

- The **equivalence point** occurs when the *number of moles of added OH^- equals the number of moles of H_3O^+* originally present. *The solution consists of the anion of the strong acid and the cation of the strong base.* Recall from Chapter 18 that *these ions do not react with water, so the solution is neutral: pH = 7.00.*
- The **end point** occurs when the indicator, which we added before the titration, changes color. *We choose an indicator with a color change close to the pH of the equivalence point*. Figure 19.6 includes two indicators suitable for a strong acid–strong base titration. Methyl red changes from red at pH 4.2 to yellow at pH 6.3, and phenolphthalein changes from colorless at pH 8.3 to pink at pH 10.0. Neither change occurs *at* the equivalence point (pH 7.00), but both occur on the vertical portion of the curve. Therefore, when methyl red turns yellow or phenolphthalein pink, we are within a drop or two of the equivalence point. In practice, then, the *visible* end point signals the *invisible* equivalence point.

Calculating the pH During This Titration By knowing the chemical species present during the titration, we can calculate the pH at various points along the way:

1. *Initial solution of strong HA*. In Figure 19.8, 40.00 mL of 0.1000 *M* HCl is titrated with 0.1000 *M* NaOH. Because a strong acid is completely dissociated, [HCl] = $[H_3O^+]$ = 0.1000 *M*. Therefore, the initial pH is*

$$\text{pH} = -\log\left[H_3O^+\right] = -\log\left(0.1000\right) = 1.00$$

2. *Before the equivalence point.* As we start adding base, some acid is neutralized and the volume of solution increases. To find the pH at various points up to the equivalence point, we find the *initial* amount (mol) of H_3O^+ and subtract the amount *reacted, which equals the amount (mol) of OH^- added,* to find the amount (mol) of H_3O^+ remaining. Then, we use the *total* volume to calculate $[H_3O^+]$ and convert to pH. For example, after adding 20.00 mL of 0.1000 *M* NaOH:

- *Find the amount (mol) of H_3O^+ remaining.*

$$\begin{aligned}
&\text{Initial amount (mol) of } H_3O^+ = 0.04000\ \text{L} \times 0.1000\ M = 0.004000\ \text{mol } H_3O^+ \\
&-\text{Amount (mol) of } OH^- \text{ added} = 0.02000\ \text{L} \times 0.1000\ M = 0.002000\ \text{mol } OH^- \\
&\text{Amount (mol) of } H_3O^+ \text{ remaining} = \qquad 0.002000\ \text{mol } H_3O^+
\end{aligned}$$

- *Calculate $[H_3O^+]$.* We divide by the *total volume* because one solution dilutes the ions in the other:

$$\left[H_3O^+\right] = \frac{\text{amount (mol) of } H_3O^+ \text{ remaining}}{\text{original volume of acid} + \text{volume of added base}}$$

$$= \frac{0.002000\ \text{mol } H_3O^+}{0.04000\ \text{L} + 0.02000\ \text{L}} = 0.03333\ M \qquad \text{pH} = -\log\left(0.03333\right) = 1.48$$

*In acid-base titrations, volumes and concentrations are usually known to four significant figures, but pH is reported to no more than two digits to the right of the decimal point.

Given the amount of OH^- added, we are halfway to the equivalence point; but we are still on the initial slow rise of the curve, so the pH is still very low. Similar calculations give values up to the equivalence point.

3. *At the equivalence point.* After 40.00 mL of 0.1000 *M* NaOH (0.004000 mol of OH^-) has been added to the initial 0.004000 mol of H_3O^+, the equivalence point is reached. The solution contains Na^+ and Cl^-, neither of which reacts with water. Because of the autoionization of water, however,

$$[H_3O^+] = 1.0\times10^{-7}\,M \qquad \text{pH} = 7.00$$

4. *After the equivalence point.* From the equivalence point on, the pH calculation is based on the amount (mol) of *excess* OH^- present. For example, after adding 50.00 mL of NaOH to the original amount of HCl, we have

$$\begin{aligned}&\text{Total amount (mol) of } OH^- \text{ added} = 0.05000\text{ L} \times 0.1000\,M = 0.005000\text{ mol } OH^-\\ &-\text{Amount (mol) of } H_3O^+ \text{ consumed} = 0.04000\text{ L} \times 0.1000\,M = 0.004000\text{ mol } H_3O^+\\ &\text{Amount (mol) of excess } OH^- = \qquad\qquad 0.001000\text{ mol } OH^-\end{aligned}$$

$$[OH^-] = \frac{0.001000\text{ mol } OH^-}{0.04000\text{ L} + 0.05000\text{ L}} = 0.01111\,M \qquad \text{pOH} = -\log(0.01111) = 1.95$$

$$\text{pH} = \text{p}K_w - \text{pOH} = 14.00 - 1.95 = 12.05$$

Weak Acid–Strong Base Titration Curves

Figure 19.9 shows a curve for the titration of a weak acid with strong base: 40.00 mL of 0.1000 *M* propanoic acid ($K_a = 1.3\times10^{-5}$) titrated with 0.1000 *M* NaOH. (We abbreviate the acid, CH_3CH_2COOH, as HPr and the conjugate base, $CH_3CH_2COO^-$, as Pr^-.)

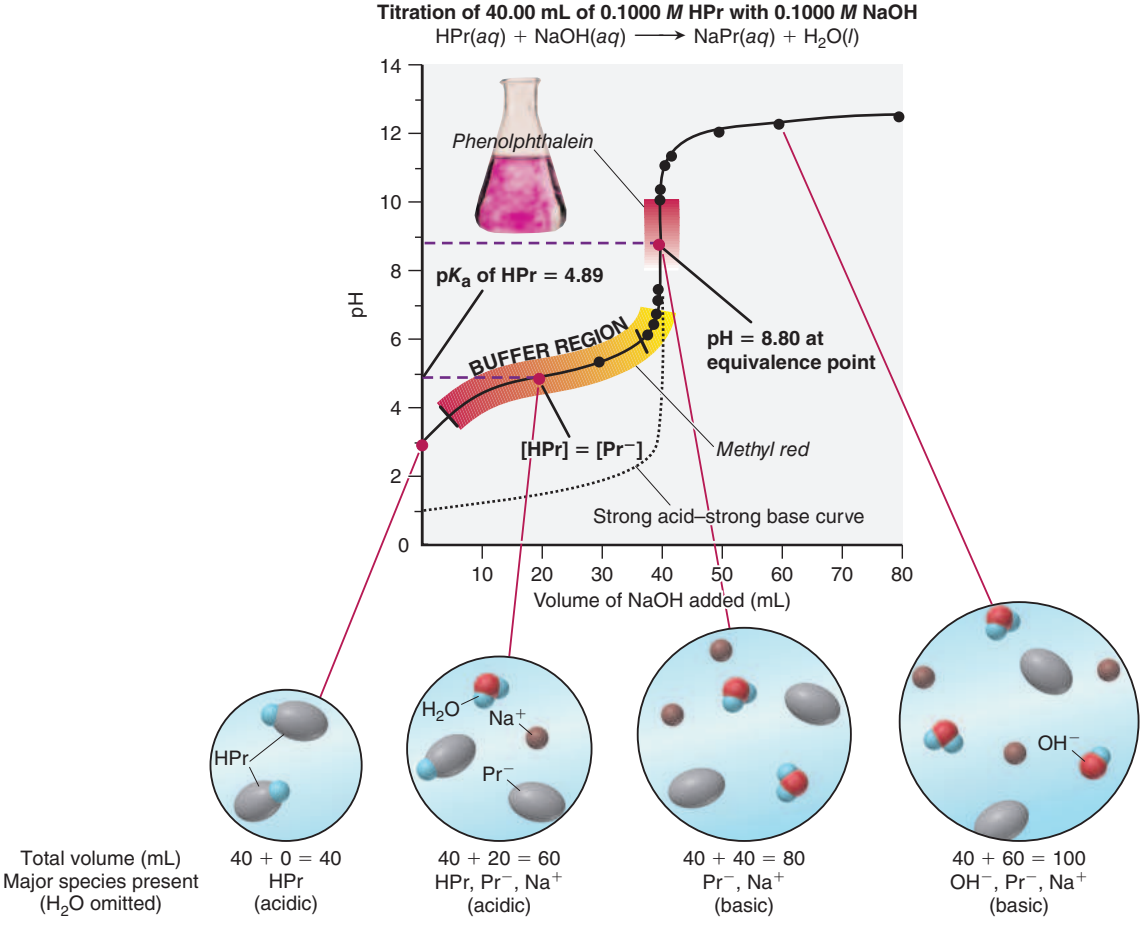

Figure 19.9 Curve for a weak acid–strong base titration.

Features of the Curve The dotted portion of the curve in Figure 19.9 corresponds to the bottom half of the strong acid–strong base curve (Figure 19.8). There are four key points to note for the weak acid curve (the first three differ from the strong acid curve):

1. *The initial pH is higher.* Because the weak acid (HPr) dissociates slightly, much less H_3O^+ is present than with the strong acid.
2. *The curve rises gradually in the so-called buffer region before the steep rise to the equivalence point.* As HPr reacts with strong base, more Pr^- forms, which creates an HPr/Pr^- buffer. At the midpoint of the buffer region, half the initial HPr has reacted (that is, half of the OH^- needed to reach the equivalence point has been added), so [HPr] = [Pr^-], or [Pr^-]/[HPr] = 1. Therefore, *the pH equals the* pK_a:

$$\text{Middle of buffer region: } \text{pH} = pK_a + \log\left(\frac{[Pr^-]}{[HPr]}\right) = pK_a + \log 1 = pK_a + 0 = pK_a$$

   The pH observed at this point, halfway through the titration, is used to estimate the pK_a of an unknown acid.
3. *The pH at the equivalence point is above 7.00.* The solution contains the strong-base cation Na^+, which does not react with water, and the weak-acid anion Pr^-, which acts as a weak base to accept a proton from H_2O and yield OH^-.
4. *The pH increases slowly* beyond the equivalence point as excess OH^- is added.

The choice of indicator here is more limited than for a strong acid–strong base titration because the steep rise occurs over a smaller pH range. Phenolphthalein will work because it changes color within this range. But methyl red will not because its color change requires about 30 mL of titrant, rather than just a drop or two.

Calculating the pH During This Titration During the weak acid–strong base titration we must take into account the partial dissociation of the weak acid, the presence of the buffer, and the reaction of the conjugate base with water. Thus, each of four regions of the curve requires its own calculation to find [H_3O^+]:

1. *Initial HA solution*. Before base is added, a weak acid dissociates:

$$HPr(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + Pr^-(aq)$$

We find [H_3O^+] as in Section 18.4 by setting up a reaction table with $x = [HPr]_{dissoc}$, assuming [H_3O^+] (and [Pr^-]) = $[HPr]_{dissoc} << [HPr]_{init}$, and solving for x:

$$K_a = \frac{[H_3O^+][Pr^-]}{[HPr]} \approx \frac{x^2}{[HPr]_{init}} \qquad \text{therefore,} \qquad x = [H_3O^+] \approx \sqrt{K_a \times [HPr]_{init}}$$

2. *Solution of HA and added base.* As we add NaOH, HPr forms Pr^-. Thus, for much of the titration up to the equivalence point, we have an HPr/Pr^- buffer. Therefore, we find [H_3O^+] from

$$[H_3O^+] = K_a \times \frac{[HPr]}{[Pr^-]}$$

(Or, we can find pH directly with the Henderson-Hasselbalch equation.) Because *volumes cancel in the concentration ratio,* that is, [HPr]/[Pr^-] = amount (mol) of HPr/amount (mol) of Pr^-, we don't need volumes or have to calculate concentrations.

3. *Equivalent amounts of HA and added base.* At the equivalence point, all of the HPr has reacted, so the solution contains Pr^-, which reacts with water to form OH^-:

$$Pr^-(aq) + H_2O(l) \rightleftharpoons HPr(aq) + OH^-(aq)$$

This explains why, in a weak acid–strong base titration, pH > 7.00 at the equivalence point. To calculate [H_3O^+] (see Section 18.6), we first find K_b of Pr^- from K_a of HPr, set up a reaction table (assume [Pr^-] >> $[Pr^-]_{reacting}$), and solve for [OH^-]. Since we use a single concentration, [Pr^-], to solve for [OH^-], we *do* need the total volume. Then, we convert [OH^-] to [H_3O^+]. These two steps are

$$(1)\ K_b = \frac{[OH^-][HPr]}{[Pr^-]} \approx \frac{x^2}{[Pr^-]}, \text{ or } x = [OH^-] \approx \sqrt{K_b \times [Pr^-]},$$

$$\text{where} \quad K_b = \frac{K_w}{K_a} \quad \text{and} \quad [Pr^-] = \frac{\text{amount (mol) of } HPr_{init}}{\text{total volume}}$$

$$(2)\ [H_3O^+] = \frac{K_w}{[OH^-]}$$

Combining them into one step gives

$$[H_3O^+] \approx \frac{K_w}{\sqrt{K_b \times [Pr^-]}}$$

4. *Solution of excess base.* Beyond the equivalence point, as in the strong acid–strong base titration, we are adding excess OH^-:

$$[H_3O^+] = \frac{K_w}{[OH^-]} \qquad \text{where} \qquad [OH^-] = \frac{\text{amount (mol) of excess } OH^-}{\text{total volume}}$$

Sample Problem 19.4 shows the overall approach.

SAMPLE PROBLEM 19.4 Finding the pH During a Weak Acid–Strong Base Titration

Problem Calculate the pH during the titration of 40.00 mL of 0.1000 *M* propanoic acid (HPr; $K_a = 1.3\times10^{-5}$) after each of the following additions of 0.1000 *M* NaOH:
(a) 0.00 mL **(b)** 30.00 mL **(c)** 40.00 mL **(d)** 50.00 mL

Plan **(a)** 0.00 mL: No base has been added yet, so this is a weak-acid dissociation. We calculate the pH as we did in Section 18.4. **(b)** 30.00 mL: We find the amount (mol) of Pr^- and of HPr, and substitute into the K_a expression to solve for $[H_3O^+]$, and convert to pH. **(c)** 40.00 mL: The amount (mol) of NaOH added equals the initial amount (mol) of HPr, so a solution of Na^+ and Pr^- exists. We calculate the pH as we did in Section 18.6, except that we need *total* volume to find $[Pr^-]$. **(d)** 50.00 mL: We calculate the amount (mol) of excess OH^- in the total volume, convert to $[H_3O^+]$ and then to pH.

Solution **(a)** 0.00 mL of 0.1000 *M* NaOH added. Following the approach used in Sample Problem 18.8 and just described in the text, we obtain

$$[H_3O^+] \approx \sqrt{K_a \times [HPr]_{init}} = \sqrt{(1.3\times10^{-5})(0.1000)} = 1.1\times10^{-3}\ M$$

$$pH = 2.96$$

(b) 30.00 mL of 0.1000 *M* NaOH added. Calculating the ratio of moles of HPr to Pr^-:

$$\text{Initial amount (mol) of HPr} = 0.04000\ \text{L} \times 0.1000\ M = 0.004000\ \text{mol HPr}$$
$$\text{Amount (mol) of NaOH added} = 0.03000\ \text{L} \times 0.1000\ M = 0.003000\ \text{mol } OH^-$$

For every mole of NaOH, 1 mol of Pr^- forms, so we have this stoichiometry reaction table:

Amount (mol)	HPr(*aq*)	+	OH^-(*aq*)	⟶	Pr^-(*aq*)	+	H_2O(*l*)
Initial	0.004000		0.003000		0		—
Change	−0.003000		−0.003000		+0.003000		—
Final	0.001000		0		0.003000		—

The last line of the table gives the new initial amounts of HPr and Pr^- that react to attain a new equilibrium. With *x* very small, we assume that the [HPr]/[Pr^-] ratio at equilibrium is essentially equal to the ratio of these new initial amounts (see Comment in Sample Problem 19.1). Thus,

$$\frac{[HPr]}{[Pr^-]} = \frac{0.001000\ \text{mol}}{0.003000\ \text{mol}} = 0.3333$$

Solving for $[H_3O^+]$:

$$[H_3O^+] = K_a \times \frac{[HPr]}{[Pr^-]} = (1.3\times10^{-5})(0.3333) = 4.3\times10^{-6}\ M$$

$$pH = 5.37$$

(c) 40.00 mL of 0.1000 *M* NaOH added. Calculating $[Pr^-]$ after all HPr has reacted:

$$[Pr^-] = \frac{0.004000\ \text{mol}}{0.04000\ \text{L} + 0.04000\ \text{L}} = 0.05000\ M$$

Calculating K_b using the given K_a (see Sample Problem 18.12 for similar steps):

$$K_b = \frac{K_w}{K_a} = \frac{1.0\times10^{-14}}{1.3\times10^{-5}} = 7.7\times10^{-10}$$

Solving for $[H_3O^+]$ as described earlier in the text for region 3 of the curve:

$$[H_3O^+] \approx \frac{K_w}{\sqrt{K_b \times [Pr^-]}} = \frac{1.0\times10^{-14}}{\sqrt{(7.7\times10^{-10})(0.05000)}} = 1.6\times10^{-9}\,M$$

$$pH = 8.80$$

(d) 50.00 mL of 0.1000 *M* NaOH added.

$$\text{Amount (mol) of excess } OH^- = (0.1000\,M)(0.05000\text{ L} - 0.04000\text{ L}) = 0.001000\text{ mol}$$

$$[OH^-] = \frac{\text{amount (mol) of excess } OH^-}{\text{total volume}} = \frac{0.001000\text{ mol}}{0.09000\text{ L}} = 0.01111\,M$$

$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0\times10^{-14}}{0.01111} = 9.0\times10^{-13}\,M$$

$$pH = 12.05$$

Check As expected, the pH increases through the four regions of the titration. Be sure to round off and check the arithmetic along the way.

FOLLOW-UP PROBLEMS

19.4A A chemist titrates 20.00 mL of 0.2000 *M* HBrO ($K_a = 2.3\times10^{-9}$) with 0.1000 *M* NaOH. What is the pH:
(a) before any base is added?
(b) when [HBrO] = $[BrO^-]$?
(c) at the equivalence point?
(d) when the amount (mol) of OH^- added is twice the amount of HBrO present initially?
(e) Sketch the titration curve; label the pK_a and the equivalence point.

19.4B For the titration of 30.00 mL of 0.1000 *M* benzoic acid (C_6H_5COOH; $K_a = 6.3\times10^{-5}$) with 0.1500 *M* NaOH, calculate:
(a) the initial pH, before the titration begins;
(b) the pH after the addition of 12.00 mL of base;
(c) the pH at the equivalence point; and
(d) the pH after addition of 22.00 mL of base.

SOME SIMILAR PROBLEMS 19.56, 19.58(a), and 19.59(a)

Weak Base–Strong Acid Titration Curves

The opposite of a weak acid–strong base titration is the titration of a weak base (NH_3) with a strong acid (HCl). This titration curve, shown in Figure 19.10 *(next page),* has the *same shape as the weak acid–strong base curve, but it is inverted.*

Thus, we have the same features as the weak acid–strong base curve, but *the pH decreases* throughout the process:

1. *The initial weak-base solution has a pH well above 7.00* since NH_3 in water produces OH^-:

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

$[H_3O^+]$ can be calculated from the following relationship (see Sample Problem 18.11):

$$[H_3O^+] \approx \frac{K_w}{\sqrt{K_b \times [NH_3]}}$$

2. *The pH decreases gradually in the buffer region,* where significant amounts of NH_3 and its conjugate acid, NH_4^+, are present. At the midpoint of this region, *the pH equals the* pK_a of NH_4^+:

$$\text{Middle of buffer region: } pH = pK_a + \log\left(\frac{[NH_3]}{[NH_4^+]}\right) = pK_a + \log 1 = pK_a + 0 = pK_a$$

3. *The curve drops steeply at the equivalence point.* All the NH_3 has reacted with added HCl, and the solution contains only NH_4^+ and Cl^-. Note that *the pH at the equivalence point is below 7.00* because Cl^- does not react with water and NH_4^+ is acidic:

$$NH_4^+(aq) + H_2O(l) \rightleftharpoons NH_3(aq) + H_3O^+(aq)$$

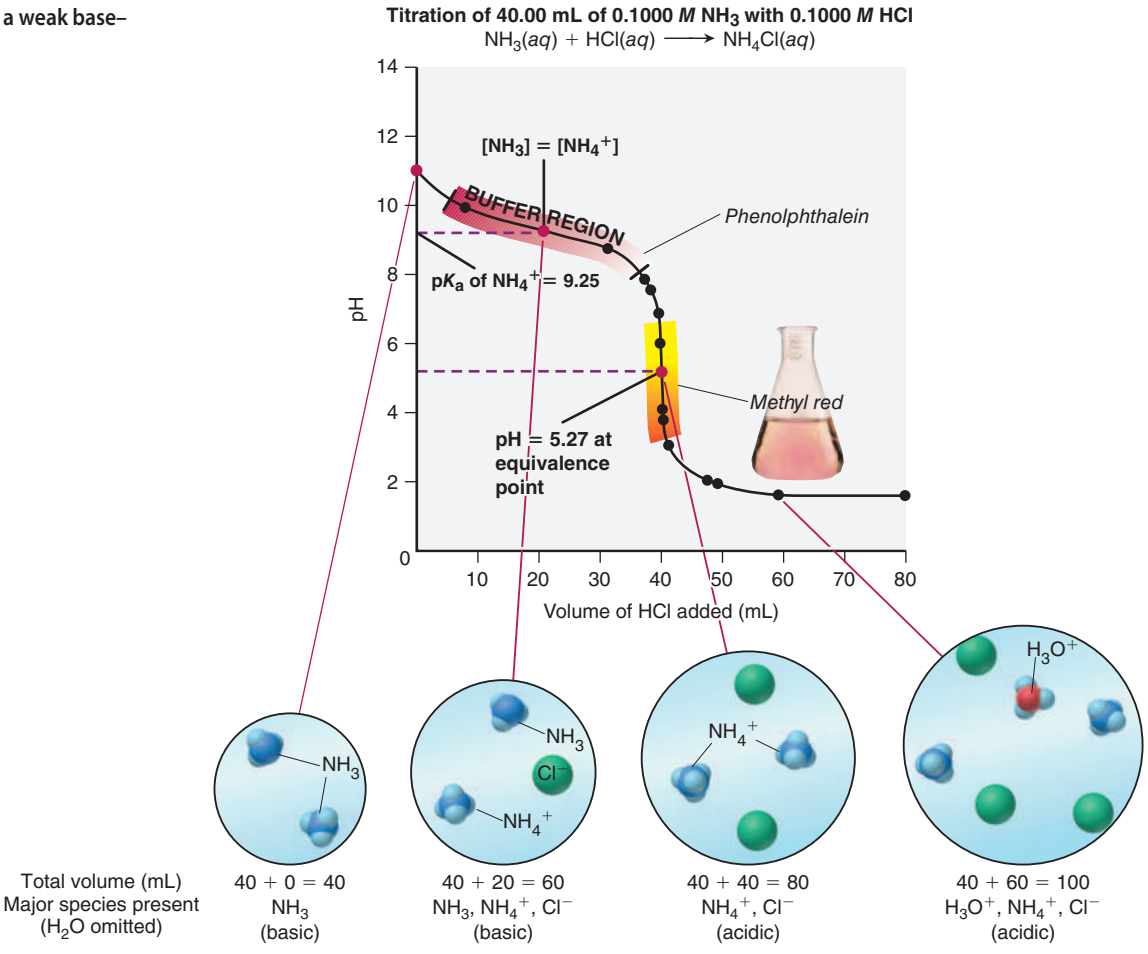

Figure 19.10 Curve for a weak base–strong acid titration.

The pH at the equivalence point is calculated with this relationship:

$$[H_3O^+] \approx \sqrt{K_a \times [NH_4^+]}$$

4. *The pH decreases slowly* beyond the equivalence point as excess H_3O^+ is added.

$$[H_3O^+] = \frac{\text{amount (mol) of excess } H_3O^+}{\text{total volume}}$$

For this titration, phenolphthalein changes color too slowly, but methyl red's change occurs on the steep portion of the curve and straddles the equivalence point, so it is the perfect choice.

Titration Curves for Polyprotic Acids

Except for sulfuric acid, the common polyprotic acids are all weak. The successive K_a values for a polyprotic acid differ by several orders of magnitude, as these values for sulfurous acid show:

$$H_2SO_3(aq) + H_2O(l) \rightleftharpoons HSO_3^-(aq) + H_3O^+(aq)$$
$$K_{a1} = 1.4\times10^{-2} \quad \text{and} \quad pK_{a1} = 1.85$$
$$HSO_3^-(aq) + H_2O(l) \rightleftharpoons SO_3^{2-}(aq) + H_3O^+(aq)$$
$$K_{a2} = 6.5\times10^{-8} \quad \text{and} \quad pK_{a2} = 7.19$$

In a titration of a diprotic acid such as H_2SO_3, two OH^- ions are required to react with the two H^+ ions of each acid molecule. Figure 19.11 shows the titration curve for sulfurous acid with strong base. Because of the large difference in K_a values, each mole of H^+ is titrated separately, so H_2SO_3 molecules lose one H^+ before any HSO_3^- ions do:

$$H_2SO_3 \xrightarrow{1\text{ mol } OH^-} HSO_3^- \xrightarrow{1\text{ mol } OH^-} SO_3^{2-}$$

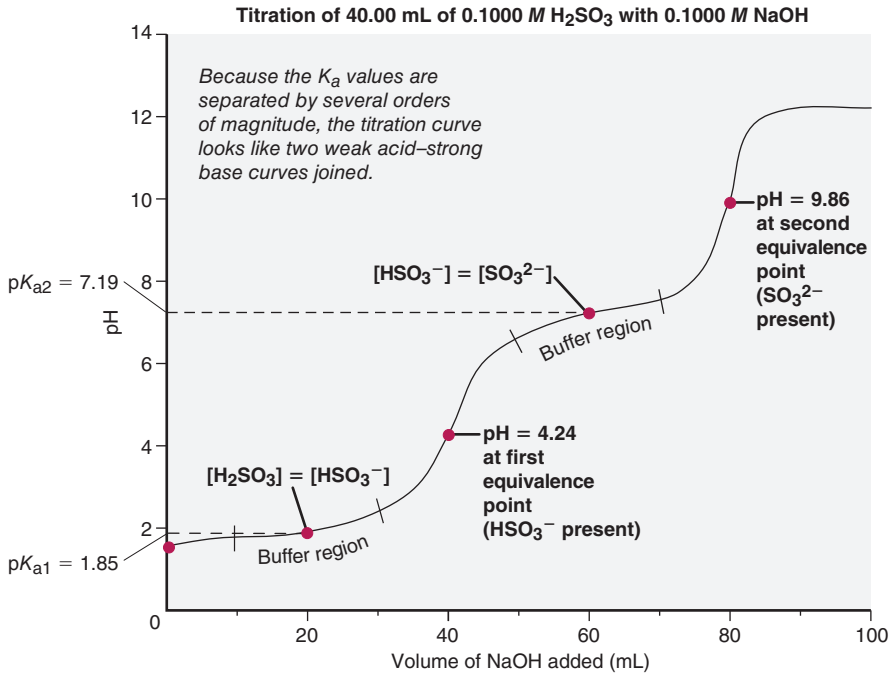

Figure 19.11 Curve for the titration of a weak polyprotic acid.

Several features of the curve are

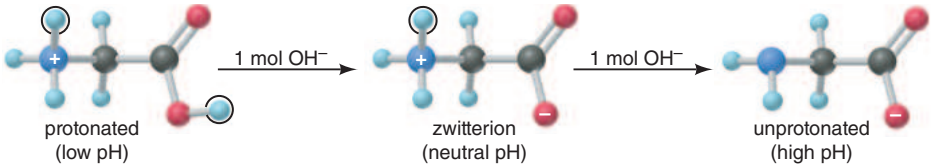
- The same amount of base (0.004000 mol OH^-) is required per mole of H^+.
- There are two equivalence points and two buffer regions. The pH at the midpoint of each buffer region is equal to the pK_a of the acidic species present then.
- The pH of the first equivalence point is below 7.00, because HSO_3^- is a stronger acid than it is a base (K_a of HSO_3^- = 6.5×10^{-8}; K_b of HSO_3^- = 7.1×10^{-13}).
- The pH of the second equivalence point is above 7.00, because SO_3^{2-} acts as a weak base and accepts a proton from H_2O to yield OH^-.

Amino Acids as Biological Polyprotic Acids

Amino acids have the general formula NH_2—CH(R)—COOH, where R can be one of about 20 different groups (Sections 13.2 and 15.6). In essence, amino acids contain a weak base (—NH_2) and a weak acid (—COOH) on the same molecule. Both the amino and carboxylic acid groups are protonated at low pH: $^+NH_3$—CH(R)—COOH. Thus, in this form, the amino acid behaves like a polyprotic acid. For glycine, the simplest amino acid (R = H), the dissociation reactions and pK_a values are

$$^+NH_3CH_2COOH(aq) + H_2O(l) \rightleftharpoons {}^+NH_3CH_2COO^-(aq) + H_3O^+(aq) \quad pK_{a1} = 2.35$$
$$^+NH_3CH_2COO^-(aq) + H_2O(l) \rightleftharpoons NH_2CH_2COO^-(aq) + H_3O^+(aq) \quad pK_{a2} = 9.78$$

These values show that the —COOH group is *much* more acidic than the —NH_3^+ group. As we saw with H_2SO_3, the acidic protons *(black circles)* are titrated separately, so all the —COOH protons are removed before any —NH_3^+ protons are:



Thus, at physiological pH (~7), which is between the two pK_a values, *an amino acid exists as a zwitterion* (German *zwitter,* "double"), a species with opposite charges on the same molecule; the zwitterion of glycine is $^+NH_3CH_2COO^-$.

Of the 20 different R groups of amino acids, several have *additional* —COO^- or —NH_3^+ groups at pH 7 (see Figure 15.30, p. 656). When amino acids link to

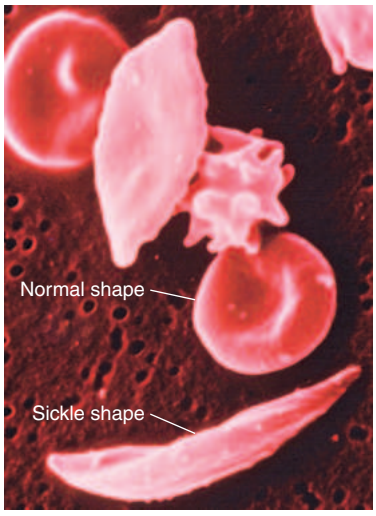


Figure 19.12 Abnormal shape of red blood cells in sickle cell anemia.

form a protein, their charged R groups give the protein its overall charge, which is often related to its function. A widely studied example of this relationship occurs in the hereditary disease sickle cell anemia. Normal red blood cells contain hemoglobin molecules that have two glutamic acid R groups ($—CH_2CH_2COO^-$), each providing a negative charge at a critical region. Abnormal hemoglobin molecules in sickle cell anemia have two valine R groups ($—CH_3$), which are uncharged, at the same region. This change in just 2 of hemoglobin's 574 amino acids lowers charge repulsions between the hemoglobin molecules. As a result, they clump together in fiber-like structures, which leads to the sickle shape of the red blood cells (Figure 19.12). The misshapen cells block capillaries, and the painful course of sickle cell anemia usually ends in early death.

Summary of Section 19.2

- An acid-base (pH) indicator is a weak acid that has a differently colored conjugate base form and changes color over about 2 pH units.
- In a strong acid–strong base titration, the pH starts out low, rises slowly, then shoots up near the equivalence point (pH = 7).
- In a weak acid–strong base titration, the pH starts out higher, rises slowly in the buffer region (pH = pK_a at the midpoint), and then rises quickly near the equivalence point (pH > 7).
- A weak base–strong acid titration curve has a shape that is the inverse of the weak acid–strong base case, with the pH decreasing to the equivalence point (pH < 7).
- Polyprotic acids have two or more acidic protons, each with its own K_a value. Because the K_a's differ by several orders of magnitude, each proton is titrated separately.
- Amino acids exist in charged forms that depend on the pH of the solution and determine the overall charge of a protein, which can affect the protein's function.

19.3 EQUILIBRIA OF SLIGHTLY SOLUBLE IONIC COMPOUNDS

In this section, we explore an equilibrium system that involves the solubility of ionic compounds. Recall from Chapter 13 that most solutes, even those called "soluble," have a limited solubility in a particular solvent. In a saturated solution at a particular temperature, equilibrium exists between dissolved and undissolved solute. Slightly soluble ionic compounds, which we've been calling "insoluble," reach equilibrium with very little solute dissolved. In this introductory discussion, we will *assume* that, like a soluble ionic compound, the small amount of a slightly soluble ionic compound that does dissolve dissociates completely into ions.

The Ion-Product Expression (Q_{sp}) and the Solubility-Product Constant (K_{sp})

For a slightly soluble ionic compound, *equilibrium exists between solid solute and aqueous ions.* Thus, for example, for a saturated solution of lead(II) fluoride, we have

$$PbF_2(s) \rightleftharpoons Pb^{2+}(aq) + 2F^-(aq)$$

As for any equilibrium system, we can write a reaction quotient:

$$Q_c = \frac{[Pb^{2+}][F^-]^2}{[PbF_2]}$$

And, as in earlier cases, the concentration term for the pure solid, $[PbF_2]$ in this case, equals 1, and so we obtain a relationship called the *ion-product expression,* Q_{sp}:

$$Q_c(1) = Q_{sp} = [Pb^{2+}][F^-]^2$$

When the solution is saturated, the numerical value of Q_{sp} attains a constant value called the **solubility-product constant, K_{sp}.** The K_{sp} for PbF_2 at 25°C, for example, is 3.6×10^{-8}. Like other equilibrium constants, K_{sp} depends *only* on the temperature, not on the individual ion concentrations.

Writing the Ion-Product Expression The form of Q_{sp} is identical to that of other reaction quotients: each concentration is raised to an exponent equal to the coefficient in the balanced equation, which in this case also *equals the subscript of each ion in the compound's formula.* At saturation, the concentration terms have their equilibrium values. Thus, in general, for a slightly soluble ionic compound, M_pX_q, composed of the ions M^{n+} and X^{z-}, the ion-product expression at equilibrium is

$$Q_{sp} = [M^{n+}]^p[X^{z-}]^q = K_{sp} \qquad (19.2)$$

We'll write Q_{sp} directly with the symbol K_{sp}.

The Special Case of Metal Sulfides The aqueous equilibria of metal sulfides have a special form of the ion-product expression. The sulfide ion, S^{2-}, is so basic that it reacts completely with water to form the hydrogen sulfide ion (HS^-) and OH^-:

$$S^{2-}(aq) + H_2O(l) \longrightarrow HS^-(aq) + OH^-(aq)$$

Although S^{2-} is not stable in water, we can think of the dissolution process as the sum of two steps, with S^{2-} formed in the first and consumed immediately in the second. Thus, for instance, for manganese(II) sulfide, we have

$$\begin{aligned} MnS(s) &\rightleftharpoons Mn^{2+}(aq) + \cancel{S^{2-}(aq)} \\ \cancel{S^{2-}(aq)} + H_2O(l) &\longrightarrow HS^-(aq) + OH^-(aq) \\ \hline MnS(s) + H_2O(l) &\rightleftharpoons Mn^{2+}(aq) + HS^-(aq) + OH^-(aq) \end{aligned}$$

Substituting 1 for the concentration term for the pure solid ([MnS]) and for the term for water ($[H_2O]$) gives the ion-product expression at equilibrium:

$$K_{sp} = [Mn^{2+}][HS^-][OH^-]$$

SAMPLE PROBLEM 19.5 Writing Ion-Product Expressions

Problem Write the ion-product expression at equilibrium for each compound: **(a)** magnesium carbonate; **(b)** iron(II) hydroxide; **(c)** calcium phosphate; **(d)** silver sulfide.

Plan We write an equation for a saturated solution and then write the ion-product expression at equilibrium, K_{sp} (Equation 19.2), noting the sulfide in part (d).

Solution **(a)** Magnesium carbonate:

$$MgCO_3(s) \rightleftharpoons Mg^{2+}(aq) + CO_3^{2-}(aq) \qquad K_{sp} = [Mg^{2+}][CO_3^{2-}]$$

(b) Iron(II) hydroxide:

$$Fe(OH)_2(s) \rightleftharpoons Fe^{2+}(aq) + 2OH^-(aq) \qquad K_{sp} = [Fe^{2+}][OH^-]^2$$

(c) Calcium phosphate:

$$Ca_3(PO_4)_2(s) \rightleftharpoons 3Ca^{2+}(aq) + 2PO_4^{3-}(aq) \qquad K_{sp} = [Ca^{2+}]^3[PO_4^{3-}]^2$$

(d) Silver sulfide:

$$\begin{aligned} Ag_2S(s) &\rightleftharpoons 2Ag^+(aq) + \cancel{S^{2-}(aq)} \\ \cancel{S^{2-}(aq)} + H_2O(l) &\longrightarrow HS^-(aq) + OH^-(aq) \\ \hline Ag_2S(s) + H_2O(l) &\rightleftharpoons 2Ag^+(aq) + HS^-(aq) + OH^-(aq) \end{aligned} \qquad K_{sp} = [Ag^+]^2[HS^-][OH^-]$$

Check Except for part (d), you can check by using the exponents as subscripts to see if you obtain the formula of the compound from K_{sp}.

FOLLOW-UP PROBLEMS

19.5A Write the ion-product expression at equilibrium for each compound: **(a)** calcium sulfate; **(b)** chromium(III) carbonate; **(c)** magnesium hydroxide; **(d)** arsenic(III) sulfide.

19.5B Write the formula and the name of the compound having each ion-product expression: **(a)** $K_{sp} = [Pb^{2+}][CrO_4^{2-}]$; **(b)** $K_{sp} = [Fe^{2+}][HS^-][OH^-]$; **(c)** $K_{sp} = [Sr^{2+}][F^-]^2$; **(d)** $K_{sp} = [Cu^{2+}]^3[PO_4^{3-}]^2$.

SOME SIMILAR PROBLEMS 19.66–19.69

Calculations Involving the Solubility-Product Constant

In Chapters 17 and 18, we considered two types of equilibrium problems. In one type, we use concentrations (or other quantities) to find K, and in the other, we use K to find concentrations. Here we encounter the same two types.

The Problem with Assuming Complete Dissociation Before we focus on calculations, let's address a complication that affects accuracy and results in approximate answers. Our assumption that the small dissolved amount of these compounds dissociates completely into separate ions is an oversimplification. Many slightly soluble salts have polar covalent metal-nonmetal bonds (Section 9.5), and partially dissociated or even undissociated species occur in solution. Here are two of many examples:

- With slightly soluble lead(II) chloride in water, the solution contains not only the separate $Pb^{2+}(aq)$ and $Cl^-(aq)$ ions we expect from complete dissociation, but also undissociated $PbCl_2(aq)$ molecules and $PbCl^+(aq)$ ions.
- In an aqueous solution of $CaSO_4$, undissociated ion pairs, $Ca^{2+}SO_4^{2-}(aq)$, are present.

These partly dissociated and undissociated species increase the *apparent* solubility of a slightly soluble salt above the value obtained by assuming complete dissociation. More advanced courses discuss these factors, but we simply mention them in the Comments of several sample problems. Thus, it is best to view the specific results of the calculations as first approximations.

The Meaning of K_{sp} and How to Determine It from Solubility Values The K_{sp} value indicates *how far the dissolution proceeds at equilibrium (saturation).* Table 19.2 presents a few K_{sp} values; Appendix C lists many more. Note that all the values are low, but they range over many orders of magnitude. In Sample Problem 19.6, we find K_{sp} from the solubility of a compound.

Table 19.2 Solubility-Product Constants (K_{sp}) of Selected Ionic Compounds at 25°C

Name, Formula	K_{sp}
Aluminum hydroxide, $Al(OH)_3$	3×10^{-34}
Cobalt(II) carbonate, $CoCO_3$	1.0×10^{-10}
Iron(II) hydroxide, $Fe(OH)_2$	4.1×10^{-15}
Lead(II) fluoride, PbF_2	3.6×10^{-8}
Lead(II) sulfate, $PbSO_4$	1.6×10^{-8}
Mercury(I) iodide, Hg_2I_2	4.7×10^{-29}
Silver sulfide, Ag_2S	8×10^{-48}
Zinc iodate, $Zn(IO_3)_2$	3.9×10^{-6}

SAMPLE PROBLEM 19.6 Determining K_{sp} from Solubility

Problem **(a)** Lead(II) sulfate ($PbSO_4$) is a key component in lead-acid car batteries. Its solubility in water at 25°C is 4.25×10^{-3} g/100. mL solution. What is the K_{sp} of $PbSO_4$?
(b) When lead(II) fluoride (PbF_2) is shaken with pure water at 25°C, the solubility is found to be 0.64 g/L. Calculate the K_{sp} of PbF_2.

Plan We are given solubilities in various units and must find K_{sp} values. As always, we write the dissolution equation and ion-product expression for each compound, which show the number of moles of each ion. We use the molar mass to convert the solubility of the compound from the given mass units to *molar solubility* (molarity), then use that value to find the molarity of each ion, and substitute into the ion-product expression to calculate K_{sp}.

Solution **(a)** For $PbSO_4$. Writing the equation and ion-product (K_{sp}) expression:

$$PbSO_4(s) \rightleftharpoons Pb^{2+}(aq) + SO_4^{2-}(aq) \qquad K_{sp} = [Pb^{2+}][SO_4^{2-}]$$

Converting solubility to molar solubility:

$$\text{Molar solubility of } PbSO_4 = \frac{0.00425 \text{ g } PbSO_4}{100. \text{ mL soln}} \times \frac{1000 \text{ mL}}{1 \text{ L}} \times \frac{1 \text{ mol } PbSO_4}{303.3 \text{ g } PbSO_4}$$
$$= 1.40\times10^{-4}\ M\ PbSO_4$$

Determining molarities of the ions: Because 1 mol of Pb^{2+} and 1 mol of SO_4^{2-} form when 1 mol of $PbSO_4$ dissolves, $[Pb^{2+}] = [SO_4^{2-}] = 1.40\times10^{-4}\ M$.
Substituting these values into the ion-product expression to calculate K_{sp}:

$$K_{sp} = [Pb^{2+}][SO_4^{2-}] = (1.40\times10^{-4})^2 = 1.96\times10^{-8}$$

(b) For PbF_2. Writing the equation and K_{sp} expression:

$$PbF_2(s) \rightleftharpoons Pb^{2+}(aq) + 2F^-(aq) \qquad K_{sp} = [Pb^{2+}][F^-]^2$$

Converting solubility to molar solubility:

$$\text{Molar solubility of } PbF_2 = \frac{0.64 \text{ g } PbF_2}{1 \text{ L soln}} \times \frac{1 \text{ mol } PbF_2}{245.2 \text{ g } PbF_2} = 2.6\times10^{-3}\, M\ PbF_2$$

Determining molarities of the ions: Since 1 mol of Pb^{2+} and 2 mol of F^- form when 1 mol of PbF_2 dissolves, we have

$$[Pb^{2+}] = 2.6\times10^{-3}\, M \quad \text{and} \quad [F^-] = 2(2.6\times10^{-3}\, M) = 5.2\times10^{-3}\, M$$

Substituting these values into the ion-product expression to calculate K_{sp}:

$$K_{sp} = [Pb^{2+}][F^-]^2 = (2.6\times10^{-3})(5.2\times10^{-3})^2 = \boxed{7.0\times10^{-8}}$$

Check The low solubilities are consistent with K_{sp} values being small. **(a)** The molar solubility seems about right: $\sim \frac{4\times10^{-2} \text{ g/L}}{3\times10^{2} \text{ g/mol}} \approx 1.3\times10^{-4}\, M$. Squaring this number gives 1.7×10^{-8}, close to the calculated K_{sp}. **(b)** Let's check the math in the final step as follows: $\sim(3\times10^{-3})(5\times10^{-3})^2 = 7.5\times10^{-8}$, close to the calculated K_{sp}.

Comment **1.** In part (b), the formula PbF_2 means that $[F^-]$ is twice $[Pb^{2+}]$. We follow the ion-product expression exactly and square this value of $[F^-]$.

2. The tabulated K_{sp} values for these compounds (Table 19.2) are lower than our calculated values. For PbF_2, for instance, the tabulated value is 3.6×10^{-8}, but we calculated 7.0×10^{-8} from solubility data. The discrepancy arises because we assumed that PbF_2 in solution dissociates completely to Pb^{2+} and F^-. Here is an example of the complication pointed out earlier. Actually, about a third of the PbF_2 dissolves as $PbF^+(aq)$ and a small amount dissolves as undissociated $PbF_2(aq)$. The solubility given in the problem statement (0.64 g/L) is determined experimentally and includes these other species, which we did *not* include in our calculation.

FOLLOW-UP PROBLEMS

19.6A When fluorite (CaF_2; *see photo*) is pulverized and shaken in water at 18°C, 10.0 mL of the solution contains 1.5×10^{-4} g of solute. Find the K_{sp} of CaF_2 at 18°C.

19.6B At 20°C, 3.2×10^{-4} g of silver phosphate (Ag_3PO_4) is soluble in 50. mL of solution. Find the K_{sp} of Ag_3PO_4 at 20°C.

SOME SIMILAR PROBLEMS 19.70–19.73

A sample of fluorite.

Determining Solubility from K_{sp} The reverse of Sample Problem 19.6 involves finding the solubility of a compound based on its formula and K_{sp} value. We'll use an approach similar to the one we used for weak acids in Sample Problem 18.8: we define the unknown amount dissolved—the molar solubility—as S, include ion concentrations in terms of this unknown in a reaction table, and solve for S.

SAMPLE PROBLEM 19.7 Determining Solubility from K_{sp}

Problem Calcium hydroxide (slaked lime) is a major component of mortar, plaster, and cement, and solutions of $Ca(OH)_2$ are used in industry as a strong, inexpensive base. Calculate the molar solubility of $Ca(OH)_2$ in water given that the K_{sp} is 6.5×10^{-6}.

Plan We write the dissolution equation and the ion-product expression. We know K_{sp} (6.5×10^{-6}), so to find molar solubility (S), we set up a reaction table that expresses $[Ca^{2+}]$ and $[OH^-]$ in terms of S, substitute into the ion-product expression, and solve for S.

Solution Writing the equation and ion-product expression:

$$Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2OH^-(aq) \qquad K_{sp} = [Ca^{2+}][OH^-]^2 = 6.5\times10^{-6}$$

Setting up a reaction table, with S = molar solubility:

Concentration (M)	$Ca(OH)_2(s)$	$\rightleftharpoons$	$Ca^{2+}(aq)$	+	$2OH^-(aq)$
Initial	—		0		0
Change	—		$+S$		$+2S$
Equilibrium	—		S		$2S$

Substituting into the ion-product expression and solving for S:

$$K_{sp} = [Ca^{2+}][OH^-]^2 = (S)(2S)^2 = (S)(4S^2) = 4S^3 = 6.5\times10^{-6}$$

$$S = \sqrt[3]{\frac{6.5\times10^{-6}}{4}} = 1.2\times10^{-2}\ M$$

Check We expect a low solubility from a slightly soluble salt. If we reverse the calculation, we should obtain the given K_{sp}: $4(1.2\times10^{-2})^3 = 6.9\times10^{-6}$, close to 6.5×10^{-6}.

Comment **1.** Note that we did not double and *then* square $[OH^-]$. $2S$ *is* the $[OH^-]$, so we just squared it, as the ion-product expression required.

2. Once again, we assumed that the solid dissociates completely. Actually, the solubility is increased to about $2.0\times10^{-2}\ M$ by the presence of $CaOH^+(aq)$ formed in the reaction $Ca(OH)_2(s) \rightleftharpoons CaOH^+(aq) + OH^-(aq)$. Our calculated answer is only approximate because we did not take this other species into account.

FOLLOW-UP PROBLEMS

19.7A Milk of magnesia, a suspension of $Mg(OH)_2$ in water, relieves indigestion by neutralizing stomach acid. What is the molar solubility of $Mg(OH)_2$ ($K_{sp} = 6.3\times10^{-10}$) in water?

19.7B Calcium phosphate, $Ca_3(PO_4)_2$, is used as a dietary supplement to treat low blood calcium. What is the molar solubility of $Ca_3(PO_4)_2$ ($K_{sp} = 1.2\times10^{-29}$) in water?

SOME SIMILAR PROBLEMS 19.74(a) and 19.75(a)

Using K_{sp} Values to Compare Solubilities As long as we compare compounds with the *same total number of ions* in their formulas, K_{sp} values indicate *relative* solubility: *the higher the* K_{sp}, *the greater the solubility* (Table 19.3). Note that for compounds that form three ions, the relationship holds whether the cation/anion ratio is 1/2 or 2/1, because the mathematical expression containing S is the same ($4S^3$) in the calculation (see Sample Problem 19.7).

Table 19.3 Relationship Between K_{sp} and Solubility at 25°C

No. of Ions	Formula	Cation/Anion	K_{sp}	Solubility (M)
2	$MgCO_3$	1/1	3.5×10^{-8}	1.9×10^{-4}
2	$PbSO_4$	1/1	1.6×10^{-8}	1.3×10^{-4}
2	$BaCrO_4$	1/1	2.1×10^{-10}	1.4×10^{-5}
3	$Ca(OH)_2$	1/2	6.5×10^{-6}	1.2×10^{-2}
3	BaF_2	1/2	1.5×10^{-6}	7.2×10^{-3}
3	CaF_2	1/2	3.2×10^{-11}	2.0×10^{-4}
3	Ag_2CrO_4	2/1	2.6×10^{-12}	8.7×10^{-5}

Effect of a Common Ion on Solubility

From Le Châtelier's principle (Section 17.6), we know that *adding a common ion decreases the solubility of a slightly soluble ionic compound.* Consider a saturated solution of lead(II) chromate:

$$PbCrO_4(s) \rightleftharpoons Pb^{2+}(aq) + CrO_4^{2-}(aq) \qquad K_{sp} = [Pb^{2+}][CrO_4^{2-}] = 2.3\times10^{-13}$$

At a given temperature, K_{sp} depends on the product of the ion concentrations. If the concentration of either ion goes up, the other goes down to maintain K_{sp}. Suppose we add Na_2CrO_4, a soluble salt, to the saturated $PbCrO_4$ solution. The concentration of the common ion, CrO_4^{2-}, increases, and some of it combines with Pb^{2+} ion to form more solid $PbCrO_4$ (Figure 19.13). That is, the equilibrium position shifts to the left:

$$PbCrO_4(s) \rightleftharpoons Pb^{2+}(aq) + CrO_4^{2-}(aq;\ \text{added})$$

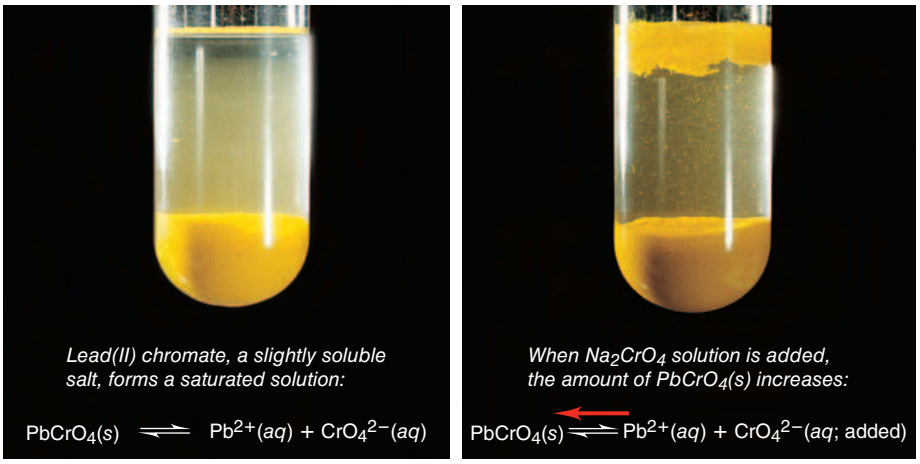

Figure 19.13 The effect of a common ion on solubility.

As a result of the addition, $[Pb^{2+}]$ is lower. And, since $[Pb^{2+}]$ defines the solubility of $PbCrO_4$, in effect, the solubility of $PbCrO_4$ has decreased. Note that we would get the same result if Na_2CrO_4 solution were the solvent; that is, $PbCrO_4$ is more soluble in water than in aqueous Na_2CrO_4.

SAMPLE PROBLEM 19.8 Calculating the Effect of a Common Ion on Solubility

Problem In Sample Problem 19.7, we calculated the solubility of $Ca(OH)_2$ in water. What is its solubility in 0.10 *M* $Ca(NO_3)_2$ (K_{sp} of $Ca(OH)_2 = 6.5\times10^{-6}$)?

Plan Addition of Ca^{2+}, the common ion, should lower the solubility. We write the equation and ion-product expression and set up a reaction table, with $[Ca^{2+}]_{init}$ reflecting the 0.10 *M* $Ca(NO_3)_2$ and *S* equal to $[Ca^{2+}]_{from\ Ca(OH)_2}$. To simplify the math, we assume that, because K_{sp} is low, *S* is so small relative to $[Ca^{2+}]_{init}$ that it can be neglected. Then we solve for *S* and check the assumption.

Solution Writing the equation and ion-product expression:

$$Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2OH^-(aq) \qquad K_{sp} = [Ca^{2+}][OH^-]^2 = 6.5\times10^{-6}$$

Setting up the reaction table, with $S = [Ca^{2+}]_{from\ Ca(OH)_2}$:

Concentration (*M*)	$Ca(OH)_2(s)$	⇌	$Ca^{2+}(aq)$	+	$2OH^-(aq)$
Initial	—		0.10 (from $Ca(NO_3)_2$)		0
Change	—		$+S$ (from $Ca(OH)_2$)		$+2S$
Equilibrium	—		$0.10 + S$		$2S$

Making the assumption: K_{sp} is small, so $S << 0.10\ M$; thus, $0.10\ M + S \approx 0.10\ M$. Substituting into the ion-product expression and solving for *S*:

$$K_{sp} = [Ca^{2+}][OH^-]^2 = 6.5\times10^{-6} \approx (0.10)(2S)^2$$

Therefore, $$4S^2 \approx \frac{6.5\times10^{-6}}{0.10} \quad \text{so} \quad S \approx \sqrt{\frac{6.5\times10^{-5}}{4}} = 4.0\times10^{-3}\ M$$

Checking the assumption: $$\frac{4.0\times10^{-3}\ M}{0.10\ M} \times 100 = 4.0\% < 5\%$$

Check In Sample Problem 19.7, the solubility of $Ca(OH)_2$ was 0.012 *M*; here it is 0.0040 *M*, one-third as much. As expected, the solubility *decreased* in the presence of added Ca^{2+}, the common ion.

$BaSO_4$ imaging of a large intestine.

Figure 19.14 Test for the presence of a carbonate. When a carbonate mineral is treated with HCl, bubbles of CO_2 form.

FOLLOW-UP PROBLEMS

19.8A To improve the x-ray image used to diagnose intestinal disorders, a patient drinks an aqueous suspension of $BaSO_4$ because Ba^{2+} is opaque to x-rays *(photo)*. However, Ba^{2+} is also toxic; thus, $[Ba^{2+}]$ is lowered by adding dilute Na_2SO_4. What is the solubility of $BaSO_4$ ($K_{sp} = 1.1\times10^{-10}$) in **(a)** water and **(b)** 0.10 *M* Na_2SO_4?

19.8B Calculate the solubility of CaF_2 ($K_{sp} = 3.2\times10^{-11}$) in **(a)** water; **(b)** 0.20 *M* $CaCl_2$; and **(c)** 0.20 *M* NiF_2.

SOME SIMILAR PROBLEMS 19.74(b), 19.75(b), 19.76, and 19.77

Effect of pH on Solubility

If a slightly soluble ionic compound contains the anion of a weak acid, *addition of H_3O^+ (from a strong acid) increases its solubility.* Once again, Le Châtelier's principle explains why. Consider a saturated solution of calcium carbonate:

$$CaCO_3(s) \rightleftharpoons Ca^{2+}(aq) + CO_3^{2-}(aq)$$

Adding strong acid introduces H_3O^+, which reacts with the anion of a weak acid, CO_3^{2-}, to form the anion of another weak acid, HCO_3^-:

$$CO_3^{2-}(aq) + H_3O^+(aq) \longrightarrow HCO_3^-(aq) + H_2O(l)$$

If enough H_3O^+ is added, carbonic acid forms, which decomposes to H_2O and CO_2, and the gas escapes the container:

$$HCO_3^-(aq) + H_3O^+(aq) \longrightarrow [H_2CO_3(aq)] + H_2O(l) \longrightarrow CO_2(g) + 2H_2O(l)$$

The net effect of adding H_3O^+ is a shift in the equilibrium position to the right, and more $CaCO_3$ dissolves:

$$CaCO_3(s) \rightleftharpoons Ca^{2+} + CO_3^{2-} \xrightarrow{H_3O^+} HCO_3^- \xrightarrow{H_3O^+} [H_2CO_3] \longrightarrow CO_2(g) + H_2O + Ca^{2+}$$

In fact, this example illustrates a qualitative field test for carbonate minerals because the CO_2 bubbles vigorously (Figure 19.14).

In contrast, adding H_3O^+ to a saturated solution of a slightly soluble ionic compound with a strong-acid anion, such as AgCl, has no effect on its solubility:

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$$

The Cl^- ion can coexist with high $[H_3O^+]$, so the equilibrium position is not affected.

SAMPLE PROBLEM 19.9 Predicting the Effect on Solubility of Adding Strong Acid

Problem Write balanced equations to explain whether addition of H_3O^+ from a strong acid affects the solubility of each ionic compound:

(a) Lead(II) bromide **(b)** Copper(II) hydroxide **(c)** Iron(II) sulfide

Plan We write the balanced dissolution equation and note the anion:

- Weak-acid anions react with H_3O^+ and increase solubility when strong acid is added.
- Strong-acid anions do not react with H_3O^+, so addition of strong acid has no effect.

Solution **(a)** $PbBr_2(s) \rightleftharpoons Pb^{2+}(aq) + 2Br^-(aq)$

No effect. Br^- is the anion of HBr, a strong acid, so it does not react with H_3O^+.

(b) $Cu(OH)_2(s) \rightleftharpoons Cu^2(aq) + 2OH^-(aq)$

Increases solubility. OH^- is the anion of H_2O, a very weak acid, so it reacts with the added H_3O^+:

$$OH^-(aq) + H_3O^+(aq) \longrightarrow 2H_2O(l)$$

(c) $FeS(s) + H_2O(l) \rightleftharpoons Fe^{2+}(aq) + HS^-(aq) + OH^-(aq)$

Increases solubility. The S^{2-} ion reacts completely with water to form HS^- and OH^-. The added H_3O^+ reacts with both of these weak-acid anions:

$$HS^-(aq) + H_3O^+(aq) \longrightarrow H_2S(aq) + H_2O(l)$$
$$OH^-(aq) + H_3O^+(aq) \longrightarrow 2H_2O(l)$$

FOLLOW-UP PROBLEMS

19.9A Write balanced equations to show how addition of $HNO_3(aq)$ affects the solubility of: **(a)** calcium fluoride; **(b)** zinc sulfide; **(c)** silver iodide.

19.9B Write balanced equations to show how addition of HBr(*aq*) affects the solubility of: **(a)** silver cyanide; **(b)** copper(I) chloride; **(c)** magnesium phosphate.
SOME SIMILAR PROBLEMS 19.82–19.85

Applying Ionic Equilibria to the Formation of a Limestone Cave

Limestone caves and the remarkable structures within them provide striking evidence of the results of aqueous ionic equilibria involving carbonate rocks and the carbon dioxide and water that have flowed through them for many hundreds of millennia (Figure 19.15).

Figure 19.15 Limestone cave in Nerja, Málaga, Spain.

The Cave-Forming Reactions Limestone is mostly calcium carbonate ($CaCO_3$; $K_{sp} = 3.3\times10^{-9}$). Two key reactions help us understand how limestone caves form:

1. Gaseous CO_2 in air is in equilibrium with aqueous CO_2 in natural waters:

$$CO_2(g) \overset{H_2O(l)}{\rightleftharpoons} CO_2(aq) \qquad \textbf{(equation 1)}$$

The concentration of aqueous CO_2 is proportional to the partial pressure of $CO_2(g)$ in contact with the water (Henry's law; Section 13.4):

$$[CO_2(aq)] \propto P_{CO_2}$$

Due to the continual release of CO_2 from within Earth (outgassing), P_{CO_2} in soil-trapped air is *higher* than P_{CO_2} in the atmosphere.

2. The reaction of CO_2 with water produces H_3O^+:

$$CO_2(aq) + 2H_2O(l) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq)$$

Thus, since $CaCO_3$ contains the anion of a weak acid, this formation of H_3O^+ increases the solubility of $CaCO_3$:

$$CaCO_3(s) + CO_2(aq) + H_2O(l) \rightleftharpoons Ca^{2+}(aq) + 2HCO_3^-(aq) \qquad \textbf{(equation 2)}$$

The Cave-Forming Process Here is an overview of the process that forms most limestone caves:

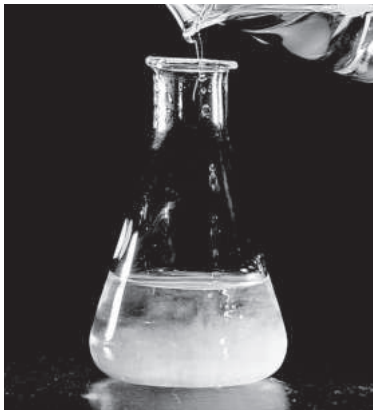
1. As surface water trickles through cracks in the ground, it meets soil-trapped air with a high P_{CO_2}. As a result, $[CO_2(aq)]$ increases (equation 1 shifts to the right), and the solution becomes more acidic.
2. When this CO_2-rich water contacts $CaCO_3$, more $CaCO_3$ dissolves (equation 2 shifts to the right). As a result, more rock is carved out, more water flows in, and so on. Centuries pass, and a cave slowly begins to form.
3. Some of the aqueous solution, dilute $Ca(HCO_3)_2$, passes through the ceiling of the growing cave. As it drips, it meets air, which has a lower P_{CO_2} than the soil, so some $CO_2(aq)$ comes out of solution (equation 1 shifts to the left).
4. Consequently, some $CaCO_3$ precipitates on the ceiling and on the floor below, where the drops land (equation 2 shifts to the left). After many decades, the ceiling bears a *stalactite*, while a spike, called a *stalagmite*, grows up from the floor. Eventually, they meet to form a column of precipitated limestone.

The same chemical process can lead to different shapes. Standing pools of $Ca(HCO_3)_2$ solution form limestone "lily pads" or "corals." Cascades of solution form delicate limestone "draperies" on a cave wall, with fabulous colors arising from trace metal ions, such as iron (reddish brown) or copper (bluish green).

Predicting the Formation of a Precipitate: Q_{sp} vs. K_{sp}

As in Chapter 17, here we compare the values of Q_{sp} and K_{sp} to see if a reaction has reached equilibrium and, if not, in which net direction it will progress until it does. Using solutions of *soluble* salts that contain the ions of *slightly* soluble salts, we can calculate the ion concentrations and predict the result when we mix the solutions:

- If $Q_{sp} = K_{sp}$, the solution is saturated and no change will occur.
- If $Q_{sp} > K_{sp}$, a precipitate will form until the remaining solution is saturated.
- If $Q_{sp} < K_{sp}$, no precipitate will form because the solution is unsaturated.



Precipitation of CaF_2.

SAMPLE PROBLEM 19.10 Predicting Whether a Precipitate Will Form

Problem A common laboratory method for preparing a precipitate is to mix solutions containing the component ions. Does a precipitate form when 0.100 L of 0.30 *M* $Ca(NO_3)_2$ is mixed with 0.200 L of 0.060 *M* NaF?

Plan First, we decide which slightly soluble salt could form, look up its K_{sp} value in Appendix C, and write a dissolution equation and ion-product expression. To see whether mixing these solutions forms the precipitate, we find the initial ion concentrations by calculating the amount (mol) of each ion from its concentration and volume, and dividing by the *total* volume because each solution dilutes the other. Finally, we substitute these concentrations to calculate Q_{sp}, and compare Q_{sp} with K_{sp}.

Solution The ions present are Ca^{2+}, Na^+, F^-, and NO_3^-. All sodium and all nitrate salts are soluble (Table 4.1, p. 153), so the only possibility is CaF_2 ($K_{sp} = 3.2\times10^{-11}$). Writing the equation and ion-product expression:

$$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2F^-(aq) \qquad Q_{sp} = [Ca^{2+}][F^-]^2$$

Calculating the ion concentrations:

$$\text{Amount (mol) of } Ca^{2+} = 0.30\ M\ Ca^{2+} \times 0.100\ \text{L} = 0.030\ \text{mol}\ Ca^{2+}$$

$$[Ca^{2+}]_{init} = \frac{0.030\ \text{mol}\ Ca^{2+}}{0.100\ \text{L} + 0.200\ \text{L}} = 0.10\ M\ Ca^{2+}$$

$$\text{Amount (mol) of } F^- = 0.060\ M\ F^- \times 0.200\ \text{L} = 0.012\ \text{mol}\ F^-$$

$$[F^-]_{init} = \frac{0.012\ \text{mol}\ F^-}{0.100\ \text{L} + 0.200\ \text{L}} = 0.040\ M\ F^-$$

Substituting into the ion-product expression and comparing Q_{sp} with K_{sp}:

$$Q_{sp} = [Ca^{2+}]_{init}[F^-]^2_{init} = (0.10)(0.040)^2 = 1.6\times10^{-4}$$

Because $Q_{sp} > K_{sp}$, CaF_2 will precipitate until $Q_{sp} = 3.2\times10^{-11}$.

Check Make sure you round off and quickly check the math. For example, $Q_{sp} = (1\times10^{-1})(4\times10^{-2})^2 = 1.6\times10^{-4}$. With K_{sp} so low, CaF_2 must have a low solubility, and given the sizable concentrations being mixed, we would expect CaF_2 to precipitate.

FOLLOW-UP PROBLEMS

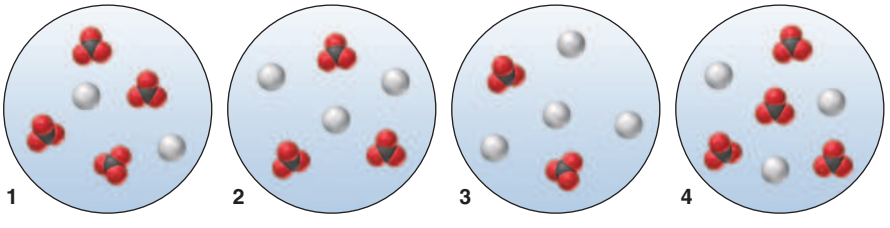
19.10A As a result of mineral erosion and biological activity, phosphate ion is common in natural waters, where it often precipitates as insoluble salts such as $Ca_3(PO_4)_2$. If $[Ca^{2+}]_{init} = [PO_4^{3-}]_{init} = 1.0\times10^{-9}\ M$ in a given river, will $Ca_3(PO_4)_2$ ($K_{sp} = 1.2\times10^{-29}$) precipitate?

19.10B Addition of a soluble sulfide compound such as sodium sulfide is an effective way to remove metals such as lead from wastewater. Does a precipitate form when 0.500 L of 0.10 *M* Na_2S is added to 25 L of wastewater containing 0.015 g Pb^{2+}/L?

SOME SIMILAR PROBLEMS 19.86–19.89

SAMPLE PROBLEM 19.11 Using Molecular Scenes to Predict Whether a Precipitate Will Form

Problem These four scenes represent solutions of silver *(gray)* and carbonate *(black and red)* ions above solid silver carbonate. (The solid, other ions, and water are not shown.)



(a) Which scene best represents the solution in equilibrium with the solid?
(b) In which, if any, other scene(s) will additional solid silver carbonate form?
(c) Explain how, if at all, addition of a small volume of concentrated strong acid affects the $[Ag^+]$ in scene 4 and the mass of solid present.

Plan **(a)** The solution of silver and carbonate ions in equilibrium with the solid (Ag_2CO_3) should have the same relative numbers of cations and anions as in the formula. We examine the scenes to see which has a ratio of 2 Ag^+ to 1 CO_3^{2-}. **(b)** A solid forms if the value of Q_{sp} exceeds the K_{sp}. We write the dissolution equation and Q_{sp} expression. Then we count ions to calculate Q_{sp} in each scene and see which, if any, exceeds the value for the solution from part (a). **(c)** The CO_3^{2-} ion reacts with added H_3O^+, so adding strong acid will shift the equilibrium to the right. We write the equations and determine how a shift to the right affects $[Ag^+]$ and the mass of solid Ag_2CO_3.

Solution **(a)** Scene 3 is the only one with an Ag^+/CO_3^{2-} ratio of 2/1, as in the solid's formula.

(b) Calculating the ion products:

$$Ag_2CO_3(s) \rightleftharpoons 2Ag^+(aq) + CO_3^{2-}(aq) \qquad Q_{sp} = [Ag^+]^2[CO_3^{2-}]$$

Scene 1: $Q_{sp} = (2)^2(4) = 16$ Scene 2: $Q_{sp} = (3)^2(3) = 27$
Scene 3: $Q_{sp} = (4)^2(2) = 32$ Scene 4: $Q_{sp} = (3)^2(4) = 36$

Therefore, from scene 3, $K_{sp} = 32$; the Q_{sp} value for scene 4 is the only other one that equals or exceeds 32, so a precipitate of Ag_2CO_3 will form there.

(c) Writing the equations:

(1) $Ag_2CO_3(s) \rightleftharpoons 2Ag^+(aq) + CO_3^{2-}(aq)$

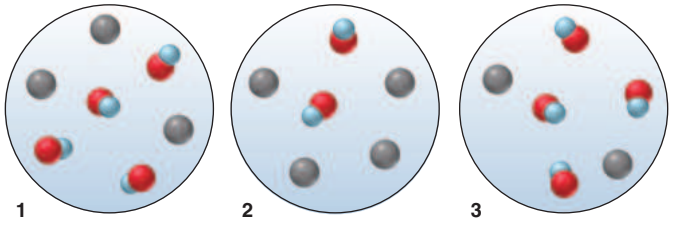
(2) $CO_3^{2-}(aq) + 2H_3O^+(aq) \longrightarrow [H_2CO_3(aq)] + 2H_2O(l) \longrightarrow 3H_2O(l) + CO_2(g)$

The CO_2 leaves as a gas, so adding H_3O^+ shifts the equilibrium position of reaction 2 to the right. This change lowers the $[CO_3^{2-}]$ in reaction 1, thereby causing more CO_3^{2-} to form. As a result, more solid dissolves, which means that the $[Ag^+]$ increases and the mass of Ag_2CO_3 decreases.

Check **(a)** In scene 1, the formula has two CO_3^{2-} per formula unit, not two Ag^+.
(b) Even though scene 4 has fewer Ag^+ ions than scene 3, its Q_{sp} value is higher and exceeds the K_{sp}.

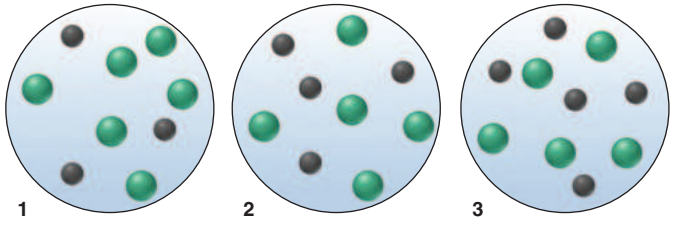
FOLLOW-UP PROBLEMS

19.11A The following scenes represent solutions of nickel(II) *(gray)* and hydroxide *(red and blue)* ions that are above solid nickel(II) hydroxide. (The solid, other ions, and water are not shown.)



(a) Which scene best depicts the solution at equilibrium with the solid?
(b) In which, if any, other scene(s) will additional solid form?
(c) Will addition of a small amount of concentrated strong acid or strong base affect the mass of solid present in any scene? Explain.

19.11B The following scenes represent solutions of lead(II) *(black)* and chloride *(green)* ions that are above solid lead(II) chloride. (The solid, other ions, and water are not shown.)



(a) Which scene best represents the solution in equilibrium with the solid?
(b) In which, if any, other scene(s) will additional solid form?
(c) Explain how, if at all, addition of a small amount of concentrated HCl(*aq*) will affect the mass of solid present in any scene.

SOME SIMILAR PROBLEMS 19.121 and 19.148

Separating Ions by Selective Precipitation and Simultaneous Equilibria

Let's consider two ways to separate one ion from another by reacting them with a given precipitating ion to form compounds with different solubilities.

Selective Precipitation In the process of **selective precipitation,** a solution of one precipitating ion is added to a solution of two ionic compounds until the Q_{sp} of the *more soluble* compound is almost equal to its K_{sp}. This method ensures that the K_{sp} of the *less soluble* compound is exceeded as much as possible. As a result, the maximum amount of the less soluble compound precipitates, but none of the more soluble compound does.

SAMPLE PROBLEM 19.12 Separating Ions by Selective Precipitation

Problem A solution consists of 0.20 *M* $MgCl_2$ and 0.10 *M* $CuCl_2$. Calculate the $[OH^-]$ that would separate the metal ions. K_{sp} of $Mg(OH)_2$ is 6.3×10^{-10}; K_{sp} of $Cu(OH)_2$ is 2.2×10^{-20}.

Plan Because both compounds have 1/2 ratios of cation/anion (see p. 850), when we compare their K_{sp} values, we find that $Mg(OH)_2$ is about 10^{10} times more soluble than $Cu(OH)_2$; thus, $Cu(OH)_2$ precipitates first. We write the dissolution equations and ion-product expressions. We are given both cation concentrations, so we solve for the $[OH^-]$ that gives a saturated solution of $Mg(OH)_2$, because this $[OH^-]$ will precipitate the most Cu^{2+}. Then, we calculate the $[Cu^{2+}]$ remaining to see if the separation was accomplished.

Solution Writing the equations and ion-product expressions:

$$Mg(OH)_2(s) \rightleftharpoons Mg^{2+}(aq) + 2OH^-(aq) \quad K_{sp} = [Mg^{2+}][OH^-]^2 = 6.3\times10^{-10}$$
$$Cu(OH)_2(s) \rightleftharpoons Cu^{2+}(aq) + 2OH^-(aq) \quad K_{sp} = [Cu^{2+}][OH^-]^2 = 2.2\times10^{-20}$$

Calculating the $[OH^-]$ that gives a saturated $Mg(OH)_2$ solution:

$$[OH^-] = \sqrt{\frac{K_{sp}}{[Mg^{2+}]}} = \sqrt{\frac{6.3\times10^{-10}}{0.20}} = 5.6\times10^{-5}\,M$$

This is the maximum $[OH^-]$ that will *not* precipitate Mg^{2+} ion.
Calculating the $[Cu^{2+}]$ remaining in the solution with this $[OH^-]$:

$$[Cu^{2+}] = \frac{K_{sp}}{[OH^-]^2} = \frac{2.2\times10^{-20}}{(5.6\times10^{-5})^2} = 7.0\times10^{-12}\,M$$

Since the initial $[Cu^{2+}]$ is 0.10 *M*, virtually all the Cu^{2+} ion is precipitated.

Check Rounding, we find that $[OH^-]$ seems right: $\sim\sqrt{(6\times10^{-10})/0.2} = 5\times10^{-5}$. The $[Cu^{2+}]$ remaining also seems correct: $(200\times10^{-22})/(5\times10^{-5})^2 = 8\times10^{-12}$.

FOLLOW-UP PROBLEMS

19.12A A solution is 0.050 *M* $BaCl_2$ and 0.025 *M* $CaCl_2$. What concentration of SO_4^{2-} will separate the cations in solution? K_{sp} of $BaSO_4$ is 1.1×10^{-10}, and K_{sp} of $CaSO_4$ is 2.4×10^{-5}.

19.12B A solution consists of 0.020 *M* $Ba(NO_3)_2$ and 0.015 *M* $Ca(NO_3)_2$. What concentration of NaF will separate the cations in solution? K_{sp} of BaF_2 is 1.5×10^{-6}, and K_{sp} of CaF_2 is 3.2×10^{-11}.

A SIMILAR PROBLEM 19.91

Simultaneous Equilibria Sometimes two or more equilibrium systems are controlled simultaneously to separate one metal ion from another as their sulfides, using HS^- as the precipitating ion. We control the $[HS^-]$ in order to exceed the K_{sp} value of one metal sulfide but not the other, and we do so by shifting H_2S dissociation through adjustments of $[H_3O^+]$:

$$H_2S(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + HS^-(aq)$$

These interactions are controlled in the following way:

- If we add strong acid, the high $[H_3O^+]$ shifts H_2S dissociation to the left, which decreases $[HS^-]$, so the *less* soluble sulfide precipitates.
- If we add strong base, the low $[H_3O^+]$ shifts H_2S dissociation to the right, which increases $[HS^-]$, so the *more* soluble sulfide precipitates.

Thus, we shift one equilibrium system (H_2S dissociation) by adjusting a second (H_2O ionization) to control a third (metal sulfide solubility).

As the Chemical Connections essay below demonstrates, the principles of ionic equilibria often help us understand the chemical basis of complex environmental problems and may provide ways to solve them.

Summary of Section 19.3

- Only as a first approximation does the dissolved portion of a slightly soluble salt dissociate completely into ions.
- In a saturated solution, dissolved ions and the undissolved solid salt are in equilibrium. The product of the ion concentrations, each raised to the power of its subscript in the formula, has a constant value ($Q_{sp} = K_{sp}$).
- The value of K_{sp} can be obtained from the solubility, and vice versa.
- Adding a common ion lowers a compound's solubility.
- Adding H_3O^+ (lowering pH) increases a compound's solubility if the anion of the compound is also that of a weak acid.
- Limestone caves result from shifts in the $CaCO_3/CO_2$ equilibrium system.
- When two solutions, each containing one of the ions of a slightly soluble ionic compound, are mixed, an ionic solid forms if $Q_{sp} > K_{sp}$.
- Ions are precipitated selectively from a solution of two compounds by adding a precipitating ion until the K_{sp} of one compound is exceeded as much as possible without exceeding the K_{sp} of the other. An extension of this approach uses simultaneous control of three equilibrium systems to separate metal ions as their sulfides.
- Lakes bounded by limestone-rich soils form buffer systems that prevent acidification.

CHEMICAL CONNECTIONS TO ENVIRONMENTAL SCIENCE

The Acid-Rain Problem

Acid rain, the deposition of acids in wet form as rain, snow, or fog or in dry form as solid particles, is a global environmental problem. It has been observed in the United States, Canada, Mexico, the Amazon basin, Europe, Russia, many parts of Asia, and even at the North and South Poles. Let's see how it arises and how to prevent some of its harmful effects.

Origins of Acid Rain

The strong acids H_2SO_4 and HNO_3 cause the greatest concern, so let's see how they form (Figure B19.1, on the next page):

1. *Sulfuric acid.* Sulfur dioxide (SO_2), produced mostly by the burning of high-sulfur coal, forms sulfurous acid (H_2SO_3) in contact with water. The atmospheric pollutants hydrogen peroxide (H_2O_2) and ozone (O_3) dissolve in the water in clouds and oxidize the sulfurous acid to sulfuric acid:

$$H_2O_2(aq) + H_2SO_3(aq) \longrightarrow H_2SO_4(aq) + H_2O(l)$$

Alternatively, SO_2 is oxidized by atmospheric hydroxyl radicals ($HO\cdot$) to sulfur trioxide (SO_3), which forms H_2SO_4 with water.

2. *Nitric acid.* Nitrogen oxides (NO_x) form from N_2 and O_2 during high-temperature combustion in car and truck engines and electric power plants. NO then forms NO_2 and HNO_3 in a process that creates smog (p. 593). At night, NO_x is converted to N_2O_5, which reacts with water to form HNO_3:

$$N_2O_5(g) + H_2O(l) \longrightarrow 2HNO_3(aq)$$

Ammonium salts, deposited as NH_4HSO_4 or NH_4NO_3, produce HNO_3 in soil through biochemical oxidation.

The pH of Acid Rain

Normal rainwater is weakly acidic from the reaction of atmospheric CO_2 with water (see Problem 19.142):

$$CO_2(g) + 2H_2O(l) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq)$$

Yet, as long ago as 1984, rainfall in the United States had already reached an average pH of 4.2, an increase of about 25 times as much H_3O^+. Rain in Wheeling, West Virginia, has had a pH of 1.8, lower than the pH of lemon juice. And rain in industrial parts of Sweden once had a pH of 2.7, about the same as vinegar.

Effects of Acid Rain

Some fish and shellfish die at pH values between 4.5 and 5.0. The young of most species are generally more vulnerable. At pH 5, most fish eggs cannot hatch. With tens of thousands of rivers and lakes around the world becoming or already acidified, the loss of freshwater fish became a major concern long ago.

(continued)

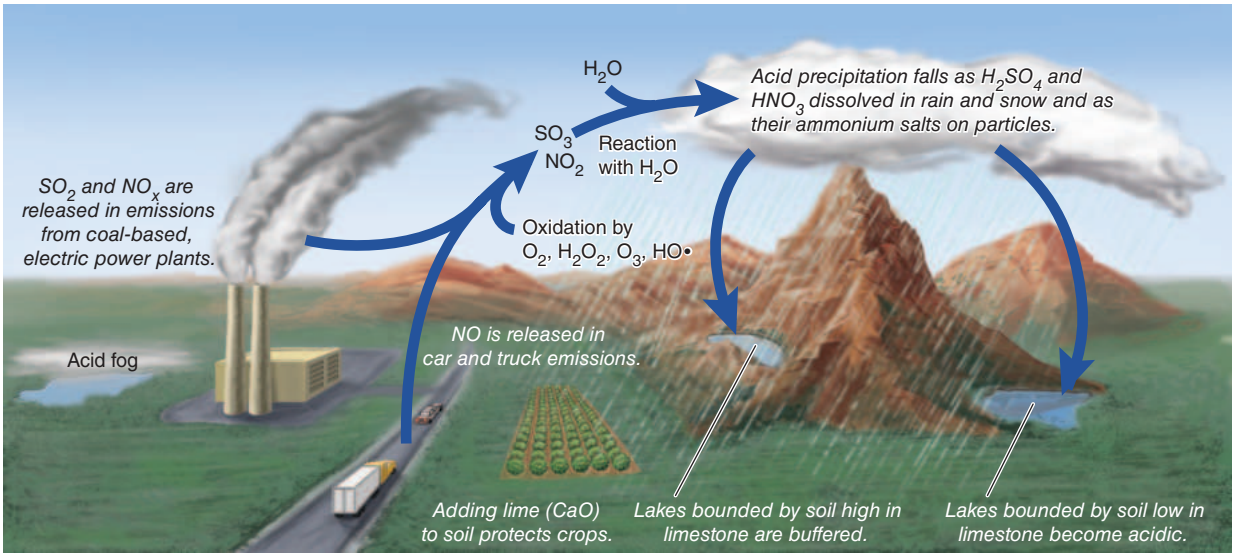


Figure B19.1 **Formation of acidic precipitation.** A complex interplay of human activities, atmospheric chemistry, and environmental distribution leads to acidic precipitation and its harmful effects.

In addition, acres of forest have been harmed by the acid, which removes nutrients and releases toxic substances from the soil. The aluminosilicates that make up most soils are extremely insoluble in water. Through a complex series of simultaneous equilibria, contact with water at pH < 5 causes these materials to release some bound Al^{3+}, which is toxic to fish and plants. At the same time, acid rain dissolves Ca^{2+} and Mg^{2+} ions from the soil, which are nutrients for plants and animals.

Marble and limestone (both primarily $CaCO_3$) in buildings and monuments react with sulfuric acid to form gypsum ($CaSO_4 \cdot 2H_2O$), which flakes off. Ironically, the same process that destroys these structures rescues lakes that are bounded by limestone-rich soil. Limestone dissolves sufficiently in lake water to form an HCO_3^-/CO_3^{2-} buffer capable of absorbing the incoming H_3O^+ and maintaining a mildly basic pH:

$$CO_3^{2-}(aq) + H_3O^+(aq) \rightleftharpoons HCO_3^-(aq) + H_2O(l)$$

Acidified lakes and rivers that are in contact with granite and other weathering-resistant bedrock can be remediated by *liming* (treating with limestone). This approach is expensive and only a stopgap because the lakes are acidic again within several years.

Preventing Acid Rain

Effective prevention of acid rain has to address the sources of the sulfur and nitrogen pollutants:

1. *Sulfur pollutants*. As was pointed out earlier (Chemical Connections, p. 273), the principal means of minimizing sulfur dioxide release is by "scrubbing" power plant emissions with limestone in both dry and wet form. Another method reduces SO_2 with methane, coal, or H_2S, and the mixture is converted catalytically to sulfur, which is sold as a byproduct:

$$16H_2S(g) + 8SO_2(g) \xrightarrow{\text{catalyst}} 3S_8(s) + 16H_2O(l)$$

Although low-sulfur coal is rare and expensive to mine, coal can be converted into gaseous and liquid low-sulfur fuels. The sulfur is removed (as H_2S) in an acid-gas scrubber after gasification.

2. *Nitrogen pollutants*. Through the use of a catalytic converter in an auto exhaust system, NO_x species are reduced to N_2. In power plant emissions, NO_x is decreased by adjusting conditions and by treating hot stack gases with ammonia in the presence of a heterogeneous catalyst:

$$4NO(g) + 4NH_3(g) + O_2(g) \xrightarrow{\text{catalyst}} 4N_2(g) + 6H_2O(g)$$

Reducing power plant emissions in North America and Europe has increased the pH of rainfall and some surface waters. Lime (CaO) is routinely used to react with acid rain falling on croplands. Further progress is expected under current legislation, but, in much of eastern North America and northern Europe, additional measures are needed for full recovery.

Problems

B19.1 An environmental technician collects a sample of rainwater. Back in the lab, her pH meter isn't working, so she uses indicator solutions to estimate the pH. A piece of litmus paper turns red, indicating acidity, so she divides the sample into thirds and obtains the following results: thymol blue turns yellow; bromphenol blue turns green; and methyl red turns red. Estimate the pH of the rainwater.

B19.2 A lake that has a surface area of 10.0 acres (1 acre $= 4.840 \times 10^3$ yd^2) receives 1.00 inch of rain of pH 4.20. (Assume that the acidity of the rain is due to a strong, monoprotic acid.)
(a) How many moles of H_3O^+ are in the rain falling on the lake?
(b) If the lake is unbuffered and its average depth is 10.0 ft before the rain, find the pH after the rain has been mixed with lake water. (Assume the initial pH is 7.00, and ignore runoff from the surrounding land.)
(c) If the lake contains hydrogen carbonate ions (HCO_3^-), what mass of HCO_3^- would neutralize the acid in the rain?

19.4 EQUILIBRIA INVOLVING COMPLEX IONS

A third kind of aqueous ionic equilibrium involves a type of ion we mentioned briefly in Section 18.9. A *simple ion,* such as Na^+ or CH_3COO^-, consists of one or a few bonded atoms, with an excess or deficit of electrons. A **complex ion** consists of a central metal ion covalently bonded to two or more anions or molecules, called **ligands.** Hydroxide, chloride, and cyanide ions are examples of ionic ligands; water, carbon monoxide, and ammonia are some molecular ligands. In the complex ion $Cr(NH_3)_6^{3+}$, for example, the central Cr^{3+} is surrounded by six NH_3 ligands (Figure 19.16). Hydrated metal ions are complex ions with water as ligands (Section 18.5). In Chapter 23, we discuss the transition metals and the structures and properties of the numerous complex ions they form. Here, we focus on equilibria of hydrated ions with ligands other than water.

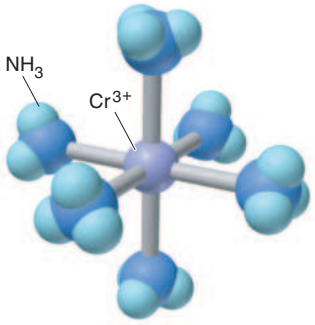

Figure 19.16 $Cr(NH_3)_6^{3+}$, a typical complex ion.

Formation of Complex Ions

When a salt dissolves in water, a complex ion forms, with water as ligands around the metal ion. In many cases, when we treat this hydrated cation with a solution of another ligand, the bound water molecules are replaced by the other ligand. For example, a hydrated M^{2+} ion, $M(H_2O)_4^{2+}$, forms the ammoniated ion, $M(NH_3)_4^{2+}$, in aqueous NH_3:

$$M(H_2O)_4^{2+}(aq) + 4NH_3(aq) \rightleftharpoons M(NH_3)_4^{2+}(aq) + 4H_2O(l)$$

At equilibrium, this system is expressed by a ratio of concentration terms whose form follows that of any other equilibrium expression:

$$K_c = \frac{[M(NH_3)_4^{2+}][H_2O]^4}{[M(H_2O)_4^{2+}][NH_3]^4}$$

Once again, because $[H_2O]$ is essentially constant, water is treated as a pure liquid, with a concentration term equal to 1. Thus, we obtain the expression for a new equilibrium constant called the **formation constant, K_f:**

$$\frac{K_c}{(1)^4} = K_f = \frac{[M(NH_3)_4^{2+}]}{[M(H_2O)_4^{2+}][NH_3]^4}$$

At the molecular level, depicted in Figure 19.17 *(next page),* the actual process is stepwise, with ammonia molecules replacing water molecules one at a time. This process yields a series of intermediate species, each with its own formation constant:

$$M(H_2O)_4^{2+}(aq) + NH_3(aq) \rightleftharpoons M(H_2O)_3(NH_3)^{2+}(aq) + H_2O(l)$$
$$K_{f1} = \frac{[M(H_2O)_3(NH_3)^{2+}]}{[M(H_2O)_4^{2+}][NH_3]}$$

$$M(H_2O)_3(NH_3)^{2+}(aq) + NH_3(aq) \rightleftharpoons M(H_2O)_2(NH_3)_2^{2+}(aq) + H_2O(l)$$
$$K_{f2} = \frac{[M(H_2O)_2(NH_3)_2^{2+}]}{[M(H_2O)_3(NH_3)^{2+}][NH_3]}$$

$$M(H_2O)_2(NH_3)_2^{2+}(aq) + NH_3(aq) \rightleftharpoons M(H_2O)(NH_3)_3^{2+}(aq) + H_2O(l)$$
$$K_{f3} = \frac{[M(H_2O)(NH_3)_3^{2+}]}{[M(H_2O)_2(NH_3)_2^{2+}][NH_3]}$$

$$M(H_2O)(NH_3)_3^{2+}(aq) + NH_3(aq) \rightleftharpoons M(NH_3)_4^{2+}(aq) + H_2O(l)$$
$$K_{f4} = \frac{[M(NH_3)_4^{2+}]}{[M(H_2O)(NH_3)_3^{2+}][NH_3]}$$

The *sum* of the equations gives the overall equation, so the *product* of the individual formation constants gives the overall formation constant:

$$K_f = K_{f1} \times K_{f2} \times K_{f3} \times K_{f4}$$

Recall that *all complex ions are Lewis adducts* (Section 18.9). The metal ion acts as a Lewis acid (accepts an electron pair), and the ligand acts as a Lewis base (donates an

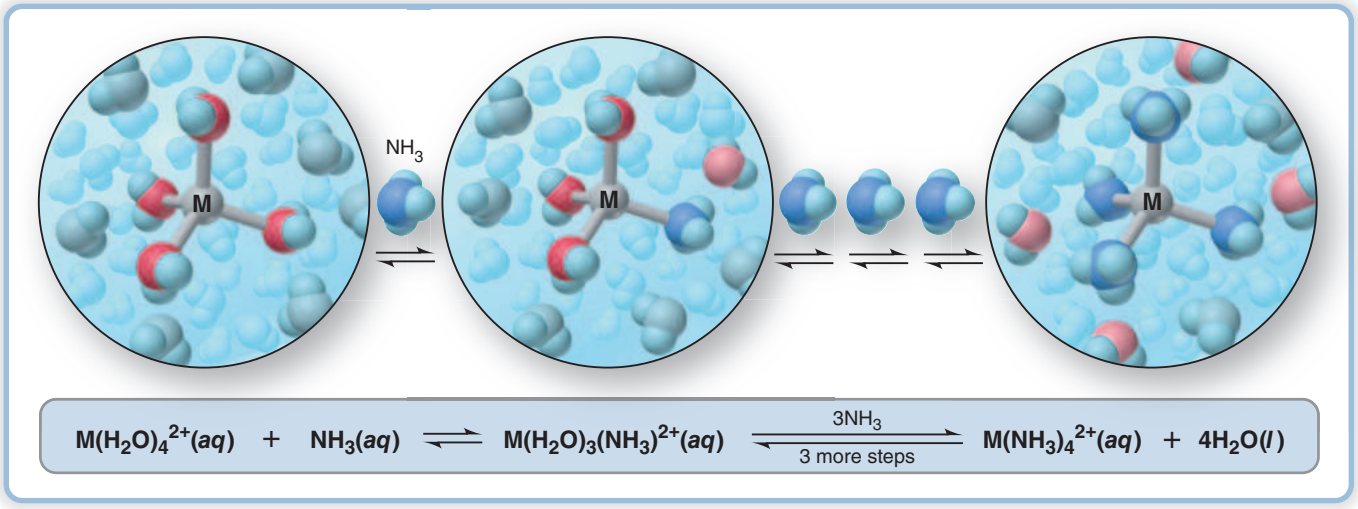

Figure 19.17 **The stepwise exchange of NH_3 for H_2O in $M(H_2O)_4^{2+}$.** The molecular views show the first exchange and the fully ammoniated ion.

electron pair). In the formation of $M(NH_3)_4^{2+}$, the K_f for each step is much larger than 1 because ammonia is a stronger Lewis base than water. Therefore, if we add excess ammonia to the $M(H_2O)_4^{2+}$ solution, nearly all the M^{2+} ions exist as $M(NH_3)_4^{2+}(aq)$.

Table 19.4 (and Appendix C) shows K_f values of some complex ions. Notice that they are all of the order 10^6 or greater, which means that these ions form readily from the hydrated ion. Because of this behavior, some uses of complex-ion formation are to retrieve a metal from its ore, eliminate a toxic or unwanted metal ion from a solution, or convert a metal ion to a different form, as Sample Problem 19.13 shows for the zinc ion.

Table 19.4 **Formation Constants (K_f) of Some Complex Ions at 25°C**

Complex Ion	K_f	Complex Ion	K_f
$Ag(CN)_2^-$	3.0×10^{20}	$Fe(CN)_6^{4-}$	3×10^{35}
$Ag(NH_3)_2^+$	1.7×10^{7}	$Fe(CN)_6^{3-}$	4.0×10^{43}
$Ag(S_2O_3)_2^{3-}$	4.7×10^{13}	$Hg(CN)_4^{2-}$	9.3×10^{38}
AlF_6^{3-}	4×10^{19}	$Ni(NH_3)_6^{2+}$	2.0×10^{8}
$Al(OH)_4^-$	3×10^{33}	$Pb(OH)_3^-$	8×10^{13}
$Be(OH)_4^{2-}$	4×10^{18}	$Sn(OH)_3^-$	3×10^{25}
CdI_4^{2-}	1×10^{6}	$Zn(CN)_4^{2-}$	4.2×10^{19}
$Co(OH)_4^{2-}$	5×10^{9}	$Zn(NH_3)_4^{2+}$	7.8×10^{8}
$Cr(OH)_4^-$	8.0×10^{29}	$Zn(OH)_4^{2-}$	3×10^{15}
$Cu(NH_3)_4^{2+}$	5.6×10^{11}		

SAMPLE PROBLEM 19.13 Calculating the Concentration of a Complex Ion

Problem An industrial chemist converts $Zn(H_2O)_4^{2+}$ to the more stable $Zn(NH_3)_4^{2+}$ ($K_f = 7.8\times10^8$) by mixing 50.0 L of 0.0020 *M* $Zn(H_2O)_4^{2+}$ and 25.0 L of 0.15 *M* NH_3. What is the $[Zn(H_2O)_4^{2+}]$ at equilibrium?

Plan We write the equation and the K_f expression and use a reaction table to calculate the equilibrium concentrations. To set up the table, we must first find $[Zn(H_2O)_4^{2+}]_{init}$ and $[NH_3]_{init}$. We are given the individual volumes and molar concentrations, so we find the number of moles and divide by the *total* volume because the solutions are mixed. With the large excess of NH_3 and the high K_f, we assume that almost all the

$Zn(H_2O)_4^{2+}$ is converted to $Zn(NH_3)_4^{2+}$. Because $[Zn(H_2O)_4^{2+}]$ at equilibrium is very small, we use x to represent it.

Solution Writing the equation and the K_f expression:

$$Zn(H_2O)_4^{2+}(aq) + 4NH_3(aq) \rightleftharpoons Zn(NH_3)_4^{2+}(aq) + 4H_2O(l)$$

$$K_f = \frac{[Zn(NH_3)_4^{2+}]}{[Zn(H_2O)_4^{2+}][NH_3]^4}$$

Finding the initial reactant concentrations:

$$[Zn(H_2O)_4^{2+}]_{init} = \frac{50.0\ L \times 0.0020\ M}{50.0\ L + 25.0\ L} = 1.3\times10^{-3}\ M$$

$$[NH_3]_{init} = \frac{25.0\ L \times 0.15\ M}{50.0\ L + 25.0\ L} = 5.0\times10^{-2}\ M$$

Setting up a reaction table: We assume that nearly all the $Zn(H_2O)_4^{2+}$ is converted to $Zn(NH_3)_4^{2+}$, so we set up the table with $x = [Zn(H_2O)_4^{2+}]$ at equilibrium. Because 4 mol of NH_3 is needed per mole of $Zn(H_2O)_4^{2+}$, the change in $[NH_3]$ is

$$[NH_3]_{reacted} \approx 4(1.3\times10^{-3}\ M) = 5.2\times10^{-3}\ M \quad \text{and} \quad [Zn(NH_3)_4^{2+}] \approx 1.3\times10^{-3}\ M$$

Concentration (*M*)	$Zn(H_2O)_4^{2+}(aq)$	+ $4NH_3(aq)$	$\rightleftharpoons$ $Zn(NH_3)_4^{2+}(aq)$	+ $4H_2O(l)$
Initial	1.3×10^{-3}	5.0×10^{-2}	0	—
Change	$\sim(-1.3\times10^{-3})$	$\sim(-5.2\times10^{-3})$	$\sim(+1.3\times10^{-3})$	—
Equilibrium	x	4.5×10^{-2}	1.3×10^{-3}	—

Solving for x, the $[Zn(H_2O)_4^{2+}]$ remaining at equilibrium:

$$K_f = \frac{[Zn(NH_3)_4^{2+}]}{[Zn(H_2O)_4^{2+}][NH_3]^4} = 7.8\times10^8 \approx \frac{1.3\times10^{-3}}{x(4.5\times10^{-2})^4}$$

$$x = [Zn(H_2O)_4^{2+}] \approx 4.1\times10^{-7}\ M$$

Check The K_f is large, so we expect the $[Zn(H_2O)_4^{2+}]$ remaining to be very low.

FOLLOW-UP PROBLEMS

19.13A Cyanide ion is toxic because it forms stable complex ions with the Fe^{3+} ion in certain proteins involved in cellular energy production. To study this effect, a biochemist mixes 25.5 mL of 3.1×10^{-2} *M* $Fe(H_2O)_6^{3+}$ with 35.0 mL of 1.5 *M* NaCN. What is the final $[Fe(H_2O)_6^{3+}]$? K_f of $Fe(CN)_6^{3-}$ is 4.0×10^{43}.

19.13B The production of aluminum from its ore utilizes a stable complex ion formed from the reaction of $Al(H_2O)_6^{3+}$ with F^-. When 2.4 g of $AlCl_3$ is dissolved in 250 mL of 0.560 *M* NaF, what is the final $[Al(H_2O)_6^{3+}]$? K_f of AlF_6^{3-} is 4×10^{19}.

SOME SIMILAR PROBLEMS 19.99, 19.100, 19.103, and 19.104

Complex Ions and the Solubility of Precipitates

In Section 19.3, you saw that H_3O^+ increases the solubility of a slightly soluble ionic compound if its anion is that of a weak acid. Similarly, *a ligand increases the solubility of a slightly soluble ionic compound if it forms a complex ion with the cation.* For example, iron(II) sulfide is very slightly soluble:

$$FeS(s) + H_2O(l) \rightleftharpoons Fe^{2+}(aq) + HS^-(aq) + OH^-(aq) \qquad K_{sp} = 8\times10^{-16}$$

When we add some 1.0 *M* NaCN, the CN^- ions act as ligands and react with the small amount of $Fe^{2+}(aq)$ to form the complex ion $Fe(CN)_6^{4-}$:

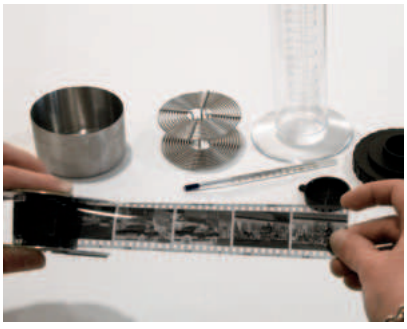
$$Fe^{2+}(aq) + 6CN^-(aq) \rightleftharpoons Fe(CN)_6^{4-}(aq) \qquad K_f = 3\times10^{35}$$

To see the effect of complex-ion formation on the solubility of FeS, we add the equations and, therefore, multiply their equilibrium constants:

$$FeS(s) + 6CN^-(aq) + H_2O(l) \rightleftharpoons Fe(CN)_6^{4-}(aq) + HS^-(aq) + OH^-(aq)$$

$$K_{overall} = K_{sp} \times K_f = (8\times10^{-16})(3\times10^{35}) = 2\times10^{20}$$

The overall dissociation of FeS into ions increased by more than a factor of 10^{35} in the presence of the ligand.



Developing an image in "hypo."

SAMPLE PROBLEM 19.14 Calculating the Effect of Complex-Ion Formation on Solubility

Problem In black-and-white film developing *(see photo)*, excess AgBr is removed from a film negative with "hypo," an aqueous solution of sodium thiosulfate ($Na_2S_2O_3$), which forms the complex ion $Ag(S_2O_3)_2^{3-}$. Calculate the solubility of AgBr in **(a)** H_2O; **(b)** 1.0 *M* hypo. K_f of $Ag(S_2O_3)_2^{3-}$ is 4.7×10^{13} and K_{sp} of AgBr is 5.0×10^{-13}.

Plan **(a)** After writing the equation and the ion-product expression, we use the given K_{sp} to solve for *S*, the molar solubility of AgBr. **(b)** In hypo, Ag^+ forms a complex ion with $S_2O_3^{2-}$, which shifts the equilibrium and dissolves more AgBr. We write the complex-ion equation and add it to the equation for dissolving AgBr to obtain the overall equation for dissolving AgBr in hypo. We multiply K_{sp} by K_f to find $K_{overall}$. To find the solubility of AgBr in hypo, we set up a reaction table, with $S = [Ag(S_2O_3)_2^{3-}]$, substitute into the expression for $K_{overall}$, and solve for *S*.

Solution **(a)** Solubility in water. Writing the equation for the saturated solution and the ion-product expression:

$$AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq) \qquad K_{sp} = [Ag^+][Br^-]$$

Solving for solubility (*S*) directly from the equation: We know that

$$S = [AgBr]_{dissolved} = [Ag^+] = [Br^-]$$

Thus, $$K_{sp} = [Ag^+][Br^-] = S^2 = 5.0\times10^{-13}$$

so $$S = 7.1\times10^{-7}\ M$$

(b) Solubility in 1.0 *M* hypo. Writing the overall equation:

$$AgBr(s) \rightleftharpoons \cancel{Ag^+(aq)} + Br^-(aq)$$
$$\cancel{Ag^+(aq)} + 2S_2O_3^{2-}(aq) \rightleftharpoons Ag(S_2O_3)_2^{3-}(aq)$$
$$AgBr(s) + 2S_2O_3^{2-}(aq) \rightleftharpoons Ag(S_2O_3)_2^{3-}(aq) + Br^-(aq)$$

Calculating $K_{overall}$:

$$K_{overall} = \frac{[Ag(S_2O_3)_2^{3-}][Br^-]}{[S_2O_3^{2-}]^2} = K_{sp} \times K_f = (5.0\times10^{-13})(4.7\times10^{13}) = 24$$

Setting up a reaction table, with $S = [AgBr]_{dissolved} = [Ag(S_2O_3)_2^{3-}]$:

Concentration (*M*)	$AgBr(s)$	+ $2S_2O_3^{2-}(aq)$	⇌ $Ag(S_2O_3)_2^{3-}(aq)$	+ $Br^-(aq)$
Initial	—	1.0	0	0
Change	—	$-2S$	$+S$	$+S$
Equilibrium	—	$1.0 - 2S$	S	S

Substituting the values into the expression for $K_{overall}$ and solving for *S*:

$$K_{overall} = \frac{[Ag(S_2O_3)_2^{3-}][Br^-]}{[S_2O_3^{2-}]^2} = \frac{S^2}{(1.0\ M - 2S)^2} = 24$$

Taking the square root of both sides gives

$$\frac{S}{1.0\ M - 2S} = \sqrt{24} = 4.9 \quad \text{so} \quad S = 4.9\ M - 9.8S \quad \text{and} \quad 10.8S = 4.9\ M$$

$$[Ag(S_2O_3)_2^{3-}] = S = 0.45\ M$$

Check **(a)** From the number of ions in the formula of AgBr, we know that $S = \sqrt{K_{sp}}$, so the order of magnitude seems right: $\sim\sqrt{10^{-14}} \approx 10^{-7}$. **(b)** The $K_{overall}$ seems correct: the exponents cancel, and $5 \times 5 = 25$. Most importantly, the answer makes sense because the photographic process requires the remaining AgBr to be washed off the film and the large $K_{overall}$ confirms that. We can check *S* by rounding and working backward to find $K_{overall}$: from the reaction table, we find that

$$[(S_2O_3)^{2-}] = 1.0\ M - 2S = 1.0\ M - 2(0.45\ M) = 1.0\ M - 0.90\ M = 0.1\ M$$

so $K_{overall} \approx (0.45)^2/(0.1)^2 = 20$, within rounding of the calculated value.

FOLLOW-UP PROBLEMS

19.14A How does the solubility of AgBr in 1.0 *M* NH_3 compare with its solubility in 1.0 *M* hypo, as calculated in the Sample Problem? K_f of $Ag(NH_3)_2^+$ is 1.7×10^7.

19.14B Calculate the solubility of $PbCl_2$ in 0.75 *M* NaOH. K_f of $Pb(OH)_3^-$ is 8×10^{13}, and K_{sp} of $PbCl_2$ is 1.7×10^{-5}.

SOME SIMILAR PROBLEMS 19.101 and 19.102

Complex Ions of Amphoteric Hydroxides

Many of the same metals that form amphoteric oxides (Chapter 8, p. 346) also form slightly soluble *amphoteric hydroxides.* These compounds dissolve very little in water, but they dissolve to a much greater extent in both acidic and basic solutions. Aluminum hydroxide is one of several examples:

$$Al(OH)_3(s) \rightleftharpoons Al^{3+}(aq) + 3OH^-(aq)$$

It is insoluble in water ($K_{sp} = 3\times10^{-34}$), but

- It dissolves in acid because H_3O^+ reacts with the OH^- anion [Sample Problem 19.9(b)],

  $$3H_3O^+(aq) + 3OH^-(aq) \longrightarrow 6H_2O(l)$$

  giving the overall equation

  $$Al(OH)_3(s) + 3H_3O^+(aq) \longrightarrow Al^{3+}(aq) + 6H_2O(l)$$

- It dissolves in base through the formation of a complex ion:

  $$Al(OH)_3(s) + OH^-(aq) \longrightarrow Al(OH)_4^-(aq)$$

Let's look more closely at this behavior. When we dissolve a soluble aluminum salt, such as $Al(NO_3)_3$, in water and then slowly add a strong base, a white precipitate first forms and then dissolves as more base is added. What reactions are occurring? The formula for the hydrated Al^{3+} ion is $Al(H_2O)_6^{3+}(aq)$. It acts as a weak polyprotic acid and reacts with added OH^- ions in a stepwise manner. In each step, one of the bound H_2O molecules loses a proton and becomes a bound OH^- ion, so the number of bound H_2O molecules is reduced by 1:

$$Al(H_2O)_6^{3+}(aq) + OH^-(aq) \rightleftharpoons Al(H_2O)_5OH^{2+}(aq) + H_2O(l)$$
$$Al(H_2O)_5OH^{2+}(aq) + OH^-(aq) \rightleftharpoons Al(H_2O)_4(OH)_2^+(aq) + H_2O(l)$$
$$Al(H_2O)_4(OH)_2^+(aq) + OH^-(aq) \rightleftharpoons Al(H_2O)_3(OH)_3(s) + H_2O(l)$$

After three protons have been removed from each $Al(H_2O)_6^{3+}$, the white precipitate has formed, which is the insoluble hydroxide $Al(H_2O)_3(OH)_3(s)$, often written more simply as $Al(OH)_3(s)$. Now you can see that the precipitate actually consists of the hydrated Al^{3+} ion with an H^+ removed from each of three bound H_2O molecules (Figure 19.18, *next page, center*). Addition of H_3O^+ protonates the OH^- ions and re-forms the hydrated Al^{3+} ion (Figure 19.18, *left*).

Further addition of OH^- removes a fourth H^+ and the precipitate dissolves as the soluble ion $Al(H_2O)_2(OH)_4^-(aq)$ forms (Figure 19.18, *right*), which we usually write with the formula $Al(OH)_4^-(aq)$:

$$Al(H_2O)_3(OH)_3(s) + OH^-(aq) \rightleftharpoons Al(H_2O)_2(OH)_4^-(aq) + H_2O(l)$$

In other words, this complex ion is not created by ligands substituting for bound water molecules but through an acid-base reaction in which added OH^- ions titrate bound water molecules.

Several other slightly soluble hydroxides, including those of cadmium, chromium(III), cobalt(III), lead(II), tin(II), and zinc, are amphoteric and exhibit similar reactions:

$$Zn(H_2O)_2(OH)_2(s) + OH^-(aq) \rightleftharpoons Zn(H_2O)(OH)_3^-(aq) + H_2O(l)$$

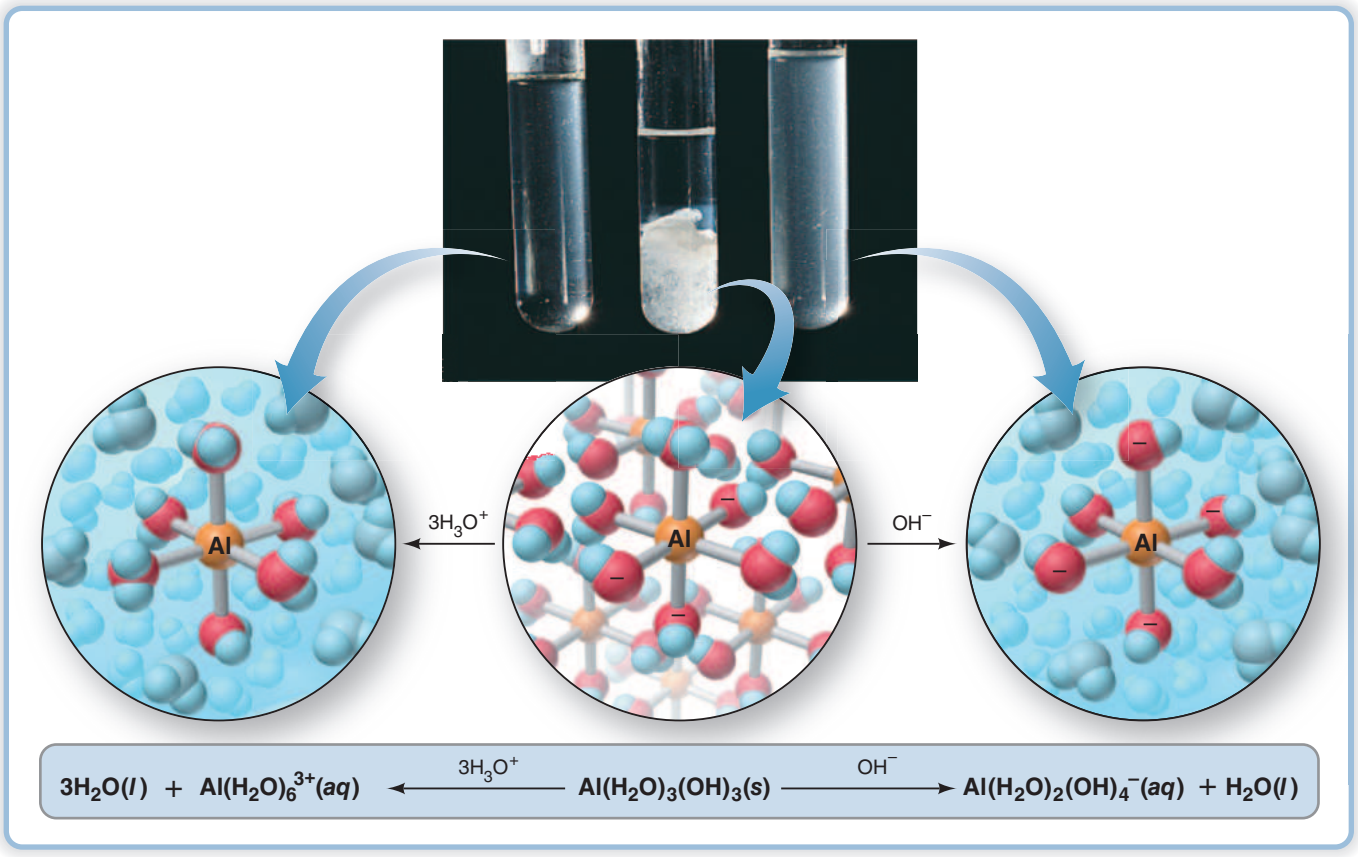


Figure 19.18 The amphoteric behavior of aluminum hydroxide. When solid $Al(OH)_3$ is treated with H_3O^+ *(left)* or with OH^- *(right)*, it dissolves as a result of the formation of soluble complex ions.

In contrast, the slightly soluble hydroxides of iron(II), iron(III), and calcium dissolve in acid, but do *not* dissolve in base, because the three remaining bound water molecules are not acidic enough to lose any of their protons:

$$Fe(H_2O)_3(OH)_3(s) + 3H_3O^+(aq) \longrightarrow Fe(H_2O)_6^{3+}(aq) + 3H_2O(l)$$
$$Fe(H_2O)_3(OH)_3(s) + OH^-(aq) \longrightarrow \text{no reaction}$$

This difference in solubility in base between $Al(OH)_3$ and $Fe(OH)_3$ is the key to an important separation step in the production of aluminum metal, so we'll consider it again in Section 22.4.

Summary of Section 19.4

- A complex ion consists of a central metal ion covalently bonded to two or more negatively charged or neutral ligands. Its formation is described by a formation constant, K_f.
- A hydrated metal ion is a complex ion with water molecules as ligands. Other ligands (stronger Lewis bases) can displace the water in a stepwise process. In most cases, the K_f value of each step is large, so the fully substituted complex ion forms almost completely in the presence of excess ligand.
- Adding a solution containing a ligand increases the solubility of an ionic precipitate if the cation forms a complex ion with the ligand.
- Amphoteric metal hydroxides dissolve in acid and base due to reactions that involve complex ions.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How the presence of a common ion suppresses a reaction that forms it (§19.1)
2. Why the concentrations of buffer components must be high to minimize the change in pH from addition of small amounts of H_3O^+ or OH^- (§19.1)
3. How buffer capacity depends on buffer concentration and on the pK_a of the acid component; why buffer range is within ± 1 pH unit of the pK_a (§19.1)
4. The nature of an acid-base indicator as a conjugate acid-base pair with differently colored acidic and basic forms (§19.2)
5. The distinction between equivalence point and end point in an acid-base titration (§19.2)
6. Why the shapes of strong acid–strong base, weak acid–strong base, and weak base–strong acid titration curves differ (§19.2)
7. How the pH at the equivalence point is determined by the species present; why the pH at the midpoint of the buffer region equals the pK_a of the acid (§19.2)
8. How the titration curve of a polyprotic acid has a buffer region and equivalence point for each ionizable proton (§19.2)
9. How a slightly soluble ionic compound reaches equilibrium in water, expressed by an equilibrium (solubility-product) constant, K_{sp} (§19.3)
10. Why incomplete dissociation of an ionic compound leads to approximate calculated values for K_{sp} and solubility (§19.3)
11. Why a common ion in a solution decreases the solubility of its compounds (§19.3)
12. How pH affects the solubility of a compound that contains a weak-acid anion (§19.3)
13. How precipitate formation depends on the relative values of Q_{sp} and K_{sp} (§19.3)
14. How selective precipitation and simultaneous equilibria are used to separate ions (§19.3)
15. How complex-ion formation is stepwise and expressed by an overall equilibrium (formation) constant, K_f (§19.4)
16. Why addition of a ligand increases the solubility of a compound whose metal ion forms a complex ion (§19.4)
17. How the aqueous chemistry of amphoteric hydroxides involves precipitation, complex-ion formation, and acid-base equilibria (§19.4)

Master These Skills

1. Using stoichiometry and equilibrium problem-solving techniques to calculate the effect of added H_3O^+ or OH^- on buffer pH (SP 19.1)
2. Using the Henderson-Hasselbalch equation to calculate buffer pH (§19.1)
3. Using molecular scenes to examine buffers (SP 19.2)
4. Choosing the components of a buffer that has a given pH and calculating their quantities (SP 19.3)
5. Calculating the pH at any point in an acid-base titration (§19.2 and SP 19.4)
6. Choosing an appropriate indicator based on the pH at various points in a titration (§19.2)
7. Writing K_{sp} expressions for slightly soluble ionic compounds (SP 19.5)
8. Calculating a K_{sp} value from solubility data (SP 19.6)
9. Calculating solubility from a K_{sp} value (SP 19.7)
10. Using K_{sp} values to compare solubilities for compounds with the same total number of ions (§19.3)
11. Calculating the decrease in solubility caused by the presence of a common ion (SP 19.8)
12. Predicting the effect of added H_3O^+ on solubility (SP 19.9)
13. Using ion concentrations to calculate Q_{sp} and compare it with K_{sp} to predict whether a precipitate forms (SPs 19.10, 19.11)
14. Comparing K_{sp} values in order to separate ions by selective precipitation (SP 19.12)
15. Calculating the concentration of metal ion remaining after addition of excess ligand forms a complex ion (SP 19.13)
16. Using an overall equilibrium constant ($K_{sp} \times K_f$) to calculate the effect of complex-ion formation on solubility (SP 19.14)

Key Terms

Page numbers appear in parentheses.

Section 19.1
acid-base buffer (827)
common-ion effect (828)
Henderson-Hasselbalch equation (832)
buffer capacity (833)
buffer range (833)

Section 19.2
acid-base titration curve (837)
equivalence point (839)
end point (839)

Section 19.3
solubility-product constant (K_{sp}) (846)
selective precipitation (856)

Section 19.4
complex ion (859)
ligand (859)
formation constant (K_f) (859)

Key Equations and Relationships

Page numbers appear in parentheses.

19.1 Finding the pH from known concentrations of a conjugate acid-base pair (Henderson-Hasselbalch equation) (832):

$$\text{pH} = \text{p}K_a + \log\left(\frac{[\text{base}]}{[\text{acid}]}\right)$$

19.2 Defining the equilibrium condition for a saturated solution of a slightly soluble compound, M_pX_q, composed of M^{n+} and X^{z-} ions (847):

$$Q_{sp} = [M^{n+}]^p[X^{z-}]^q = K_{sp}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

19.1A (a) Before addition:
Assuming x is small enough to be neglected,
$[HF] = 0.50\ M$ and $[F^-] = 0.45\ M$

$$[H_3O^+] = K_a \times \frac{[HF]}{[F^-]} \approx (6.8\times10^{-4})\left(\frac{0.50}{0.45}\right) = 7.6\times10^{-4}\ M$$

$$pH = 3.12$$

(b) After addition of 0.40 g of NaOH (0.010 mol of NaOH) to 1.0 L of buffer:
$[HF] = 0.49\ M$ and $[F^-] = 0.46\ M$

$$[H_3O^+] \approx (6.8\times10^{-4})\left(\frac{0.49}{0.46}\right) = 7.2\times10^{-4}\ M;\ pH = 3.14$$

19.1B (a) Before addition:

$$K_b \text{ of } (CH_3)_2NH = 10^{-pK_b} = 10^{-3.23} = 5.9\times10^{-4}$$

$$K_a \text{ of } (CH_3)_2NH_2^+ = \frac{K_w}{K_b \text{ of } (CH_3)_2NH} = \frac{1.0\times10^{-14}}{5.9\times10^{-4}} = 1.7\times10^{-11}$$

$[(CH_3)_2NH_2^+] = 0.25\ M$ and $[(CH_3)_2NH] = 0.30\ M$

$$[H_3O^+] = K_a \times \frac{[(CH_3)_2NH_2^+]}{[(CH_3)_2NH]} \approx (1.7\times10^{-11})\left(\frac{0.25\ M}{0.30\ M}\right)$$

$$= 1.4\times10^{-11}\ M$$

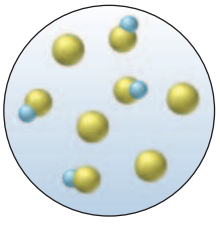
$$pH = 10.85$$

(b) After addition of 0.73 g of HCl (0.020 mol of HCl) to 1.0 L of buffer:
$[(CH_3)_2NH_2^+] = 0.27\ M$ and $[(CH_3)_2NH] = 0.28\ M$

$$[H_3O^+] \approx (1.7\times10^{-11})\left(\frac{0.27}{0.28}\right) = 1.6\times10^{-11}\ M;\ pH = 10.80$$

19.2A (a) Strong base would convert HB to B^-, thereby making the ratio closer to 1.

(b)



19.2B (a) $pH = pK_a + \log\left(\frac{[A^-]}{[HA]}\right)$, and sample 3 has

$[A^-]/[HA] = 6/3 = 2$; $\frac{[A^-]}{[HA]} > 1$ results in $pH > pK_a$.

(b) Added strong base reacts with the acid HA; sample 2 has the largest concentration of HA.
(c) pH of buffer $= pK_a \pm 1 = 4.2 \pm 1$, so the buffer range is 3.2–5.2; the acid-base pair HA/A^- is not suitable for preparing a buffer with a pH of 6.1.

19.3A $pK_a = -\log K_a = -\log(6.3\times10^{-5}) = 4.20$

$$pH = pK_a + \log\left(\frac{[C_6H_5COO^-]}{[C_6H_5COOH]}\right)$$

$$4.25 = 4.20 + \log\left(\frac{[C_6H_5COO^-]}{[C_6H_5COOH]}\right)$$

$$\left(\frac{[C_6H_5COO^-]}{[C_6H_5COOH]}\right) = 1.1$$

Mass (g) of C_6H_5COOH

$$= 5.0\text{ L soln} \times \frac{0.050\text{ mol } C_6H_5COO^-}{1\text{ L soln}} \times \frac{1.0\text{ mol } C_6H_5COOH}{1.1\text{ mol } C_6H_5COO^-} \times \frac{122.12\text{ g } C_6H_5COOH}{1\text{ mol } C_6H_5COOH}$$

$$= 28\text{ g } C_6H_5COOH$$

Dissolve 28 g of C_6H_5COOH into about 4.8 L of 0.050 M C_6H_5COONa and add more 0.050 M C_6H_5COONa for a total volume of 5.0 L. Add strong acid or base dropwise as needed.

19.3B $K_a \text{ of } NH_4^+ = \frac{K_w}{K_b \text{ of } NH_3} = \frac{1.0\times10^{-14}}{1.76\times10^{-5}} = 5.68\times10^{-10}$

$$pK_a = -\log(5.68\times10^{-10}) = 9.25$$

$$pH = pK_a + \log\left(\frac{[NH_3]}{[NH_4^+]}\right)$$

$$9.18 = 9.25 + \log\left(\frac{[NH_3]}{[NH_4^+]}\right)$$

$$\left(\frac{[NH_3]}{[NH_4^+]}\right) = 0.85$$

$$\text{Mass of } NH_4Cl = 0.75\text{ L soln} \times \frac{0.15\text{ mol } NH_3}{1\text{ L soln}} \times \frac{1\text{ mol } NH_4Cl}{0.85\text{ mol } NH_3} \times \frac{53.49\text{ mol } NH_4Cl}{1\text{ mol } NH_4Cl}$$

$$= 7.1\text{ g } NH_4Cl$$

19.4A (a) $[H_3O^+] \approx \sqrt{(2.3\times10^{-9})(0.2000)} = 2.1\times10^{-5}\ M$

$$pH = 4.68$$

(b) $[H_3O^+] = K_a \times \frac{[HBrO]}{[BrO^-]} = (2.3\times10^{-9})(1) = 2.3\times10^{-9}\ M$

$$pH = 8.64$$

(c) $[BrO^-] = \frac{\text{amount (mol) of } BrO^-}{\text{total volume (L)}} = \frac{0.004000\text{ mol}}{0.06000\text{ L}}$

$$= 0.06667\ M$$

$$K_b \text{ of } BrO^- = \frac{K_w}{K_a \text{ of HBrO}} = 4.3\times10^{-6}$$

$$[H_3O^+] = \frac{K_w}{\sqrt{K_b \times [BrO^-]}} \approx \frac{1.0\times10^{-14}}{\sqrt{(4.3\times10^{-6})(0.06667)}} = 1.9\times10^{-11}\ M$$

$$pH = 10.72$$

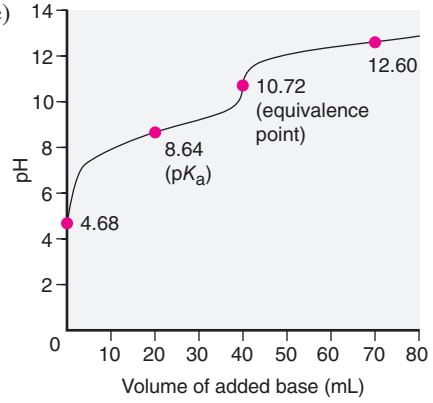
(d) Amount (mol) of OH^- added $= 0.008000$ mol
Volume (L) of OH^- soln $= 0.08000$ L

$$[OH^-] = \frac{\text{amount (mol) of } OH^- \text{ unreacted}}{\text{total volume (L)}} = \frac{0.008000\text{ mol} - 0.004000\text{ mol}}{(0.02000 + 0.08000)\text{ L}} = 0.04000\ M$$

$$[H_3O^+] = \frac{K_w}{[OH^-]} = 2.5\times10^{-13}$$

$$pH = 12.60$$

(e)



19.4B (a) $[H_3O^+] \approx \sqrt{(6.3\times10^{-5})(0.1000)} = 2.5\times10^{-3}\,M$

$$\text{pH} = 2.60$$

(b) $$[H_3O^+] = K_a \times \frac{[C_6H_5COOH]}{[C_6H_5COO^-]}$$

$$= (6.3\times10^{-5}) \times \frac{0.001200\text{ mol}}{0.001800\text{ mol}}$$

$$= 4.2\times10^{-5}\,M$$

$$\text{pH} = 4.38$$

(c) $$[C_6H_5COO^-] = \frac{\text{amount (mol) of } C_6H_5COO^-}{\text{total volume (L)}}$$

$$= \frac{0.003000\text{ mol}}{0.05000\text{ L}} = 0.06000\,M$$

$$K_b \text{ of } C_6H_5COO^- = \frac{K_w}{K_a \text{ of } C_6H_5COOH} = 1.6\times10^{-10}$$

$$[H_3O^+] = \frac{K_w}{\sqrt{K_b \times [C_6H_5COO^-]}}$$

$$\approx \frac{1.0\times10^{-14}}{\sqrt{(1.6\times10^{-10})(0.06000)}} = 3.2\times10^{-9}\,M$$

$$\text{pH} = 8.49$$

(d) $$[OH^-] = \frac{\text{amount (mol) of } OH^- \text{ unreacted}}{\text{total volume (L)}}$$

$$= \frac{0.003300\text{ mol} - 0.003000\text{ mol}}{(0.03000 + 0.02200)\text{ L}} = 0.00577\,M$$

$$[H_3O^+] = \frac{K_w}{[OH^-]} = 1.73\times10^{-12}\,M$$

$$\text{pH} = 11.76 \text{ (pH is shown to two decimal places)}$$

19.5A (a) $K_{sp} = [Ca^{2+}][SO_4^{2-}]$

(b) $K_{sp} = [Cr^{3+}]^2[CO_3^{2-}]^3$

(c) $K_{sp} = [Mg^{2+}][OH^-]^2$

(d) $K_{sp} = [As^{3+}]^2[HS^-]^3[OH^-]^3$

19.5B (a) $PbCrO_4$, lead(II) chromate; (b) FeS, iron(II) sulfide; (c) SrF_2, strontium fluoride; (d) $Cu_3(PO_4)_2$, copper(II) phosphate

19.6A $$[CaF_2] = \frac{1.5\times10^{-4}\text{ g } CaF_2}{10.0\text{ mL soln}} \times \frac{1000\text{ mL}}{1\text{ L}} \times \frac{1\text{ mol } CaF_2}{78.08\text{ g } CaF_2}$$

$$= 1.9\times10^{-4}\,M$$

$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2F^-(aq)$

$[Ca^{2+}] = 1.9\times10^{-4}\,M$ and $[F^-] = 3.8\times10^{-4}\,M$

$K_{sp} = [Ca^{2+}][F^-]^2 = (1.9\times10^{-4})(3.8\times10^{-4})^2 = 2.7\times10^{-11}$

19.6B $$[Ag_3PO_4] = \frac{3.2\times10^{-4}\text{ g } Ag_3PO_4}{50.\text{ mL soln}} \times \frac{1000\text{ mL}}{1\text{ L}} \times \frac{1\text{ mol } Ag_3PO_4}{418.7\text{ g } Ag_3PO_4}$$

$$= 1.5\times10^{-5}\,M$$

$Ag_3PO_4(s) \rightleftharpoons 3Ag^+(aq) + PO_4^{3-}(aq)$

$[Ag^+] = 4.5\times10^{-5}\,M$ and $[PO_4^{3-}] = 1.5\times10^{-5}\,M$

$K_{sp} = [Ag^+]^3[PO_4^{3-}] = (4.5\times10^{-5})^3(1.5\times10^{-5}) = 1.4\times10^{-18}$

$S = 1.0\times10^{-5}\,M$

(b) In 0.10 M Na_2SO_4: $[SO_4^{2-}] = 0.10\,M$;

$K_{sp} = 1.1\times10^{-10} \approx S \times 0.10$; $S = 1.1\times10^{-9}\,M$

S decreases in presence of the common ion SO_4^{2-}.

19.8B (a) In water: $K_{sp} = [Ca^{2+}][F^-]^2 = 4S^3 = 3.2\times10^{-11}$

$S = 2.0\times10^{-4}\,M$

(b) In 0.20 M $CaCl_2$: $[Ca^{2+}] = 0.20\,M$;

$K_{sp} = 3.2\times10^{-11} \approx 0.20 \times (2S)^2$; $S = 6.3\times10^{-6}\,M$

(c) In 0.20 M NiF_2: $[F^-] = 0.40\,M$;

$K_{sp} = 3.2\times10^{-11} \approx S \times (0.40)^2$; $S = 2.0\times10^{-10}\,M$

19.9A (a) Increases solubility.

$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2F^-(aq)$

$F^-(aq) + H_3O^+(aq) \longrightarrow HF(aq) + H_2O(l)$

(b) Increases solubility.

$ZnS(s) + H_2O(l) \rightleftharpoons Zn^{2+}(aq) + HS^-(aq) + OH^-(aq)$

$HS^-(aq) + H_3O^+(aq) \longrightarrow H_2S(aq) + H_2O(l)$

$OH^-(aq) + H_3O^+(aq) \longrightarrow 2H_2O(l)$

(c) No effect. $I^-(aq)$ is the conjugate base of strong acid HI.

19.9B (a) Increases solubility.

$AgCN(s) \rightleftharpoons Ag^+(aq) + CN^-(aq)$

$CN^-(aq) + H_3O^+(aq) \longrightarrow HCN(aq) + H_2O(l)$

(b) No effect. $Cl^-(aq)$ is the conjugate base of strong acid HCl.

(c) Increases solubility.

$Mg_3(PO_4)_2(s) \rightleftharpoons 3Mg^{2+}(aq) + 2PO_4^{3-}(aq)$

$PO_4^{3-}(aq) + H_3O^+(aq) \longrightarrow HPO_4^{2-}(aq) + H_2O(l)$

$HPO_4^{2-}(aq) + H_3O^+(aq) \longrightarrow H_2PO_4^-(aq) + H_2O(l)$

$H_2PO_4^-(aq) + H_3O^+(aq) \longrightarrow H_3PO_4(aq) + H_2O(l)$

19.10A $Ca_3(PO_4)_2(s) \rightleftharpoons 3Ca^{2+}(aq) + 2PO_4^{3-}(aq)$

$Q_{sp} = [Ca^{2+}]^3[PO_4^{3-}]^2 = (1.0\times10^{-9})^5 = 1.0\times10^{-45}$

$Q_{sp} < K_{sp}$, so $Ca_3(PO_4)_2$ will not precipitate.

19.10B $PbS(s) \rightleftharpoons Pb^{2+}(aq) + S^{2-}(aq)$

$$\text{Amount (mol) of } Pb^{2+} = 25\text{ L} \times \frac{0.015\text{ g } Pb^{2+}}{1.0\text{ L}} \times \frac{1\text{ mol } Pb^{2+}}{207.2\text{ g } Pb^{2+}}$$

$$= 1.8\times10^{-3}\text{ mol}$$

$$[Pb^{2+}] = \frac{1.8\times10^{-3}\text{ mol } Pb^{2+}}{25\text{ L} + 0.500\text{ L}} = 7.1\times10^{-5}\,M$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

Amount (mol) of $S^{2-} = 0.10\ M\ S^{2-} \times 0.500\ L = 0.050$ mol

$$[S^{2-}] = \frac{0.050\ \text{mol}}{25\ L + 0.500\ L} = 2.0\times10^{-3}\ M$$

$Q_{sp} = [Pb^{2+}][S^{2-}] = [7.1\times10^{-5}][2.0\times10^{-3}] = 1.4\times10^{-7}$

$Q_{sp} > K_{sp}$ (which is 3×10^{-25}), so PbS will precipitate.

19.11A (a) Scene 3 has the same relative numbers of ions as in the formula.
(b) Based on $Ni(OH)_2(s) \rightleftharpoons Ni^{2+}(aq) + 2OH^-(aq)$ and $Q_{sp} = [Ni^{2+}][OH^-]^2$, the ion products are $(3)(4)^2 = 48$ in scene 1; $(4)(2)^2 = 16$ in scene 2; and $(2)(4)^2 = 32 = K_{sp}$ in scene 3. Since Q_{sp} for scene 1 exceeds K_{sp} for scene 3, more solid forms.
(c) Addition of acid will decrease the mass of $Ni(OH)_2(s)$ by reacting with OH^-, thereby causing more solid to dissolve; addition of base will increase the mass of $Ni(OH)_2(s)$ due to the common-ion effect.

19.11B (a) Scene 1 has the same relative numbers of ions as in the formula.
(b) Based on $PbCl_2(s) \rightleftharpoons Pb^{2+}(aq) + 2Cl^-(aq)$ and $Q_{sp} = [Pb^{2+}][Cl^-]^2$, the ion products are $(3)(6)^2 = 108 = K_{sp}$ in scene 1; $(4)(5)^2 = 100$ in scene 2; and $(5)(5)^2 = 125$ in scene 3. Since Q_{sp} for scene 3 exceeds K_{sp} for scene 1, more solid forms.
(c) Addition of $HCl(aq)$ will increase the mass of $PbCl_2$ due to the common-ion effect (Cl^- is the common ion).

19.12A Both are 1/1 salts, and K_{sp} values show that $CaSO_4$ is more soluble:

$$[SO_4^{2-}] = \frac{K_{sp}}{[Ca^{2+}]} = \frac{2.4\times10^{-5}}{0.025} = 9.6\times10^{-4}\ M$$

19.12B Both are 1/2 salts, and K_{sp} values show that BaF_2 is more soluble:

$$[F^-] = \sqrt{\frac{K_{sp}}{[Ba^{2+}]}} = \sqrt{\frac{1.5\times10^{-6}}{0.020\ M}} = 8.7\times10^{-3}\ M$$

19.13A $[Fe(H_2O)_6^{3+}]_{init} = \dfrac{(0.0255\ L)(3.1\times10^{-2}\ M)}{0.0255\ L + 0.0350\ L} = 1.3\times10^{-2}\ M$

Similarly, $[CN^-]_{init} = 0.87\ M$. From the reaction table,

$$K_f = \frac{[Fe(CN)_6^{3-}]}{[Fe(H_2O)_6^{3+}][CN^-]^6} = 4.0\times10^{43} \approx \frac{1.3\times10^{-2}}{x(0.79)^6}$$

$x = [Fe(H_2O)_6^{3+}] \approx 1.3\times10^{-45}\ M$

19.13B $[Al(H_2O)_6^{3+}]_{init} = \dfrac{2.4\ \text{g}\ AlCl_3 \times \dfrac{1\ \text{mol}\ AlCl_3}{133.33\ \text{g}\ AlCl_3}}{0.250\ L} = 0.072\ M$

$[F^-]_{init} = 0.560\ M$

From the reaction table,

$$K_f = \frac{[AlF_6^{3-}]}{[Al(H_2O)_6^{3+}][F^-]^6} = 4\times10^{19} \approx \frac{0.072}{x(0.128)^6}$$

$x = [Al(H_2O)_6^{3+}] \approx 4\times10^{-16}\ M$

19.14A $AgBr(s) + 2NH_3(aq) \rightleftharpoons Ag(NH_3)_2^+(aq) + Br^-(aq)$

$K_{overall} = K_{sp}$ of AgBr $\times$ K_f of $Ag(NH_3)_2^+$
$= 8.5\times10^{-6}$

From the reaction table, $\dfrac{S}{1.0 - 2S} = \sqrt{8.5\times10^{-6}} = 2.9\times10^{-3}$

$S = [Ag(NH_3)_2^+] = 2.9\times10^{-3}\ M$

Solubility is greater in 1.0 M hypo than in 1.0 M NH_3.

19.14B $PbCl_2(s) + 3OH^-(aq) \rightleftharpoons Pb(OH)_3^-(aq) + 2Cl^-(aq)$

$K_{overall} = K_{sp} \times K_f = 1\times10^9$

From the reaction table, $\dfrac{\sqrt[3]{4}\,S}{0.75 - 3S} = \sqrt[3]{1\times10^9}$

$S = [Pb(OH)_3^-] = 0.25\ M$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Note: Unless stated otherwise, all of the problems for this chapter refer to aqueous solutions at 298 K (25°C).

Equilibria of Acid-Base Buffers

(Sample Problems 19.1 to 19.3)

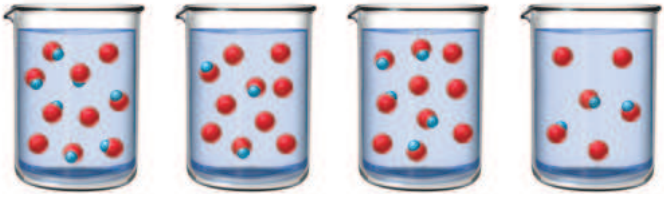
Concept Review Questions

19.1 What is the purpose of an acid-base buffer?

19.2 How do the acid and base components of a buffer function? Why are they often a conjugate acid-base pair of a weak acid?

19.3 What is the common-ion effect? How is it related to Le Châtelier's principle? Explain with equations that include HF and NaF.

19.4 The scenes below depict solutions of the same HA/A^- buffer (with other ions and water molecules omitted for clarity). (a) Which solution has the greatest buffer capacity? (b) Explain how the pH ranges of the buffers compare. (c) Which solution can react with the largest amount of added strong acid?



19.5 What is the difference between buffers with high and low capacities? Will adding 0.01 mol of HCl produce a greater pH change in a buffer with a high or a low capacity? Explain.

19.6 Which of these factors influence buffer capacity? How?
(a) Conjugate acid-base pair
(b) pH of the buffer

(c) Concentration of buffer components
(d) Buffer range
(e) pK_a of the acid component

19.7 What is the relationship between the buffer range and the buffer-component concentration ratio?

19.8 A chemist needs a pH 3.5 buffer. Should she use NaOH with formic acid ($K_a = 1.8\times10^{-4}$) or with acetic acid ($K_a = 1.8\times10^{-5}$)? Why? What is the disadvantage of choosing the other acid? What is the role of the NaOH?

19.9 State and explain the relative change in the pH and in the buffer-component concentration ratio, [NaA]/[HA], for each of the following additions:
(a) Add 0.1 *M* NaOH to the buffer
(b) Add 0.1 *M* HCl to the buffer
(c) Dissolve pure NaA in the buffer
(d) Dissolve pure HA in the buffer

19.10 Does the pH increase or decrease, and does it do so to a large or small extent, with each of the following additions?
(a) 5 drops of 0.1 *M* NaOH to 100 mL of 0.5 *M* acetate buffer
(b) 5 drops of 0.1 *M* HCl to 100 mL of 0.5 *M* acetate buffer
(c) 5 drops of 0.1 *M* NaOH to 100 mL of 0.5 *M* HCl
(d) 5 drops of 0.1 *M* NaOH to distilled water

Skill-Building Exercises (grouped in similar pairs)

19.11 What are the $[H_3O^+]$ and the pH of a propanoic acid–propanoate buffer that consists of 0.35 *M* CH_3CH_2COONa and 0.15 *M* CH_3CH_2COOH (K_a of propanoic acid $= 1.3\times10^{-5}$)?

19.12 What are the $[H_3O^+]$ and the pH of a benzoic acid–benzoate buffer that consists of 0.33 *M* C_6H_5COOH and 0.28 *M* C_6H_5COONa (K_a of benzoic acid $= 6.3\times10^{-5}$)?

19.13 What are the $[H_3O^+]$ and the pH of a buffer that consists of 0.55 *M* HNO_2 and 0.75 *M* KNO_2 (K_a of $HNO_2 = 7.1\times10^{-4}$)?

19.14 What are the $[H_3O^+]$ and the pH of a buffer that consists of 0.20 *M* HF and 0.25 *M* KF (K_a of $HF = 6.8\times10^{-4}$)?

19.15 Find the pH of a buffer that consists of 0.45 *M* HCOOH and 0.63 *M* HCOONa (pK_a of HCOOH = 3.74).

19.16 Find the pH of a buffer that consists of 0.95 *M* HBrO and 0.68 *M* KBrO (pK_a of HBrO = 8.64).

19.17 Find the pH of a buffer that consists of 1.3 *M* sodium phenolate (C_6H_5ONa) and 1.2 *M* phenol (C_6H_5OH) (pK_a of phenol = 10.00).

19.18 Find the pH of a buffer that consists of 0.12 *M* boric acid (H_3BO_3) and 0.82 *M* sodium borate (NaH_2BO_3) (pK_a of boric acid = 9.24).

19.19 Find the pH of a buffer that consists of 0.25 *M* NH_3 and 0.15 *M* NH_4Cl (pK_b of NH_3 = 4.75).

19.20 Find the pH of a buffer that consists of 0.50 *M* methylamine (CH_3NH_2) and 0.60 *M* CH_3NH_3Cl (pK_b of CH_3NH_2 = 3.35).

19.21 A buffer consists of 0.22 *M* $KHCO_3$ and 0.37 *M* K_2CO_3. Carbonic acid is a diprotic acid with $K_{a1} = 4.5\times10^{-7}$ and $K_{a2} = 4.7\times10^{-11}$. (a) Which K_a value is more important to this buffer? (b) What is the buffer pH?

19.22 A buffer consists of 0.50 *M* NaH_2PO_4 and 0.40 *M* Na_2HPO_4. Phosphoric acid is a triprotic acid ($K_{a1} = 7.2\times10^{-3}$, $K_{a2} = 6.3\times10^{-8}$, and $K_{a3} = 4.2\times10^{-13}$). (a) Which K_a value is most important to this buffer? (b) What is the buffer pH?

19.23 What is the component concentration ratio, $[Pr^-]/[HPr]$, of a buffer that has a pH of 5.44 (K_a of $HPr = 1.3\times10^{-5}$)?

19.24 What is the component concentration ratio, $[NO_2^-]/[HNO_2]$, of a buffer that has a pH of 2.95 (K_a of $HNO_2 = 7.1\times10^{-4}$)?

19.25 What is the component concentration ratio, $[BrO^-]/[HBrO]$, of a buffer that has a pH of 7.95 (K_a of $HBrO = 2.3\times10^{-9}$)?

19.26 What is the component concentration ratio, $[CH_3COO^-]/[CH_3COOH]$, of a buffer that has a pH of 4.39 (K_a of $CH_3COOH = 1.8\times10^{-5}$)?

19.27 A buffer containing 0.2000 *M* of acid, HA, and 0.1500 *M* of its conjugate base, A^-, has a pH of 3.35. What is the pH after 0.0015 mol of NaOH is added to 0.5000 L of this solution?

19.28 A buffer that contains 0.40 *M* of a base, B, and 0.25 *M* of its conjugate acid, BH^+, has a pH of 8.88. What is the pH after 0.0020 mol of HCl is added to 0.25 L of this solution?

19.29 A buffer that contains 0.110 *M* HY and 0.220 *M* Y^- has a pH of 8.77. What is the pH after 0.0015 mol of $Ba(OH)_2$ is added to 0.350 L of this solution?

19.30 A buffer that contains 1.05 *M* B and 0.750 *M* BH^+ has a pH of 9.50. What is the pH after 0.0050 mol of HCl is added to 0.500 L of this solution?

19.31 A buffer is prepared by mixing 204 mL of 0.452 *M* HCl and 0.500 L of 0.400 *M* sodium acetate. (See Appendix C.) (a) What is the pH? (b) How many grams of KOH must be added to 0.500 L of the buffer to change the pH by 0.15 units?

19.32 A buffer is prepared by mixing 50.0 mL of 0.050 *M* sodium bicarbonate and 10.7 mL of 0.10 *M* NaOH. (See Appendix C.) (a) What is the pH? (b) How many grams of HCl must be added to 25.0 mL of the buffer to change the pH by 0.07 units?

19.33 Choose specific acid-base conjugate pairs to make the following buffers: (a) pH ≈ 4.5; (b) pH ≈ 7.0. (See Appendix C.)

19.34 Choose specific acid-base conjugate pairs to make the following buffers: (a) $[H_3O^+] \approx 1\times10^{-9}$ *M*; (b) $[OH^-] \approx 3\times10^{-5}$ *M*. (See Appendix C.)

19.35 Choose specific acid-base conjugate pairs to make the following buffers: (a) pH ≈ 3.5; (b) pH ≈ 5.5. (See Appendix C.)

19.36 Choose specific acid-base conjugate pairs to make the following buffers: (a) $[OH^-] \approx 1\times10^{-6}$ *M*; (b) $[H_3O^+] \approx 4\times10^{-4}$ *M*. (See Appendix C.)

Problems in Context

19.37 An industrial chemist studying bleaching and sterilizing prepares several hypochlorite buffers. Find the pH of (a) 0.100 *M* HClO and 0.100 *M* NaClO; (b) 0.100 *M* HClO and 0.150 *M* NaClO; (c) 0.150 *M* HClO and 0.100 *M* NaClO; (d) 1.0 L of the solution in part (a) after 0.0050 mol of NaOH has been added.

19.38 Oxoanions of phosphorus are buffer components in blood. For a KH_2PO_4/Na_2HPO_4 solution with pH = 7.40 (pH of normal arterial blood), what is the buffer-component concentration ratio?

Acid-Base Titration Curves

(Sample Problem 19.4)

Concept Review Questions

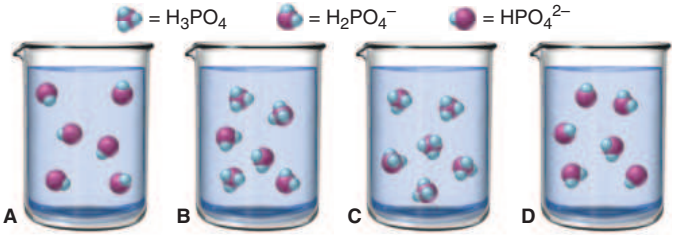
19.39 How can you estimate the pH range of an indicator's color change? Why do some indicators have two separate pH ranges?

19.40 Why does the color change of an indicator take place over a range of about 2 pH units?

19.41 Why doesn't the addition of an acid-base indicator affect the pH of the test solution?

19.42 What is the difference between the end point of a titration and the equivalence point? Is the equivalence point always reached first? Explain.

19.43 The scenes below depict the relative concentrations of H_3PO_4, $H_2PO_4^-$, and HPO_4^{2-} during a titration with aqueous NaOH, but they are out of order. (Phosphate groups are purple, hydrogens are blue, and Na^+ ions and water molecules are not shown.) (a) List the scenes in the correct order. (b) What is the pH in the correctly ordered second scene (see Appendix C)? (c) If it requires 10.00 mL of the NaOH solution to reach this scene, how much more is needed to reach the last scene?



19.44 Explain how *strong acid*–strong base, *weak acid*–strong base, and *weak base*–strong acid titrations using the same concentrations differ in terms of (a) the initial pH and (b) the pH at the equivalence point. (The component in italics is in the flask.)

19.45 What species are in the buffer region of a weak acid–strong base titration? How are they different from the species at the equivalence point? How are they different from the species in the buffer region of a weak base–strong acid titration?

19.46 Why is the center of the buffer region of a weak acid–strong base titration significant?

19.47 How does the titration curve of a monoprotic acid differ from that of a diprotic acid?

Skill-Building Exercises (grouped in similar pairs)

19.48 The indicator cresol red has $K_a = 3.5\times10^{-9}$. Over what approximate pH range does it change color?

19.49 The indicator ethyl red has $K_a = 3.8\times10^{-6}$. Over what approximate pH range does it change color?

19.50 Use Figure 19.6 to find an indicator for these titrations:
(a) 0.10 *M* HCl with 0.10 *M* NaOH
(b) 0.10 *M* HCOOH (Appendix C) with 0.10 *M* NaOH

19.51 Use Figure 19.6 to find an indicator for these titrations:
(a) 0.10 *M* CH_3NH_2 (Appendix C) with 0.10 *M* HCl
(b) 0.50 *M* HI with 0.10 *M* KOH

19.52 Use Figure 19.6 to find an indicator for these titrations:
(a) 0.5 *M* $(CH_3)_2NH$ (Appendix C) with 0.5 *M* HBr
(b) 0.2 *M* KOH with 0.2 *M* HNO_3

19.53 Use Figure 19.6 to find an indicator for these titrations:
(a) 0.25 *M* C_6H_5COOH (Appendix C) with 0.25 *M* KOH
(b) 0.50 *M* NH_4Cl (Appendix C) with 0.50 *M* NaOH

19.54 Calculate the pH during the titration of 40.00 mL of 0.1000 *M* HCl with 0.1000 *M* NaOH solution after the following additions of base:
(a) 0 mL (b) 25.00 mL (c) 39.00 mL (d) 39.90 mL
(e) 40.00 mL (f) 40.10 mL (g) 50.00 mL

19.55 Calculate the pH during the titration of 30.00 mL of 0.1000 *M* KOH with 0.1000 *M* HBr solution after the following additions of acid:
(a) 0 mL (b) 15.00 mL (c) 29.00 mL (d) 29.90 mL
(e) 30.00 mL (f) 30.10 mL (g) 40.00 mL

19.56 Find the pH during the titration of 20.00 mL of 0.1000 *M* butanoic acid, $CH_3CH_2CH_2COOH$ ($K_a = 1.54\times10^{-5}$), with 0.1000 *M* NaOH solution after the following additions of titrant:
(a) 0 mL (b) 10.00 mL (c) 15.00 mL (d) 19.00 mL
(e) 19.95 mL (f) 20.00 mL (g) 20.05 mL (h) 25.00 mL

19.57 Find the pH during the titration of 20.00 mL of 0.1000 *M* triethylamine, $(CH_3CH_2)_3N$ ($K_b = 5.2\times10^{-4}$), with 0.1000 *M* HCl solution after the following additions of titrant:
(a) 0 mL (b) 10.00 mL (c) 15.00 mL (d) 19.00 mL
(e) 19.95 mL (f) 20.00 mL (g) 20.05 mL (h) 25.00 mL

19.58 Find the pH of the equivalence point(s) and the volume (mL) of 0.0372 *M* NaOH needed to reach the point(s) in titrations of
(a) 42.2 mL of 0.0520 *M* CH_3COOH
(b) 28.9 mL of 0.0850 *M* H_2SO_3 (two equivalence points)

19.59 Find the pH of the equivalence point(s) and the volume (mL) of 0.0588 *M* KOH needed to reach the point(s) in titrations of
(a) 23.4 mL of 0.0390 *M* HNO_2
(b) 17.3 mL of 0.130 *M* H_2CO_3 (two equivalence points)

19.60 Find the pH of the equivalence point(s) and the volume (mL) of 0.125 *M* HCl needed to reach the point(s) in titrations of
(a) 65.5 mL of 0.234 *M* NH_3
(b) 21.8 mL of 1.11 *M* CH_3NH_2

19.61 Find the pH of the equivalence point(s) and the volume (mL) of 0.447 *M* HNO_3 needed to reach the point(s) in titrations of
(a) 2.65 L of 0.0750 *M* pyridine (C_5H_5N)
(b) 0.188 L of 0.250 *M* ethylenediamine ($H_2NCH_2CH_2NH_2$)

Equilibria of Slightly Soluble Ionic Compounds

(Sample Problems 19.5 to 19.12)

Concept Review Questions

19.62 The molar solubility (S) of M_2X is 5×10^{-5} *M*. Find S of each ion. How do you set up the calculation to find K_{sp}? What assumption must you make about the dissociation of M_2X into ions? Why is the calculated K_{sp} higher than the actual value?

19.63 Why does pH affect the solubility of BaF_2 but not of $BaCl_2$?

19.64 A list of K_{sp} values like that in Appendix C can be used to compare the solubility of silver chloride directly with that of silver bromide but not with that of silver chromate. Explain.

19.65 In a gaseous equilibrium, the reverse reaction occurs when $Q_c > K_c$. What occurs in aqueous solution when $Q_{sp} > K_{sp}$?

Skill-Building Exercises (grouped in similar pairs)

19.66 Write the ion-product expressions for (a) silver carbonate; (b) barium fluoride; (c) copper(II) sulfide.

19.67 Write the ion-product expressions for (a) iron(III) hydroxide; (b) barium phosphate; (c) tin(II) sulfide.

19.68 Write the ion-product expressions for (a) calcium chromate; (b) silver cyanide; (c) nickel(II) sulfide.

19.69 Write the ion-product expressions for (a) lead(II) iodide; (b) strontium sulfate; (c) cadmium sulfide.

19.70 The solubility of silver carbonate is 0.032 *M* at 20°C. Calculate its K_{sp}.

19.71 The solubility of zinc oxalate is 7.9×10^{-3} *M* at 18°C. Calculate its K_{sp}.

19.72 The solubility of silver dichromate at 15°C is 8.3×10^{-3} g/100. mL solution. Calculate its K_{sp}.

19.73 The solubility of calcium sulfate at 30°C is 0.209 g/100. mL solution. Calculate its K_{sp}.

19.74 Find the molar solubility of $SrCO_3$ ($K_{sp} = 5.4\times10^{-10}$) in (a) pure water and (b) 0.13 *M* $Sr(NO_3)_2$.

19.75 Find the molar solubility of $BaCrO_4$ ($K_{sp} = 2.1\times10^{-10}$) in (a) pure water and (b) 1.5×10^{-3} *M* Na_2CrO_4.

19.76 Calculate the molar solubility of $Ca(IO_3)_2$ in (a) 0.060 *M* $Ca(NO_3)_2$ and (b) 0.060 *M* $NaIO_3$. (See Appendix C.)

19.77 Calculate the molar solubility of Ag_2SO_4 in (a) 0.22 *M* $AgNO_3$ and (b) 0.22 *M* Na_2SO_4. (See Appendix C.)

19.78 Which compound in each pair is more soluble in water?
(a) Magnesium hydroxide or nickel(II) hydroxide
(b) Lead(II) sulfide or copper(II) sulfide
(c) Silver sulfate or magnesium fluoride

19.79 Which compound in each pair is more soluble in water?
(a) Strontium sulfate or barium chromate
(b) Calcium carbonate or copper(II) carbonate
(c) Barium iodate or silver chromate

19.80 Which compound in each pair is more soluble in water?
(a) Barium sulfate or calcium sulfate
(b) Calcium phosphate or magnesium phosphate
(c) Silver chloride or lead(II) sulfate

19.81 Which compound in each pair is more soluble in water?
(a) Manganese(II) hydroxide or calcium iodate
(b) Strontium carbonate or cadmium sulfide
(c) Silver cyanide or copper(I) iodide

19.82 Write equations to show whether the solubility of either of the following is affected by pH: (a) AgCl; (b) $SrCO_3$.

19.83 Write equations to show whether the solubility of either of the following is affected by pH: (a) CuBr; (b) $Ca_3(PO_4)_2$.

19.84 Write equations to show whether the solubility of either of the following is affected by pH: (a) $Fe(OH)_2$; (b) CuS.

19.85 Write equations to show whether the solubility of either of the following is affected by pH: (a) PbI_2; (b) $Hg_2(CN)_2$.

19.86 Does any solid $Cu(OH)_2$ form when 0.075 g of KOH is dissolved in 1.0 L of 1.0×10^{-3} *M* $Cu(NO_3)_2$?

19.87 Does any solid $PbCl_2$ form when 3.5 mg of NaCl is dissolved in 0.250 L of 0.12 *M* $Pb(NO_3)_2$?

19.88 Does any solid $Ba(IO_3)_2$ form when 7.5 mg of $BaCl_2$ is dissolved in 500. mL of 0.023 *M* $NaIO_3$?

19.89 Does any solid Ag_2CrO_4 form when 2.7×10^{-5} g of $AgNO_3$ is dissolved in 15.0 mL of 4.0×10^{-4} *M* K_2CrO_4?

Problems in Context

19.90 When blood is donated, sodium oxalate solution is used to precipitate Ca^{2+}, which triggers clotting. A 104-mL sample of blood contains 9.7×10^{-5} g Ca^{2+}/mL. A technologist treats the sample with 100.0 mL of 0.1550 *M* $Na_2C_2O_4$. Calculate $[Ca^{2+}]$ after the treatment. (See Appendix C for K_{sp} of $CaC_2O_4\cdot H_2O$.)

19.91 A 50.0-mL volume of 0.50 *M* $Fe(NO_3)_3$ is mixed with 125 mL of 0.25 *M* $Cd(NO_3)_2$.
(a) If aqueous NaOH is added, which ion precipitates first? (See Appendix C.)
(b) Describe how the metal ions can be separated using NaOH.
(c) Calculate the $[OH^-]$ that will accomplish the separation.

Equilibria Involving Complex Ions

(Sample Problems 19.13 and 19.14)

Concept Review Questions

19.92 How can a metal cation be at the center of a complex anion?

19.93 Write equations to demonstrate the stepwise reaction of $Cd(H_2O)_4^{2+}$ in an aqueous solution of KI to form CdI_4^{-2}. Show that $K_{f(overall)} = K_{f1} \times K_{f2} \times K_{f3} \times K_{f4}$.

19.94 Consider the dissolution of PbS in water:

$$PbS(s) + H_2O(l) \rightleftharpoons Pb^{2+}(aq) + HS^-(aq) + OH^-(aq)$$

Adding aqueous NaOH causes more PbS to dissolve. Does this violate Le Châtelier's principle? Explain.

Skill-Building Exercises (grouped in similar pairs)

19.95 Write a balanced equation for the reaction of $Hg(H_2O)_4^{2+}$ in aqueous KCN.

19.96 Write a balanced equation for the reaction of $Zn(H_2O)_4^{2+}$ in aqueous NaCN.

19.97 Write a balanced equation for the reaction of $Ag(H_2O)_2^+$ in aqueous $Na_2S_2O_3$.

19.98 Write a balanced equation for the reaction of $Al(H_2O)_6^{3+}$ in aqueous KF.

19.99 What is $[Ag^+]$ when 25.0 mL each of 0.044 *M* $AgNO_3$ and 0.57 *M* $Na_2S_2O_3$ are mixed [K_f of $Ag(S_2O_3)_2^{3-} = 4.7\times10^{13}$]?

19.100 Potassium thiocyanate, KSCN, is often used to detect the presence of Fe^{3+} ions in solution through the formation of the red $Fe(H_2O)_5SCN^{2+}$ (or, more simply, $FeSCN^{2+}$; $K_f = 8.9\times10^2$). What is $[Fe^{3+}]$ when 0.50 L each of 0.0015 *M* $Fe(NO_3)_3$ and 0.20 *M* KSCN are mixed?

19.101 Find the solubility of $Cr(OH)_3$ in a buffer of pH 13.0 [K_{sp} of $Cr(OH)_3 = 6.3\times10^{-31}$; K_f of $Cr(OH)_4^- = 8.0\times10^{29}$].

19.102 Find the solubility of AgI in 2.5 *M* NH_3 [K_{sp} of AgI = 8.3×10^{-17}; K_f of $Ag(NH_3)_2^+ = 1.7\times10^7$].

19.103 When 0.84 g of $ZnCl_2$ is dissolved in 245 mL of 0.150 *M* NaCN, what are $[Zn^{2+}]$, $[Zn(CN)_4^{2-}]$, and $[CN^-]$ [K_f of $Zn(CN)_4^{2-} = 4.2\times10^{19}$]?

19.104 When 2.4 g of $Co(NO_3)_2$ is dissolved in 0.350 L of 0.22 *M* KOH, what are $[Co^{2+}]$, $[Co(OH)_4^{2-}]$, and $[OH^-]$ [K_f of $Co(OH)_4^{2-} = 5\times10^9$]?

Comprehensive Problems

19.105 What volumes of 0.200 *M* HCOOH and 2.00 *M* NaOH would make 500. mL of a buffer with the same pH as one made from 475 mL of 0.200 *M* benzoic acid and 25 mL of 2.00 *M* NaOH?

19.106 A microbiologist is preparing a medium on which to culture *E. coli* bacteria. She buffers the medium at pH 7.00 to minimize the effect of acid-producing fermentation. What volumes of equimolar aqueous solutions of K_2HPO_4 and KH_2PO_4 must she combine to make 100. mL of the pH 7.00 buffer?

19.107 As an FDA physiologist, you need 0.700 L of formic acid–formate buffer with a pH of 3.74. (a) What is the required buffer-component concentration ratio? (b) How do you prepare this solution from stock solutions of 1.0 *M* HCOOH and 1.0 *M* NaOH? (c) What is the final concentration of HCOOH in this solution?

19.108 Tris(hydroxymethyl)aminomethane [$(HOCH_2)_3CNH_2$], known as TRIS, is a weak base used in biochemical experiments to make buffer solutions in the pH range of 7 to 9. A certain TRIS buffer has a pH of 8.10 at 25°C and a pH of 7.80 at 37°C. Why does the pH change with temperature?

19.109 Water flowing through pipes of carbon steel must be kept at pH 5 or greater to limit corrosion. If an 8.0×10^3 lb/h water stream contains 10 ppm sulfuric acid and 0.015% acetic acid, how many pounds per hour of sodium acetate trihydrate must be added to maintain that pH?

19.110 Gout is caused by an error in metabolism that leads to a buildup of uric acid in body fluids, which is deposited as slightly soluble sodium urate ($C_5H_3N_4O_3Na$) in the joints. If the extracellular $[Na^+]$ is 0.15 *M* and the solubility of sodium urate is 0.085 g/100. mL, what is the minimum urate ion concentration (abbreviated $[Ur^-]$) that will cause a deposit of sodium urate?

19.111 In the process of cave formation (p. 853), the dissolution of CO_2 (equation 1) has a K_{eq} of 3.1×10^{-2}, and the formation of aqueous $Ca(HCO_3)_2$ (equation 2) has a K_{eq} of 1×10^{-12}. The fraction by volume of atmospheric CO_2 is 4×10^{-4}. (a) Find $[CO_2(aq)]$ in equilibrium with atmospheric CO_2. (b) Determine $[Ca^{2+}]$ arising from (equation 2) given current levels of atmospheric CO_2. (c) Calculate $[Ca^{2+}]$ if atmospheric CO_2 doubles.

19.112 Phosphate systems form essential buffers in organisms. Calculate the pH of a buffer made by dissolving 0.80 mol of NaOH in 0.50 L of 1.0 *M* H_3PO_4.

19.113 The solubility of KCl is 3.7 *M* at 20°C. Two beakers contain 100. mL of saturated KCl solution: 100. mL of 6.0 *M* HCl is added to the first beaker and 100. mL of 12 *M* HCl to the second. (a) Find the ion-product constant of KCl at 20°C. (b) What mass, if any, of KCl will precipitate from each beaker?

19.114 It is possible to detect NH_3 gas over 10^{-2} *M* NH_3. To what pH must 0.15 *M* NH_4Cl be raised to form detectable NH_3?

19.115 Manganese(II) sulfide is one of the compounds found in the nodules on the ocean floor that may eventually be a primary source of many transition metals. The solubility of MnS is 4.7×10^{-4} g/100. mL solution. Estimate the K_{sp} of MnS.

19.116 The normal pH of blood is 7.40 ± 0.05 and is controlled in part by the H_2CO_3/HCO_3^- buffer system.
(a) Assuming that the K_a value for carbonic acid at 25°C applies to blood, what is the $[H_2CO_3]/[HCO_3^-]$ ratio in normal blood?
(b) In a condition called *acidosis*, the blood is too acidic. What is the $[H_2CO_3]/[HCO_3^-]$ ratio in a patient whose blood pH is 7.20?

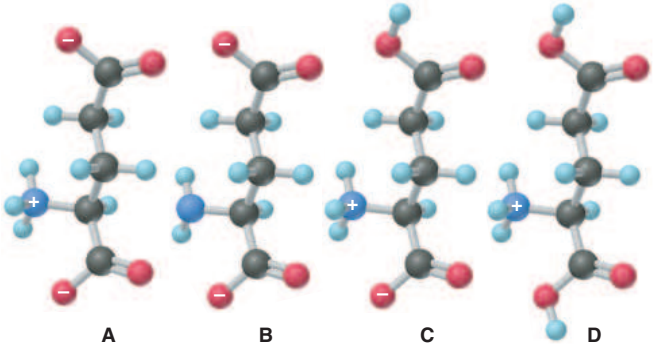
19.117 A bioengineer preparing cells for cloning bathes a small piece of rat epithelial tissue in a TRIS buffer (see Problem 19.108). The buffer is made by dissolving 43.0 g of TRIS ($pK_b = 5.91$) in enough 0.095 *M* HCl to make 1.00 L of solution. What is the molarity of TRIS and the pH of the buffer?

19.118 Sketch a qualitative curve for the titration of ethylenediamine, $H_2NCH_2CH_2NH_2$, with 0.1 *M* HCl.

19.119 A solution contains 0.10 *M* $ZnCl_2$ and 0.020 *M* $MnCl_2$. Given the following information, how would you adjust the pH to separate the ions as their sulfides ($[H_2S]$ of a saturated aqueous solution at 25°C = 0.10 *M*; $K_w = 1.0\times10^{-14}$ at 25°C)?

$$MnS + H_2O \rightleftharpoons Mn^{2+} + HS^- + OH^- \qquad K_{sp} = 3\times10^{-11}$$
$$ZnS + H_2O \rightleftharpoons Zn^{2+} + HS^- + OH^- \qquad K_{sp} = 2\times10^{-22}$$
$$H_2S + H_2O \rightleftharpoons H_3O^+ + HS^- \qquad K_{a1} = 9\times10^{-8}$$

19.120 Amino acids [general formula $NH_2CH(R)COOH$] can be considered polyprotic acids. In many cases, the R group contains additional amine and carboxyl groups.
(a) Can an amino acid dissolved in pure water have a protonated COOH group and an unprotonated NH_2 group (K_a of COOH group = 4.47×10^{-3}; K_b of NH_2 group = 6.03×10^{-5})? Use glycine, NH_2CH_2COOH, to explain why.
(b) Calculate $[^+NH_3CH_2COO^-]/[^+NH_3CH_2COOH]$ at pH 5.5.
(c) The R group of lysine is $—CH_2CH_2CH_2CH_2NH_2$ ($pK_b = 3.47$). Draw the structure of lysine at pH 1, physiological pH (~7), and pH 13.
(d) The R group of glutamic acid is $—CH_2CH_2COOH$ ($pK_a = 4.07$). Of the forms of glutamic acid that are shown below, which predominates at (1) pH 1, (2) physiological pH (~7), and (3) pH 13?



19.121 The scene at right depicts a saturated solution of $MCl_2(s)$ in the presence of dilute aqueous NaCl; each sphere represents 1.0×10^{-6} mol of ion, and the volume is 250.0 mL (solid MCl_2 is shown as *green* chunks, M^{2+} is *blue,* and Cl^- is *yellow;* Na^+ ions and water molecules are not shown).

(a) Calculate the K_{sp} of MCl_2. (b) If $M(NO_3)_2(s)$ is added, is there an increase, decrease, or no change in the number of Cl^- particles? In K_{sp}? In the mass of $MCl_2(s)$?

19.122 Tooth enamel consists of hydroxyapatite, $Ca_5(PO_4)_3OH$ ($K_{sp} = 6.8\times10^{-37}$). Fluoride ion added to drinking water reacts with $Ca_5(PO_4)_3OH$ to form the more tooth decay–resistant fluorapatite, $Ca_5(PO_4)_3F$ ($K_{sp} = 1.0\times10^{-60}$). Fluoridated water has dramatically decreased cavities among children. Calculate the solubility of $Ca_5(PO_4)_3OH$ and of $Ca_5(PO_4)_3F$ in water.

19.123 The acid-base indicator ethyl orange turns from red to yellow over the pH range 3.4 to 4.8. Estimate K_a for ethyl orange.

19.124 Use the values obtained in Problem 19.54 to sketch a curve of $[H_3O^+]$ vs. mL of added titrant. Are there advantages or disadvantages to viewing the results in this form? Explain.

19.125 Instrumental acid-base titrations use a pH meter to monitor the changes in pH and volume. The equivalence point is found from the volume at which the curve has the steepest slope.
(a) Use the data in Figure 19.8 (p. 838) to calculate the slope ($\Delta pH/\Delta V$) for all pairs of adjacent points and to calculate the average volume (V_{avg}) for each interval.
(b) Plot $\Delta pH/\Delta V$ vs. V_{avg} to find the steepest slope, and thus the volume at the equivalence point. (For example, the first pair of points gives $\Delta pH = 0.22$, $\Delta V = 10.00$ mL; hence, $\Delta pH/\Delta V = 0.022$ mL^{-1}, and $V_{avg} = 5.00$ mL.)

19.126 What is the pH of a solution of 6.5×10^{-9} mol of $Ca(OH)_2$ in 10.0 L of water [K_{sp} of $Ca(OH)_2 = 6.5\times10^{-6}$]?

19.127 Muscle physiologists study the accumulation of lactic acid [$CH_3CH(OH)COOH$] during exercise. Food chemists study its occurrence in sour milk, beer, wine, and fruit. Industrial microbiologists study its formation by various bacterial species from carbohydrates. A biochemist prepares a lactic acid–lactate buffer by mixing 225 mL of 0.85 *M* lactic acid ($K_a = 1.38\times10^{-4}$) with 435 mL of 0.68 *M* sodium lactate. What is the buffer pH?

19.128 A student wants to dissolve the maximum amount of CaF_2 ($K_{sp} = 3.2\times10^{-11}$) to make 1 L of aqueous solution.
(a) Into which of the following solvents should she dissolve the salt?
(I) Pure water (II) 0.01 *M* HF
(III) 0.01 *M* NaOH (IV) 0.01 *M* HCl
(V) 0.01 *M* $Ca(OH)_2$
(b) Which would dissolve the least amount of salt?

19.129 A 500.-mL solution consists of 0.050 mol of solid NaOH and 0.13 mol of hypochlorous acid (HClO; $K_a = 3.0\times10^{-8}$) dissolved in water.
(a) Aside from water, what is the concentration of each species that is present?
(b) What is the pH of the solution?
(c) What is the pH after adding 0.0050 mol of HCl to the flask?

19.130 Calcium ion present in water supplies is easily precipitated as calcite ($CaCO_3$):

$$Ca^{2+}(aq) + CO_3^{2-}(aq) \rightleftharpoons CaCO_3(s)$$

Because the K_{sp} decreases with temperature, heating hard water forms a calcite "scale," which clogs pipes and water heaters. Find the solubility of calcite in water (a) at 10°C ($K_{sp} = 4.4\times10^{-9}$) and (b) at 30°C ($K_{sp} = 3.1\times10^{-9}$).

19.131 Calculate the molar solubility of $Hg_2C_2O_4$ ($K_{sp} = 1.75\times10^{-13}$) in 0.13 *M* $Hg_2(NO_3)_2$.

19.132 Environmental engineers use alkalinity as a measure of the capacity of carbonate buffering systems in water samples:

$$\text{Alkalinity (mol/L)} = [HCO_3^-] + 2[CO_3^{2-}] + [OH^-] - [H^+]$$

Find the alkalinity of a water sample that has a pH of 9.5, 26.0 mg/L CO_3^{2-}, and 65.0 mg/L HCO_3^-.

19.133 Human blood contains one buffer system based on phosphate species and one based on carbonate species. Assuming that blood has a normal pH of 7.4, what are the principal phosphate and carbonate species present? What is the ratio of the two phosphate species? (In the presence of the dissolved ions and other species in blood, K_{a1} of $H_3PO_4 = 1.3\times10^{-2}$, $K_{a2} = 2.3\times10^{-7}$, and $K_{a3} = 6\times10^{-12}$; K_{a1} of $H_2CO_3 = 8\times10^{-7}$ and $K_{a2} = 1.6\times10^{-10}$.)

19.134 A 0.050 *M* H_2S solution contains 0.15 *M* $NiCl_2$ and 0.35 *M* $Hg(NO_3)_2$. What pH is required to precipitate the maximum amount of HgS but none of the NiS? (See Appendix C.)

19.135 Quantitative analysis of Cl^- ion is often performed by a titration with silver nitrate, using sodium chromate as an indicator. As standardized $AgNO_3$ is added, both white AgCl and red Ag_2CrO_4 precipitate, but so long as some Cl^- remains, the Ag_2CrO_4 redissolves as the mixture is stirred. When the red color is permanent, the equivalence point has been reached.
(a) Calculate the equilibrium constant for the reaction

$$2AgCl(s) + CrO_4^{2-}(aq) \rightleftharpoons Ag_2CrO_4(s) + 2Cl^-(aq)$$

(b) Explain why the silver chromate redissolves.
(c) If 25.00 cm^3 of 0.1000 *M* NaCl is mixed with 25.00 cm^3 of 0.1000 *M* $AgNO_3$, what is the concentration of Ag^+ remaining in solution? Is this sufficient to precipitate any silver chromate?

19.136 An ecobotanist separates the components of a tropical bark extract by chromatography. She discovers a large proportion of quinidine, a dextrorotatory isomer of quinine used for control of arrhythmic heartbeat. Quinidine has two basic nitrogens ($K_{b1} = 4.0\times10^{-6}$ and $K_{b2} = 1.0\times10^{-10}$). To measure the concentration, she carries out a titration. Because of the low solubility of quinidine, she first protonates both nitrogens with excess HCl and titrates the acidified solution with standardized base. A 33.85-mg sample of quinidine ($\mathcal{M} = 324.41$ g/mol) is acidified with 6.55 mL of 0.150 *M* HCl.
(a) How many milliliters of 0.0133 *M* NaOH are needed to titrate the excess HCl?
(b) How many additional milliliters of titrant are needed to reach the first equivalence point of quinidine dihydrochloride?
(c) What is the pH at the first equivalence point?

19.137 Some kidney stones form by the precipitation of calcium oxalate monohydrate ($CaC_2O_4\cdot H_2O$, $K_{sp} = 2.3\times10^{-9}$). The pH

of urine varies from 5.5 to 7.0, and the average $[Ca^{2+}]$ in urine is 2.6×10^{-3} *M*.
(a) If the [oxalic acid] in urine is 3.0×10^{-13} *M*, will kidney stones form at pH = 5.5?
(b) At pH = 7.0?
(c) Vegetarians have a urine pH above 7. Are they more or less likely to form kidney stones?

19.138 A biochemist needs a medium for acid-producing bacteria. The pH of the medium must not change by more than 0.05 pH units for every 0.0010 mol of H_3O^+ generated by the organisms per liter of medium. A buffer consisting of 0.10 *M* HA and 0.10 *M* A^- is included in the medium to control its pH. What volume of this buffer must be included in 1.0 L of medium?

19.139 A 35.00-mL solution of 0.2500 *M* HF is titrated with a standardized 0.1532 *M* solution of NaOH at 25°C.
(a) What is the pH of the HF solution before titrant is added?
(b) How many milliliters of titrant are required to reach the equivalence point?
(c) What is the pH at 0.50 mL before the equivalence point?
(d) What is the pH at the equivalence point?
(e) What is the pH at 0.50 mL after the equivalence point?

19.140 Because of the toxicity of mercury compounds, mercury(I) chloride is used in antibacterial salves. The mercury(I) ion (Hg_2^{2+}) consists of two bound Hg^+ ions.
(a) What is the empirical formula of mercury(I) chloride?
(b) Calculate $[Hg_2^{2+}]$ in a saturated solution of mercury(I) chloride ($K_{sp} = 1.5\times10^{-18}$).
(c) A seawater sample contains 0.20 lb of NaCl per gallon. Find $[Hg_2^{2+}]$ if the seawater is saturated with mercury(I) chloride.
(d) How many grams of mercury(I) chloride are needed to saturate 4900 km^3 of pure water (the volume of Lake Michigan)?
(e) How many grams of mercury(I) chloride are needed to saturate 4900 km^3 of seawater?

19.141 A 35.0-mL solution of 0.075 *M* $CaCl_2$ is mixed with 25.0 mL of 0.090 *M* $BaCl_2$.
(a) If aqueous KF is added, which fluoride precipitates first?
(b) Describe how the metal ions can be separated using KF to form the fluorides.
(c) Calculate the fluoride ion concentration that will accomplish the separation.

19.142 Rainwater is slightly acidic due to dissolved CO_2. Use the following data to calculate the pH of unpolluted rainwater at 25°C: vol % in air of CO_2 = 0.040 vol %; solubility of CO_2 in pure water at 25°C and 1 atm = 88 mL CO_2/100. mL H_2O; K_{a1} of $H_2CO_3 = 4.5\times10^{-7}$.

19.143 Seawater at the surface has a pH of about 8.5.
(a) Which of the following species has the highest concentration at this pH: H_2CO_3; HCO_3^-; CO_3^{2-}? Explain.
(b) What are the concentration ratios $[CO_3^{2-}]/[HCO_3^-]$ and $[HCO_3^-]/[H_2CO_3]$ at this pH?
(c) In the deep sea, light levels are low, and the pH is around 7.5. Suggest a reason for the lower pH at the greater ocean depth. (*Hint:* Consider the presence or absence of plant and animal life and the effects on carbon dioxide concentrations.)

19.144 Ethylenediaminetetraacetic acid (abbreviated H_4EDTA) is a tetraprotic acid. Its salts are used to treat toxic metal poisoning by forming soluble complex ions that are then excreted. Because $EDTA^{4-}$ also binds essential calcium ions, it is often administered as the calcium disodium salt. For example, when $Na_2Ca(EDTA)$ is given to a patient, the $[Ca(EDTA)]^{2-}$ ions react with circulating Pb^{2+} ions and the metal ions are exchanged:

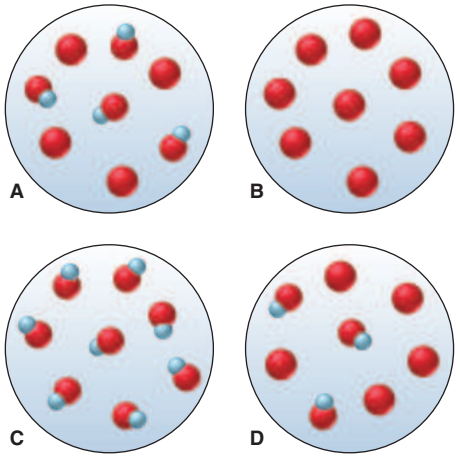
$$[Ca(EDTA)]^{2-}(aq) + Pb^{2+}(aq) \rightleftharpoons [Pb(EDTA)]^{2-}(aq) + Ca^{2+}(aq) \qquad K_c = 2.5\times10^7$$

A child has a dangerous blood lead level of 120 μg/100 mL. If the child is administered 100. mL of 0.10 *M* $Na_2Ca(EDTA)$, assuming the exchange reaction and excretion process are 100% efficient, what is the final concentration of Pb^{2+} in μg/100 mL blood? (Total blood volume is 1.5 L.)

19.145 Buffers that are based on 3-morpholinopropanesulfonic acid (MOPS) are often used in RNA analysis. The useful pH range of a MOPS buffer is 6.5 to 7.9. Estimate the K_a of MOPS.

19.146 NaCl is purified by adding HCl to a saturated solution of NaCl (317 g/L). Will pure NaCl precipitate when 28.5 mL of 8.65 *M* HCl is added to 0.100 L of saturated solution?

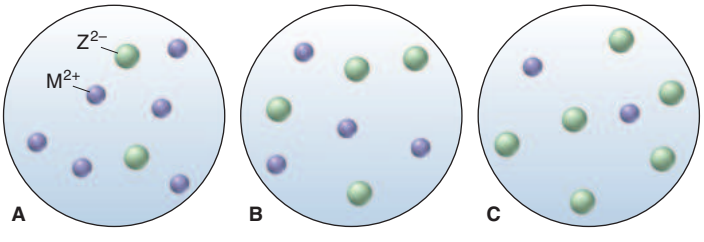
19.147 Scenes A to D represent tiny portions of 0.10 *M* aqueous solutions of a weak acid HA (*red and blue;* $K_a = 4.5\times10^{-5}$), its conjugate base A^- *(red),* or a mixture of the two (only these species are shown):



(a) Which scene(s) show(s) a buffer?
(b) What is the pH of each solution?
(c) Arrange the scenes in sequence, assuming that they represent stages in a weak acid–strong base titration.
(d) Which scene represents the titration at its equivalence point?

19.148 Scenes A to C represent aqueous solutions of the slightly soluble salt MZ (only the ions of this salt are shown):

$$MZ(s) \rightleftharpoons M^{2+}(aq) + Z^{2-}(aq)$$



(a) Which scene represents the solution just after solid MZ is stirred thoroughly in distilled water?
(b) If each sphere represents an ion concentration of $2.5\times10^{-6}\,M$, what is the K_{sp} of MZ?
(c) Which scene represents the solution after $Na_2Z(aq)$ has been added?
(d) If Z^{2-} is CO_3^{2-}, which scene represents the solution after the pH has been lowered?

19.149 The solubility of Ag(I) in aqueous solutions containing different concentrations of Cl^- is based on the following equilibria:

$$Ag^+(aq) + Cl^-(aq) \rightleftharpoons AgCl(s) \qquad K_{sp} = 1.8\times10^{-10}$$
$$Ag^+(aq) + 2Cl^-(aq) \rightleftharpoons AgCl_2^-(aq) \qquad K_f = 1.8\times10^{5}$$

When solid AgCl is shaken with a solution containing Cl^-, Ag(I) is present as both Ag^+ and $AgCl_2^-$. The solubility of AgCl is the sum of the concentrations of Ag^+ and $AgCl_2^-$.

(a) Show that $[Ag^+]$ in solution is given by

$$[Ag^+] = 1.8\times10^{-10}/[Cl^-]$$

and that $[AgCl_2^-]$ in solution is given by

$$[AgCl_2^-] = (3.2\times10^{-5})([Cl^-])$$

(b) Find the $[Cl^-]$ at which $[Ag^+] = [AgCl_2^-]$.
(c) Explain the shape of a plot of AgCl solubility vs. $[Cl^-]$.
(d) Find the solubility of AgCl at the $[Cl^-]$ of part (b), which is the minimum solubility of AgCl in the presence of Cl^-.

19.150 EDTA binds metal ions to form complex ions (see Problem 19.144), so it is used to determine the concentrations of metal ions in solution:

$$M^{n+}(aq) + EDTA^{4-}(aq) \longrightarrow MEDTA^{n-4}(aq)$$

A 50.0-mL sample of 0.048 M Co^{2+} is titrated with 0.050 M $EDTA^{4-}$. Find $[Co^{2+}]$ and $[EDTA^{4-}]$ after addition of (a) 25.0 mL and (b) 75.0 mL of $EDTA^{4-}$ ($\log K_f$ of $CoEDTA^{2-} = 16.31$).

Concepts and Skills to Review Before You Study This Chapter

- internal energy, heat, and work (Section 6.1)
- state functions (Section 6.1) and standard states (Section 6.6)
- enthalpy, ΔH, and Hess's law (Sections 6.2 and 6.5)
- entropy and solution formation (Section 13.3)
- comparing Q and K to find reaction direction (Section 17.4)

In the last few chapters, we've examined some fundamental questions about change, whether chemical or physical: How fast does it occur? How far does it go toward completion? How is a change affected by concentration and temperature? And we've explored these questions in systems ranging from the stratosphere to a limestone cave to the cells of your body.

But why does the change occur in the first place? Some changes seem to happen *in one direction* but not the other. A fuel burns in air and forms carbon dioxide and water vapor as it runs a jet engine *(photo),* but those products will never react to reform the fuel and oxygen. A new shovel left outside slowly rusts, but bring the rusty one inside and it won't become shiny. A cube of sugar dissolves in a cup of coffee after a little stirring, but wait for another millennium and the dissolved sugar won't form the cube again. Chemists call these *spontaneous* changes. Most release energy, but some absorb it.

The principles of thermodynamics, developed almost 200 years ago, explain *why* a spontaneous change occurs. And, as far as we know, they apply to every change in every system in the universe—every working machine, every growing plant, every thinking student, every moving continent, every exploding star.

IN THIS CHAPTER . . . *We discuss* ***why*** *changes occur and how we can utilize them by focusing on the concepts of entropy and free energy and their relation to the direction of a spontaneous change.*

- We discuss the need for a criterion to predict the *direction* of a spontaneous change.
- We review the first law of thermodynamics and see that it accounts for the energy of a change but *not* the direction.
- We see that the sign of the enthalpy change does not predict direction either.
- We find the criterion for predicting the direction of a spontaneous change in the second law of thermodynamics, which focuses on entropy (S), a state function based on the natural tendency of a system's energy to become dispersed.
- We examine entropy changes for exothermic and endothermic processes.
- We develop the concept of free energy as a simplified criterion for spontaneous change and see how it relates to the work a system can do.
- We explore the key relationship between the free energy change of a reaction and its equilibrium constant.

20.1 THE SECOND LAW OF THERMODYNAMICS: PREDICTING SPONTANEOUS CHANGE

A **spontaneous change** of a system is one that occurs under specified conditions without a continuous input of energy from outside the system. The freezing of water, for example, is spontaneous at 1 atm and −5°C. A spontaneous process, such as burning or falling, may need a little "push" to get started—a spark to ignite gasoline vapors in your car's engine, a shove to knock a book off your desk—but once the process begins, the process itself supplies the energy to continue. In contrast, a *nonspontaneous* change occurs only if the surroundings *continuously* supply the system with an input of energy. Under given conditions, *if a change* ***is*** *spontaneous in one direction, it is* ***not*** *spontaneous in the other.*

The term *spontaneous* does not mean *instantaneous* nor does it reveal anything about how long a process takes to occur; it means that, given enough time, the process will happen by itself. Many processes are spontaneous but slow—ripening, rusting, and aging.

Can we predict the direction of a spontaneous change in cases that are not as obvious as burning gasoline or falling books? In this section, we first briefly consider two concepts that do *not* predict the direction of a spontaneous change and then focus on one that does—the concept of entropy.

The First Law of Thermodynamics Does Not Predict Spontaneous Change

Let's see whether energy changes can predict the spontaneous direction. Recall from Chapter 6 that the first law of thermodynamics (law of conservation of energy) states that the internal energy (E) of a system, the sum of the kinetic and potential energies of its particles, changes when heat (q) and/or work (w) are absorbed or released:

$$\Delta E = q + w$$

Whatever is not part of the system (sys) is part of the surroundings (surr); thus, *the change in energy and, therefore, heat and/or work absorbed by the system is released by the surroundings,* and vice versa:

$$\Delta E_{sys} = -\Delta E_{surr} \qquad \text{or} \qquad (q + w)_{sys} = -(q + w)_{surr}$$

Since the system plus the surroundings is the universe (univ), it follows that *the total energy of the universe is constant, so the change in energy of the universe is zero:**

$$\Delta E_{sys} + \Delta E_{surr} = -\Delta E_{surr} + \Delta E_{surr} = 0 = \Delta E_{univ}$$

The first law accounts for the energy, but not the direction, of a process. When gasoline burns in a car engine, the first law states that the potential energy difference between the bonds in the fuel mixture and those in the exhaust gases is converted to the kinetic energy of the moving car and its parts plus the heat released to the environment. But, why doesn't the heat released in the engine convert exhaust fumes back into gasoline and oxygen? When an ice cube melts in your hand, the first law tells that energy from your hand is converted to kinetic energy as the solid changes to a liquid. But, why doesn't the pool of water in your cupped hand transfer the heat back to your hand and refreeze? Neither of these events violates the first law—if you measure the work and heat in each case, you find that energy is conserved—but these reverse changes never happen. That is, *the first law by itself does not predict the* ***direction*** *of a spontaneous change*.

The Sign of ΔH Does Not Predict Spontaneous Change

Perhaps the sign of the enthalpy change (ΔH), the heat gained or lost at constant pressure (q_P), is the criterion for spontaneity; in fact, leading scientists thought so through most of the 19th century. If so, we would expect exothermic processes ($\Delta H < 0$) to be spontaneous and endothermic processes ($\Delta H > 0$) nonspontaneous. Let's examine some examples to see if this is true.

1. *Spontaneous processes with* $\Delta H < 0$. All freezing and condensing processes are exothermic and spontaneous at certain conditions:

$$H_2O(l) \longrightarrow H_2O(s) \qquad \Delta H^\circ_{rxn} = -\Delta H^\circ_{fus} = -6.02 \text{ kJ (1 atm; } T = 0^\circ\text{C)}$$

The burning of methane and all other combustion reactions are spontaneous and exothermic:

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g) \qquad \Delta H^\circ_{rxn} = -802 \text{ kJ}$$

*Any modern statement of conservation of energy must take into account mass-energy equivalence and the processes in stars, which convert enormous amounts of matter into energy. Thus, the total *mass-energy* of the universe is constant.

Oxidation of iron and other metals occurs spontaneously and exothermically:

$$2Fe(s) + \tfrac{3}{2}O_2(g) \longrightarrow Fe_2O_3(s) \qquad \Delta H^\circ_{rxn} = -826 \text{ kJ}$$

Ionic compounds form spontaneously and exothermically from their elements:

$$Na(s) + \tfrac{1}{2}Cl_2(g) \longrightarrow NaCl(s) \qquad \Delta H^\circ_{rxn} = -411 \text{ kJ}$$

2. *Spontaneous processes with* $\Delta H > 0$. In many cases, an exothermic process occurs spontaneously under one set of conditions, whereas the opposite, endothermic, process occurs spontaneously under another set. All melting and vaporizing processes are endothermic *and* spontaneous at certain conditions:

$$H_2O(s) \longrightarrow H_2O(l) \qquad \Delta H^\circ_{rxn} = \Delta H^\circ_{fus} = +6.02 \text{ kJ (1 atm; } T = 0^\circ\text{C)}$$

At ordinary pressure, water vaporizes spontaneously:

$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H^\circ_{rxn} = \Delta H^\circ_{vap} = +44.0 \text{ kJ (1 atm; } T = 100^\circ\text{C)}$$

Most soluble salts dissolve endothermically *and* spontaneously:

$$NaCl(s) \xrightarrow{H_2O} Na^+(aq) + Cl^-(aq) \qquad \Delta H^\circ_{soln} = +3.9 \text{ kJ}$$

$$RbClO_3(s) \xrightarrow{H_2O} Rb^+(aq) + ClO_3^-(aq) \qquad \Delta H^\circ_{soln} = +47.7 \text{ kJ}$$

$$NH_4NO_3(s) \xrightarrow{H_2O} NH_4^+(aq) + NO_3^-(aq) \qquad \Delta H^\circ_{soln} = +25.7 \text{ kJ}$$

Even some endothermic reactions are spontaneous:

$$N_2O_5(s) \longrightarrow 2NO_2(g) + \tfrac{1}{2}O_2(g) \qquad \Delta H^\circ_{rxn} = +109.5 \text{ kJ}$$

$$Ba(OH)_2 \cdot 8H_2O(s) + 2NH_4NO_3(s) \longrightarrow Ba^{2+}(aq) + 2NO_3^-(aq) + 2NH_3(aq) + 10H_2O(l) \qquad \Delta H^\circ_{rxn} = +62.3 \text{ kJ}$$

In the latter reaction, ionic solids are mixed (Figure 20.1A) and the waters of hydration released by one of them solvate the ions. The reaction mixture absorbs heat from the surroundings so quickly that the beaker freezes to a wet board (Figure 20.1B).

Given just these few examples, we see that, as for the first law, *the sign of* ΔH *by itself does not predict the* ***direction*** *of a spontaneous change*.

Figure 20.1 **A spontaneous endothermic reaction.**

Freedom of Particle Motion and Dispersal of Kinetic Energy

When we look closely at the previous examples of spontaneous *endothermic* processes, they have one major feature in common: in every case, the chemical entities—atoms, molecules, or ions—have more freedom of motion *after* the change. Put another way, after the change, the particles have a wider range of energy of motion (kinetic energy); we say that the energy has become more dispersed, distributed, or spread out:

- The phase changes convert a solid, in which motion is restricted, to a liquid, in which particles have more freedom to move around each other, and then to a gas, in which the particles have much greater freedom of motion. Thus, the energy of motion is more dispersed.
- Dissolving a salt changes a crystalline solid and a pure liquid into separate ions and solvent molecules moving and interacting, so their freedom of motion is greater and their energy of motion more dispersed.
- In the chemical reactions, *fewer* moles of crystalline solids produce *more* moles of gases and/or solvated ions, so once again, the freedom of motion of the particles increases and their energy of motion is more dispersed:

	less freedom of particle motion ⟶ more freedom of particle motion
	localized energy of motion ⟶ dispersed energy of motion
Phase change:	solid ⟶ liquid ⟶ gas
Dissolving of salt:	crystalline solid + liquid ⟶ ions in solution
Chemical change:	crystalline solids ⟶ gases + ions in solution

In thermodynamic terms, a change in the freedom of motion of particles in a system, that is, in the dispersal of their energy of motion, is a key factor for predicting the ***direction*** *of a spontaneous process.*

Entropy and the Number of Microstates

Earlier, we discussed the quantized *electronic* energy levels of an atom (Chapter 7) and a molecule (Chapter 11), and mentioned the quantized *kinetic* energy levels—vibrational, rotational, and translational—of a molecule (see Chapter 9, Tools of the Laboratory, pp. 374–375). Now, we'll see that the energy state of a whole system of atoms or molecules is quantized, too.

Energy Dispersal and the Meaning of Entropy Let's see why freedom of motion and dispersal of energy relate to spontaneous change:

- *Quantization of energy*. Picture a system of, say, 1 mol of N_2 gas and focus on one molecule. At any instant, it is moving through space (translating) at some speed and rotating at some frequency, and its atoms are vibrating at some frequency. In the next instant, the molecule collides with another or with the container, and these motional (kinetic) energy states change to different values. The complete quantum state of the molecule at any instant consists of its electronic states and these translational, rotational, and vibrational states. In this discussion, we focus on the latter three, that is, on the kinetic energy states.
- *Number of microstates*. The energy of all the molecules in a system is similarly quantized. Each quantized state of the system is called a **microstate,** and at any instant, the total energy of the system is dispersed throughout one microstate. In the next instant, it is dispersed throughout a different microstate. The number of microstates possible for a system of 1 mol of molecules is staggering, on the order of $10^{10^{23}}$.
- *Dispersal of energy*. At a given set of conditions, each microstate has the *same* total energy as any other. Therefore, each microstate is equally possible for the system, and the laws of probability say that, over time, all microstates are equally likely. The number of microstates for a system is the number of ways it can disperse (distribute or spread) its kinetic energy among the various motions of all its particles.

In 1877, the Austrian mathematician and physicist Ludwig Boltzmann related the number of microstates (W) to the **entropy (S)** of a system:

$$S = k \ln W \qquad \textbf{(20.1)}$$

where k, the *Boltzmann constant,* is the universal gas constant (R) divided by Avogadro's number (N_A), or R/N_A, and equals 1.38×10^{-23} J/K. The term W is the number of microstates, so it has no units; therefore, S has units of joules/kelvin (J/K). Thus,

- A system with fewer microstates (smaller W) has *lower entropy (lower S).*
- A system with more microstates (larger W) has *higher entropy (higher S).*

For our earlier examples of endothermic processes,

lower entropy (fewer microstates) ⟶ higher entropy (more microstates)

Phase change: solid ⟶ liquid ⟶ gas

Dissolving of salt: crystalline solid + liquid ⟶ ions in solution

Chemical change: crystalline solids ⟶ gases + ions in solution

(Recall from Chapter 13 that entropy is a key factor in the formation of solutions.)

Entropy as a State Function If a change results in a greater number of microstates, there are more ways to disperse the energy of the system and the entropy increases:

$$S_{\text{more microstates}} > S_{\text{fewer microstates}}$$

If a change results in a lower number of microstates, the entropy decreases. Like internal energy (E) and enthalpy (H), *entropy is a state function,* so it depends only on the present state of the system, not on how it arrived at that state (see Chapter 6, pp. 256–257). Therefore, the change in entropy of the system (ΔS_{sys}) depends only on the *difference* between its final and initial values:

$$\Delta S_{sys} = S_{final} - S_{initial}$$

As with any state function, $\Delta S_{sys} > 0$ when its value increases during a change. For example, for the phase change when dry ice sublimes, the entropy increases:

$$CO_2(s) \longrightarrow CO_2(g) \qquad \Delta S_{sys} = S_{final} - S_{initial} = S_{\text{gaseous } CO_2} - S_{\text{solid } CO_2} > 0$$

And, $\Delta S_{sys} < 0$ when the entropy decreases, as when water vapor condenses:

$$H_2O(g) \longrightarrow H_2O(l) \qquad \Delta S_{sys} = S_{\text{liquid } H_2O} - S_{\text{gaseous } H_2O} < 0$$

As an example of a reaction during which entropy increases, consider the decomposition of dinitrogen tetroxide (N_2O_4, written here as $O_2N—NO_2$):

$$O_2N—NO_2(g) \longrightarrow 2NO_2(g)$$

When the N—N bond in 1 mol of dinitrogen tetroxide breaks, the 2 mol of NO_2 molecules have many more possible motions; thus, at any instant, the energy of the system is dispersed into any one of a larger number of microstates. Thus, the change in entropy of the system, which is the change in entropy of the reaction (ΔS_{rxn}), goes up:

$$\Delta S_{sys} = \Delta S_{rxn} = S_{final} - S_{initial} = S_{products} - S_{reactants} = 2S_{NO_2} - S_{O_2N—NO_2} > 0$$

Quantitative Meaning of an Entropy Change There are two approaches for quantifying an entropy change, but they give the same result. The first is based on counting the number of microstates possible for a system, and the second on the heat absorbed (or released) by the system. We'll examine both with a system of 1 mol of a gas expanding from 1 L to 2 L and behaving ideally, much as neon does at 298 K:

$$1 \text{ mol neon (initial: 1 L and 298 K)} \longrightarrow 1 \text{ mol neon (final: 2 L and 298 K)}$$

1. *Quantifying ΔS_{sys} from the number of microstates.* Figure 20.2 shows two flasks connected by a stopcock—the right flask is evacuated, and the left flask contains 1 mol of neon. When we open the stopcock, the gas expands until each flask contains 0.5 mol—but *why*? Opening the stopcock increases the volume, which increases the number of translational energy levels the particles can occupy as they move to more locations. Thus, the number of microstates—and the entropy—increases.

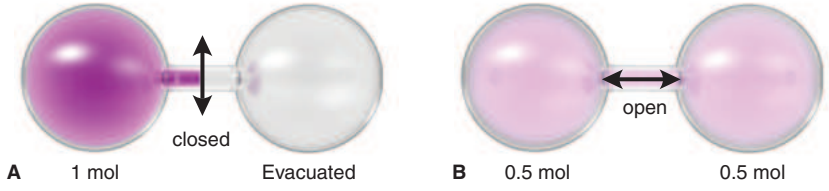

Figure 20.2 Spontaneous expansion of a gas. A, With the stopcock closed, the left flask contains 1 mol of Ne. **B,** With the stopcock open, the gas expands and each flask contains 0.5 mol of Ne.

Figure 20.3 presents this idea with particles on energy levels in a box of changeable volume. When the stopcock opens, there are more energy levels, and they are closer together on average, so more distributions of particles are possible.

In Figure 20.4 *(next page),* the number of microstates is represented by the placement of particles in the left and/or right flasks:

- *One Ne atom.* At a given instant, an Ne atom in the left flask has its energy in one of some number (W) of microstates. Opening the stopcock increases the volume, which increases the number of possible locations and the number of translational energy levels. Thus, the system has 2^1, or 2, times as many microstates available when the atom moves through both flasks (final state, W_{final}) as when it is confined to the left flask (initial state, $W_{initial}$).
- *Two Ne atoms.* For atoms A and B moving through both flasks, there are 2^2, or 4, times as many microstates as when the atoms were initially in the left flask—some number of microstates with both A and B in the left, that many with A in the left and B in the right or with B in the left and A in the right, and that many with both in the right.
- *Three Ne atoms.* Add another atom, and there are 2^3, or 8, times as many microstates when the stopcock is open.
- *Ten Ne atoms.* With 10 Ne atoms, there are 2^{10}, or 1024, times as many microstates for the atoms in both flasks as there were for the 10 atoms in the left flask.
- *One mole of Ne atoms.* With 1 mol (N_A) of Ne, there are 2^{N_A} times as many microstates for the atoms in the larger volume (W_{final}) than in the smaller ($W_{initial}$):

$$\frac{W_{final}}{W_{initial}} = 2^{N_A}$$

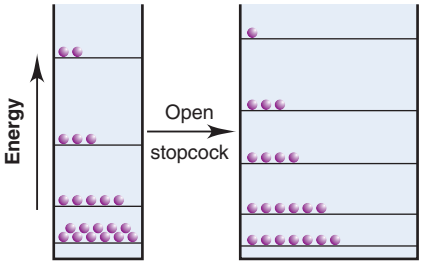

Figure 20.3 The entropy increase due to expansion of a gas. Energy levels are shown as lines in a box of narrow width *(left)*. Each distribution of energies for the 21 particles is one microstate. When the stopcock is opened, the box is wider (volume increases, *right*), and the particles have more energy levels available.

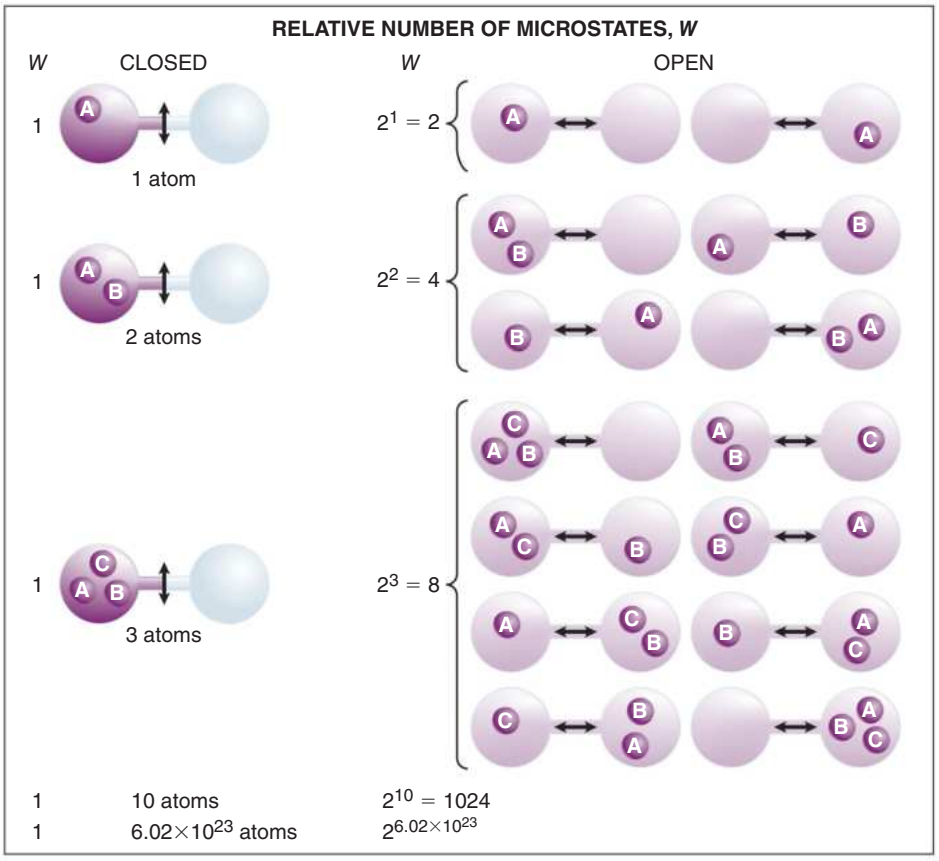

Figure 20.4 Expansion of a gas and the increase in number of microstates. Each set of particle locations represents a different microstate. When the volume increases (stopcock opens), the *relative* number of microstates is 2^n, where n is the number of particles.

Now let's find ΔS_{sys} through the Boltzmann equation, $S = k \ln W$. From the properties of logarithms (Appendix A), we know that $\ln A - \ln B = \ln A/B$. Thus,

$$\Delta S_{sys} = S_{final} - S_{initial} = k \ln W_{final} - k \ln W_{initial} = k \ln \frac{W_{final}}{W_{initial}} = k \ln 2^{6.02\times10^{23}}$$

Also, from Appendix A, $\ln A^y = y \ln A$; so we have

$$\Delta S_{sys} = k \ln 2^{6.02\times10^{23}} = k(6.02\times10^{23})(\ln 2)$$
$$= (1.38\times10^{-23}\ \text{J/K})(6.02\times10^{23})(0.693) = 5.76\ \text{J/K}$$

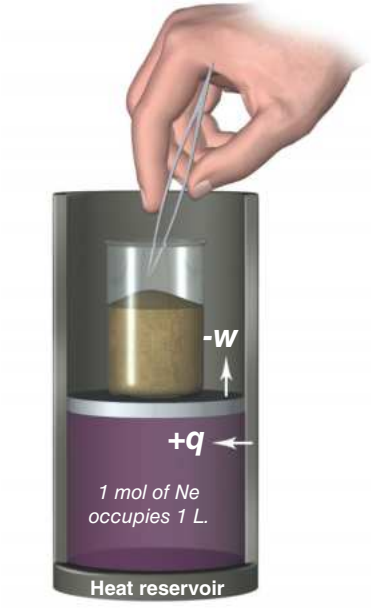

Figure 20.5 Simulating a reversible process.

2. *Quantifying ΔS_{sys} from the changes in heat.* Now let's compare the ΔS_{sys} we just found for a gas expanding into an evacuated flask with the ΔS_{sys} for a gas that is heated and does work on the surroundings. This approach uses the relationship

$$\Delta S_{sys} = \frac{q_{rev}}{T} \qquad \textbf{(20.2)}$$

where T is the temperature at which the heat change occurs and q is the heat absorbed. The subscript "rev" refers to a *reversible process,* one that occurs in such tiny increments that the system remains at equilibrium and the direction of the change can be reversed by an *infinitesimal* reversal of conditions.

We'll approximate a reversible expansion by placing 1 mol of Ne gas in a piston-cylinder assembly within a heat reservoir (to maintain a constant T of 298 K) and start by confining the gas to a volume of 1 L by the "pressure" of a beaker of sand on the piston (Figure 20.5). We remove one grain of sand (an "infinitesimal" decrease in pressure) with a pair of tweezers, and the gas (system) expands a tiny amount, raising the piston and doing work, $-w$. Assuming Ne behaves ideally, it absorbs an equivalent tiny increment of heat, q, from the heat reservoir. With each grain of sand removed, the expanding gas absorbs another tiny increment of heat. This process simulates a reversible expansion because we can reverse it by putting back a grain of sand, which causes the surroundings to do a tiny quantity of work compressing the gas, thus releasing a tiny quantity of heat to the reservoir.

If we continue this nearly reversible expansion to 2 L and use calculus to integrate the tiny increments of heat together, q_{rev} is 1718 J. From Equation 20.2,

$$\Delta S_{sys} = \frac{q_{rev}}{T} = \frac{1718\ \text{J}}{298\ \text{K}} = 5.76\ \text{J/K}$$

This is the same value we obtained from counting the number of microstates.

Entropy and the Second Law of Thermodynamics

The change in entropy determines the direction of a spontaneous process, but we must consider more than just the entropy change of the *system.* After all, at 20°C, solid water melts spontaneously and ΔS_{sys} goes up, while at −10°C, liquid water freezes spontaneously and ΔS_{sys} goes down. But when we consider *both* the system *and* its surroundings, we find that *all real processes occur spontaneously in the direction that increases the entropy of the universe (system plus surroundings).* This is one way to state the **second law of thermodynamics.**

The second law says that *either* the entropy change of the system *or* of the surroundings may be negative. But, for a process to be spontaneous, the *sum* of the two entropy changes must be positive. If the entropy of the system decreases, the entropy of the surroundings must increase even more to offset that decrease, so that the entropy of the universe (system *plus* surroundings) increases. A quantitative statement of the second law is, for any real spontaneous process,

$$\Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr} > 0 \qquad \textbf{(20.3)}$$

(We return to this idea in Section 20.2.)

Standard Molar Entropies and the Third Law

Entropy and enthalpy are state functions, but their values differ in a fundamental way:

- For *enthalpy,* there is no zero point, so we can measure only *changes*.
- For *entropy,* there *is* a zero point, and we can determine *absolute* values by applying the **third law of thermodynamics:** *a perfect crystal has zero entropy at absolute zero:* $S_{sys} = 0$ at 0 K.

A "perfect" crystal means all the particles are aligned flawlessly. At absolute zero, the particles have minimum energy, so there is only one microstate. Thus, in Equation 20.1,

$$W = 1 \qquad \text{so} \qquad S = k \ln 1 = 0$$

When we warm the crystal to any temperature above 0 K, the total energy increases, so it can be dispersed into more than one microstate. Thus,

$$W > 1 \qquad \text{and} \qquad \ln W > 0 \qquad \text{so} \qquad S > 0$$

In principle, to find S of a substance at a given temperature, we cool it to as close to 0 K as possible. Then we heat it in small increments, dividing q by T to get the increase in S for each increment, and add up all the entropy increases to the temperature of interest, usually 298 K. Therefore, S of a substance at a given temperature is an *absolute* value. As with other thermodynamic variables,

- We compare entropy values for substances at the temperature of interest in their *standard states: 1 atm for gases, 1 M for solutions, and the pure substance in its most stable form for solids or liquids.*
- Because entropy is an *extensive* property—one that depends on the amount of substance—we specify the **standard molar entropy ($S°$),** in units of J/mol·K (or J mol^{-1} K^{-1}). ($S°$ values at 298 K for many elements, compounds, and ions appear, with other thermodynamic variables, in Appendix B.)

Predicting Relative $S°$ of a System

Let's see how the standard molar entropy of a substance is affected by several parameters: temperature, physical state, dissolution, and atomic size or molecular complexity. (Unless stated otherwise, the $S°$ values refer to the system at 298 K.)

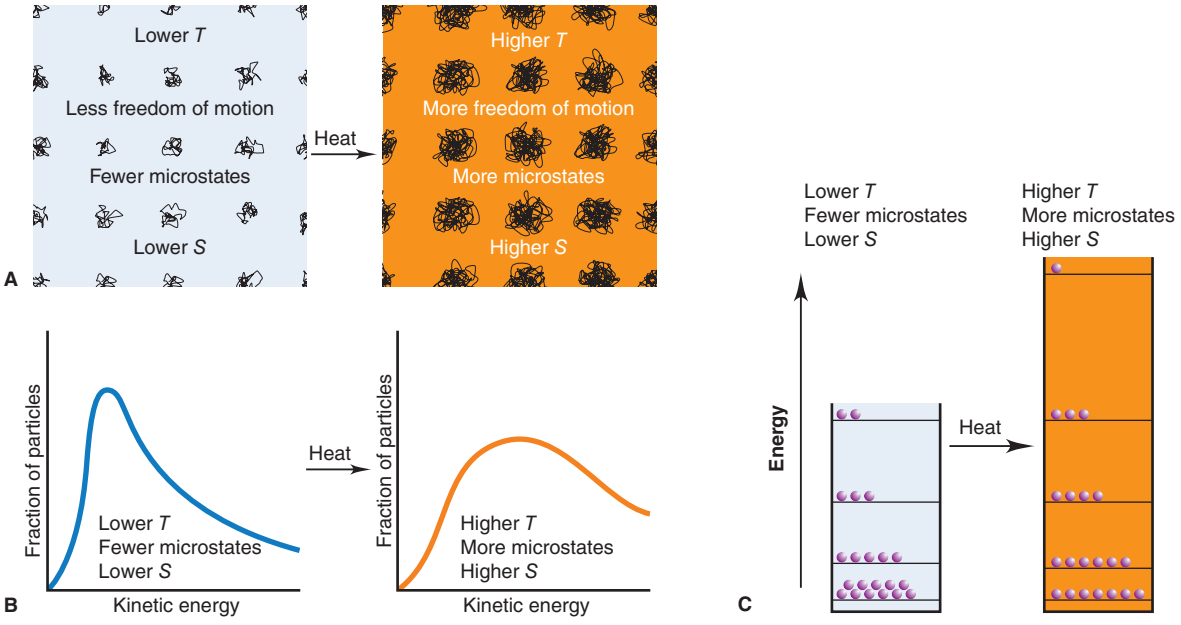

Figure 20.6 **Visualizing the effect of temperature on entropy. A,** Computer simulations show each particle in a crystal moving about its lattice position. Adding heat increases *T* and the total energy, so the particles have greater freedom of motion, and their energy is more dispersed. Thus, *S* increases. **B,** At any *T*, there is a range of occupied energy levels and, thus, a certain number of microstates. Adding heat increases the total energy *(area under curve)*, so the range of occupied energy levels becomes greater, as does the number of microstates (higher *S*). **C,** A system of 21 particles occupy energy levels *(lines)* in a box whose height represents the total energy. When heat is added, the total energy increases *(box is higher) and* becomes more dispersed *(more lines)*, so *S* increases.

Temperature Changes Temperature has a direct effect on entropy—for any substance, *S*° *increases as T rises,* as these values for copper metal show:

T (K):	273	295	298
S°:	31.0	32.9	33.2

As heat is absorbed ($q > 0$), temperature, which is a measure of the average kinetic energy of the particles, increases. Recall that the kinetic energies of gas particles are distributed over a range, which becomes wider as *T* rises (Figure 5.14, p. 225); liquids and solids behave the same. Thus, at any instant, there are more microstates available in which the energy can be dispersed, so the entropy of the substance goes up. Figure 20.6 presents three ways to view the effect of temperature on entropy.

Physical States and Phase Changes In melting or vaporizing, heat is absorbed ($q > 0$). The particles have more freedom of motion, and their energy is more dispersed. Thus, *S*° *increases as the physical state of a substance changes from solid to liquid to gas:*

	Na	H_2O	C(graphite)
S°(*s* or *l*):	51.4(*s*)	69.9(*l*)	5.7(*s*)
S°(*g*):	153.6	188.7	158.0

Figure 20.7 plots entropy versus *T* as solid O_2 is heated and changes to liquid and then to gas, with *S*° values at various points; this behavior is typical of many substances. At the molecular scale, several stages occur:

- Particles in the solid vibrate about their positions but, on average, remain fixed. The energy of the solid is dispersed least, that is, has the fewest microstates, so the solid has the lowest entropy.
- As *T* rises, the entropy increases gradually as the particles' kinetic energy increases.
- When the solid melts, the particles move much more freely between and around each other, so there is an abrupt increase in entropy (ΔS°_{fus}).

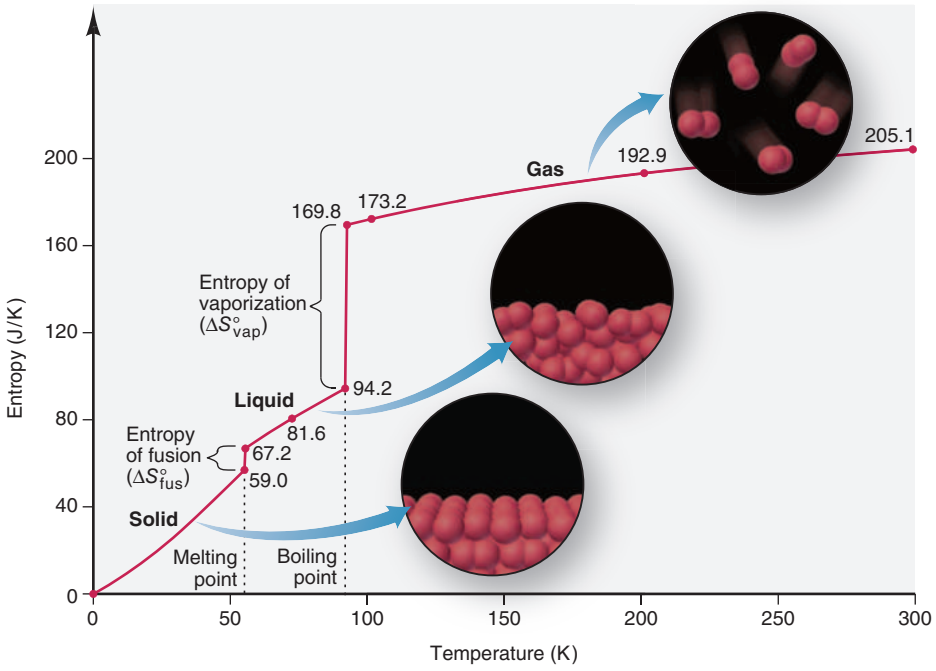

Figure 20.7 **The increase in entropy during phase changes from solid to liquid to gas.**

- Further heating of the liquid increases the speed of the particles, and the entropy increases gradually.
- When the liquid vaporizes and becomes a gas, the particles undergo a much larger, abrupt entropy increase (ΔS°_{vap}); *the increase in entropy from liquid to gas is much larger than from solid to liquid:* $\Delta S^\circ_{vap} >> \Delta S^\circ_{fus}$.
- Finally, with further heating of the gas, the entropy increases gradually.

Dissolving a Solid or a Liquid in Water Recall from Chapter 13 that, in general, *entropy increases when a solid or liquid solute dissolves in a solvent:* $S_{soln} > (S_{solute} + S_{solvent})$. But, when water is the solvent, the entropy may also depend on the nature of solute *and* solvent interactions and includes two opposing events:

1. *For ionic solutes,* when the crystal dissolves in water, the ions have much more freedom of motion and their energy is dispersed into more microstates. That is, the entropy of the ions themselves is greater in the solution. However, water molecules become arranged around the ions (Figure 20.8), which limits the molecules' freedom of motion (see also Figure 13.2, p. 519). In fact, around small, multiply charged ions, H_2O molecules become so organized that their energy of motion becomes *less* dispersed. This negative portion of the total entropy change can lead to *negative* S° values for the ions in solution. In the case of $AlCl_3$, the $Al^{3+}(aq)$ ion has such a negative S° value (-313 J/mol·K) that when $AlCl_3$ dissolves in water, even though S° of $Cl^-(aq)$ is positive, the entropy of aqueous $AlCl_3$ is lower than that of solid $AlCl_3$.*

	NaCl	$AlCl_3$	CH_3OH
$S^\circ(s \text{ or } l)$:	72.1(s)	167(s)	127(l)
$S^\circ(aq)$:	115.1	-148	132

*An S° value for a hydrated ion can be negative because it is relative to the S° value for the hydrated proton, $H^+(aq)$, which is assigned a value of 0. In other words, $Al^{3+}(aq)$ has a lower entropy than $H^+(aq)$.

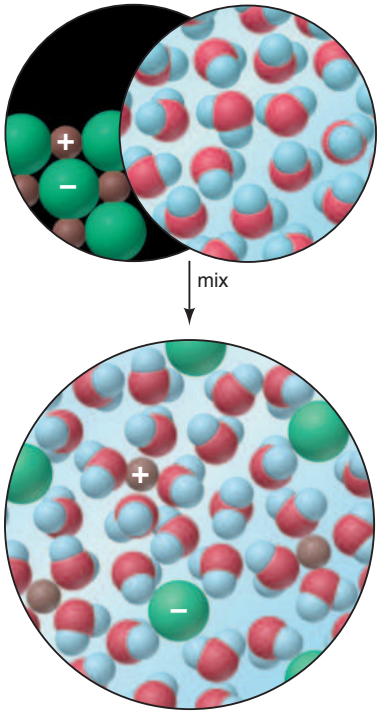

Figure 20.8 **The entropy change accompanying the dissolution of a salt.** The entropy of a salt solution is usually *greater* than that of the solid and of water, but it is affected by water molecules becoming organized around each ion.

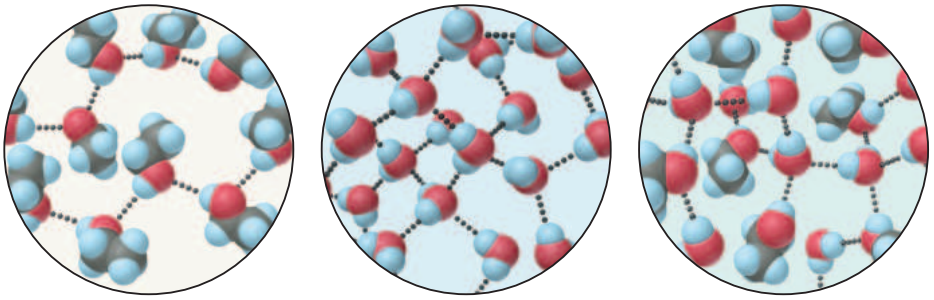

Figure 20.9 The small increase in entropy when ethanol dissolves in water. In pure ethanol **(A)** and water **(B),** molecules form many H bonds to other like molecules. **C,** In solution, these two kinds of molecules form H bonds to each other, so their freedom of motion does not change significantly.

2. *For molecular solutes,* the increase in entropy upon dissolving is typically much smaller than for ionic solutes. After all, for a solid such as glucose, there is no separation into ions, and for a liquid such as methanol or ethanol (Figure 20.9), there is no breakdown of a crystal structure. Furthermore, in these small alcohols, as in pure water, the molecules form many H bonds, so there is relatively little change in their freedom of motion either before or after they are mixed.

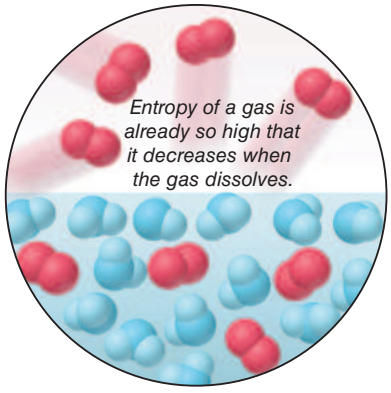

Figure 20.10 The entropy of a gas dissolved in a liquid.

Dissolving a Gas in a Liquid The particles in a gas already have so much freedom of motion—and, thus, such highly dispersed energy—that they lose some when they dissolve in a liquid or solid. Therefore, *the entropy of a solution of a gas in a liquid or a solid is always* ***less*** *than the entropy of the gas itself.* For instance, when gaseous O_2 [$S°(g)$ = 205.0 J/mol·K] dissolves in water, its entropy decreases considerably [$S°(aq)$ = 110.9 J/mol·K] (Figure 20.10). When a gas dissolves in another gas, however, the entropy increases as a result of the separation and mixing of the molecules.

Atomic Size and Molecular Complexity Differences in $S°$ values for substances in the same phase are usually based on atomic size and molecular complexity.

1. *Within a periodic group,* energy levels become closer together for heavier atoms, so the number of microstates, and thus the molar entropy, increases:

	Li	Na	K	Rb	Cs
Molar mass (g/mol):	6.941	22.99	39.10	85.47	132.9
$S°(s)$:	29.1	51.4	64.7	69.5	85.2

The same trend of increasing entropy holds for similar compounds down a group:

	HF	HCl	HBr	HI
Molar mass (g/mol):	20.01	36.46	80.91	127.9
$S°(g)$:	173.7	186.8	198.6	206.3

2. *For different forms of an element (allotropes),* the entropy is *higher* in the form that allows the atoms more freedom of motion. For example, $S°$ of graphite is 5.69 J/mol·K, whereas $S°$ of diamond is 2.44 J/mol·K. In graphite, covalent bonds extend within a two-dimensional sheet, and the sheets move past each other relatively easily; in diamond, covalent bonds extend in three dimensions, allowing the atoms little movement (Table 12.6, p. 490).

3. *For compounds,* entropy increases with chemical complexity (that is, with number of atoms in the formula), and this trend holds for ionic and covalent substances:

	NaCl	$AlCl_3$	P_4O_{10}	NO	NO_2	N_2O_4
$S°(s)$:	72.1	167	229			
$S°(g)$:				211	240	304

The trend is also based on the different motions that are available. Thus, for example, among the nitrogen oxides listed, the number of different vibrational motions increases with the number of atoms in the molecule (Figure 20.11; see also Chapter 9, p. 374).

For larger compounds, we also consider the motion of different parts of a molecule. A long hydrocarbon chain can rotate and vibrate in more ways than a short one, so *entropy increases with chain length.* A ring compound, such as cyclopentane (C_5H_{10}), has lower entropy than the chain compound with the same molar mass, pentene (C_5H_{10}), because the ring structure restricts freedom of motion:

	$CH_4(g)$	$C_2H_6(g)$	$C_3H_8(g)$	$C_4H_{10}(g)$	$C_5H_{10}(g)$	C_5H_{10}(cyclo, g)	$C_2H_5OH(l)$
$S°$:	186	230	270	310	348	293	161

Remember, these trends hold only for *substances in the same physical state.* Gaseous methane (CH_4) has higher entropy than liquid ethanol (C_2H_5OH), even though ethanol molecules are more complex. When gases are compared with liquids, *the effect of physical state dominates the effect of molecular complexity.*

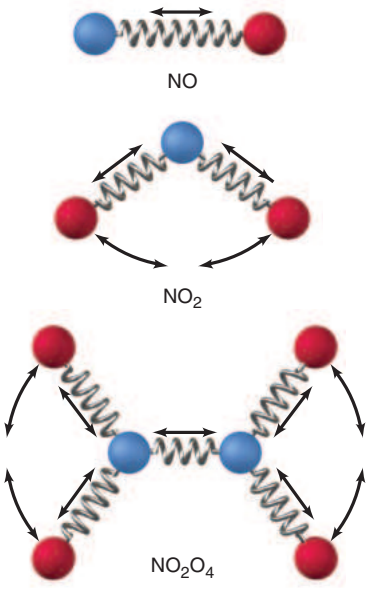

Figure 20.11 Entropy, vibrational motion, and molecular complexity.

SAMPLE PROBLEM 20.1 Predicting Relative Entropy Values

Problem Select the substance with the higher entropy in each pair, and explain your choice [assume constant temperature, except in part (e)]:
(a) 1 mol of $SO_2(g)$ or 1 mol of $SO_3(g)$
(b) 1 mol of $CO_2(s)$ or 1 mol of $CO_2(g)$
(c) 3 mol of $O_2(g)$ or 2 mol of $O_3(g)$
(d) 1 mol of KBr(s) or 1 mol of KBr(aq)
(e) Seawater at 2°C or at 23°C
(f) 1 mol of $CF_4(g)$ or 1 mol of $CCl_4(g)$

Plan In general, particles with more freedom of motion have more microstates in which to disperse their kinetic energy, so they have higher entropy. We know that either raising temperature or having *more* particles increases entropy. We apply the general categories described in the text to choose the member with the higher entropy.

Solution **(a)** 1 mol of $SO_3(g)$. For equal numbers of moles of substances with the same types of atoms in the same physical state, the more atoms in the molecule, the more types of motion available, and thus the higher the entropy.
(b) 1 mol of $CO_2(g)$. For a given substance, entropy increases in the sequence $s < l < g$.
(c) 3 mol of $O_2(g)$. The two samples contain the same number of oxygen atoms but different numbers of molecules. Despite the greater complexity of O_3, the greater number of molecules dominates because there are many more microstates possible for 3 mol of particles than for 2 mol.
(d) 1 mol of KBr(aq). The two samples have the same number of ions, but their motion is more limited and their energy less dispersed in the solid than in the solution.
(e) Seawater at 23°C. Entropy increases with rising temperature.
(f) 1 mol of $CCl_4(g)$. For similar compounds, entropy increases with molar mass.

FOLLOW-UP PROBLEMS

Brief Solutions to ***all*** *Follow-up Problems appear at the end of the chapter.*

20.1A Select the substance with the *higher* entropy in each pair, and explain your choice (assume 1 mol of each at the same T):
(a) $PCl_3(g)$ or $PCl_5(g)$ **(b)** $CaF_2(s)$ or $BaCl_2(s)$ **(c)** $Br_2(g)$ or $Br_2(l)$

20.1B Select the substance with the *lower* entropy in each pair, and explain your choice (assume 1 mol of each at the same T):
(a) LiBr(aq) or NaBr(aq) **(b)** quartz or glass **(c)**  ethylcyclobutane or  cyclohexane

SOME SIMILAR PROBLEMS 20.22–20.29

Summary of Section 20.1

- A change is spontaneous under specified conditions if it occurs without a continuous input of energy.
- Neither the first law of thermodynamics nor the sign of ΔH predicts the direction of a spontaneous change.
- Many spontaneous processes involve an increase in the freedom of motion of the system's particles and, thus, in the dispersal of the system's energy of motion.
- Entropy is a state function that measures the extent of energy dispersed into the number of microstates possible for a system. Each microstate consists of the quantized energy levels of the system at a given instant.
- The second law of thermodynamics states that, in a spontaneous process, the entropy of the universe (system plus surroundings) increases.
- Absolute entropy values can be determined because perfect crystals have zero entropy at 0 K (third law of thermodynamics).
- Standard molar entropy, S° (J/mol·K), is affected by temperature, phase changes, dissolution, and atomic size or molecular complexity.

20.2 CALCULATING THE CHANGE IN ENTROPY OF A REACTION

Chemists are especially interested in learning how to predict the sign *and* calculate the value of the entropy change that occurs during a reaction.

Entropy Changes in the System: Standard Entropy of Reaction (ΔS°_{rxn})

The **standard entropy of reaction, ΔS°_{rxn},** is the entropy change that occurs when all reactants and products are in their standard states.

Predicting the Sign of ΔS°_{rxn} Changes in structure and especially in amount (mol) of gas help us predict the sign of ΔS°_{rxn}. Because gases have such great freedom of motion and, thus, high molar entropies, *if the number of moles of gas increases,* ΔS°_{rxn} *is positive; if the number decreases,* ΔS°_{rxn} *is negative.* Here are a few examples:

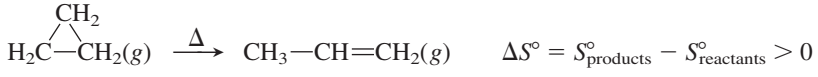
- *Increase in amount of gas*. When gaseous H_2 reacts with solid I_2 to form gaseous HI, the total number of moles of *substance* stays the same. Nevertheless, the sign of ΔS°_{rxn} is positive (entropy increases) because the number of moles of *gas* increases:

$$H_2(g) + I_2(s) \longrightarrow 2HI(g) \qquad \Delta S^\circ_{rxn} = S^\circ_{products} - S^\circ_{reactants} > 0$$

- *Decrease in amount of gas*. When ammonia forms from its elements, 4 mol of gas produce 2 mol of gas, so ΔS°_{rxn} is negative (entropy decreases):

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) \qquad \Delta S^\circ_{rxn} = S^\circ_{products} - S^\circ_{reactants} < 0$$

- *No change in amount of gas, but change in structure*. When the amount (mol) of gas doesn't change, we *cannot* predict the sign of ΔS°_{rxn}. But, a change in one of the structures can make it easier to predict the sign of ΔS°_{rxn}. For example, when cyclopropane is heated to 500°C, the ring opens and propene forms. The chain has more freedom of motion than the ring, so ΔS°_{rxn} is positive:



$$\Delta S^\circ = S^\circ_{products} - S^\circ_{reactants} > 0$$

Keep in mind, however, that in general *we cannot predict the sign of the entropy change unless the reaction involves a change in number of moles of gas.*

Calculating ΔS°_{rxn} from S° Values By applying Hess's law (Chapter 6), we combined ΔH°_f values to find ΔH°_{rxn}. Similarly, we combine S° values to find the standard entropy of reaction, ΔS°_{rxn}:

$$\Delta S^\circ_{rxn} = \Sigma m S^\circ_{products} - \Sigma n S^\circ_{reactants} \qquad (20.4)$$

where m and n are the amounts (mol) of products and reactants, respectively, given by the coefficients in the balanced equation. For the formation of ammonia, we have

$$\Delta S^\circ_{rxn} = [(2 \text{ mol } NH_3)(S^\circ \text{ of } NH_3)] - [(1 \text{ mol } N_2)(S^\circ \text{ of } N_2) + (3 \text{ mol } H_2)(S^\circ \text{ of } H_2)]$$

From Appendix B, we find the S° values:

$$\Delta S^\circ_{rxn} = [(2 \text{ mol})(193 \text{ J/mol·K})] - [(1 \text{ mol})(191.5 \text{ J/mol·K}) + (3 \text{ mol})(130.6 \text{ J/mol·K})]$$
$$= -197 \text{ J/K}$$

As we predicted from the decrease in number of moles of gas, $\Delta S^\circ_{rxn} < 0$.

SAMPLE PROBLEM 20.2 Calculating the Standard Entropy of Reaction, ΔS°_{rxn}

Problem Predict the sign of ΔS°_{rxn}, if possible, and calculate its value for the combustion of 1 mol of propane at 25°C:

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(l)$$

Plan We use the change in the number of moles of gas to predict the sign of ΔS°_{rxn}. To find ΔS°_{rxn}, we apply Equation 20.4.

Solution The amount (mol) of gas decreases (6 mol yields 3 mol), so the entropy should decrease ($\Delta S^\circ_{rxn} < 0$).

Calculating ΔS°_{rxn}. Using Appendix B values,

$$\Delta S^\circ_{rxn} = [(3 \text{ mol } CO_2)(S^\circ \text{ of } CO_2) + (4 \text{ mol } H_2O)(S^\circ \text{ of } H_2O)] - [(1 \text{ mol } C_3H_8)(S^\circ \text{ of } C_3H_8) + (5 \text{ mol } O_2)(S^\circ \text{ of } O_2)]$$
$$= [(3 \text{ mol})(213.7 \text{ J/mol·K}) + (4 \text{ mol})(69.940 \text{ J/mol·K})] - [(1 \text{ mol})(269.9 \text{ J/mol·K}) + (5 \text{ mol})(205.0 \text{ J/mol·K})]$$
$$= -374.0 \text{ J/K}$$

Check $\Delta S^\circ_{rxn} < 0$, so our prediction is correct. Rounding gives $[3(200) + 4(70)] - [270 + 5(200)] = 880 - 1270 = -390$, close to the calculated value.

FOLLOW-UP PROBLEMS

20.2A Balance each equation, predict the sign of ΔS°_{rxn} if possible, and calculate its value at 298 K:

(a) $NO(g) \longrightarrow N_2O(g) + N_2O_3(g)$

(b) $CH_3OH(g) \longrightarrow CO(g) + H_2(g)$

20.2B Balance each equation, predict the sign of ΔS°_{rxn} if possible, and calculate its value at 25°C:

(a) $NaOH(s) + CO_2(g) \longrightarrow Na_2CO_3(s) + H_2O(l)$

(b) $Fe(s) + H_2O(g) \longrightarrow Fe_2O_3(s) + H_2(g)$

SOME SIMILAR PROBLEMS 20.33–20.38

Entropy Changes in the Surroundings: The Other Part of the Total

In the synthesis of ammonia, the combustion of propane, and many other spontaneous reactions, the entropy of the *system* decreases ($\Delta S^\circ_{rxn} < 0$). Remember that the second law dictates that, for a spontaneous process, a ***decrease*** *in the entropy of the system is outweighed by an* ***increase*** *in the entropy of the surroundings.* In this section, we examine the influence of the surroundings—in particular, the addition (or removal) of heat and the temperature at which this heat flow occurs—on the *total* entropy change.

The Role of the Surroundings

In essence, the surroundings *add heat to or remove heat from the system.* That is, the surroundings function as an enormous heat source or heat sink, one so large that its temperature remains constant, even though its entropy changes. The surroundings participate in the two types of enthalpy changes as follows:

1. *In an exothermic change, heat released by the system is absorbed by the surroundings.* More heat increases the freedom of motion of the particles and makes the energy more dispersed, so the entropy of the surroundings increases:

   For an exothermic change: $q_{sys} < 0$, $q_{surr} > 0$, and $\Delta S_{surr} > 0$

2. *In an endothermic change, heat absorbed by the system is released by the surroundings*. Less heat reduces the freedom of motion of the particles and makes the energy less dispersed, so the entropy of the surroundings decreases:

For an endothermic change: $q_{sys} > 0$, $q_{surr} < 0$, and $\Delta S_{surr} < 0$

Temperature at Which Heat Is Transferred The *temperature* of the surroundings when the heat is transferred also affects ΔS_{surr}. Consider the effect of an exothermic reaction at a low or at a high temperature:

- At a low T, such as 20 K, there is little motion in the surroundings due to little energy. This means there are few energy levels in each microstate and few microstates in which to disperse the energy. Transferring a given quantity of heat to these surroundings causes a relatively large change in how much energy is dispersed.
- At a high T, such as 298 K, the surroundings have a large quantity of energy dispersed. There are more energy levels in each microstate and a greater number of microstates. Transferring the same given quantity of heat to these surroundings causes a relatively small change in how much energy is dispersed.

A Checkbook Analogy for Heating the Surroundings

If you have $10 in your checking account, a $10 deposit represents a 100% increase in your net worth; that is, a given change to a low initial state has a large impact. If, however, you have a $1000 balance, a $10 deposit represents only a 1% increase. Thus, the same absolute change to a high initial state has a smaller impact.

In other words, ΔS_{surr} is greater when heat is added at a lower T. Putting these ideas together, ΔS_{surr} *is directly related to an opposite change in the heat of the system* (q_{sys}) *and inversely related to the temperature at which the heat is transferred:*

$$\Delta S_{surr} = -\frac{q_{sys}}{T}$$

For a process at *constant pressure,* the heat (q_P) is ΔH (Section 6.2), so

$$\Delta S_{surr} = -\frac{\Delta H_{sys}}{T} \qquad (20.5)$$

Thus, we find ΔS_{surr} by measuring ΔH_{sys} and T at which the change takes place.

The main point: If a spontaneous reaction has a negative ΔS_{sys} (fewer microstates into which energy is dispersed), ΔS_{surr} must be positive enough (even more microstates into which energy is dispersed) for ΔS_{univ} to be positive (net increase in number of microstates for dispersing the energy).

SAMPLE PROBLEM 20.3 Determining Reaction Spontaneity

Problem At 298 K, the formation of ammonia has a negative ΔS°_{sys}:

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g) \qquad \Delta S^\circ_{sys} = -197 \text{ J/K}$$

Calculate ΔS_{univ}, and state whether the reaction occurs spontaneously at this temperature.

Plan For the reaction to occur spontaneously, $\Delta S_{univ} > 0$, so ΔS_{surr} must be greater than +197 J/K. To find ΔS_{surr}, we need ΔH°_{sys}, which is the same as ΔH°_{rxn}. We use ΔH°_f values from Appendix B to find ΔH°_{rxn}. Then, we divide ΔH°_{rxn} by the given T (298 K) to find ΔS_{surr}. To find ΔS_{univ}, we add the calculated ΔS_{surr} to the given ΔS°_{sys} (−197 J/K).

Solution Calculating ΔH°_{sys}:

$$\begin{aligned}\Delta H^\circ_{sys} &= \Delta H^\circ_{rxn} \\ &= [(2 \text{ mol } NH_3)(-45.9 \text{ kJ/mol})] - [(3 \text{ mol } H_2)(0 \text{ kJ/mol}) + (1 \text{ mol } N_2)(0 \text{ kJ/mol})] \\ &= -91.8 \text{ kJ}\end{aligned}$$

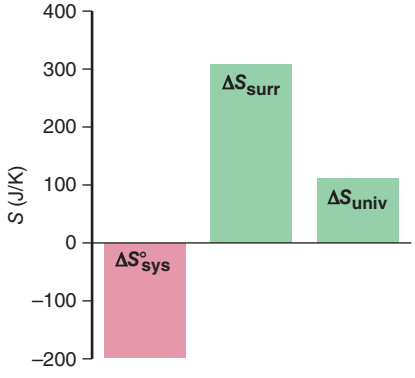
Calculating ΔS_{surr}:

$$\Delta S_{surr} = -\frac{\Delta H^\circ_{sys}}{T} = -\frac{-91.8 \text{ kJ} \times \dfrac{1000 \text{ J}}{1 \text{ kJ}}}{298 \text{ K}} = 308 \text{ J/K}$$

Determining ΔS_{univ}:

$$\Delta S_{univ} = \Delta S^\circ_{sys} + \Delta S_{surr} = -197 \text{ J/K} + 308 \text{ J/K} = 111 \text{ J/K}$$

$\Delta S_{univ} > 0$, so the reaction occurs spontaneously at 298 K *(see margin).*



Check Rounding to check the math, we have

$$\Delta H^\circ_{rxn} \approx 2(-45\text{ kJ}) = -90\text{ kJ}$$
$$\Delta S_{surr} \approx -(-90{,}000\text{ J})/300\text{ K} = 300\text{ J/K}$$
$$\Delta S_{univ} \approx -200\text{ J/K} + 300\text{ J/K} = 100\text{ J/K}$$

Given the negative ΔH°_{rxn}, Le Châtelier's principle says that low T favors NH_3 formation, so the answer is reasonable (see Section 17.6).

Comment **1.** Because ΔH° has units of kJ, and ΔS has units of J/K, don't forget to convert kJ to J, or you'll introduce a large error.
2. This example highlights the distinction between thermodynamics and kinetics. NH_3 forms spontaneously, but so slowly that catalysts are required to achieve a practical rate.

FOLLOW-UP PROBLEMS

20.3A Gaseous phosphorus trichloride forms from the elements through this reaction:

$$P_4(s) + 6Cl_2(g) \longrightarrow 4PCl_3(g)$$

Calculate ΔH°_{rxn}, ΔS_{surr}, and ΔS°_{rxn} to determine if the reaction is spontaneous at 298 K.

20.3B Does the oxidation of $FeO(s)$ to $Fe_2O_3(s)$ occur spontaneously at 298 K? (Show the calculation for 1 mol Fe_2O_3.)

SOME SIMILAR PROBLEMS 20.39–20.42

Do Organisms Obey the Laws of Thermodynamics? Taking the surroundings into account is crucial, not only for determining reaction spontaneity, as in Sample Problem 20.3, but also for understanding the relevance of thermodynamics to biology. Let's examine the first and second laws to see if they apply to living systems.

1. *Do organisms comply with the first law?* The chemical bond energy in food and oxygen is converted into the mechanical energy of jumping, flying, crawling, swimming, and countless other movements; the electrical energy of nerve conduction; the thermal energy of warming the body; and so forth. Many experiments have demonstrated that the total energy is conserved in these situations. Some of the earliest were performed by Lavoisier, who showed that "animal heat" was produced by slow, continual combustion. In experiments with guinea pigs, he invented a calorimeter to measure the heat released from intake of food and O_2 and output of CO_2 and water, and he included respiration in his new theory of combustion. Modern, room-sized calorimeters measure these and other variables to confirm the conservation of energy for an exercising human (Figure 20.12).

Figure 20.12 **A whole-body calorimeter.** In this room-sized apparatus, a person exercises while respiratory gases, energy input and output, and other physiological variables are monitored.

2. *Do organisms comply with the second law?* Mature humans are far more complex than the egg and sperm cells from which they develop, and modern organisms are far more complex than the one-celled ancestral specks from which they evolved. Are the growth of an organism and the evolution of life exceptions to the spontaneous tendency of natural processes to increase freedom of motion and disperse energy? For an organism to grow or a species to evolve, many moles of oxygen and nutrients—carbohydrates, proteins, and fats—undergo exothermic reactions to form many *more* moles of gaseous CO_2 and H_2O. Formation of these waste gases and the accompanying release of heat result in an enormous *increase* in the entropy of the surroundings. Thus, the localization of energy and synthesis of macromolecular structures required for the growth and evolution of organisms (system) cause a far greater dispersal of energy and freedom of motion in the environment (surroundings). When system *and* surroundings are considered together, the entropy of the universe, as always, increases.

The Entropy Change and the Equilibrium State

For a process approaching equilibrium, $\Delta S_{univ} > 0$. When the process reaches equilibrium, there is no further *net* change, $\Delta S_{univ} = 0$, because any entropy change in the system is balanced by an opposite entropy change in the surroundings:

$$\text{At equilibrium:} \quad \Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr} = 0 \text{ so } \Delta S_{sys} = -\Delta S_{surr}$$

As an example, let's calculate ΔS_{univ} for the vaporization-condensation of 1 mol of water at 100°C (373 K),

$$H_2O(l;\ 373\text{ K}) \rightleftharpoons H_2O(g;\ 373\text{ K})$$

First, we find ΔS°_{sys} for the forward change (vaporization) of 1 mol of water:

$$\Delta S^\circ_{sys} = \Sigma m S^\circ_{products} - \Sigma n S^\circ_{reactants} = S^\circ \text{ of } H_2O(g;\ 373\ K) - S^\circ \text{ of } H_2O(l;\ 373\ K)$$
$$= 195.9\ J/K - 86.8\ J/K = 109.1\ J/K$$

As we expect, the entropy of the system increases ($\Delta S^\circ_{sys} > 0$) as the liquid absorbs heat and changes to a gas.

For ΔS_{surr} of the vaporization step, we have

$$\Delta S_{surr} = -\frac{\Delta H^\circ_{sys}}{T}$$

where $\Delta H^\circ_{sys} = \Delta H^\circ_{vap}$ at 373 K = 40.7 kJ/mol = 40.7×10^3 J/mol. For 1 mol of water, we have

$$\Delta S_{surr} = -\frac{\Delta H^\circ_{vap}}{T} = -\frac{40.7\times10^3\ J}{373\ K} = -109\ J/K$$

The surroundings lose heat, and the negative sign means that the entropy of the surroundings decreases. The two entropy changes have the same magnitude but opposite signs, so they cancel:

$$\Delta S_{univ} = 109\ J/K + (-109\ J/K) = 0$$

For the reverse change (condensation), ΔS_{univ} also equals zero, but ΔS°_{sys} and ΔS_{surr} have signs opposite those for vaporization.

A similar treatment of a chemical change shows the same result: the entropy change of the forward reaction is *equal in magnitude but opposite in sign* to the entropy change of the reverse reaction. Thus, *when a system reaches equilibrium, neither the forward nor the reverse reaction is spontaneous,* and so there is no net reaction in either direction.

Spontaneous Exothermic and Endothermic Changes

No matter what its *enthalpy* change, a reaction occurs because the total *entropy* of the reacting system *and* its surroundings increases. There are two ways this can happen:

1. *In an exothermic reaction* ($\Delta H_{sys} < 0$), the heat released by the system increases the freedom of motion and dispersal of energy in the surroundings; thus, $\Delta S_{surr} > 0$.

- If the entropy of the products is *more* than that of the reactants ($\Delta S_{sys} > 0$), the total entropy change ($\Delta S_{sys} + \Delta S_{surr}$) will be positive (Figure 20.13A). For example, in the oxidation of glucose, an essential reaction for all higher organisms,

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g) + \textbf{\textit{heat}}$$

  6 mol of gas yields 12 mol of gas; thus, $\Delta S_{sys} > 0$, $\Delta S_{surr} > 0$, and $\Delta S_{univ} > 0$.
- If the entropy of the products is *less* than that of the reactants ($\Delta S_{sys} < 0$), the entropy of the surroundings must increase even more ($\Delta S_{surr} >> 0$) to make the total ΔS positive (Figure 20.13B). For example, when calcium oxide and carbon dioxide form calcium carbonate, the amount (mol) of gas decreases from 1 to 0:

$$CaO(s) + CO_2(g) \longrightarrow CaCO_3(s) + \textbf{\textit{heat}}$$

  However, even though the system's entropy goes down, the heat released increases the entropy of the surroundings even more; thus, $\Delta S_{sys} < 0$, but $\Delta S_{surr} >> 0$, so $\Delta S_{univ} > 0$.

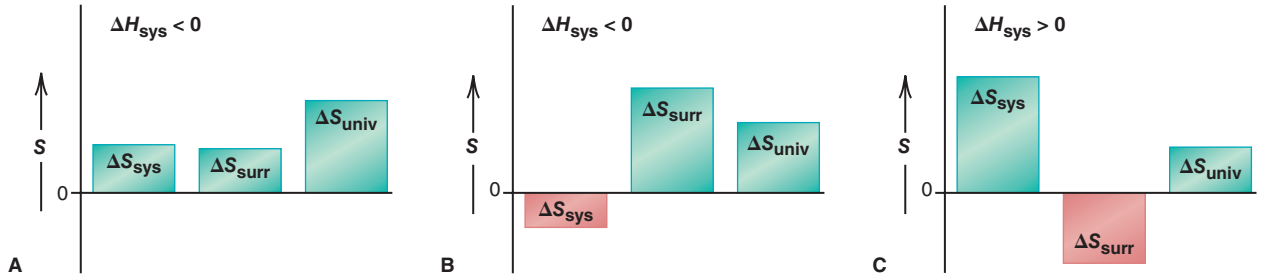


Figure 20.13 Components of ΔS_{univ} for spontaneous reactions. For a reaction to occur spontaneously, ΔS_{univ} must be positive. **A,** An exothermic reaction in which ΔS_{sys} increases; the size of ΔS_{surr} is not important. **B,** An exothermic reaction in which ΔS_{sys} decreases; ΔS_{surr} must be larger than ΔS_{sys}. **C,** An endothermic reaction in which ΔS_{sys} increases; ΔS_{surr} must be smaller than ΔS_{sys}.

2. *In an endothermic reaction* ($\Delta H_{sys} > 0$), the heat absorbed by the system decreases molecular freedom of motion and dispersal of energy in the surroundings; so $\Delta S_{surr} < 0$. Thus, the only way an endothermic reaction can occur spontaneously is if ΔS_{sys} is positive and large enough to outweigh the negative ΔS_{surr} (Figure 20.13C).

- In the solution process for many ionic compounds, heat is absorbed to form the solution, so the entropy of the surroundings decreases ($\Delta S_{surr} < 0$). However, when the crystalline solid becomes freely moving ions, the entropy increase is so large ($\Delta S_{sys} >> 0$) that it outweighs the negative ΔS_{surr}. Thus, ΔS_{univ} is positive.
- Spontaneous endothermic reactions are similar. Recall the reaction between barium hydroxide octahydrate and ammonium nitrate (Figure 20.1, p. 879),

$$\textit{heat} + Ba(OH)_2 \cdot 8H_2O(s) + 2NH_4NO_3(s) \longrightarrow Ba^{2+}(aq) + 2NO_3^-(aq) + 2NH_3(aq) + 10H_2O(l)$$

3 mol of crystalline solids absorb heat from the surroundings ($\Delta S_{surr} < 0$) and yields 15 mol of dissolved ions and molecules, which have much more freedom of motion and, therefore, much greater entropy ($\Delta S_{sys} >> 0$).

Summary of Section 20.2

- The standard entropy of reaction, ΔS°_{rxn}, is calculated from S° values.
- When the amount (mol) of gas increases in a reaction, usually $\Delta S^\circ_{rxn} > 0$.
- ΔS_{surr} is related directly to $-\Delta H^\circ_{sys}$ and inversely to the T at which the change occurs.
- In a spontaneous change, the entropy of the system can decrease only if the entropy of the surroundings increases even more, so that $\Delta S_{univ} > 0$.
- The second law is obeyed in living systems when we consider system *plus* surroundings.
- For a system at equilibrium, $\Delta S_{univ} = 0$, so $\Delta S^\circ_{sys} = -\Delta S_{surr}$.
- Even if $\Delta S^\circ_{sys} < 0$, an exothermic reaction ($\Delta H^\circ_{rxn} < 0$) is spontaneous ($\Delta S_{univ} > 0$) if $\Delta S_{surr} >> 0$; an endothermic reaction ($\Delta H^\circ_{rxn} > 0$) is spontaneous only if $\Delta S^\circ_{sys} > \Delta S_{surr}$.

20.3 ENTROPY, FREE ENERGY, AND WORK

By measuring *both* ΔS_{sys} *and* ΔS_{surr}, we can predict whether a reaction will be spontaneous at a particular temperature. It would be useful to have *one* criterion for spontaneity that we can determine *by measuring the system only*. The Gibbs free energy, or simply **free energy (*G*),** combines the system's enthalpy and entropy:

$$G = H - TS$$

One of the greatest but least recognized American scientists, Josiah Willard Gibbs (1839–1903), established chemical thermodynamics as well as major principles of equilibrium and electrochemistry. Although the great European scientists of his time, James Clerk Maxwell and Henri Le Châtelier, realized Gibbs's achievements, he was not recognized by his American colleagues until nearly 50 years after his death!

Free Energy Change and Reaction Spontaneity

The free energy change (ΔG) is a measure of the spontaneity of a process and of the useful energy available from it.

Deriving the Gibbs Equation Let's examine the meaning of ΔG by deriving it from the second law. By definition, the entropy change of the universe is the sum of the entropy changes of the system and the surroundings:

$$\Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr}$$

At constant pressure,

$$\Delta S_{surr} = -\frac{\Delta H_{sys}}{T}$$

Substituting for ΔS_{surr} gives a relationship that relies solely on the system:

$$\Delta S_{univ} = \Delta S_{sys} - \frac{\Delta H_{sys}}{T}$$

Multiplying both sides by $-T$ and rearranging gives

$$-T\Delta S_{univ} = \Delta H_{sys} - T\Delta S_{sys}$$

Using the Gibbs free energy relationship, $G = H - TS$, we obtain the *Gibbs equation* for the *change* in the free energy of the system (ΔG_{sys}) at constant T and P:

$$\Delta G_{sys} = \Delta H_{sys} - T\Delta S_{sys} \qquad (20.6)$$

Combining Equation 20.6 with the one preceding it shows that

$$-T\Delta S_{univ} = \Delta G_{sys} = \Delta H_{sys} - T\Delta S_{sys}$$

Spontaneity and the Sign of ΔG Let's see how the *sign* of ΔG tells if a reaction is spontaneous. According to the second law,

- $\Delta S_{univ} > 0$ for a spontaneous process
- $\Delta S_{univ} < 0$ for a nonspontaneous process
- $\Delta S_{univ} = 0$ for a process at equilibrium

Since the absolute temperature is always positive, for a spontaneous process,

$$T\Delta S_{univ} > 0 \qquad \text{so} \qquad -T\Delta S_{univ} < 0$$

From our derivation above, $\Delta G = -T\Delta S_{univ}$, so we have

- $\Delta G < 0$ for a spontaneous process
- $\Delta G > 0$ for a nonspontaneous process
- $\Delta G = 0$ for a process at equilibrium

Without incorporating any new ideas, we can now predict spontaneity with one variable (ΔG_{sys}) rather than two (ΔS_{sys} and ΔS_{surr}).

Calculating Standard Free Energy Changes

The *sign* of ΔG reveals *whether* a reaction is spontaneous, but the *magnitude* of ΔG tells *how* spontaneous it is. Because free energy (G) combines three state functions, H, S, and T, it is also a state function. As we do with enthalpy, we focus on the free energy *change* (ΔG). As we do with other thermodynamic variables, to compare the free energy changes of different reactions, we calculate the ***standard* free energy change ($\Delta G°$),** which occurs when all components of the system are in their standard states.

Using the Gibbs Equation to Find $\Delta G°$ One way to calculate $\Delta G°$ is by writing the Gibbs equation (20.6) at standard-state conditions and using Appendix B to find $\Delta H°_{sys}$ and $\Delta S°_{sys}$. Adapting the Gibbs equation, we have

$$\Delta G°_{sys} = \Delta H°_{sys} - T\Delta S°_{sys} \qquad (20.7)$$

This important relationship is used to find any one of these three variables, given the other two, as in Sample Problem 20.4.

Fireworks explode spontaneously.

SAMPLE PROBLEM 20.4 **Calculating $\Delta G°_{rxn}$ from Enthalpy and Entropy Values**

Problem Potassium chlorate, a common oxidizing agent in fireworks *(see photo)* and matchheads, undergoes a solid-state disproportionation reaction when heated:

$$\overset{+5}{4KClO_3(s)} \xrightarrow{\Delta} \overset{+7}{3KClO_4(s)} + \overset{-1}{KCl(s)}$$

Use $\Delta H°_f$ and $S°$ values to calculate $\Delta G°_{sys}$ (which is $\Delta G°_{rxn}$) at 25°C for this reaction.

Plan To solve for $\Delta G°$, we need values from Appendix B. We use $\Delta H°_f$ values to calculate $\Delta H°_{rxn}$ ($\Delta H°_{sys}$), use $S°$ values to calculate $\Delta S°_{rxn}$ ($\Delta S°_{sys}$), and then apply Equation 20.7.

Solution Calculating ΔH°_{sys} from ΔH°_f values (with Equation 6.9, p. 271):

$$\begin{aligned}\Delta H^\circ_{sys} &= \Delta H^\circ_{rxn} = \Sigma m\Delta H^\circ_{f(products)} - \Sigma n\Delta H^\circ_{f(reactants)}\\ &= [(3\text{ mol } KClO_4)(\Delta H^\circ_f \text{ of } KClO_4) + (1\text{ mol KCl})(\Delta H^\circ_f \text{ of KCl})]\\ &\quad - [(4\text{ mol } KClO_3)(\Delta H^\circ_f \text{ of } KClO_3)]\\ &= [(3\text{ mol})(-432.75\text{ kJ/mol}) + (1\text{ mol})(-436.7\text{ kJ/mol})]\\ &\quad - [(4\text{ mol})(-397.7\text{ kJ/mol})]\\ &= -144.2\text{ kJ}\end{aligned}$$

Calculating ΔS°_{sys} from S° values (with Equation 20.4):

$$\begin{aligned}\Delta S^\circ_{sys} &= \Delta H^\circ_{rxn} = \Sigma mS^\circ_{products} - \Sigma nS^\circ_{reactants}\\ &= [(3\text{ mol } KClO_4)(S^\circ \text{ of } KClO_4) + (1\text{ mol KCl})(S^\circ \text{ of KCl})]\\ &\quad - [(4\text{ mol } KClO_3)(S^\circ \text{ of } KClO_3)]\\ &= [(3\text{ mol})(151.0\text{ J/mol·K}) + (1\text{ mol})(82.6\text{ J/mol·K})]\\ &\quad - [(4\text{ mol})(143.1\text{ J/mol·K})]\\ &= -36.8\text{ J/K}\end{aligned}$$

Calculating ΔG°_{sys} at 298 K:

$$\Delta G^\circ_{sys} = \Delta H^\circ_{sys} - T\Delta S^\circ_{sys} = -144.2\text{ kJ} - \left[(298\text{ K})(-36.8\text{ J/K})\left(\frac{1\text{ kJ}}{1000\text{ J}}\right)\right] = \boxed{-133.2\text{ kJ}}$$

Check Rounding to check the math:

$$\Delta H^\circ \approx [3(-433\text{ kJ}) + (-440\text{ kJ})] - [4(-400\text{ kJ})] = -1740\text{ kJ} + 1600\text{ kJ} = -140\text{ kJ}$$
$$\Delta S^\circ \approx [3(150\text{ J/K}) + 85\text{ J/K}] - [4(145\text{ J/K})] = 535\text{ J/K} - 580\text{ J/K} = -45\text{ J/K}$$
$$\Delta G^\circ \approx -140\text{ kJ} - 300\text{ K}(-0.04\text{ kJ/K}) = -140\text{ kJ} + 12\text{ kJ} = -128\text{ kJ}$$

Comment **1.** Recall from Section 20.1 that reaction spontaneity tells nothing about rate. Even though this reaction is spontaneous, the rate is very low in the solid. When $KClO_3$ is heated slightly above its melting point, the ions can move and the reaction occurs readily.
2. Under *any* conditions, a spontaneous reaction has a negative change in free energy: $\Delta G < 0$. Under standard-state conditions, a spontaneous reaction has a negative *standard* free energy change: $\Delta G^\circ < 0$.

FOLLOW-UP PROBLEMS

20.4A Use ΔH°_{rxn} and ΔS°_{rxn} to calculate ΔG°_{rxn} at 298 K for this reaction:

$$2NO(g) + Cl_2(g) \longrightarrow 2NOCl(g)$$

20.4B Determine the standard free energy change at 298 K for this reaction:

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

SOME SIMILAR PROBLEMS 20.53 and 20.54

Using Standard Free Energies of Formation to Find ΔG°_{rxn} Another way to calculate ΔG°_{rxn} is with values for the **standard free energy of formation (ΔG°_f)** of the components. Analogously to the standard enthalpy of formation, ΔH°_f (Section 6.6), ΔG°_f is the free energy change that occurs when 1 mol of compound is made *from its elements,* with all components in their standard states. Because free energy is a state function, we can apply Hess's law and combine ΔG°_f values of reactants and products to calculate ΔG°_{rxn}, no matter how the reaction takes place:

$$\Delta G^\circ_{rxn} = \Sigma m\Delta G^\circ_{f(products)} - \Sigma n\Delta G^\circ_{f(reactants)} \qquad \textbf{(20.8)}$$

ΔG°_f values have properties similar to ΔH°_f values:

- ΔG°_f of an element in its standard state is zero.
- An equation coefficient (m or n above) multiplies ΔG°_f by that number.
- Reversing a reaction changes the sign of ΔG°_f.

Many ΔG°_f values appear along with those for ΔH°_f and S° in Appendix B.

SAMPLE PROBLEM 20.5 Calculating ΔG°_{rxn} from ΔG°_f Values

Problem Use ΔG°_f values to calculate ΔG°_{rxn} for the reaction in Sample Problem 20.4:

$$4KClO_3(s) \longrightarrow 3KClO_4(s) + KCl(s)$$

Plan We apply Equation 20.8 to calculate ΔG°_{rxn}.

Solution Applying Equation 20.8 with values from Appendix B:

$$\begin{aligned}\Delta G^\circ_{rxn} &= \Sigma m\Delta G^\circ_{f(products)} - \Sigma n\Delta G^\circ_{f(reactants)}\\ &= [(3\text{ mol } KClO_4)(\Delta G^\circ_f \text{ of } KClO_4) + (1\text{ mol KCl})(\Delta G^\circ_f \text{ of KCl})]\\ &\quad - [(4\text{ mol } KClO_3)(\Delta G^\circ_f \text{ of } KClO_3)]\\ &= [(3\text{ mol})(-303.2\text{ kJ/mol}) + (1\text{ mol})(-409.2\text{ kJ/mol})]\\ &\quad - [(4\text{ mol})(-296.3\text{ kJ/mol})]\\ &= -134\text{ kJ}\end{aligned}$$

Check Rounding to check the math:

$$\begin{aligned}\Delta G^\circ_{rxn} &\approx [3(-300\text{ kJ}) + 1(-400\text{ kJ})] - 4(-300\text{ kJ})\\ &= -1300\text{ kJ} + 1200\text{ kJ} = -100\text{ kJ}\end{aligned}$$

Comment The slight discrepancy between this answer and the one obtained in Sample Problem 20.4 is due to rounding. As you can see, when ΔG°_f values are available, this method is simpler arithmetically than the approach in Sample Problem 20.4.

FOLLOW-UP PROBLEMS

20.5A Use ΔG°_f values to calculate ΔG°_{rxn} at 298 K:
(a) $2NO(g) + Cl_2(g) \longrightarrow 2NOCl(g)$ (from Follow-up Problem 20.4A)
(b) $3H_2(g) + Fe_2O_3(s) \longrightarrow 2Fe(s) + 3H_2O(g)$

20.5B Use ΔG°_f values to calculate ΔG°_{rxn} at 25°C:
(a) $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$ (from Follow-up Problem 20.4B)
(b) $2C(\text{graphite}) + O_2(g) \longrightarrow 2CO(g)$

SOME SIMILAR PROBLEMS 20.51, 20.52, 20.55(b), and 20.56(b)

The Free Energy Change and the Work a System Can Do

Thermodynamics developed after the invention of the steam engine, a major advance that spawned a new generation of machines. Thus, some of the field's key ideas applied the relationships between the free energy change and the work a system can do:

- ΔG is the *maximum useful work* that can be done ***by*** a system during a *spontaneous* process at constant T and P:

$$\Delta G = w_{max} \qquad (20.9)$$

- ΔG is the *minimum work* that must be done ***to*** a system to make a *nonspontaneous* process occur at constant T and P.

The free energy change is the maximum work the system can *possibly* do. But the work it *actually* does is always less and depends on how the free energy is released. Let's consider the work done by two common systems—a car engine and a battery.

1. *"Useful" work done by a car engine*. When gasoline (represented by octane, C_8H_{18}) is burned in a car engine,

$$C_8H_{18}(l) + \tfrac{25}{2}O_2(g) \longrightarrow 8CO_2(g) + 9H_2O(g)$$

a large amount of energy is released as heat ($\Delta H_{sys} < 0$), and because the number of moles of gas increases, the entropy of the system increases ($\Delta S_{sys} > 0$). Therefore, the reaction is spontaneous ($\Delta G_{sys} < 0$). The free energy released turns the wheels, moves the belts, plays the radio, and so on—all examples of "useful" work. However, the *maximum* work is done by any spontaneous process *only if the free energy is released reversibly,* that is, *in an infinite number of steps.* Of course, in any *real* process, work is performed in a *finite* number of steps, that is, *irreversibly,* so *the maximum work is never done*. Any free energy not used for work is lost to the surroundings

as heat. For a car engine, much of the free energy released just warms the engine and the outside air, which increases the freedom of motion of the particles in the universe, in accord with the second law.

2. *"Useful" work done by a battery.* As you'll see in Chapter 21, a battery is essentially a packaged spontaneous redox reaction that releases free energy in the form of an electric current to the surroundings (flashlight, computer, motor, etc.). If we connect the battery terminals to each other through a short piece of wire, the free energy change is released all at once but does no work—it just heats the wire and battery. If we connect the terminals to a motor, a significant portion of the free energy runs the motor, but some is still converted to heat. If we connect the battery to a more "efficient" device, one that discharges the free energy still more slowly, more of the energy does work and less is converted to heat. However, as with all systems, only when the battery discharges infinitely slowly can it do the maximum work.

Efficiency can be defined as the percentage of work output relative to the energy input. The range of efficiencies among common devices is very large: an incandescent bulb converts <7% of incoming electricity to light, the rest being given off as heat. At the other extreme, an electrical generator converts 95% of the incoming mechanical energy to electricity. Here are the efficiencies of some other devices: home oil furnace, 65%; hand-tool motor, 63%; liquid fuel rocket, 50%; car engine, <30%; compact fluorescent bulb, 18%; solar cell, ~15%. Therefore, all engineers must face the fact that *no **real** process uses all the available free energy to do work because some is always "wasted" as heat.*

Let's summarize the relation between the free energy change of a reaction and the work it can do:

- A spontaneous reaction ($\Delta G_{sys} < 0$) will do work on the surroundings ($-w$). For any real machine, the actual work done is *always less than the maximum* because some of the ΔG is released as heat.
- A nonspontaneous reaction ($\Delta G_{sys} > 0$) will occur only if the surroundings do work on the system ($+w$). For any real machine, the actual work done on the system is *always more than the minimum* because some of the added free energy is wasted as heat.
- A reaction at equilibrium ($\Delta G_{sys} = 0$) can no longer do any work.

The Effect of Temperature on Reaction Spontaneity

In most cases, the enthalpy contribution (ΔH) to the free energy change (ΔG) is much *larger* than the entropy contribution ($T\Delta S$). In fact, the reason most exothermic reactions are spontaneous is that the large negative ΔH makes ΔG negative. However, the *temperature of a reaction influences the magnitude of the $T\Delta S$ term,* so, for many reactions, the overall spontaneity depends on the temperature. From the signs of ΔH and ΔS, we can predict how the temperature affects the sign of ΔG. (The values we'll use below for the thermodynamic variables are standard-state values from Appendix B, but we show them without the degree sign to emphasize that the relationships among ΔG, ΔH, and ΔS are valid at any conditions. Also, we assume that ΔH and ΔS change little with temperature, which is true as long as no phase change occurs.)

Let's examine the four combinations of positive and negative ΔH and ΔS—two that are independent of temperature and two that are dependent on temperature:

- *Temperature-independent cases.* When ΔH and ΔS have *opposite* signs, the reaction occurs spontaneously either at all temperatures or at none (nonspontaneous).
  1. *Reaction is spontaneous at all temperatures:* $\Delta H < 0$, $\Delta S > 0$. Since ΔS is positive, $-T\Delta S$ is negative; thus, both contributions favor a negative ΔG. Most combustion reactions are in this category. The decomposition of hydrogen peroxide, a common disinfectant, is also spontaneous at all temperatures:

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$
$$\Delta H = -196 \text{ kJ} \quad \text{and} \quad \Delta S = 125 \text{ J/K}$$

2. *Reaction is nonspontaneous at all temperatures:* $\Delta H > 0$, $\Delta S < 0$. Both contributions oppose spontaneity: ΔH is positive and ΔS is negative, so $-T\Delta S$ is positive; thus, ΔG is always positive. The formation of ozone from oxygen requires a continual energy input, so it is not spontaneous at any temperature:

$$3O_2(g) \longrightarrow 2O_3(g)$$
$$\Delta H = 286 \text{ kJ} \quad \text{and} \quad \Delta S = -137 \text{ J/K}$$

- *Temperature-dependent cases.* When ΔH and ΔS have the *same* sign, the relative magnitudes of $-T\Delta S$ and ΔH determine the sign of ΔG. In these cases, the *direction* of the change in T is crucial.

3. *Reaction becomes spontaneous as temperature increases:* $\Delta H > 0$ *and* $\Delta S > 0$. With a positive ΔH, the reaction will occur spontaneously only when $-T\Delta S$ becomes large enough to make ΔG negative, which will happen as the temperature rises. For example,

$$2N_2O(g) + O_2(g) \longrightarrow 4NO(g)$$
$$\Delta H = 197.1 \text{ kJ} \quad \text{and} \quad \Delta S = 198.2 \text{ J/K}$$

The oxidation of N_2O occurs spontaneously at any $T > 994$ K.

4. *Reaction becomes spontaneous as temperature decreases:* $\Delta H < 0$ *and* $\Delta S < 0$. Here, ΔH favors spontaneity, but ΔS does not ($-T\Delta S > 0$). The reaction will occur spontaneously only when $-T\Delta S$ becomes smaller than ΔH, and this happens as the temperature drops. For example,

$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$$
$$\Delta H = -1651 \text{ kJ} \quad \text{and} \quad \Delta S = -549.4 \text{ J/K}$$

The production of iron(III) oxide occurs spontaneously at any $T < 3005$ K.

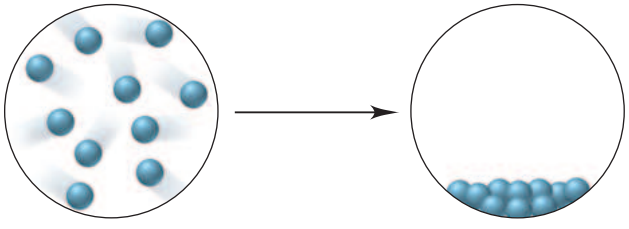
Table 20.1 summarizes these four possible combinations of ΔH and ΔS, and Sample Problem 20.6 applies them.

Table 20.1 Reaction Spontaneity and the Signs of ΔH, ΔS, and ΔG

ΔH	ΔS	$-T\Delta S$	ΔG	Description
−	+	−	−	Spontaneous at all T
+	−	+	+	Nonspontaneous at all T
+	+	−	+ or −	Spontaneous at higher T; nonspontaneous at lower T
−	−	+	+ or −	Spontaneous at lower T; nonspontaneous at higher T

SAMPLE PROBLEM 20.6 Using Molecular Scenes to Determine the Signs of ΔH, ΔS, and ΔG

Problem The scenes below represent a familiar phase change for water *(blue spheres):*



(a) What are the signs of ΔH and ΔS for this process? Explain.
(b) Is the process spontaneous at all T, no T, low T, or high T? Explain.

Plan **(a)** From the scenes, we determine any change in amount of gas and/or any change in the freedom of motion of the particles, which will indicate the sign of ΔS.

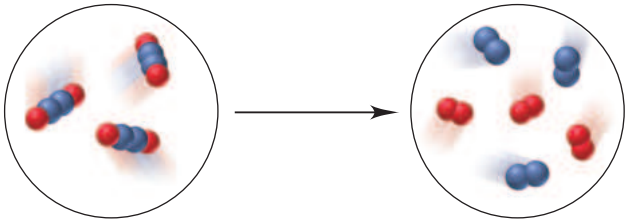
Also, since the scenes represent a physical change, freedom of particle motion indicates whether heat is absorbed or released, and thus tells us the sign of ΔH. **(b)** The question refers to the sign of ΔG (+ or −) at the different temperature possibilities, so we apply Equation 20.6 and refer to the previous text discussion and Table 20.1.

Solution **(a)** The scenes represent the condensation of water vapor, so the amount of gas decreases dramatically, and the separated molecules give up energy as they come closer together. Therefore, $\Delta S < 0$ and $\Delta H < 0$.
(b) With ΔS negative, the $-T\Delta S$ term is positive. In order for $\Delta G < 0$, the magnitude of T must be small. Therefore, the process is spontaneous at low T.

Check The answer in part (b) seems reasonable based on our analysis in part (a). The answer makes sense because we know from everyday experience that water condenses spontaneously, and it does so at low temperatures.

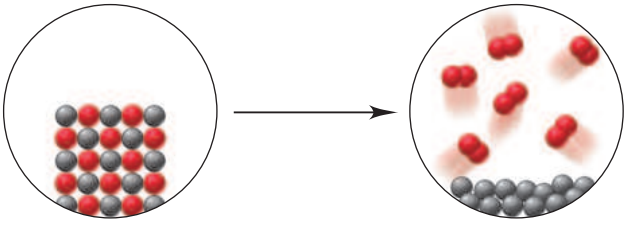
FOLLOW-UP PROBLEMS

20.6A The scenes below represent the reaction of X_2Y_2 to yield X_2 *(red)* and Y_2 *(blue)*:



(a) What is the sign of ΔS for the reaction?
(b) If the reaction is spontaneous only above 325°C, what is the sign of ΔH? Explain.

20.6B The scenes below represent the reaction of AB to yield A *(gray)* and B_2 *(red)*:



(a) What are the signs of ΔS and ΔH for the reaction?
(b) Is $\Delta G < 0$ at higher T, lower T, all T, or no T? Explain.

SOME SIMILAR PROBLEMS 20.47 and 20.48

As you saw in Sample Problem 20.4, one way to calculate ΔG is from enthalpy and entropy changes. As long as phase changes don't occur, ΔH and ΔS usually change little with temperature, so we use their values at 298 K in Sample Problem 20.7 to examine the effect of T on ΔG and, thus, on reaction spontaneity.

SAMPLE PROBLEM 20.7 Determining the Effect of Temperature on ΔG

Problem A key step in the production of sulfuric acid is the oxidation of $SO_2(g)$ to $SO_3(g)$:

$$2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$$

At 298 K, $\Delta G = -141.6$ kJ; $\Delta H = -198.4$ kJ; and $\Delta S = -187.9$ J/K.
(a) Use the data to decide if this reaction is spontaneous at 25°C, and predict how ΔG will change with increasing T.
(b) Assuming that ΔH and ΔS are constant with T (no phase change occurs), is the reaction spontaneous at 900.°C?

Plan **(a)** We note the sign of ΔG to see if the reaction is spontaneous and the signs of ΔH and ΔS to see the effect of T. **(b)** We use Equation 20.7 to calculate ΔG from the given ΔH and ΔS at the higher T (in K).

Solution **(a)** $\Delta G < 0$, so the reaction is spontaneous at 298 K: SO_2 and O_2 will form SO_3 spontaneously. With $\Delta S < 0$, the term $-T\Delta S > 0$, and this term will become more positive at higher T. Therefore, ΔG will become less negative, and the reaction less spontaneous, with increasing T.

(b) Calculating ΔG at 900.°C ($T = 273 + 900. = 1173$ K):

$$\Delta G = \Delta H - T\Delta S = -198.4 \text{ kJ} - [(1173 \text{ K})(-187.9 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] = 22.0 \text{ kJ}$$

$\Delta G > 0$, so the reaction is nonspontaneous at the higher T.

Check The answer in part (b) seems reasonable based on our prediction in part (a). The arithmetic seems correct, given considerable rounding:

$$\Delta G \approx -200 \text{ kJ} - [(1200 \text{ K})(-200 \text{ J/K})(1 \text{ kJ}/1000 \text{ J})] = +40 \text{ kJ}$$

FOLLOW-UP PROBLEMS

20.7A For the following reaction at 298 K, $\Delta S = -308.2$ J/K and $\Delta H = -192.7$ kJ:

$$4NO(g) \longrightarrow N_2O(g) + N_2O_3(g)$$

(a) Is the reaction spontaneous at 298 K?
(b) Would the reaction become more or less spontaneous at higher T?
(c) Assuming that ΔS and ΔH don't change with T, find ΔG at 500.°C.

20.7B A reaction is nonspontaneous at room temperature but *is* spontaneous at −40°C. What can you say about the signs and relative magnitudes of ΔH, ΔS, and $-T\Delta S$?

SOME SIMILAR PROBLEMS 20.57(b) and 20.58(b)

The Temperature at Which a Reaction Becomes Spontaneous

As you've just seen, when the signs are the same for ΔH and ΔS of a reaction, it can be nonspontaneous at one temperature and spontaneous at another. The "crossover" temperature occurs when a positive ΔG switches to a negative ΔG because of the magnitude of the $-T\Delta S$ term. We find this temperature by setting ΔG equal to zero and solving for T:

$$\Delta G = \Delta H - T\Delta S = 0$$

Therefore,

$$\Delta H = T\Delta S \quad \text{and} \quad T = \frac{\Delta H}{\Delta S} \tag{20.10}$$

Consider the reaction of copper(I) oxide with carbon. It does *not* occur at very low temperatures but does at higher temperatures and is used to extract copper from one of its ores:

$$Cu_2O(s) + C(s) \xrightarrow{\Delta} 2Cu(s) + CO(g)$$

We predict that this reaction has a positive ΔS because the number of moles of gas increases; in fact, $\Delta S = 165$ J/K. Furthermore, because the reaction is *non*spontaneous at lower temperatures, it must have a positive ΔH; the actual value is 58.1 kJ. As the $-T\Delta S$ term becomes more negative with higher T, it eventually outweighs the positive ΔH term, so ΔG becomes negative and the reaction occurs spontaneously.

SAMPLE PROBLEM 20.8 Finding the Temperature at Which a Reaction Becomes Spontaneous

Problem At 25°C (298 K), the reduction of copper(I) oxide to copper is nonspontaneous ($\Delta G = 8.9$ kJ). Calculate the temperature at which the reaction becomes spontaneous.

Plan As just discussed, we want the temperature at which ΔG crosses over from a positive to a negative value. We set ΔG equal to zero, and use Equation 20.10 to solve for T, using the ΔH (58.1 kJ) and ΔS (165 J/K) values from the text.

Solution From $\Delta G = \Delta H - T\Delta S = 0$, we have

$$T = \frac{\Delta H}{\Delta S} = \frac{58.1 \text{ kJ} \times \dfrac{1000 \text{ J}}{1 \text{ kJ}}}{165 \text{ J/K}} = 352 \text{ K}$$

Thus, at any temperature above 352 K (79°C), which is a moderate temperature for extracting a metal from its ore, $\Delta G < 0$, so the reaction becomes spontaneous.

Check Rounding to quickly check the math gives

$$T = \frac{60{,}000\ \text{J}}{150\ \text{J/K}} = 400\ \text{K}$$

which is close to the answer.

FOLLOW-UP PROBLEMS

20.8A Find the temperature (in °C) above which the reaction in Follow-up Problem 20.7A is no longer spontaneous.

20.8B Use Appendix B values to find the temperature at which the following reaction becomes spontaneous (assume ΔH and ΔS are constant with T):

$$CaO(s) + CO_2(g) \longrightarrow CaCO_3(s)$$

SOME SIMILAR PROBLEMS 20.59(d) and 20.60(d)

Figure 20.14 shows that the line for $T\Delta S$ rises steadily (and thus the $-T\Delta S$ term becomes more negative) with increasing temperature. This line crosses the relatively constant ΔH line at 352 K, as we found in Sample Problem 20.8. At any higher temperature, the $-T\Delta S$ term is greater than the ΔH term, so ΔG is negative.

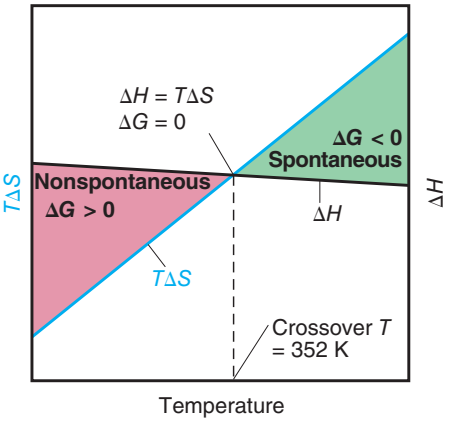


Figure 20.14 The effect of temperature on reaction spontaneity. At low T, $\Delta G > 0$ because ΔH dominates. At 352 K, $\Delta H = T\Delta S$, so $\Delta G = 0$. At any higher T, $\Delta G < 0$ because $-T\Delta S$ dominates.

Coupling of Reactions to Drive a Nonspontaneous Change

In a complex, multistep reaction, we often see a nonspontaneous step driven by a spontaneous step. In such a **coupling of reactions,** *one step supplies enough free energy for the other to occur,* just as burning gasoline supplies enough free energy to move a car.

Look again at the reduction of copper(I) oxide by carbon. In Sample Problem 20.8, we found that the *overall* reaction becomes spontaneous at any temperature above 352 K. Dividing the reaction into two steps, however, we find that even at a higher temperature, say 375 K, copper(I) oxide does not spontaneously decompose to its elements:

$$Cu_2O(s) \longrightarrow 2Cu(s) + \tfrac{1}{2}O_2(g) \qquad \Delta G_{375} = 140.0\ \text{kJ}$$

However, the oxidation of carbon to CO at 375 K is quite spontaneous:

$$C(s) + \tfrac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta G_{375} = -143.8\ \text{kJ}$$

Coupling these reactions means having the carbon in contact with the Cu_2O, which allows the reaction with the larger negative ΔG to "drive" the one with the smaller positive ΔG. Adding the reactions together and canceling the common substance ($\frac{1}{2}O_2$) gives an overall reaction with a negative ΔG:

$$Cu_2O(s) + C(s) \longrightarrow 2Cu(s) + CO(g) \qquad \Delta G_{375} = -3.8\ \text{kJ}$$

Many biochemical reactions are also nonspontaneous, including key steps in the syntheses of proteins and nucleic acids, the formation of fatty acids, the maintenance of ion balance, and the breakdown of nutrients. Driving a nonspontaneous step by coupling it to a spontaneous one is a life-sustaining strategy common to all organisms, as you'll see in the upcoming Chemical Connections essay.

Summary of Section 20.3

- The sign of the free energy change, $\Delta G = \Delta H - T\Delta S$, is directly related to reaction spontaneity: a negative ΔG corresponds to a positive ΔS_{univ}.
- We use the standard free energy of formation (ΔG_f°) to calculate ΔG_{rxn}° at 298 K.
- The maximum work a system can do is never obtained from a real (irreversible) process because some free energy is always converted to heat.
- The magnitude of T influences the spontaneity of a temperature-dependent reaction (same signs of ΔH and ΔS) by affecting the size of $T\Delta S$. For such a reaction, the T at which the reaction becomes spontaneous can be found by setting $\Delta G = 0$.
- A nonspontaneous reaction ($\Delta G > 0$) can be coupled to a more spontaneous one ($\Delta G << 0$) to make it occur. For example, in organisms, the hydrolysis of ATP drives many reactions that have a positive ΔG.

The Universal Role of ATP

Despite their incredible diversity, virtually all organisms use the same amino acids to make their proteins, the same nucleotides to make their nucleic acids, and the same carbohydrate (glucose) to provide energy.

In addition, *all organisms use the same spontaneous reaction to drive a variety of nonspontaneous ones*. This reaction is the hydrolysis of **adenosine triphosphate (ATP)** to adenosine diphosphate (ADP):*

$$ATP^{4-} + H_2O \rightleftharpoons ADP^{3-} + HPO_4^{2-} + H^+$$
$$\Delta G^{\circ\prime} = -30.5 \text{ kJ}$$

In the metabolic breakdown of glucose, for example, the first step, addition of HPO_4^{2-} to glucose, is nonspontaneous:

$$\text{Glucose} + HPO_4^{2-} + H^+ \rightleftharpoons [\text{glucose phosphate}]^- + H_2O$$
$$\Delta G^{\circ\prime} = 13.8 \text{ kJ}$$

Coupling this nonspontaneous reaction to ATP hydrolysis makes the overall process spontaneous. If we add the two reactions, HPO_4^{2-}, H^+, and H_2O cancel:

$$\text{Glucose} + ATP^{4-} \rightleftharpoons [\text{glucose phosphate}]^- + ADP^{3-}$$
$$\Delta G^{\circ\prime} = -16.7 \text{ kJ}$$

Coupling cannot occur if reactions are physically separated, so these reactions take place on an enzyme (Section 16.7) that simultaneously binds glucose and ATP, and the phosphate group of ATP that will be transferred lies next to the —OH group of glucose that will bind it (Figure B20.1).

The ADP produced in energy-releasing reactions combines with phosphate to regenerate ATP in energy-absorbing reactions catalyzed by other enzymes. Thus, there is a continuous cycling of ATP to ADP and back to ATP again to supply energy to the cells (Figure B20.2).

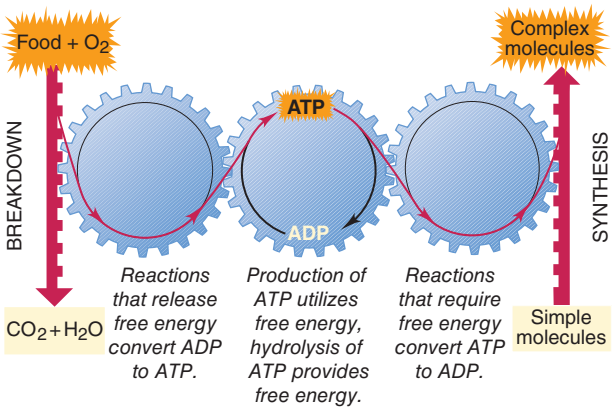

Figure B20.2 **The cycling of metabolic free energy.**

Why is ATP a "high-energy" molecule? By examining the phosphate portions of ATP, ADP, and HPO_4^{2-}, we can see two basic chemical reasons why ATP hydrolysis supplies so much free energy (Figure B20.3):

1. *Charge repulsion*. At physiological pH (~7), the triphosphate group of ATP has four negative charges close together. This *high charge repulsion* is reduced in ADP (Figure B20.3, part A).
2. *Electron delocalization*. Once HPO_4^{2-} is free, there is extensive delocalization and resonance stabilization of the π electrons (Figure B20.3, part B).

*In biochemical systems, the standard-state concentration of H^+ is 10^{-7} *M*, not the usual 1 *M*, and the standard free energy change has the symbol $\Delta G^{\circ\prime}$.

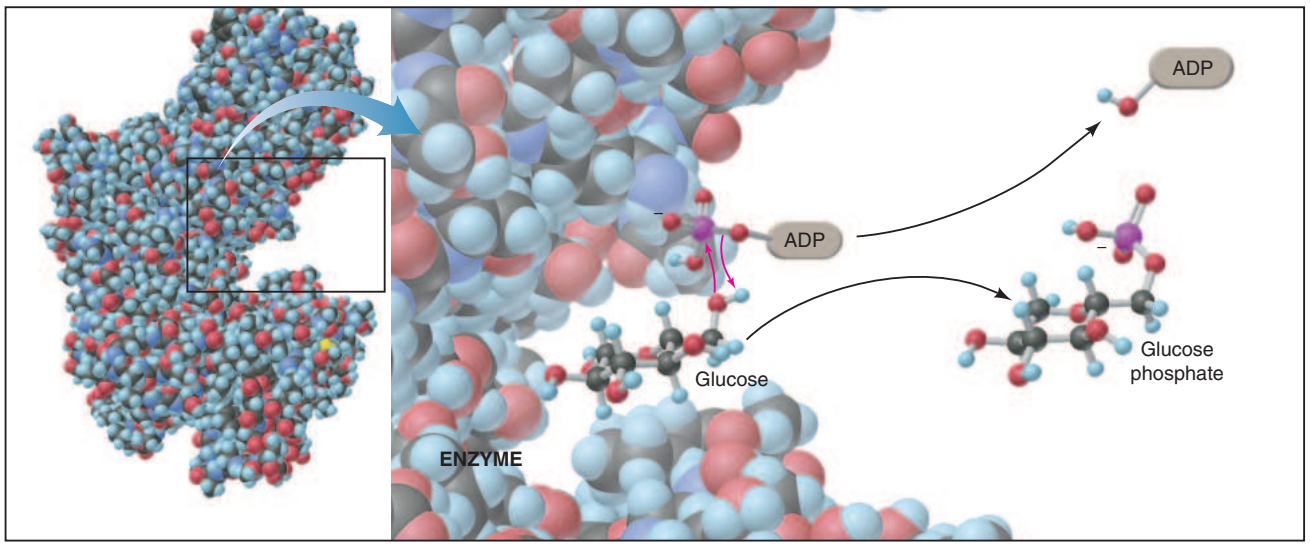

Figure B20.1 **The coupling of a nonspontaneous reaction to the hydrolysis of ATP.** Glucose lies next to ATP (shown as ADP—O—PO_3H) in the enzyme's active site. ADP (shown as ADP—OH) and glucose phosphate are released.

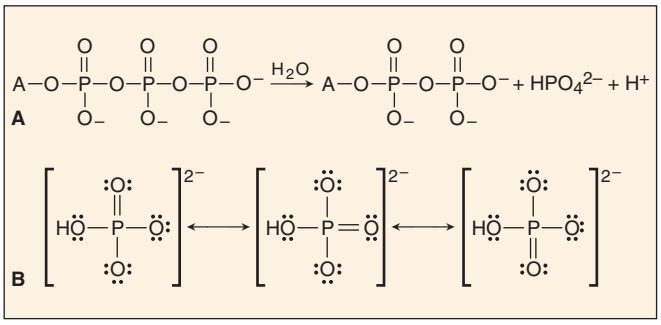

Figure B20.3 ATP is a high-energy molecule.

Thus, greater charge repulsion and less electron delocalization make ATP higher in energy (less stable) than the sum of the energies of ADP and HPO_4^{2-}. When ATP is hydrolyzed, some of this additional energy is released and harnessed by the organism to drive metabolic reactions that could not otherwise take place.

Problems

B20.1 The oxidation of 1 mol of glucose supplies enough metabolic energy to form 36 mol of ATP. Oxidation of 1 mol of a typical dietary fat like tristearin ($C_{57}H_{116}O_6$) yields enough energy to form 458 mol of ATP. How many molecules of ATP can form per gram of (a) glucose; (b) tristearin?

B20.2 Nonspontaneous processes like muscle contraction, protein synthesis, and nerve conduction are coupled to the spontaneous hydrolysis of ATP to ADP. ATP is then regenerated by coupling its synthesis to energy-yielding reactions such as

Creatine phosphate $\longrightarrow$ creatine + phosphate

$$\Delta G^{\circ\prime} = -43.1 \text{ kJ/mol}$$

Find $\Delta G^{\circ\prime}$ for the overall reaction that regenerates ATP from ADP and HPO_4^{2-} by coupling with the breakdown of creatine phosphate.

20.4 FREE ENERGY, EQUILIBRIUM, AND REACTION DIRECTION

A chemical reaction proceeding toward equilibrium is a spontaneous change. But *why* is there a drive to attain equilibrium? And what determines the value of the equilibrium constant?

As you know from earlier discussions, the sign of ΔG is not the only way to predict reaction direction. In Chapter 17, we did so by comparing the values of the reaction quotient (Q) and the equilibrium constant (K). Recall that

- If $Q < K$ ($Q/K < 1$): reaction proceeds spontaneously to the right.
- If $Q > K$ ($Q/K > 1$): reaction proceeds spontaneously to the left.
- If $Q = K$ ($Q/K = 1$): reaction has attained equilibrium and no longer proceeds spontaneously in either direction.

It is easier to see the relation between these two ways to predict reaction spontaneity—the sign of ΔG and the magnitude of Q/K—when we compare the sign of the natural logarithm of Q/K ($\ln Q/K$) with the sign of ΔG (refer to Appendix A if necessary):

- If $Q/K < 1$, then $\ln Q/K < 0$: reaction proceeds spontaneously to the right ($\Delta G < 0$).
- If $Q/K > 1$, then $\ln Q/K > 0$: reaction proceeds spontaneously to the left ($\Delta G > 0$).
- If $Q/K = 1$, then $\ln Q/K = 0$: reaction is at equilibrium ($\Delta G = 0$).

Note that the signs of ΔG and of $\ln Q/K$ are the same for a given direction; in fact, ΔG equals $\ln Q/K$ multiplied by the proportionality constant RT:

$$\Delta G = RT \ln \frac{Q}{K} = RT \ln Q - RT \ln K \qquad (20.11)$$

Q represents the concentrations (or pressures) of a system's components at any time during the reaction, and K represents these quantities at equilibrium. Therefore,

Equation 20.11 says that ΔG is a measure of how different the concentrations at any time, Q, are from the concentrations at equilibrium, K:

- If Q and K are very different, the reaction releases (or absorbs) a *lot* of free energy.
- If Q and K are nearly the same, the reaction releases (or absorbs) relatively *little*.

The Standard Free Energy Change and the Equilibrium Constant When we choose standard-state values for Q (1 atm for gases, 1 M for solutions, etc.) in Equation 20.11, ΔG becomes, by definition, $\Delta G°$ and Q equals 1:

$$\Delta G° = RT \ln 1 - RT \ln K$$

Since $\ln 1 = 0$, the term "$RT \ln Q$" drops out, which allows us to find the standard free energy change of a reaction ($\Delta G°_{rxn}$) from its equilibrium constant, or vice versa:

$$\Delta G° = -RT \ln K \qquad \textbf{(20.12)}$$

The following sample problem applies this central relationship.

SAMPLE PROBLEM 20.9 Exploring the Relationship Between $\Delta G°$ and K

Problem **(a)** Use Appendix B to find K at 298 K for the following reaction:

$$NO(g) + \tfrac{1}{2}O_2(g) \rightleftharpoons NO_2(g)$$

(b) Use the equilibrium constant to calculate $\Delta G°$ at 298 K for the following reaction:

$$2HCl(g) \rightleftharpoons H_2(g) + Cl_2(g) \qquad K = 3.89\times10^{-34} \text{ at } 298 \text{ K}$$

Plan **(a)** We use $\Delta G°_f$ values from Appendix B with Equation 20.8 to find $\Delta G°$, and then we use Equation 20.12 to solve for K. **(b)** In this calculation, we do the reverse of the second calculation in part (a): we are given that $K = 3.89\times10^{-34}$, so we use Equation 20.12 to solve for $\Delta G°$.

Solution **(a)** Solving for $\Delta G°$ using $\Delta G°_f$ values from Appendix B and Equation 20.8 (see Sample Problem 20.5):

$$\begin{aligned}\Delta G° &= [(1 \text{ mol } NO_2)(\Delta G°_f \text{ of } NO_2)] - [(1 \text{ mol NO})(\Delta G°_f \text{ of NO}) \\ &\quad + (\tfrac{1}{2} \text{ mol of } O_2)(\Delta G°_f \text{ of } O_2)] \\ &= [(1 \text{ mol})(51 \text{ kJ/mol})] - [(1 \text{ mol})(86.60 \text{ kJ/mol}) + (\tfrac{1}{2} \text{ mol})(0 \text{ kJ/mol})] \\ &= -36 \text{ kJ}\end{aligned}$$

Solving for K using Equation 20.12:

$$\Delta G° = -RT \ln K$$

so

$$\ln K = -\frac{\Delta G°}{RT} = -\frac{(-36 \text{ kJ})(1000 \text{ J}/1 \text{ kJ})}{(8.314 \text{ J/mol·K})(298 \text{ K})} = 14.53$$

$$K = e^{14.53} = \boxed{2.0\times10^6}$$

(b) Solving for $\Delta G°$ using Equation 20.12:

$$K = 3.89\times10^{-34} \qquad \text{so} \qquad \ln K = -76.9$$

$$\Delta G° = -RT \ln K = -(8.314 \text{ J/mol·K})(298 \text{ K})(-76.9)$$

$$= 1.91\times10^5 \text{ J} = \boxed{191 \text{ kJ}}$$

Check **(a)** A negative free energy change is consistent with a positive K. Rounding to confirm the value of $\Delta G°$ gives 50 kJ − 90 kJ = −40 kJ, close to the calculated value. **(b)** A very negative K is consistent with a highly positive $\Delta G°$. Looking up $\Delta G°_f$ values to check the value of $\Delta G°$ gives (0 kJ + 0 kJ) − [2(−95.30 kJ)] = −190.6 kJ.

FOLLOW-UP PROBLEMS

20.9A Use Appendix B to find K at 298 K for the following reaction:

$$2C(\text{graphite}) + O_2(g) \rightleftharpoons 2CO(g)$$

20.9B Use the given value of K to calculate $\Delta G°$ at 298 K for the following reaction:

$$2HCl(g) + Br_2(l) \rightleftharpoons 2HBr(g) + Cl_2(g) \qquad K = 2.22\times10^{-15} \text{ at } 298 \text{ K}$$

SOME SIMILAR PROBLEMS 20.67–20.70

Table 20.2 The Relationship Between $\Delta G°$ and K at 298 K

$\Delta G°$ (kJ)	K	Significance
200	9×10^{-36}	Essentially no forward reaction; reverse reaction goes to completion.
100	3×10^{-18}	
50	2×10^{-9}	
10	2×10^{-2}	
1	7×10^{-1}	
0	1	Forward and reverse reactions proceed to same extent.
−1	1.5	
−10	5×10^{1}	
−50	6×10^{8}	
−100	3×10^{17}	
−200	1×10^{35}	Forward reaction goes to completion; essentially no reverse reaction.

FORWARD REACTION

REVERSE REACTION

Table 20.2 shows that, due to their logarithmic relationship, a small change in $\Delta G°$ causes a large change in K. Note just these two examples:

- As $\Delta G°$ becomes more positive, K becomes smaller: if $\Delta G° = +10$ kJ, K is 0.02, so the product terms are $\frac{1}{50}$ the size of the reactant terms (see Figure 17.2A, p. 733).
- As $\Delta G°$ becomes more negative, K becomes larger: if $\Delta G° = -10$ kJ, the product terms are 50 times larger than the reactant terms (see Figure 17.2B, p. 733).

Finding the Free Energy Change Under Any Conditions In reality, reactions rarely begin with all components in their standard states. By substituting the relationship between $\Delta G°$ and K (Equation 20.12) into the expression for ΔG (Equation 20.11), we obtain a relationship that applies to *any starting concentrations:*

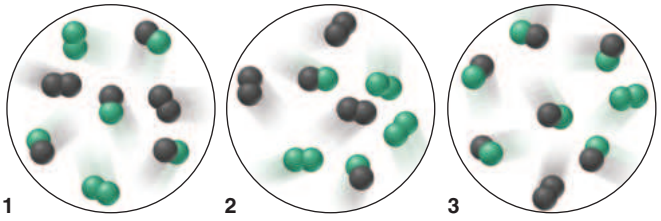
$$\Delta G = \Delta G° + RT \ln Q \qquad \textbf{(20.13)}$$

Sample Problem 20.10 uses molecular scenes to explore these ideas, and Sample Problem 20.11 applies them to an important industrial reaction.

SAMPLE PROBLEM 20.10 Using Molecular Scenes to Find ΔG for a Reaction at Nonstandard Conditions

Problem These molecular scenes represent three mixtures in which A_2 *(black)* and B_2 *(green)* are forming AB. Each molecule represents 0.10 atm. The equation is

$$A_2(g) + B_2(g) \rightleftharpoons 2AB(g) \qquad \Delta G° = -3.4 \text{ kJ/mol}$$



(a) If mixture 1 is at equilibrium, calculate K.
(b) Which mixture has the most negative ΔG, and which has the most positive?

Plan **(a)** Mixture 1 is at equilibrium, so we first write the expression for Q and then find the partial pressure of each substance from the numbers of molecules and calculate K. **(b)** To find ΔG, we apply Equation 20.13. We are given $\Delta G°$ (−3.4 kJ/mol) and know R (8.314 J/mol·K), but we still need to find T. We calculate T from Equation 20.12 using K from part (a), and substitute the partial pressure of each substance (by counting particles) to get Q.

Solution **(a)** Writing the expression for Q and calculating K:

$$A_2(g) + B_2(g) \rightleftharpoons 2AB(g) \qquad Q = \frac{P_{AB}{}^2}{P_{A_2} \times P_{B_2}} \qquad K = \frac{(0.40)^2}{(0.20)(0.20)} = 4.0$$

(b) Calculating T from Equation 20.12 for use in Equation 20.13:

$$\Delta G^\circ = -RT \ln K = -\frac{3.4\ \text{kJ}}{\text{mol}} = -\left(\frac{8.314\ \text{J}}{\text{mol·K}}\right) T \ln 4.0$$

$$T = \frac{\Delta G^\circ}{-R \ln K} = \frac{\dfrac{-3.4\ \text{kJ}}{\text{mol}}\left(\dfrac{1000\ \text{J}}{1\ \text{kJ}}\right)}{-\left(\dfrac{8.314\ \text{J}}{\text{mol·K}}\right) \ln 4.0} = 295\ \text{K}$$

Calculating ΔG from Equation 20.13 for each reaction mixture:
Mixture 1:

$$\Delta G = \Delta G^\circ + RT \ln Q = -3.4\ \text{kJ} + RT \ln 4.0$$
$$= -3.4\ \text{kJ}\left(\frac{1000\ \text{J}}{1\ \text{kJ}}\right) + \left(\frac{8.314\ \text{J}}{\text{mol·K}}\right)(295\ \text{K}) \ln 4.0$$
$$= -3400\ \text{J} + 3400\ \text{J} = 0.0\ \text{J}$$

Mixture 2:

$$\Delta G = -3.4\ \text{kJ} + RT \ln \frac{(0.20)^2}{(0.30)(0.30)}$$
$$= -3.4\ \text{kJ}\left(\frac{1000\ \text{J}}{1\ \text{kJ}}\right) + \left(\frac{8.314\ \text{J}}{\text{mol·K}}\right)(295\ \text{K}) \ln 0.44$$
$$= -5.4\times10^3\ \text{J}$$

Mixture 3:

$$\Delta G = -3.4\ \text{kJ/mol} + RT \ln \frac{(0.60)^2}{(0.10)(0.10)}$$
$$= -3.4\ \text{kJ/mol}\left(\frac{1000\ \text{J}}{1\ \text{kJ}}\right) + \left(\frac{8.314\ \text{J}}{\text{mol·K}}\right)(295\ \text{K}) \ln 36$$
$$= 5.4\times10^3\ \text{J}$$

Mixture 2 has the most negative ΔG, and mixture 3 has the most positive ΔG.

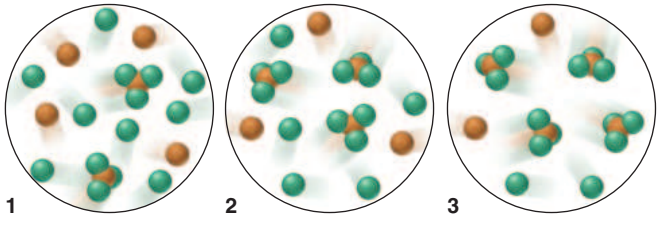
Check In (b), round to check the arithmetic; for example, for mixture 3, $\Delta G \approx -3000\ \text{J} + (8\ \text{J/mol·K})(300\ \text{K})4 \approx 7000\ \text{J}$, which is in the correct ballpark.

Comment **1.** By using the properties of logarithms, we did *not* have to calculate T and ΔG in (b). For mixture 2, $Q < 1$, so $\ln Q$ is negative, which makes ΔG more negative. Also, note that $Q(0.44) < K(4.0)$, so $\Delta G < 0$. For mixture 3, $Q > 1$ (and is greater than it is for mixture 1), so $\ln Q$ is positive, which makes ΔG positive. Also, $Q(36) > K(4.0)$, so $\Delta G > 0$.
2. In (b), the value of zero for ΔG of the equilibrium mixture (mixture 1) makes sense, because a system at equilibrium has released all of its free energy.
3. Note especially that, by definition, when the components are in their standard states, $\Delta G = \Delta G^\circ$:

$$\Delta G = \Delta G^\circ + RT \ln Q = -3.4\ \text{kJ/mol} + RT \ln \frac{(1.0)^2}{(1.0)(1.0)}$$
$$= -3.4\ \text{kJ/mol} + RT \ln 1.0 = -3.4\ \text{kJ/mol}$$

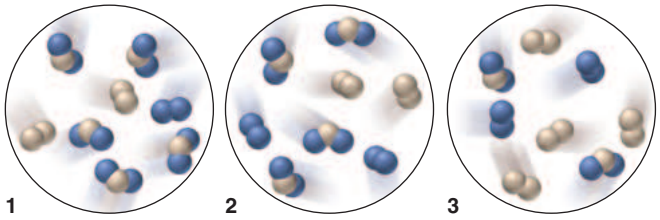
FOLLOW-UP PROBLEMS

20.10A The scenes below depict three mixtures in which A *(orange)* and B *(green)* are forming AB_3 in a reaction for which $\Delta G^\circ = -4.6$ kJ/mol. Assume that each molecule represents 0.10 mol and the volume is 1.0 L.



(a) Write a balanced equation for the reaction. **(b)** If $K = 8.0$, which mixture is at equilibrium? **(c)** Rank the three mixtures from the highest (most positive) ΔG to the lowest (most negative) ΔG.

20.10B The scenes below depict mixtures in which X_2 *(tan)* and Y_2 *(blue)* are forming XY_2. Each molecule represents 0.10 mol, and the volume is 0.10 L. The equation is $X_2(g) + 2Y_2(g) \rightleftharpoons 2XY_2(g)$; $\Delta G^\circ = -1.3$ kJ/mol.



(a) If $K = 2.0$, which mixture is at equilibrium? **(b)** Rank the three mixtures from the lowest (most negative) ΔG to highest (most positive) ΔG. **(c)** What is the sign of ΔG for the change that occurs as each nonequilibrium mixture approaches equilibrium?

SOME SIMILAR PROBLEMS 20.81 and 20.82

SAMPLE PROBLEM 20.11 Calculating ΔG at Nonstandard Conditions

Problem The oxidation of $SO_2(g)$, $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$, is the key reaction in the manufacture of sulfuric acid.

(a) Calculate K at 298 K. ($\Delta G^\circ_{298} = -141.6$ kJ/mol of reaction as written.)

(b) A container is filled with 0.500 atm of SO_2, 0.0100 atm of O_2, and 0.100 atm of SO_3 and kept at 25°C. In which direction, if any, will the reaction proceed to reach equilibrium?

(c) Calculate ΔG for the system in part (b).

Plan **(a)** We know ΔG°, T, and R, so we can calculate K from Equation 20.12 [see Sample Problem 20.9(a)]. **(b)** To determine if a net reaction will occur, we find Q from the given partial pressures and compare it with K from part (a). **(c)** These are *not* standard-state pressures, so we find ΔG at 298 K with Equation 20.13 from the values of ΔG° (given) and Q [from part (b)].

Solution **(a)** Calculating K at 298 K:

$$\Delta G^\circ = -RT \ln K \qquad \text{so} \qquad K = e^{-(\Delta G^\circ/RT)}$$

At 298 K, the exponent is

$$-(\Delta G^\circ/RT) = -\left(\frac{-141.6 \text{ kJ/mol} \times \dfrac{1000 \text{ J}}{1 \text{ kJ}}}{8.314 \text{ J/mol·K} \times 298 \text{ K}}\right) = 57.2$$

so

$$K = e^{-(\Delta G^\circ/RT)} = e^{57.2} = 7\times10^{24}$$

(b) Calculating the value of Q:

$$Q = \frac{P^2_{SO_3}}{P^2_{SO_2} \times P_{O_2}} = \frac{0.100^2}{0.500^2 \times 0.0100} = 4.00$$

Because $Q < K$, the denominator will decrease and the numerator will increase—more SO_3 will form—until Q equals K. To reach equilibrium, the reaction will proceed to the right.

(c) Calculating ΔG, the nonstandard free energy change, at 298 K:

$$\begin{aligned}\Delta G_{298} &= \Delta G^\circ + RT \ln Q \\ &= -141.6 \text{ kJ/mol} + \left(8.314 \text{ J/mol·K} \times \frac{1 \text{ kJ}}{1000 \text{ J}} \times 298 \text{ K} \times \ln 4.00\right) \\ &= -138.2 \text{ kJ/mol}\end{aligned}$$

Check Note that in parts (a) and (c), we made the free energy units (kJ) consistent with the units in R (J). For significant figures in addition and subtraction, we retain one digit to the right of the decimal place in part (c).

Comment As in the synthesis of NH_3 (Section 17.6), where the *yield* is high but the *rate* is low at a lower temperature, this process is carried out at higher temperature *with a catalyst* to attain a higher *rate*. We discuss the details of the industrial production of sulfuric acid in Chapter 22.

FOLLOW-UP PROBLEMS

20.11A At 298 K, $\Delta G^\circ = -33.5$ kJ/mol for the formation of chloroethane from ethylene and hydrogen chloride:

$$C_2H_4(g) + HCl(g) \rightleftharpoons C_2H_5Cl(g)$$

(a) Calculate K at 298 K.
(b) Calculate ΔG at 298 K if $[C_2H_5Cl] = 1.5\ M$, $[C_2H_4] = 0.50\ M$, and $[HCl] = 1.0\ M$.

20.11B At 298 K, hypobromous acid (HBrO) dissociates in water with $K_a = 2.3\times10^{-9}$.
(a) Calculate ΔG° for the dissociation of HBrO.
(b) Calculate ΔG if $[H_3O^+] = 6.0\times10^{-4}\ M$, $[BrO^-] = 0.10\ M$, and $[HBrO] = 0.20\ M$.

SOME SIMILAR PROBLEMS 20.79 and 20.80

Another Look at the Meaning of Spontaneity At this point, we introduce two terms related to *spontaneous* and *nonspontaneous:*

1. *Product-favored reaction*. For the general reaction

$$A \rightleftharpoons B \qquad K = [B]/[A] > 1$$

and therefore, the reaction proceeds largely from left to right (Figure 20.15A). From pure A to equilibrium, $Q < K$ and the curved *green* arrow in the figure indicates that the reaction is spontaneous ($\Delta G < 0$). From there on, the curved *red* arrow indicates that the reaction is nonspontaneous ($\Delta G > 0$). Similarly, from pure B to equilibrium, $Q > K$ and the reaction is also spontaneous ($\Delta G < 0$), but not thereafter. In either case, *free energy decreases until the reaction reaches a minimum at the equilibrium mixture: $Q = K$ and $\Delta G = 0$.* For the overall reaction A $\rightleftharpoons$ B (starting with all components in their standard states), G°_B is smaller than G°_A, so ΔG° is negative, which corresponds to $K > 1$. We call this a *product-favored* reaction because in its final state the system contains mostly product.

2. *Reactant-favored reaction*. For the opposite reaction,

$$C \rightleftharpoons D \qquad K = [D]/[C] < 1$$

and the reaction proceeds slightly from left to right (Figure 20.15B). Here, too, whether we start with pure C or pure D, the reaction is spontaneous ($\Delta G < 0$) until

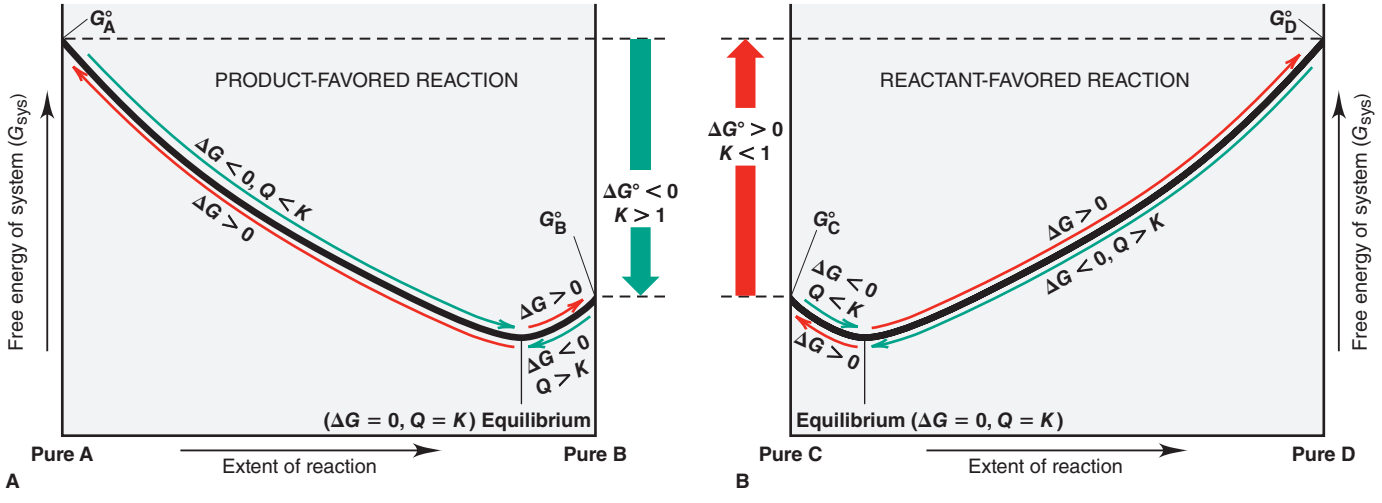


Figure 20.15 Free energy and the extent of reaction. Each reaction proceeds spontaneously *(curved green arrows)* from reactants (A or C) or products (B or D) to the equilibrium mixture, at which point $\Delta G = 0$. After that, the reaction is nonspontaneous *(curved red arrows).* **A,** For the product-favored reaction A $\rightleftharpoons$ B, $G^\circ_A > G^\circ_B$, so $\Delta G^\circ < 0$ and $K > 1$. **B,** For the reactant-favored reaction C $\rightleftharpoons$ D, $G^\circ_D > G^\circ_C$, so $\Delta G^\circ > 0$ and $K < 1$.

equilibrium. In this case, however, the equilibrium mixture contains mostly C (the reactant), so we say the reaction is *reactant favored*. Here, G°_D is *larger* than G°_C, so ΔG° is *positive,* which corresponds to $K < 1$.

Thus, "*spontaneous*" refers to that *portion* of a reaction in which the free energy decreases—from the starting mixture to the equilibrium mixture. A product-favored reaction goes predominantly, but *not* completely, toward product, and a reactant-favored reaction goes relatively little toward product (see Table 20.2).

Summary of Section 20.4

- Two ways of predicting reaction spontaneity are from the sign of ΔG or from the value of Q/K. These variables are related to each other by $\Delta G = RT \ln Q/K$. When $Q = K$, $Q/K = 1$ and $\ln Q/K = 0$. Thus, the system is at equilibrium and can release no more free energy.
- Beginning with Q at the standard state, the free energy change is ΔG° and is related to the equilibrium constant: $\Delta G^\circ = -RT \ln K$.
- Any nonequilibrium mixture of reactants and products moves spontaneously ($\Delta G < 0$) toward the equilibrium mixture.
- A product-favored reaction goes predominantly toward product and, thus, has $K > 1$ and $\Delta G^\circ < 0$; a reactant-favored reaction has $K < 1$ and $\Delta G^\circ > 0$.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How the tendency of a process to occur by itself is distinct from how long it takes to occur (Introduction)
2. The distinction between a spontaneous and a nonspontaneous change (§20.1)
3. Why the first law of thermodynamics and the sign of ΔH° cannot predict the direction of a spontaneous process (§20.1)
4. How the entropy (S) of a system is defined by the number of microstates over which its energy is dispersed (§20.1)
5. How entropy is alternatively defined by the heat absorbed (or released) at constant T in a reversible process (§20.1)
6. The criterion for spontaneity according to the second law of thermodynamics: that a change increases S_{univ} (§20.1)
7. How absolute values of standard molar entropies (S°) can be obtained because the third law of thermodynamics provides a "zero point" (§20.1)
8. How temperature, physical state, dissolution, atomic size, and molecular complexity influence S° values (§20.1)
9. How ΔS°_{rxn} is based on the difference between the summed S° values for the reactants and those for products (§20.2)
10. How the surroundings add heat to or remove heat from the system and how ΔS_{surr} influences overall ΔS°_{rxn} (§20.2)
11. The relationship between ΔS_{surr} and ΔH_{sys} (§20.2)
12. How reactions proceed spontaneously toward equilibrium ($\Delta S_{univ} > 0$) but proceed no further at equilibrium ($\Delta S_{univ} = 0$) (§20.2)
13. How the free energy change (ΔG) combines a system's entropy and enthalpy changes (§20.3)
14. How the expression for the free energy change is derived from the second law (§20.3)
15. The relationship between ΔG and the maximum work a system can perform and why this quantity of work is never performed in a real process (§20.3)
16. How temperature determines spontaneity for reactions in which ΔS and ΔH have the same sign (§20.3)
17. Why the temperature at which a reaction becomes spontaneous occurs when $\Delta G = 0$ (§20.3)
18. How a spontaneous change can be coupled to a nonspontaneous change to make it occur (§20.3)
19. How ΔG is related to the ratio of Q to K (§20.4)
20. The meaning of ΔG° and its relation to K (§20.4)
21. The relation of ΔG to ΔG° and Q (§20.4)
22. Why G decreases, no matter what the starting concentrations, as the reacting system moves toward equilibrium (§20.4)
23. The distinction between product-favored and reactant-favored reactions (§20.4)

Master These Skills

1. Predicting relative S° values of systems (§20.1 and SP 20.1)
2. Calculating ΔS°_{rxn} for a chemical change (SP 20.2)
3. Finding reaction spontaneity from ΔS_{surr} and ΔH°_{sys} (SP 20.3)
4. Calculating ΔG°_{rxn} from ΔH°_f and S° values (SP 20.4)
5. Calculating ΔG°_{rxn} from ΔG°_f values (SP 20.5)
6. Predicting the signs of ΔH, ΔS, and ΔG (SP 20.6)
7. Determining the effect of temperature on ΔG (SP 20.7)
8. Calculating the temperature at which a reaction becomes spontaneous (§20.3 and SP 20.8)
9. Calculating K from ΔG° and vice versa (§20.4 and SP 20.9)
10. Using ΔG° and Q to calculate ΔG at any conditions (SPs 20.10, 20.11)

Key Terms

Page numbers appear in parentheses.

Section 20.1
spontaneous change (877)
microstate (880)
entropy (S) (880)
second law of thermodynamics (883)
third law of thermodynamics (883)
standard molar entropy ($S°$) (883)

Section 20.2
standard entropy of reaction ($\Delta S°_{rxn}$) (888)

Section 20.3
free energy (G) (893)
standard free energy change ($\Delta G°$) (894)
standard free energy of formation ($\Delta G°_f$) (895)
coupling of reactions (901)
adenosine triphosphate (ATP) (902)

Key Equations and Relationships

Page numbers appear in parentheses.

20.1 Quantifying entropy in terms of the number of microstates (W) over which the energy of a system can be dispersed (880):

$$S = k \ln W$$

20.2 Quantifying the entropy change in terms of heat absorbed (or released) in a reversible process (882):

$$\Delta S_{sys} = \frac{q_{rev}}{T}$$

20.3 Stating the second law of thermodynamics, for a spontaneous process (883):

$$\Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr} > 0$$

20.4 Calculating the standard entropy of reaction from the standard molar entropies of reactants and products (888):

$$\Delta S°_{rxn} = \Sigma m S°_{products} - \Sigma n S°_{reactants}$$

20.5 Relating the entropy change in the surroundings to the enthalpy change of the system and the temperature (890):

$$\Delta S_{surr} = -\frac{\Delta H_{sys}}{T}$$

20.6 Expressing the free energy change of the system in terms of its component enthalpy and entropy changes (Gibbs equation) (894):

$$\Delta G_{sys} = \Delta H_{sys} - T\Delta S_{sys}$$

20.7 Calculating the standard free energy change from standard enthalpy and entropy changes (894):

$$\Delta G°_{sys} = \Delta H°_{sys} - T\Delta S°_{sys}$$

20.8 Calculating the standard free energy change from the standard free energies of formation (895):

$$\Delta G°_{rxn} = \Sigma m \Delta G°_{f(products)} - \Sigma n \Delta G°_{f(reactants)}$$

20.9 Relating the free energy change to the maximum work a process can do (896):

$$\Delta G = w_{max}$$

20.10 Finding the temperature at which a reaction becomes spontaneous (900):

$$T = \frac{\Delta H}{\Delta S}$$

20.11 Expressing the free energy change in terms of Q and K (903):

$$\Delta G = RT \ln \frac{Q}{K} = RT \ln Q - RT \ln K$$

20.12 Expressing the free energy change when Q is at standard state conditions (904):

$$\Delta G° = -RT \ln K$$

20.13 Expressing the free energy change for nonstandard initial conditions (905):

$$\Delta G = \Delta G° + RT \ln Q$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

20.1A (a) $PCl_5(g)$: higher molar mass and more complex molecule; (b) $BaCl_2(s)$: higher molar mass; (c) $Br_2(g)$: gases have more freedom of motion and dispersal of energy than liquids.

20.1B (a) LiBr(aq): same number of ions, but lower molar mass of ions; (b) quartz: the particles have less freedom of motion in the crystalline structure; (c) cyclohexane: molecule with no side chain has less freedom of motion.

20.2A (a) $4NO(g) \longrightarrow N_2O(g) + N_2O_3(g)$
$\Delta n_{gas} = -2$, so $\Delta S°_{rxn} < 0$
$\Delta S°_{rxn} = [(1 \text{ mol } N_2O)(219.7 \text{ J/mol·K}) + (1 \text{ mol } N_2O_3)(314.7 \text{ J/mol·K})] - [(4 \text{ mol NO})(210.65 \text{ J/mol·K})]$
$= -308.2 \text{ J/K}$

(b) $CH_3OH(g) \longrightarrow CO(g) + 2H_2(g)$
$\Delta n_{gas} = 2$, so $\Delta S°_{rxn} > 0$
$\Delta S°_{rxn} = [(1 \text{ mol CO})(197.5 \text{ J/mol·K}) + (2 \text{ mol } H_2)(130.6 \text{ J/mol·K})] - [(1 \text{ mol } CH_3OH)(238 \text{ J/mol·K})]$
$= 221 \text{ J/K}$

20.2B (a) $2NaOH(s) + CO_2(g) \longrightarrow Na_2CO_3(s) + H_2O(l)$
$\Delta n_{gas} = -1$, so $\Delta S°_{rxn} < 0$
$\Delta S°_{rxn} = [(1 \text{ mol } H_2O)(69.940 \text{ J/mol·K}) + (1 \text{ mol } Na_2CO_3)(139 \text{ J/mol·K})] - [(1 \text{ mol } CO_2)(213.7 \text{ J/mol·K}) + (2 \text{ mol NaOH})(64.454 \text{ J/mol·K})]$
$= -134 \text{ J/K}$

(b) $2Fe(s) + 3H_2O(g) \longrightarrow Fe_2O_3(s) + 3H_2(g)$
$\Delta n_{gas} = 0$, so cannot predict sign of $\Delta S°_{rxn}$
$\Delta S°_{rxn} = [(1 \text{ mol } Fe_2O_3)(87.400 \text{ J/mol·K}) + (3 \text{ mol } H_2)(130.6 \text{ J/mol·K})] - [(2 \text{ mol Fe})(27.3 \text{ J/mol·K}) + (3 \text{ mol } H_2O)(188.72 \text{ J/mol·K})]$
$= -141.6 \text{ J/K}$

20.3A To find ΔS_{surr}, calculate $\Delta H°_{rxn}$ and divide it by T:
$\Delta H°_{rxn} = [(4 \text{ mol } PCl_3)(-287 \text{ kJ/mol})] - [(1 \text{ mol } P_4)(0 \text{ kJ/mol}) + (6 \text{ mol } Cl_2)(0 \text{ kJ/mol})]$
$= -1148 \text{ kJ}$

$\Delta S_{surr} = \Delta H^\circ_{rxn}$

$$T = -\frac{(1148\text{ kJ})(1000\text{ J}/1\text{ kJ})}{298\text{ K}} = 3850\text{ J/K}$$

To find ΔS_{univ}, calculate ΔS°_{rxn} and add it to ΔS_{surr}:

$\Delta S^\circ_{rxn} = [(4\text{ mol } PCl_3)(312\text{ J/mol·K})]$
$- [(1\text{ mol } P_4)(41.1\text{ J/mol·K})$
$+ (6\text{ mol } Cl_2)(223.0\text{ J/mol·K})]$
$= -131\text{ J/K}$

$\Delta S_{univ} = \Delta S_{surr} + \Delta S^\circ_{rxn} = 3850\text{ J/K} + (-131\text{ J/K}) = 3719\text{ J/K}$

Reaction is spontaneous at 298 K.

20.3B $2FeO(s) + \frac{1}{2}O_2(g) \longrightarrow Fe_2O_3(s)$

$\Delta S^\circ_{sys} = (1\text{ mol } Fe_2O_3)(87.400\text{ J/mol·K})$
$- [(2\text{ mol FeO})(60.75\text{ J/mol·K})$
$+ (\frac{1}{2}\text{ mol } O_2)(205.0\text{ J/mol·K})]$
$= -136.6\text{ J/K}$

$\Delta H^\circ_{sys} = (1\text{ mol } Fe_2O_3)(-825.5\text{ kJ/mol})$
$- [(2\text{ mol FeO})(-272.0\text{ kJ/mol}) + (\frac{1}{2}\text{ mol } O_2)(0\text{ kJ/mol})]$
$= -281.5\text{ kJ}$

$$\Delta S_{surr} = -\frac{\Delta H^\circ_{sys}}{T} = -\frac{(-281.5\text{ kJ})(1000\text{ J/kJ})}{298\text{ K}} = +945\text{ J/K}$$

$\Delta S_{univ} = \Delta S^\circ_{sys} + \Delta S_{surr} = -136.6\text{ J/K} + 945\text{ J/K} = 808\text{ J/K}$

Reaction is spontaneous at 298 K.

20.4A $\Delta H^\circ_{rxn} = [(2\text{ mol NOCl})(51.71\text{ kJ/mol})]$
$- [(2\text{ mol NO})(90.29\text{ kJ/mol})$
$+ (1\text{ mol } Cl_2)(0\text{ kJ/mol})]$
$= -77.16\text{ kJ}$

$\Delta S^\circ_{rxn} = [(2\text{ mol NOCl})(261.6\text{ J/mol·K})]$
$- [(2\text{ mol NO})(210.65\text{ J/mol·K})$
$+ (1\text{ mol } Cl_2)(223.0\text{ J/mol·K})]$
$= -121.1\text{ J/K}$

$\Delta G^\circ_{rxn} = \Delta H^\circ_{rxn} - T\Delta S^\circ_{rxn}$
$= -77.16\text{ kJ} - [(298\text{ K})(-121.1\text{ J/K})(1\text{ kJ}/1000\text{ J})]$
$= -41.1\text{ kJ}$

20.4B Using ΔH°_f and S° values from Appendix B,

$\Delta H^\circ_{rxn} = -114.2\text{ kJ}$ and $\Delta S^\circ_{rxn} = -146.5\text{ J/K}$

$\Delta G^\circ_{rxn} = \Delta H^\circ_{rxn} - T\Delta S^\circ_{rxn}$
$= -114.2\text{ kJ} - [(298\text{ K})(-146.5\text{ J/K})(1\text{ kJ}/1000\text{ J})]$
$= -70.5\text{ kJ}$

20.5A (a) $\Delta G^\circ_{rxn} = [(2\text{ mol NOCl})(66.07\text{ kJ/mol})]$
$- [(2\text{ mol NO})(86.60\text{ kJ/mol})$
$+ (1\text{ mol } Cl_2)(0\text{ kJ/mol})]$
$= -41.06\text{ kJ}$

(b) $\Delta G^\circ_{rxn} = [(2\text{ mol Fe})(0\text{ kJ/mol})$
$+ (3\text{ mol } H_2O)(-228.60\text{ kJ/mol})]$
$- [(3\text{ mol } H_2)(0\text{ kJ/mol})$
$+ (1\text{ mol } Fe_2O_3)(-743.6\text{ kJ/mol})]$
$= 57.8\text{ kJ}$

20.5B (a) $\Delta G^\circ_{rxn} = (2\text{ mol } NO_2)(51\text{ kJ/mol})$
$- [(2\text{ mol NO})(86.60\text{ kJ/mol})$
$+ (1\text{ mol } O_2)(0\text{ kJ/mol})]$
$= -71\text{ kJ}$

(b) $\Delta G^\circ_{rxn} = (2\text{ mol CO})(-137.2\text{ kJ/mol}) - [(2\text{ mol C})(0\text{ kJ/mol})$
$+ (1\text{ mol } O_2)(0\text{ kJ/mol})]$
$= -274.4\text{ kJ}$

20.6A (a) More moles of gas are present after the reaction, so $\Delta S > 0$. (b) The problem says the reaction is spontaneous ($\Delta G < 0$) only above 325°C, which implies high T. If $\Delta S > 0$, $-T\Delta S < 0$, so ΔG will become negative at higher T only if $\Delta H > 0$.

20.6B (a) A solid forms a gas and a liquid, so $\Delta S > 0$, and a crystalline array breaks down, so $\Delta H > 0$. (b) For the reaction to occur spontaneously ($\Delta G < 0$), $-T\Delta S$ must be greater than ΔH, which would occur only at higher T.

20.7A (a) $\Delta G = \Delta H - T\Delta S$
$= -192.7\text{ kJ} - [(298\text{ K})(-308.2\text{ J/K})(1\text{ kJ}/1000\text{ J})]$
$= -100.9\text{ kJ}$

The reaction is spontaneous at 298 K.

(b) As T increases, $-T\Delta S$ becomes more positive, so the reaction becomes *less* spontaneous.

(c) $\Delta G = -192.7\text{ kJ}$
$- [(500.\text{ K} + 273\text{ K})(-308.2\text{ J/K})(1\text{ kJ}/1000\text{ J})]$
$= 45.5\text{ kJ}$

20.7B ΔG becomes negative at lower T, so $\Delta H < 0$, $\Delta S < 0$, and $-T\Delta S > 0$. At lower T, the negative ΔH value becomes larger than the positive $-T\Delta S$ value.

20.8A $\Delta G = 0$ when $T = \dfrac{\Delta H}{\Delta S} = \dfrac{(-192.7\text{ kJ})(1000\text{ J}/1\text{ kJ})}{-308.2\text{ J/K}}$
$= 625.2\text{ K}$

$T(°C) = 625.2\text{ K} - 273.15 = 352.0°C$

20.8B $\Delta H = \Delta H^\circ_f\ CaCO_3 - (\Delta H^\circ_f\ CaO + \Delta H^\circ_f\ CO_2)$
$= -1206.9\text{ kJ} - (-635.1\text{ kJ} - 393.5\text{ kJ})$
$= -178.3\text{ kJ}$

$\Delta S = S^\circ\ CaCO_3 - (S^\circ\ CaO + S^\circ\ CO_2)$
$= 92.9\text{ J/K} - (38.2\text{ J/K} + 213.7\text{ J/K}) = -159.0\text{ J/K}$

$$T = \frac{\Delta H}{\Delta S} = \frac{(-178.3\text{ kJ})(1000\text{ J}/1\text{ kJ})}{-159.0\text{ J/K}} = 1121\text{ K}$$

Reaction becomes spontaneous ($\Delta G < 0$) at any $T < 1121$ K.

20.9A $\Delta G^\circ = [(2\text{ mol CO})(-137.2\text{ kJ/mol})]$
$- [(2\text{ mol C})(0\text{ kJ/mol}) + (1\text{ mol } O_2)(0\text{ kJ/mol})]$
$= -274.4\text{ kJ}$

$$\ln K = -\frac{\Delta G^\circ}{RT} = -\frac{(-274.4\text{ kJ})(1000\text{ J}/1\text{ kJ})}{(8.314\text{ J/mol·K})(298\text{ K})}$$
$$= 111$$
$$K = 1.61\times10^{48}$$

20.9B $K = 2.22\times10^{-15}$, so $\ln K = -33.7$

$\Delta G^\circ = -RT \ln K = -(8.314\text{ J/mol·K})(298\text{ K})(-33.7)$
$= 8.35\times10^4\text{ J} = 83.5\text{ kJ}$

20.10A (a) $A(g) + 3B(g) \rightleftharpoons AB_3(g)$; $\Delta G^\circ = -4.6\text{ kJ/mol}$

(b) For mixture 1, $Q_1 = \dfrac{[AB_3]}{[A][B]^3} = \dfrac{0.20}{(0.40)(0.80)^3} = 0.98$

For mixture 2, $Q_2 = \dfrac{0.30}{(0.30)(0.50)^3} = 8.0$

For mixture 3, $Q_3 = \dfrac{0.40}{(0.20)(0.20)^3} = 250$

Mixture 2 is at equilibrium.

(c) Based on Comments 1 and 2 in Sample Problem 20.10, $\Delta G_1 < 0$, $\Delta G_2 = 0$, and $\Delta G_3 > 0$, so $\Delta G_3 > \Delta G_2 > \Delta G_1$.

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

20.10B (a) Mixture 2 is at equilibrium.
(b) 3 (most negative) < 2 < 1 (most positive)
(c) Any reaction mixture moves spontaneously toward equilibrium, so both changes have a negative ΔG.

20.11A (a) $\Delta G^\circ = -RT \ln K$, so

$$\ln K = -\frac{\Delta G^\circ}{RT} = -\frac{(-33.5\text{ kJ})(1000\text{ J}/1\text{ kJ})}{(8.314\text{ J/mol·K})(298\text{ K})} = 13.521$$

$$K = 7.45\times10^5$$

$$(b)\ Q = \frac{[C_2H_5Cl]}{[C_2H_4][HCl]} = \frac{1.5}{(0.50)(1.0)} = 3.0$$

$$\Delta G = \Delta G^\circ + RT \ln Q$$
$$= -33.5\text{ kJ} + [(8.314\text{ J/mol·K})(1\text{ kJ}/1000\text{ J})(298\text{ K})(\ln 3.0)]$$
$$= -30.8\text{ kJ}$$

20.11B (a) $\Delta G^\circ = -RT \ln K$

$$= -8.314\text{ J/mol·K} \times \frac{1\text{ kJ}}{1000\text{ J}} \times 298\text{ K} \times \ln(2.3\times10^{-9})$$
$$= 49\text{ kJ/mol}$$

$$(b)\ Q = \frac{[H_3O^+][BrO^-]}{[HBrO]} = \frac{(6.0\times10^{-4})(0.10)}{0.20} = 3.0\times10^{-4}$$

$$\Delta G = \Delta G^\circ + RT \ln Q$$
$$= 49\text{ kJ/mol} + \left[8.314\text{ J/mol·K} \times \frac{1\text{ kJ}}{1000\text{ J}} \times 298\text{ K} \times \ln(3.0\times10^{-4})\right]$$
$$= 29\text{ kJ/mol}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Note: Unless stated otherwise, problems refer to systems at 298 K (25°C). Solving these problems may require values from Appendix B.

The Second Law of Thermodynamics: Predicting Spontaneous Change
(Sample Problem 20.1)

Concept Review Questions

20.1 Distinguish between the terms *spontaneous* and *instantaneous*. Give an example of a process that is spontaneous but very slow, and one that is very fast but not spontaneous.

20.2 Distinguish between the terms *spontaneous* and *nonspontaneous*. Can a nonspontaneous process occur? Explain.

20.3 State the first law of thermodynamics in terms of (a) the energy of the universe; (b) the creation or destruction of energy; (c) the energy change of system and surroundings. Does the first law reveal the direction of spontaneous change? Explain.

20.4 State qualitatively the relationship between entropy and freedom of particle motion. Use this idea to explain why you will probably never (a) be suffocated because all the air near you has moved to the other side of the room; (b) see half the water in your cup of tea freeze while the other half boils.

20.5 Why is ΔS_{vap} of a substance always larger than ΔS_{fus}?

20.6 How does the entropy of the surroundings change during an exothermic reaction? An endothermic reaction? Other than the examples in text, describe a spontaneous endothermic process.

20.7 (a) What is the entropy of a perfect crystal at 0 K?
(b) Does entropy increase or decrease as the temperature rises?
(c) Why is $\Delta H_f^\circ = 0$ but $S^\circ > 0$ for an element?
(d) Why does Appendix B list ΔH_f° values but not ΔS_f° values?

Skill-Building Exercises (grouped in similar pairs)

20.8 Which of these processes are spontaneous? (a) Water evaporates from a puddle. (b) A lion chases an antelope. (c) An isotope undergoes radioactive disintegration.

20.9 Which of these processes are spontaneous? (a) Earth moves around the Sun. (b) A boulder rolls up a hill. (c) Sodium metal and chlorine gas form solid sodium chloride.

20.10 Which of these processes are spontaneous? (a) Methane burns in air. (b) A teaspoonful of sugar dissolves in a cup of hot coffee. (c) A soft-boiled egg becomes raw.

20.11 Which of these processes are spontaneous? (a) A satellite falls to Earth. (b) Water decomposes to H_2 and O_2 at 298 K and 1 atm. (c) Average car prices increase.

20.12 Predict the sign of ΔS_{sys} for each process: (a) A piece of wax melts. (b) Silver chloride precipitates from solution. (c) Dew forms on a lawn in the morning.

20.13 Predict the sign of ΔS_{sys} for each process: (a) Gasoline vapors mix with air in a car engine. (b) Hot air expands. (c) Humidity condenses in cold air.

20.14 Predict the sign of ΔS_{sys} for each process: (a) Alcohol evaporates. (b) A solid explosive converts to a gas. (c) Perfume vapors diffuse through a room.

20.15 Predict the sign of ΔS_{sys} for each process: (a) A pond freezes in winter. (b) Atmospheric CO_2 dissolves in the ocean. (c) An apple tree bears fruit.

20.16 Without using Appendix B, predict the sign of ΔS° for
(a) $2K(s) + F_2(g) \longrightarrow 2KF(s)$
(b) $NH_3(g) + HBr(g) \longrightarrow NH_4Br(s)$
(c) $NaClO_3(s) \longrightarrow Na^+(aq) + ClO_3^-(aq)$

20.17 Without using Appendix B, predict the sign of ΔS° for
(a) $H_2S(g) + \frac{1}{2}O_2(g) \longrightarrow \frac{1}{8}S_8(s) + H_2O(g)$
(b) $HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$
(c) $2NO_2(g) \longrightarrow N_2O_4(g)$

20.18 Without using Appendix B, predict the sign of $\Delta S°$ for
(a) $CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + H_2O(l) + CO_2(g)$
(b) $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$
(c) $2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$

20.19 Without using Appendix B, predict the sign of $\Delta S°$ for
(a) $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$
(b) $KBr(s) \longrightarrow KBr(aq)$
(c) $CH_3CH{=}CH_2(g) \longrightarrow H_2C\langle CH_2 \rangle CH_2(g)$

20.20 Predict the sign of ΔS for each process:
(a) $C_2H_5OH(g)$ (350 K and 500 torr) $\longrightarrow$ $C_2H_5OH(g)$ (350 K and 250 torr)
(b) $N_2(g)$ (298 K and 1 atm) $\longrightarrow$ $N_2(aq)$ (298 K and 1 atm)
(c) $O_2(aq)$ (303 K and 1 atm) $\longrightarrow$ $O_2(g)$ (303 K and 1 atm)

20.21 Predict the sign of ΔS for each process:
(a) $O_2(g)$ (1.0 L at 1 atm) $\longrightarrow$ $O_2(g)$ (0.10 L at 10 atm)
(b) $Cu(s)$ (350°C and 2.5 atm) $\longrightarrow$ $Cu(s)$ (450°C and 2.5 atm)
(c) $Cl_2(g)$ (100°C and 1 atm) $\longrightarrow$ $Cl_2(g)$ (10°C and 1 atm)

20.22 Predict which substance has greater molar entropy. Explain.
(a) Butane $CH_3CH_2CH_2CH_3(g)$ or 2-butene $CH_3CH{=}CHCH_3(g)$
(b) $Ne(g)$ or $Xe(g)$ (c) $CH_4(g)$ or $CCl_4(l)$

20.23 Predict which substance has greater molar entropy. Explain.
(a) $NO_2(g)$ or $N_2O_4(g)$ (b) $CH_3OCH_3(l)$ or $CH_3CH_2OH(l)$
(c) $HCl(g)$ or $HBr(g)$

20.24 Predict which substance has greater molar entropy. Explain.
(a) $CH_3OH(l)$ or $C_2H_5OH(l)$ (b) $KClO_3(s)$ or $KClO_3(aq)$
(c) $Na(s)$ or $K(s)$

20.25 Predict which substance has greater molar entropy. Explain.
(a) $P_4(g)$ or $P_2(g)$ (b) $HNO_3(aq)$ or $HNO_3(l)$
(c) $CuSO_4(s)$ or $CuSO_4 \cdot 5H_2O(s)$

20.26 Without consulting Appendix B, arrange each group in order of *increasing* standard molar entropy ($S°$). Explain.
(a) Graphite, diamond, charcoal
(b) Ice, water vapor, liquid water
(c) O_2, O_3, O atoms

20.27 Without consulting Appendix B, arrange each group in order of *increasing* standard molar entropy ($S°$). Explain.
(a) Glucose ($C_6H_{12}O_6$), sucrose ($C_{12}H_{22}O_{11}$), ribose ($C_5H_{10}O_5$)
(b) $CaCO_3$, $Ca + C + \frac{3}{2}O_2$, $CaO + CO_2$
(c) $SF_6(g)$, $SF_4(g)$, $S_2F_{10}(g)$

20.28 Without consulting Appendix B, arrange each group in order of *decreasing* standard molar entropy ($S°$). Explain.
(a) $ClO_4^-(aq)$, $ClO_2^-(aq)$, $ClO_3^-(aq)$
(b) $NO_2(g)$, $NO(g)$, $N_2(g)$
(c) $Fe_2O_3(s)$, $Al_2O_3(s)$, $Fe_3O_4(s)$

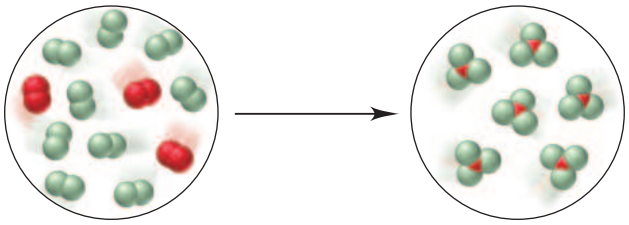
20.29 Without consulting Appendix B, arrange each group in order of *decreasing* standard molar entropy ($S°$). Explain.
(a) Mg metal, Ca metal, Ba metal
(b) Hexane (C_6H_{14}), benzene (C_6H_6), cyclohexane (C_6H_{12})
(c) $PF_2Cl_3(g)$, $PF_5(g)$, $PF_3(g)$

Calculating the Change in Entropy of a Reaction

(Sample Problems 20.2 and 20.3)

Concept Review Questions

20.30 For the reaction depicted in the molecular scenes, X is red and Y is green.



(a) Write a balanced equation.
(b) Determine the sign of ΔS_{rxn}.
(c) Which species has the highest molar entropy?

20.31 Describe the equilibrium condition in terms of the entropy changes of a system and its surroundings. What does this description mean about the entropy change of the universe?

20.32 For the reaction $H_2O(g) + Cl_2O(g) \longrightarrow 2HClO(g)$, you know $\Delta S°_{rxn}$ and $S°$ of $HClO(g)$ and of $H_2O(g)$. Write an expression that can be used to determine $S°$ of $Cl_2O(g)$.

Skill-Building Exercises (grouped in similar pairs)

20.33 For each reaction, predict the sign and find the value of $\Delta S°_{rxn}$:
(a) $3NO(g) \longrightarrow N_2O(g) + NO_2(g)$
(b) $3H_2(g) + Fe_2O_3(s) \longrightarrow 2Fe(s) + 3H_2O(g)$
(c) $P_4(s) + 5O_2(g) \longrightarrow P_4O_{10}(s)$

20.34 For each reaction, predict the sign and find the value of $\Delta S°_{rxn}$:
(a) $3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(l) + NO(g)$
(b) $N_2(g) + 3F_2(g) \longrightarrow 2NF_3(g)$
(c) $C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g)$

20.35 Find $\Delta S°_{rxn}$ for the combustion of ethane (C_2H_6) to carbon dioxide and gaseous water. Is the sign of $\Delta S°_{rxn}$ as expected?

20.36 Find $\Delta S°_{rxn}$ for the combustion of methane to carbon dioxide and liquid water. Is the sign of $\Delta S°_{rxn}$ as expected?

20.37 Find $\Delta S°_{rxn}$ for the reaction of nitrogen monoxide with hydrogen to form ammonia and water vapor. Is the sign of $\Delta S°_{rxn}$ as expected?

20.38 Find $\Delta S°_{rxn}$ for the combustion of ammonia to nitrogen dioxide and water vapor. Is the sign of $\Delta S°_{rxn}$ as expected?

20.39 (a) Find $\Delta S°_{rxn}$ for the formation of $Cu_2O(s)$ from its elements.
(b) Calculate ΔS_{univ}, and state whether the reaction is spontaneous at 298 K.

20.40 (a) Find $\Delta S°_{rxn}$ for the formation of $HI(g)$ from its elements.
(b) Calculate ΔS_{univ}, and state whether the reaction is spontaneous at 298 K.

20.41 (a) Find $\Delta S°_{rxn}$ for the formation of $CH_3OH(l)$ from its elements.
(b) Calculate ΔS_{univ}, and state whether the reaction is spontaneous at 298 K.

20.42 (a) Find $\Delta S°_{rxn}$ for the formation of $N_2O(g)$ from its elements.
(b) Calculate ΔS_{univ}, and state whether the reaction is spontaneous at 298 K.

Problems in Context

20.43 Sulfur dioxide is released in the combustion of coal. Scrubbers use aqueous slurries of calcium hydroxide to remove the SO_2 from flue gases. Write a balanced equation for this reaction and calculate $\Delta S°_{rxn}$ at 298 K [$S°$ of $CaSO_3(s) = 101.4$ J/mol·K].

20.44 Oxyacetylene welding is used to repair metal structures, including bridges, buildings, and even the Statue of Liberty. Calculate $\Delta S°_{rxn}$ for the combustion of 1 mol of acetylene (C_2H_2).

Entropy, Free Energy, and Work

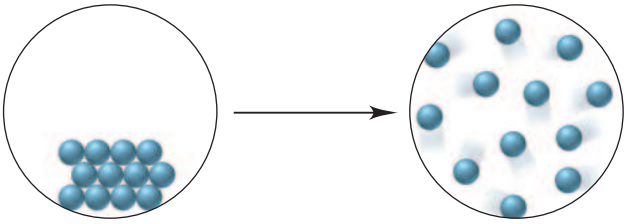
(Sample Problems 20.4 to 20.8)

Concept Review Questions

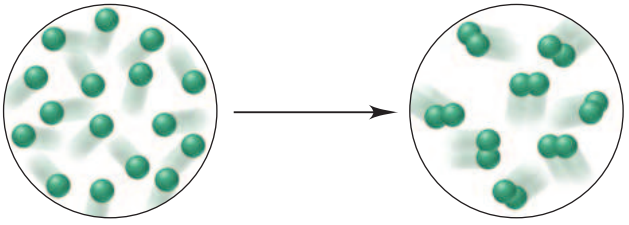
20.45 What is the advantage of calculating free energy changes rather than entropy changes to determine reaction spontaneity?

20.46 Given that $\Delta G_{sys} = -T\Delta S_{univ}$, explain how the sign of ΔG_{sys} correlates with reaction spontaneity.

20.47 (a) Is an endothermic reaction more likely to be spontaneous at higher temperatures or lower temperatures? Explain.
(b) The change depicted below occurs at constant pressure. Explain your answers to each of the following: (1) What is the sign of ΔH_{sys}? (2) What is the sign of ΔS_{sys}? (3) What is the sign of ΔS_{surr}? (4) How does the sign of ΔG_{sys} vary with temperature?



20.48 Explain your answers to each of the following for the change depicted below. (a) What is the sign of ΔH_{sys}? (b) What is the sign of ΔS_{sys}? (c) What is the sign of ΔS_{surr}? (d) How does the sign of ΔG_{sys} vary with temperature?



20.49 With its components in their standard states, a certain reaction is spontaneous only at high T. What do you know about the signs of $\Delta H°$ and $\Delta S°$? Describe a process for which this is true.

20.50 How can $\Delta S°$ be relatively independent of T if $S°$ of each reactant and product increases with T?

Skill-Building Exercises (grouped in similar pairs)

20.51 Calculate $\Delta G°$ for each reaction using $\Delta G_f°$ values:
(a) $2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$
(b) $2CH_3OH(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(g)$
(c) $BaO(s) + CO_2(g) \longrightarrow BaCO_3(s)$

20.52 Calculate $\Delta G°$ for each reaction using $\Delta G_f°$ values:
(a) $H_2(g) + I_2(s) \longrightarrow 2HI(g)$
(b) $MnO_2(s) + 2CO(g) \longrightarrow Mn(s) + 2CO_2(g)$
(c) $NH_4Cl(s) \longrightarrow NH_3(g) + HCl(g)$

20.53 Find $\Delta G°$ for the reactions in Problem 20.51 using $\Delta H_f°$ and $S°$ values.

20.54 Find $\Delta G°$ for the reactions in Problem 20.52 using $\Delta H_f°$ and $S°$ values.

20.55 Consider the oxidation of carbon monoxide:

$$CO(g) + \tfrac{1}{2}O_2(g) \longrightarrow CO_2(g)$$

(a) Predict the signs of $\Delta S°$ and $\Delta H°$. Explain.
(b) Calculate $\Delta G°$ by two different methods.

20.56 Consider the combustion of butane gas:

$$C_4H_{10}(g) + \tfrac{13}{2}O_2(g) \longrightarrow 4CO_2(g) + 5H_2O(g)$$

(a) Predict the signs of $\Delta S°$ and $\Delta H°$. Explain.
(b) Calculate $\Delta G°$ by two different methods.

20.57 For the gaseous reaction of xenon and fluorine to form xenon hexafluoride:
(a) Calculate $\Delta S°$ at 298 K ($\Delta H° = -402$ kJ/mol and $\Delta G° = -280.$ kJ/mol).
(b) Assuming that $\Delta S°$ and $\Delta H°$ change little with temperature, calculate $\Delta G°$ at 500. K.

20.58 For the gaseous reaction of carbon monoxide and chlorine to form phosgene ($COCl_2$):
(a) Calculate $\Delta S°$ at 298 K ($\Delta H° = -220.$ kJ/mol and $\Delta G° = -206$ kJ/mol).
(b) Assuming that $\Delta S°$ and $\Delta H°$ change little with temperature, calculate $\Delta G°$ at 450. K.

20.59 One reaction used to produce small quantities of pure H_2 is

$$CH_3OH(g) \rightleftharpoons CO(g) + 2H_2(g)$$

(a) Determine $\Delta H°$ and $\Delta S°$ for the reaction at 298 K.
(b) Assuming that these values are relatively independent of temperature, calculate $\Delta G°$ at 28°C, 128°C, and 228°C.
(c) What is the significance of the different values of $\Delta G°$?
(d) At what temperature (in K) does the reaction become spontaneous?

20.60 A reaction that occurs in the internal combustion engine is

$$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$$

(a) Determine $\Delta H°$ and $\Delta S°$ for the reaction at 298 K.
(b) Assuming that these values are relatively independent of temperature, calculate $\Delta G°$ at 100.°C, 2560.°C, and 3540.°C.
(c) What is the significance of the different values of $\Delta G°$?
(d) At what temperature (in K) does the reaction become spontaneous?

Problems in Context

20.61 As a fuel, $H_2(g)$ produces only nonpolluting $H_2O(g)$ when it burns. Moreover, it combines with $O_2(g)$ in a fuel cell (Chapter 21) to provide electrical energy.
(a) Calculate $\Delta H°$, $\Delta S°$, and $\Delta G°$ per mole of H_2 at 298 K.
(b) Is the spontaneity of this reaction dependent on T? Explain.
(c) At what temperature does the reaction become spontaneous?

20.62 The U.S. government requires automobile fuels to contain a renewable component. Fermentation of glucose from corn yields ethanol, which is added to gasoline to fulfill this requirement:

$$C_6H_{12}O_6(s) \longrightarrow 2C_2H_5OH(l) + 2CO_2(g)$$

Calculate $\Delta H°$, $\Delta S°$, and $\Delta G°$ for the reaction at 25°C. Is the spontaneity of this reaction dependent on T? Explain.

Free Energy, Equilibrium, and Reaction Direction

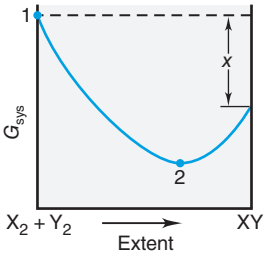
(Sample Problems 20.9 to 20.11)

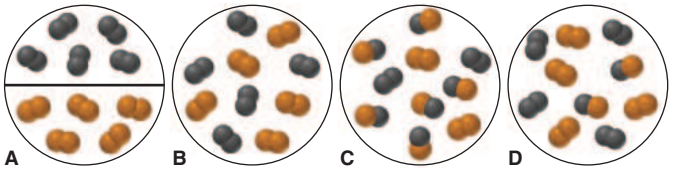
Concept Review Questions

20.63 (a) If $K << 1$ for a reaction, what do you know about the sign and magnitude of $\Delta G°$? (b) If $\Delta G° << 0$ for a reaction, what do you know about the magnitude of K? Of Q?

20.64 How is the free energy change of a process related to the work that can be obtained from the process? Is this quantity of work obtainable in practice? Explain.

20.65 The scenes and the graph relate to the reaction of $X_2(g)$ *(black)* with $Y_2(g)$ *(orange)* to form $XY(g)$.
(a) If reactants and products are in their standard states, what quantity is represented on the graph by x?
(b) Which scene represents point 1? Explain. (c) Which scene represents point 2? Explain.





20.66 What is the difference between $\Delta G°$ and ΔG? Under what circumstances does $\Delta G = \Delta G°$?

Skill-Building Exercises (grouped in similar pairs)

20.67 Calculate K at 298 K for each reaction:
(a) $MgCO_3(s) \rightleftharpoons Mg^{2+}(aq) + CO_3^{2-}(aq)$
(b) $H_2(g) + O_2(g) \rightleftharpoons H_2O_2(l)$

20.68 Calculate $\Delta G°$ at 298 K for each reaction:
(a) $2H_2S(g) + 3O_2(g) \rightleftharpoons 2H_2O(g) + 2SO_2(g)$; $K = 6.57\times10^{173}$
(b) $H_2SO_4(l) \rightleftharpoons H_2O(l) + SO_3(g)$; $K = 4.46\times10^{-15}$

20.69 Calculate K at 298 K for each reaction:
(a) $HCN(aq) + NaOH(aq) \rightleftharpoons NaCN(aq) + H_2O(l)$
(b) $SrSO_4(s) \rightleftharpoons Sr^{2+}(aq) + SO_4^{2-}(aq)$

20.70 Calculate $\Delta G°$ at 298 K for each reaction:
(a) $2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$; $K = 1.58\times10^{7}$
(b) $Cu_2S(s) + O_2(g) \rightleftharpoons 2Cu(s) + SO_2(g)$; $K = 3.25\times10^{37}$

20.71 Use $\Delta H°$ and $\Delta S°$ values for the following process at 1 atm to find the normal boiling point of Br_2:

$$Br_2(l) \rightleftharpoons Br_2(g)$$

20.72 Use $\Delta H°$ and $\Delta S°$ values to find the temperature at which these sulfur allotropes reach equilibrium at 1 atm:

$$S(\text{rhombic}) \rightleftharpoons S(\text{monoclinic})$$

20.73 Use Appendix B to determine the K_{sp} of Ag_2S.

20.74 Use Appendix B to determine the K_{sp} of CaF_2.

20.75 For the reaction $I_2(g) + Cl_2(g) \rightleftharpoons 2ICl(g)$, calculate K_p at 25°C [$\Delta G_f°$ of $ICl(g) = -6.075$ kJ/mol].

20.76 For the reaction $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$, calculate the equilibrium P_{CO_2} at 25°C.

20.77 The K_{sp} of $PbCl_2$ is 1.7×10^{-5} at 25°C. What is $\Delta G°$? Is it possible to prepare a solution that contains $Pb^{2+}(aq)$ and $Cl^-(aq)$, at their standard-state concentrations?

20.78 The K_{sp} of ZnF_2 is 3.0×10^{-2} at 25°C. What is $\Delta G°$? Is it possible to prepare a solution that contains $Zn^{2+}(aq)$ and $F^-(aq)$ at their standard-state concentrations?

20.79 The equilibrium constant for the reaction

$$2Fe^{3+}(aq) + Hg_2^{2+}(aq) \rightleftharpoons 2Fe^{2+}(aq) + 2Hg^{2+}(aq)$$

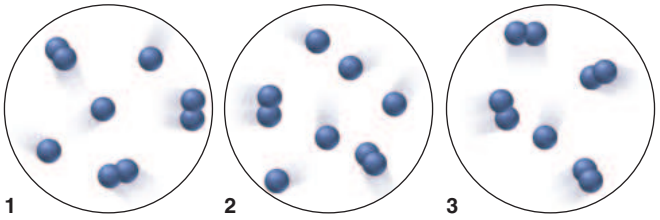
is $K_c = 9.1\times10^{-6}$ at 298 K.
(a) What is $\Delta G°$ at this temperature?
(b) If standard-state concentrations of the reactants and products are mixed, in which direction does the reaction proceed?
(c) Calculate ΔG when $[Fe^{3+}] = 0.20\ M$, $[Hg_2^{2+}] = 0.010\ M$, $[Fe^{2+}] = 0.010\ M$, and $[Hg^{2+}] = 0.025\ M$. In which direction will the reaction proceed to achieve equilibrium?

20.80 The formation constant for the reaction

$$Ni^{2+}(aq) + 6NH_3(aq) \rightleftharpoons Ni(NH_3)_6^{2+}(aq)$$

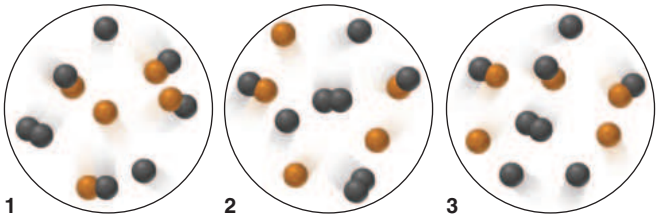
is $K_f = 5.6\times10^{8}$ at 25°C.
(a) What is $\Delta G°$ at this temperature?
(b) If standard-state concentrations of the reactants and products are mixed, in which direction does the reaction proceed?
(c) Determine ΔG when $[Ni(NH_3)_6^{2+}] = 0.010\ M$, $[Ni^{2+}] = 0.0010\ M$, and $[NH_3] = 0.0050\ M$. In which direction will the reaction proceed to achieve equilibrium?

20.81 The scenes below depict three gaseous mixtures in which A is reacting with itself to form A_2. Assume that each particle represents 0.10 mol and the volume is 0.10 L.



(a) If $K = 0.33$, which mixture is at equilibrium? (b) Rank the mixtures from the most positive ΔG to the most negative ΔG.

20.82 The scenes below depict three gaseous mixtures in which X *(orange)* and Y_2 *(black)* are reacting to form XY and Y. Assume that each gas has a partial pressure of 0.10 atm.



(a) If $K = 4.5$, which mixture is at equilibrium? (b) Rank the mixtures from the most positive ΔG to the most negative ΔG.

Problems in Context

20.83 High levels of ozone (O_3) cause rubber to deteriorate, green plants to turn brown, and many people to have difficulty breathing.
(a) Is the formation of O_3 from O_2 favored at all T, no T, high T, or low T?
(b) Calculate $\Delta G°$ for this reaction at 298 K.
(c) Calculate ΔG at 298 K for this reaction in urban smog where $[O_2] = 0.21$ atm and $[O_3] = 5\times10^{-7}$ atm.

20.84 A $BaSO_4$ slurry is ingested before the gastrointestinal tract is x-rayed because it is opaque to x-rays and defines the contours of the tract. Ba^{2+} ion is toxic, but the compound is nearly insoluble. If $\Delta G°$ at 37°C (body temperature) is 59.1 kJ/mol for the process

$$BaSO_4(s) \rightleftharpoons Ba^{2+}(aq) + SO_4^{2-}(aq)$$

what is $[Ba^{2+}]$ in the intestinal tract? (Assume that the only source of SO_4^{2-} is the ingested slurry.)

Comprehensive Problems

20.85 According to advertisements, "a diamond is forever."
(a) Calculate $\Delta H°$, $\Delta S°$, and $\Delta G°$ at 298 K for the phase change

$$\text{Diamond} \longrightarrow \text{graphite}$$

(b) Given the conditions under which diamond jewelry is normally kept, argue for and against the statement in the ad.
(c) Given the answers in part (a), what would need to be done to make synthetic diamonds from graphite?
(d) Assuming $\Delta H°$ and $\Delta S°$ do not change with temperature, can graphite be converted to diamond spontaneously at 1 atm?

20.86 Replace each question mark with the correct information:

	ΔS_{rxn}	ΔH_{rxn}	ΔG_{rxn}	Comment
(a)	+	−	−	?
(b)	?	0	−	Spontaneous
(c)	−	+	?	Not spontaneous
(d)	0	?	−	Spontaneous
(e)	?	0	+	?
(f)	+	+	?	$T\Delta S > \Delta H$

20.87 Among the many complex ions of cobalt are the following:

$$Co(NH_3)_6^{3+}(aq) + 3en(aq) \rightleftharpoons Co(en)_3^{3+}(aq) + 6NH_3(aq)$$

where "en" stands for ethylenediamine, $H_2NCH_2CH_2NH_2$. Six Co—N bonds are broken and six Co—N bonds are formed in this reaction, so $\Delta H^\circ_{rxn} \approx 0$; yet $K > 1$. What are the signs of ΔS° and ΔG°? What drives the reaction?

20.88 What is the change in entropy when 0.200 mol of potassium freezes at 63.7°C ($\Delta H_{fus} = 2.39$ kJ/mol)?

20.89 Is each statement true or false? If false, correct it.
(a) All spontaneous reactions occur quickly.
(b) The reverse of a spontaneous reaction is nonspontaneous.
(c) All spontaneous processes release heat.
(d) The boiling of water at 100°C and 1 atm is spontaneous.
(e) If a process increases the freedom of motion of the particles of a system, the entropy of the system decreases.
(f) The energy of the universe is constant; the entropy of the universe decreases toward a minimum.
(g) All systems disperse their energy spontaneously.
(h) Both ΔS_{sys} and ΔS_{surr} equal zero at equilibrium.

20.90 Hemoglobin carries O_2 from the lungs to tissue cells, where the O_2 is released. The protein is represented as Hb in its unoxygenated form and as $Hb{\cdot}O_2$ in its oxygenated form. One reason CO is toxic is that it competes with O_2 in binding to Hb:

$$Hb{\cdot}O_2(aq) + CO(g) \rightleftharpoons Hb{\cdot}CO(aq) + O_2(g)$$

(a) If $\Delta G^\circ \approx -14$ kJ at 37°C (body temperature), what is the ratio of $[Hb{\cdot}CO]$ to $[Hb{\cdot}O_2]$ at 37°C with $[O_2] = [CO]$?
(b) How is Le Châtelier's principle used to treat CO poisoning?

20.91 Magnesia (MgO) is used for fire brick, crucibles, and furnace linings because of its high melting point. It is produced by decomposing magnesite ($MgCO_3$) at around 1200°C.
(a) Write a balanced equation for magnesite decomposition.
(b) Use ΔH° and S° values to find ΔG° at 298 K.
(c) Assuming that ΔH° and S° do not change with temperature, find the minimum temperature at which the reaction is spontaneous.
(d) Calculate the equilibrium P_{CO_2} above $MgCO_3$ at 298 K.
(e) Calculate the equilibrium P_{CO_2} above $MgCO_3$ at 1200 K.

20.92 To prepare nuclear fuel, U_3O_8 ("yellow cake") is converted to $UO_2(NO_3)_2$, which is then converted to UO_3 and finally UO_2. The fuel is enriched (the proportion of the ^{235}U is increased) by a two-step conversion of UO_2 into UF_6, a volatile solid, followed by a gaseous-diffusion separation of the ^{235}U and ^{238}U isotopes:

$$UO_2(s) + 4HF(g) \longrightarrow UF_4(s) + 2H_2O(g)$$
$$UF_4(s) + F_2(g) \longrightarrow UF_6(s)$$

Calculate ΔG° for the overall process at 85°C:

	ΔH°_f (kJ/mol)	S° (J/mol·K)	ΔG°_f (kJ/mol)
$UO_2(s)$	−1085	77.0	−1032
$UF_4(s)$	−1921	152	−1830.
$UF_6(s)$	−2197	225	−2068

20.93 Methanol, a major industrial feedstock, is made by several catalyzed reactions, such as $CO(g) + 2H_2(g) \longrightarrow CH_3OH(l)$.
(a) Show that this reaction is thermodynamically feasible.
(b) Is it favored at low or at high temperatures?
(c) One concern about using CH_3OH as an auto fuel is its oxidation in air to yield formaldehyde, $CH_2O(g)$, which poses a health hazard. Calculate ΔG° at 100.°C for this oxidation.

20.94 (a) Write a balanced equation for the gaseous reaction between N_2O_5 and F_2 to form NF_3 and O_2. (b) Determine ΔG°_{rxn}. (c) Find ΔG_{rxn} at 298 K if $P_{N_2O_5} = P_{F_2} = 0.20$ atm, $P_{NF_3} = 0.25$ atm, and $P_{O_2} = 0.50$ atm.

20.95 Consider the following reaction:

$$2NOBr(g) \rightleftharpoons 2NO(g) + Br_2(g) \qquad K = 0.42 \text{ at } 373 \text{ K}$$

Given that S° of $NOBr(g) = 272.6$ J/mol·K and that ΔS°_{rxn} and ΔH°_{rxn} are constant with temperature, find
(a) ΔS°_{rxn} at 298 K (b) ΔG°_{rxn} at 373 K
(c) ΔH°_{rxn} at 373 K (d) ΔH°_f of NOBr at 298 K
(e) ΔG°_{rxn} at 298 K (f) ΔG°_f of NOBr at 298 K

20.96 Hydrogenation is the addition of H_2 to double (or triple) carbon-carbon bonds. Peanut butter and most commercial baked goods include hydrogenated oils. Find ΔH°, ΔS°, and ΔG° for the hydrogenation of ethene (C_2H_4) to ethane (C_2H_6) at 25°C.

20.97 Styrene is produced by catalytic dehydrogenation of ethylbenzene at high temperature in the presence of superheated steam.
(a) Find ΔH°_{rxn}, ΔG°_{rxn}, and ΔS°_{rxn}, given these data at 298 K:

Compound	ΔH°_f (kJ/mol)	ΔG°_f (kJ/mol)	S° (J/mol·K)
Ethylbenzene, $C_6H_5—CH_2CH_3$	−12.5	119.7	255
Styrene, $C_6H_5—CH{=}CH_2$	103.8	202.5	238

(b) At what temperature is the reaction spontaneous?
(c) What are ΔG°_{rxn} and K at 600.°C?
(d) With 5.0 parts steam to 1.0 part ethylbenzene in the reactant mixture and the total pressure kept constant at 1.3 atm, what is ΔG at 50.% conversion, that is, when 50.% of the ethylbenzene has reacted?

20.98 Propylene (propene; $CH_3CH{=}CH_2$) is used to produce polypropylene and many other chemicals. Although most is obtained from the cracking of petroleum, about 2% is produced by catalytic dehydrogenation of propane ($CH_3CH_2CH_3$):

$$CH_3CH_2CH_3 \xrightarrow{Pt/Al_2O_3} CH_3CH{=}CH_2 + H_2$$

Because this reaction is endothermic, heaters are placed between the reactor vessels to maintain the required temperature.
(a) If the molar entropy, S°, of propylene is 267.1 J/mol·K, find its entropy of formation, S°_f.
(b) Find ΔG°_f of propylene (ΔH°_f for propylene = 20.4 kJ/mol).
(c) Calculate ΔH°_{rxn} and ΔG°_{rxn} for the dehydrogenation.
(d) What is the theoretical yield of propylene at 580°C if the initial pressure of propane is 1.00 atm?
(e) Would the yield change if the reactor walls were permeable to H_2? Explain.
(f) At what temperature is the dehydrogenation spontaneous, with all substances in the standard state?

Note: Problems 20.99 and 20.100 relate to the thermodynamics of adenosine triphosphate (ATP). Refer to the Chemical Connections essay on pp. 902–903.

20.99 Find K for (a) the hydrolysis of ATP, (b) the dehydration-condensation to form glucose phosphate, and (c) the coupled reaction between ATP and glucose. (d) How does each K change when T changes from 25°C to 37°C?

20.100 Energy from ATP hydrolysis drives many nonspontaneous cell reactions:

$$ATP^{4-}(aq) + H_2O(l) \rightleftharpoons ADP^{3-}(aq) + HPO_4^{2-}(aq) + H^+(aq) \qquad \Delta G^{\circ\prime} = -30.5 \text{ kJ}$$

Energy for the reverse process comes ultimately from glucose metabolism:

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(l)$$

(a) Find K for the hydrolysis of ATP at 37°C.
(b) Find $\Delta G'^{\circ}_{rxn}$ for metabolism of 1 mol of glucose.
(c) How many moles of ATP can be produced by metabolism of 1 mol of glucose?
(d) If 36 mol of ATP is formed, what is the actual yield?

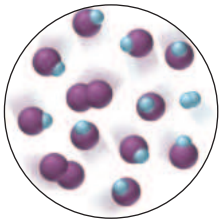
20.101 From the following reaction and data, find (a) S° of $SOCl_2$ and (b) T at which the reaction becomes nonspontaneous:

$$SO_3(g) + SCl_2(l) \longrightarrow SOCl_2(l) + SO_2(g) \qquad \Delta G^{\circ}_{rxn} = -75.2 \text{ kJ}$$

	$SO_3(g)$	$SCl_2(l)$	$SOCl_2(l)$	$SO_2(g)$
ΔH°_f (kJ/mol)	−396	−50.0	−245.6	−296.8
S° (J/mol·K)	256.7	184	—	248.1

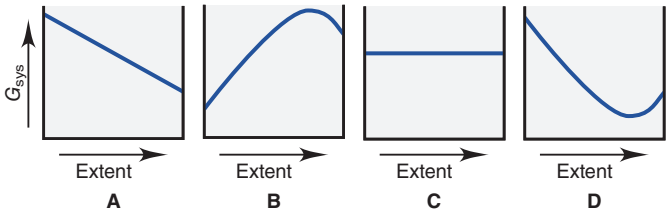
20.102 Write equations for the oxidation of Fe and of Al. Use ΔG°_f to determine whether either process is spontaneous at 25°C.

20.103 The molecular scene depicts a gaseous equilibrium mixture at 460°C for the reaction of H_2 *(blue)* and I_2 *(purple)* to form HI. Each molecule represents 0.010 mol and the container volume is 1.0 L. (a) Is $K_c >$, $=$, or < 1? (b) Is $K_p >$, $=$, or $< K_c$? (c) Calculate ΔG°_{rxn}. (d) How would the value of ΔG°_{rxn} change if the purple molecules represented H_2 and the blue I_2? Explain.



20.104 A key step in the metabolism of glucose for energy is the isomerization of glucose-6-phosphate (G6P) to fructose-6-phosphate (F6P): G6P $\rightleftharpoons$ F6P; $K = 0.510$ at 298 K.
(a) Calculate ΔG° at 298 K.
(b) Calculate ΔG when Q, the [F6P]/[G6P] ratio, equals 10.0.
(c) Calculate ΔG when $Q = 0.100$.
(d) Calculate Q if $\Delta G = -2.50$ kJ/mol.

20.105 A chemical reaction, such as HI forming from its elements, can reach equilibrium at many temperatures. In contrast, a phase change, such as ice melting, is in equilibrium at a given pressure and temperature. Each of the graphs below depicts G_{sys} vs. extent of change. (a) Which graph depicts how G_{sys} changes for the formation of HI? Explain. (b) Which graph depicts how G_{sys} changes as ice melts at 1°C and 1 atm? Explain.



20.106 When heated, the DNA double helix separates into two random coil single strands. When cooled, the random coils reform the double helix: double helix $\rightleftharpoons$ 2 random coils.
(a) What is the sign of ΔS for the forward process? Why?
(b) Energy must be added to break H bonds and overcome dispersion forces between the strands. What is the sign of ΔG for the forward process when $T\Delta S$ is smaller than ΔH?
(c) Write an expression for T in terms of ΔH and ΔS when the reaction is at equilibrium. (This temperature is called the *melting temperature* of the nucleic acid.)

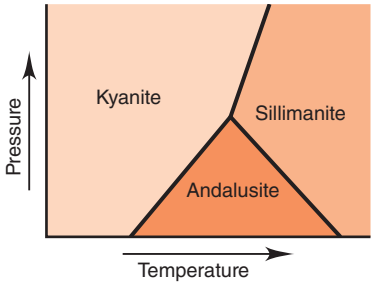
20.107 In the process of respiration, glucose is oxidized completely. In fermentation, O_2 is absent and glucose is broken down to ethanol and CO_2. Ethanol is oxidized to CO_2 and H_2O.
(a) Balance the following equations for these processes:
Respiration: $C_6H_{12}O_6(s) + O_2(g) \longrightarrow CO_2(g) + H_2O(l)$
Fermentation: $C_6H_{12}O_6(s) \longrightarrow C_2H_5OH(l) + CO_2(g)$
Ethanol oxidation: $C_2H_5OH(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(l)$
(b) Calculate ΔG°_{rxn} for respiration of 1.00 g of glucose.
(c) Calculate ΔG°_{rxn} for fermentation of 1.00 g of glucose.
(d) Calculate ΔG°_{rxn} for oxidation of the ethanol from part (c).

20.108 Consider the formation of ammonia:

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

(a) Assuming that ΔH° and ΔS° are constant with temperature, find the temperature at which $K_p = 1.00$.
(b) Find K_p at 400.°C, a typical temperature for NH_3 production.
(c) Given the lower K_p at the higher temperature, why are these conditions used industrially?

20.109 Kyanite, sillimanite, and andalusite all have the formula Al_2SiO_5. Each is stable under different conditions (see the graph at right). At the point where the three phases intersect:



(a) Which mineral, if any, has the lowest free energy?
(b) Which mineral, if any, has the lowest enthalpy?
(c) Which mineral, if any, has the highest entropy?
(d) Which mineral, if any, has the lowest density?

20.110 Acetylene is produced commercially by the partial oxidation of methane. At 1500°C and pressures of 1–10 bar, the yield of acetylene is about 20%. The major side product is carbon monoxide, and some soot and carbon dioxide also form.
(a) At what temperature is the desired reaction spontaneous:

$$2CH_4 + \tfrac{1}{2}O_2 \longrightarrow C_2H_2 + 2H_2 + H_2O$$

(b) Acetylene can also be made by the reaction of its elements, carbon (graphite) and hydrogen. At what temperature is this formation reaction spontaneous?
(c) Why must this reaction mixture be immediately cooled?

20.111 Synthesis gas, a mixture that includes the fuels CO and H_2, is used to produce liquid hydrocarbons and methanol. It is made at pressures up to 100 atm by oxidation of methane followed by the steam re-forming and water-gas shift reactions. Because the process is exothermic, temperatures reach 950–1100°C, and the conditions are such that the amounts of H_2, CO, CO_2, CH_4, and H_2O leaving the reactor are close to the equilibrium amounts for the steam re-forming and water-gas shift reactions:

$$CH_4(g) + H_2O(g) \rightleftharpoons CO(g) + 3H_2(g) \quad \text{(steam re-forming)}$$
$$CO(g) + H_2O(g) \rightleftharpoons CO_2(g) + H_2(g) \quad \text{(water-gas shift)}$$

(a) At 1000.°C, what are ΔG° and ΔH° for the steam re-forming reaction and for the water-gas shift reaction?
(b) By doubling the steam re-forming step and adding it to the water-gas shift step, we obtain the following combined reaction:

$$2CH_4(g) + 3H_2O(g) \rightleftharpoons CO_2(g) + CO(g) + 7H_2(g)$$

Is this reaction spontaneous at 1000.°C in the standard state?
(c) Is it spontaneous at 98 atm and 50.% conversion (when 50.% of the starting materials have reacted)?
(d) Is it spontaneous at 98 atm and 90.% conversion?

Concepts and Skills to Review Before You Study This Chapter

- redox terminology (Section 4.5)
- activity series of the metals (Section 4.6)
- trends in ionization energy (Section 8.3) and electronegativity (Section 9.5)
- free energy, work, and equilibrium (Sections 20.3 and 20.4)
- *Q* vs. *K* (Section 17.4) and ΔG vs. ΔG° (Section 20.4)

Thermodynamics has countless applications. Some that are within your reach right now—like a laptop computer or tablet, MP3 player, or smart phone—represent one type of application. Metal-plated jewelry and silverware represent another *(photo)*. These are a few of the objects you use every day that rely on a major field in applied thermodynamics called **electrochemistry,** the study of the relationship between chemical change and electrical work. This field relies on **electrochemical cells,** systems that incorporate a redox reaction to produce or utilize electrical energy.

IN THIS CHAPTER . . . *We examine the essential features of electrochemical cells and quantify the relationship between free energy and electrical work.*

- We review oxidation-reduction (redox) reactions and describe a method for balancing redox reactions that take place in electrochemical cells.
- We highlight key differences between the two types of electrochemical cells.
- We focus on voltaic cells, which *release* free energy to do electrical work, and see how they operate as a combination of two half-cells.
- We calculate the voltage, the cell's electrical potential, which is the sum of the voltages of the half-cells.
- We use half-cell voltages to determine the relative strengths of redox couples and to write spontaneous redox equations.
- We examine the interdependence of the standard free energy change, the standard cell potential, and the equilibrium constant.
- We follow the change in voltage as a voltaic cell operates.
- We see how differences in concentration between the solutions in the half-cells can be harnessed to generate electricity.
- We analyze the makeup and operation of some major types of batteries.
- We describe the problem of corrosion, which has key similarities to the operation of voltaic cells.
- We examine electrolytic cells, which *absorb* free energy from an external source to do electrical work. We predict the products that form under different conditions and quantify the relation between charge and amount of substance.
- We explore the redox system that generates energy in living cells.

21.1 REDOX REACTIONS AND ELECTROCHEMICAL CELLS

To begin, we review the oxidation-reduction process that we covered in Chapter 4 and describe the *half-reaction method* of balancing redox reactions. Then we see how redox reactions are used in the two types of electrochemical cells.

A Quick Review of Oxidation-Reduction Concepts

All electrochemical processes involve the *movement of electrons from one chemical species to another* in an oxidation-reduction (redox) reaction. In any redox process,

- *Oxidation* is the loss of electrons, and *reduction* is the gain of electrons. Oxidation and reduction occur *simultaneously*.

- The *oxidizing agent* does the oxidizing by *taking electrons* from the substance being oxidized. The *reducing agent* does the reducing by *giving electrons* to the substance being reduced. Therefore:

The oxidizing agent is reduced, and the reducing agent is oxidized.

- The oxidized substance ends up with a *higher* (more positive or less negative) oxidation number (O.N.), and the reduced substance ends up with a *lower* (less positive or more negative) O.N.
- The total number of electrons gained by the atoms/ions of the oxidizing agent equals the total number lost by the atoms/ions of the reducing agent.

Figure 21.1 presents these ideas for the aqueous reaction between zinc metal and H^+ from a strong acid. Be sure you can identify the oxidation and reduction parts of a redox process. You may want to review the full discussion in Section 4.5.

Figure 21.1 **A summary of redox terminology, as applied to the reaction of zinc with hydrogen ion.**

PROCESS	$\overset{0}{Zn}(s) + 2\overset{+1}{H^+}(aq) \longrightarrow \overset{+2}{Zn^{2+}}(aq) + \overset{0}{H_2}(g)$
OXIDATION • One reactant loses electrons. • Reducing agent is oxidized. • Oxidation number increases.	Zinc **loses** electrons. Zinc is the reducing agent and becomes **oxidized.** The oxidation number of Zn **increases** from 0 to +2.
REDUCTION • Other reactant gains electrons. • Oxidizing agent is reduced. • Oxidation number decreases.	Hydrogen ion **gains** electrons. Hydrogen ion is the oxidizing agent and becomes **reduced.** The oxidation number of H **decreases** from +1 to 0.

Half-Reaction Method for Balancing Redox Reactions

In Chapter 4, you learned how to determine the oxidation number of each element in a compound, how to identify oxidizing and reducing agents, and how to decide if a chemical change is a redox reaction. Now, let's see how to balance redox reactions. The **half-reaction method** is especially useful for studying electrochemistry:

- It *divides the overall redox reaction* into oxidation and reduction *half-reactions,* which, as you'll see, reflect their actual physical separation in electrochemical cells.
- It applies well to reactions in acidic or basic solution, which are common in cells.
- It (usually) does *not* require assigning O.N.s. (In cases where the half-reactions are not obvious, we assign O.N.s to determine which atoms undergo a change and write half-reactions with the species that contain those atoms.)

Steps in the Half-Reaction Method The balancing process begins with a "skeleton" ionic reaction that consists of only species that are oxidized and reduced. Here are the steps in the half-reaction method:

Step 1. Divide the skeleton reaction into two half-reactions. Each half-reaction contains the oxidized and reduced forms of one of the species: *if the oxidized form of a species is on the left side, the reduced form must be on the right, and vice versa.*

Step 2. Balance the atoms and charges in each half-reaction.
- Atoms are balanced *in this order:* atoms other than O and H, then O, then H.
- Charge is balanced by *adding* electrons (e^-) *to the left side in the reduction half-reaction* because the reactant gains them and *to the right side in the oxidation half-reaction* because the reactant loses them.

Step 3. If necessary, multiply one or both half-reactions by an integer so that

number of e^- gained in reduction = number of e^- lost in oxidation

Step 4. Add the balanced half-reactions, and include states of matter.

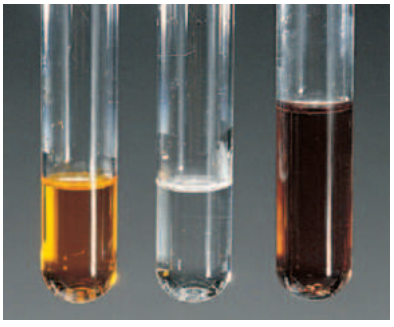
Step 5. Check that the atoms and charges are balanced.

Let's balance a redox reaction that occurs in acidic solution and then see how to balance one in basic solution in Sample Problem 21.1.

Balancing Redox Reactions in Acidic Solution For a reaction in acidic solution, H_2O molecules and H^+ ions are present for the balancing. We've usually used H_3O^+ to indicate the proton in water, but we use H^+ in this chapter because it makes the balancing simpler. To make that point, we'll also balance this first reaction with H_3O^+ to show that the only difference is in the number of water molecules.

The reaction between dichromate ion and iodide ion to form chromium(III) ion and solid iodine occurs in acidic solution *(see photo)*. The skeleton ionic reaction is

$$Cr_2O_7^{2-}(aq) + I^-(aq) \longrightarrow Cr^{3+}(aq) + I_2(s) \qquad [\text{acidic solution}]$$



Dichromate ion *(left)* and iodide ion *(center)* form chromium(III) ion and solid iodine *(right)*.

Step 1. Divide the reaction into half-reactions. Each half-reaction contains the oxidized and reduced forms of one species:

$$Cr_2O_7^{2-} \longrightarrow Cr^{3+}$$
$$I^- \longrightarrow I_2$$

Step 2. Balance atoms and charges in each half-reaction. We use H_2O to balance O, H^+ to balance H, and e^- to balance charges.

- For the $Cr_2O_7^{2-}/Cr^{3+}$ half-reaction:
  a. *Balance atoms other than O and H.* We balance the two Cr in $Cr_2O_7^{2-}$ on the left with a coefficient of 2 on the right:
  $$Cr_2O_7^{2-} \longrightarrow 2Cr^{3+}$$
  b. *Balance O atoms by adding H_2O molecules.* Each H_2O has one O atom, so we add seven H_2O on the right to balance the seven O in $Cr_2O_7^{2-}$:
  $$Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O$$
  c. *Balance H atoms by adding H^+ ions.* Each H_2O contains two H, and we added seven H_2O, so we add 14 H^+ ions on the left:
  $$14H^+ + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O$$
  d. *Balance charge by adding electrons.* Each H^+ ion has a 1+ charge, and 14 H^+ plus the 2− of $Cr_2O_7^{2-}$ gives 12+ on the left. Two Cr^{3+} give 6+ on the right. There is an excess of 6+ on the left, so we add six e^- on the left:
  $$6e^- + 14H^+ + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O \qquad [\text{reduction}]$$

This half-reaction is balanced. It is the *reduction* because electrons appear on the *left, as reactants:* $Cr_2O_7^{2-}$ gains electrons (is reduced), so $Cr_2O_7^{2-}$ is the *oxidizing agent.* The O.N. of Cr decreases from +6 on the left to +3 on the right.

- For the I^-/I_2 half-reaction:
  a. *Balance atoms other than O and H.* Two I atoms on the right require a coefficient of 2 on the left:
  $$2I^- \longrightarrow I_2$$
  b. *Balance O atoms with H_2O.* Not needed; there are no O atoms.
  c. *Balance H atoms with H^+.* Not needed; there are no H atoms.
  d. *Balance charge with e^-.* To balance the 2− on the left, we add two e^- on the right:
  $$2I^- \longrightarrow I_2 + 2e^- \qquad [\text{oxidation}]$$

This half-reaction is balanced. It is the *oxidation* because electrons appear on the *right, as products:* the reactant I^- loses electrons (is oxidized), so I^- is the *reducing agent.* The O.N. of I increases from −1 to 0.

Step 3. Multiply each half-reaction, if necessary, by an integer so that the number of e^- lost in the oxidation equals the number of e^- gained in the reduction. Two e^- are lost in the oxidation and six e^- are gained in the reduction, so we multiply the oxidation by 3:

$$3(2I^- \longrightarrow I_2 + 2e^-)$$
$$6I^- \longrightarrow 3I_2 + 6e^-$$

Step 4. Add the half-reactions, canceling species that appear on both sides, and include states of matter. In this example, only the electrons cancel:

$$\cancel{6e^-} + 14H^+ + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O$$
$$6I^- \longrightarrow 3I_2 + \cancel{6e^-}$$
$$\overline{6I^-(aq) + 14H^+(aq) + Cr_2O_7^{2-}(aq) \longrightarrow 3I_2(s) + 7H_2O(l) + 2Cr^{3+}(aq)}$$

Step 5. Check that atoms and charges balance:

Reactants (6I, 14H, 2Cr, 7O; 6+) ⟶ products (6I, 14H, 2Cr, 7O; 6+)

Using H_3O^+, Instead of H^+, to Balance H Now let's see what happens if we use H_3O^+ to supply H atoms, instead of H^+. In step 2 for the reduction half-reaction, balancing Cr atoms and balancing O atoms with H_2O are the same as before, so we have

$$Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O$$

Now we use H_3O^+ to balance H atoms. Because each H_3O^+ is an H^+ bonded to an H_2O, we balance the 14 H on the right with 14 H_3O^+ on the left and immediately add 14 more H_2O on the right:

$$14H_3O^+ + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 7H_2O + 14H_2O$$

Taking the sum of the H_2O molecules on the right gives

$$14H_3O^+ + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 21H_2O$$

None of this affects the redox change, so balancing the charge still requires six e^- on the left, and we obtain the balanced reduction half-reaction:

$$6e^- + 14H_3O^+ + Cr_2O_7^{2-} \longrightarrow 2Cr^{3+} + 21H_2O \qquad \text{[reduction]}$$

Adding the balanced oxidation half-reaction gives the balanced redox equation:

$$6I^-(aq) + 14H_3O^+(aq) + Cr_2O_7^{2-}(aq) \longrightarrow 3I_2(s) + 21H_2O(l) + 2Cr^{3+}(aq)$$

Note that, as mentioned earlier, the only difference is the number of H_2O molecules: 21 H_2O instead of 7 H_2O. So, even though this approach uses H_3O^+, which shows more closely how H^+ exists, only the number of water molecules changes and the balancing involves more steps. Therefore, we'll continue to use H^+ to balance H atoms in these equations.

Balancing Redox Reactions in Basic Solution In acidic solution, H_2O molecules and H^+ ions are available to balance a redox reaction, but in basic solution, H_2O molecules and OH^- ions are available.

We need only one additional step to balance a redox reaction that takes place in basic solution. It appears after we balance the half-reactions *as if they occur in acidic solution* and are combined (step 4). At this point, *we add one OH^-* ***to both sides of the equation*** *for every H^+ present.* (This step is labeled "4 Basic" in Sample Problem 21.1.) The OH^- ions added on the side with H^+ ions combine with them to form H_2O molecules, while the OH^- on the other side remain in the equation, and then excess H_2O is canceled.

SAMPLE PROBLEM 21.1 Balancing a Redox Reaction in Basic Solution

Problem Permanganate ion reacts in basic solution with oxalate ion to form carbonate ion and solid manganese dioxide. Balance the skeleton ionic equation for the reaction between $NaMnO_4$ and $Na_2C_2O_4$ in basic solution:

$$MnO_4^-(aq) + C_2O_4^{2-}(aq) \longrightarrow MnO_2(s) + CO_3^{2-}(aq) \qquad \text{[basic solution]}$$

Plan We follow the numbered steps as described in text, and proceed through step 4 as if this reaction occurs in acidic solution. Then, we add the appropriate number of OH^- ions and cancel excess H_2O molecules (step 4 Basic).

Solution

1. Divide into half-reactions.

$MnO_4^- \longrightarrow MnO_2$ $\qquad$ $C_2O_4^{2-} \longrightarrow CO_3^{2-}$

2. Balance.

a. Atoms other than O and H,

Not needed

b. O atoms with H_2O,

$MnO_4^- \longrightarrow MnO_2 + 2H_2O$

c. H atoms with H^+,

$4H^+ + MnO_4^- \longrightarrow MnO_2 + 2H_2O$

d. Charge with e^-,

$3e^- + 4H^+ + MnO_4^- \longrightarrow MnO_2 + 2H_2O$

[reduction]

a. Atoms other than O and H,

$C_2O_4^{2-} \longrightarrow 2CO_3^{2-}$

b. O atoms with H_2O,

$2H_2O + C_2O_4^{2-} \longrightarrow 2CO_3^{2-}$

c. H atoms with H^+,

$2H_2O + C_2O_4^{2-} \longrightarrow 2CO_3^{2-} + 4H^+$

d. Charge with e^-,

$2H_2O + C_2O_4^{2-} \longrightarrow 2CO_3^{2-} + 4H^+ + 2e^-$

[oxidation]

3. Multiply each half-reaction, if necessary, by some integer to make e^- lost equal e^- gained.

$2(3e^- + 4H^+ + MnO_4^- \longrightarrow MnO_2 + 2H_2O)$

$6e^- + 8H^+ + 2MnO_4^- \longrightarrow 2MnO_2 + 4H_2O$

$3(2H_2O + C_2O_4^{2-} \longrightarrow 2CO_3^{2-} + 4H^+ + 2e^-)$

$6H_2O + 3C_2O_4^{2-} \longrightarrow 6CO_3^{2-} + 12H^+ + 6e^-$

4. Add half-reactions, and cancel species appearing on both sides. The six e^- cancel, eight H^+ cancel to leave four H^+ on the right, and four H_2O cancel to leave two H_2O on the left:

$$\begin{array}{r} \cancel{6e^-} + \cancel{8H^+} + 2MnO_4^- \longrightarrow 2MnO_2 + \cancel{4H_2O} \\ 2\,\cancel{6}H_2O + 3C_2O_4^{2-} \longrightarrow 6CO_3^{2-} + 4\,\cancel{12}H^+ + \cancel{6e^-} \\ \hline 2MnO_4^- + 2H_2O + 3C_2O_4^{2-} \longrightarrow 2MnO_2 + 6CO_3^{2-} + 4H^+ \end{array}$$

4 Basic. Add OH^- to both sides to neutralize the H^+ present, and cancel excess H_2O. Adding four OH^- to both sides forms four H_2O on the right. Two of those cancel the two H_2O on the left and leave two H_2O on the right:

$2MnO_4^- + 2H_2O + 3C_2O_4^{2-} + 4OH^- \longrightarrow 2MnO_2 + 6CO_3^{2-} + [4H^+ + 4OH^-]$

$2MnO_4^- + \cancel{2H_2O} + 3C_2O_4^{2-} + 4OH^- \longrightarrow 2MnO_2 + 6CO_3^{2-} + 2\,\cancel{4}H_2O$

Including states of matter gives the final balanced equation:

$$2MnO_4^-(aq) + 3C_2O_4^{2-}(aq) + 4OH^-(aq) \longrightarrow 2MnO_2(s) + 6CO_3^{2-}(aq) + 2H_2O(l)$$

5. Check that atoms and charges balance.

$(2Mn, 24O, 6C, 4H; 12-) \longrightarrow (2Mn, 24O, 6C, 4H; 12-)$

Comment As a final step, let's see how to obtain the balanced *molecular* equation for this reaction. We note the amount (mol) of each anion in the balanced ionic equation and add the correct amount (mol) of spectator ions (in this case, Na^+, as given in the problem statement) to obtain neutral compounds. The balanced molecular equation is

$$2NaMnO_4(aq) + 3Na_2C_2O_4(aq) + 4NaOH(aq) \longrightarrow 2MnO_2(s) + 6Na_2CO_3(aq) + 2H_2O(l)$$

FOLLOW-UP PROBLEMS

Brief Solutions to ***all*** *Follow-up Problems appear at the end of the chapter.*

21.1A Write a balanced molecular equation for the reaction between $KMnO_4$ and KI in basic solution. The skeleton ionic reaction is

$$MnO_4^-(aq) + I^-(aq) \longrightarrow MnO_4^{2-}(aq) + IO_3^-(aq)$$

21.1B Write a balanced molecular equation for the reaction between chromium(III) hydroxide and sodium iodate in basic solution. The skeleton ionic reaction is

$$Cr(OH)_3(s) + IO_3^-(aq) \longrightarrow CrO_4^{2-}(aq) + I^-(aq)$$

SOME SIMILAR PROBLEMS 21.12–21.19

An Overview of Electrochemical Cells

The fundamental difference between the two types of electrochemical cells is based on whether the overall redox reaction in the cell is spontaneous (free energy is released) or nonspontaneous (free energy is absorbed):

1. A **voltaic cell** (also called a **galvanic cell**) uses a *spontaneous* reaction ($\Delta G < 0$) to generate electrical energy. In the cell reaction, some of the difference in free energy between higher energy reactants and lower energy products is converted into electrical energy, which operates the load—flashlight, MP3 player, car starter motor, and so forth. Thus, *the system does work on the surroundings (load).* All batteries contain voltaic cells.
2. An **electrolytic cell** uses electrical energy to drive a *nonspontaneous* reaction ($\Delta G > 0$). In the cell reaction, an external power source supplies free energy to convert lower energy reactants into higher energy products. Thus, *the surroundings (power supply) do work on the system.* Electroplating and the recovery of metals from ores utilize electrolytic cells.

The two types of cell have several similarities. Two **electrodes,** which conduct the electricity between cell and surroundings, are dipped into an **electrolyte,** a mixture of ions (usually in aqueous solution) that are involved in the reaction or that carry the charge (Figure 21.2). An electrode is identified as either **anode** or **cathode** depending on the half-reaction that takes place there:

- *The oxidation half-reaction occurs at the anode.* Electrons lost by the substance being oxidized (reducing agent) *leave the oxidation half-cell* at the anode.
- *The reduction half-reaction occurs at the cathode.* Electrons gained by the substance being reduced (oxidizing agent) *enter the reduction half-cell* at the cathode.

Note that, for reasons we discuss shortly, *the relative charges of the electrodes are* ***opposite in sign*** *in the two types of cell.*

Which Half-Reaction Occurs at Which Electrode?

Here are some memory aids to help you remember which half-reaction occurs at which electrode:

1. The words *anode* and *oxidation* start with vowels; the words *cathode* and *reduction* start with consonants.
2. Alphabetically, the *A* in anode comes before the *C* in cathode, and the *O* in oxidation comes before the *R* in reduction.
3. Look at the first syllables and use your imagination:
   ANode, OXidation; REDuction,
   CAThode ⟹ AN OX and a RED CAT

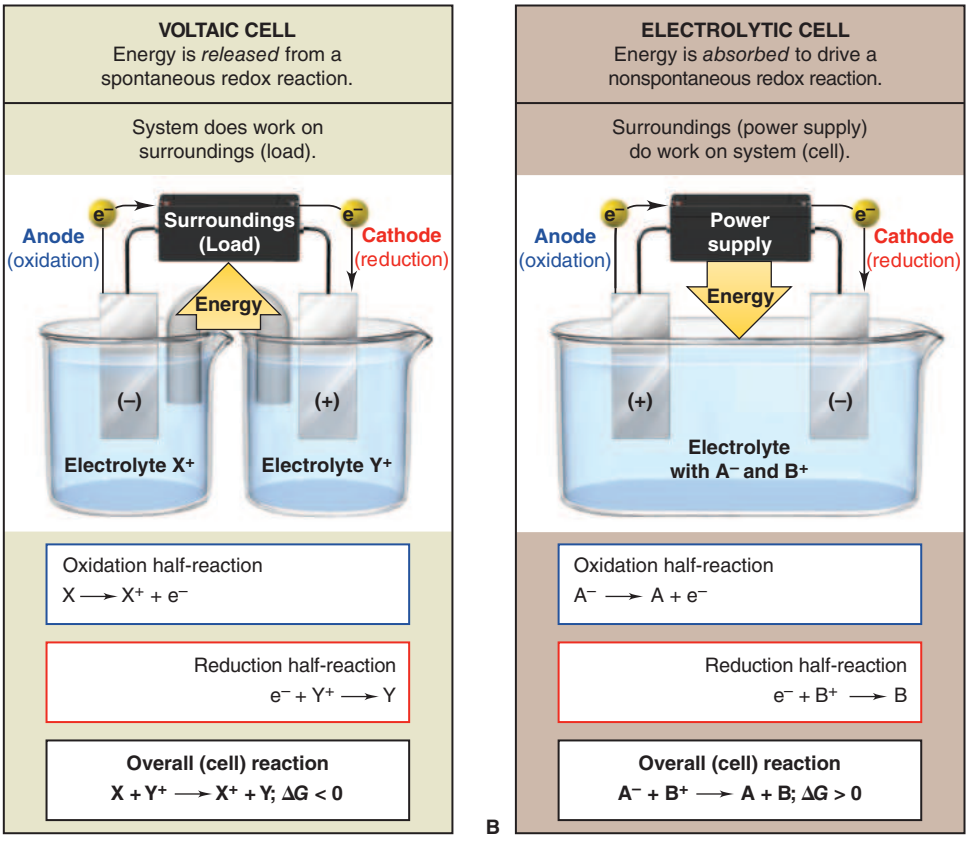


Figure 21.2 General characteristics of (A) voltaic cells and (B) electrolytic cells.

Summary of Section 21.1

- An oxidation-reduction (redox) reaction involves the transfer of electrons from a reducing agent to an oxidizing agent.
- The half-reaction method of balancing divides the overall reaction into half-reactions that are balanced separately and then recombined.
- There are two types of electrochemical cells. In a voltaic cell, a spontaneous reaction generates electricity and does work on the surroundings. In an electrolytic cell, the surroundings supply electricity that does work to drive a nonspontaneous reaction.
- In both types of cell, two electrodes dip into electrolyte solutions; oxidation occurs at the anode, and reduction occurs at the cathode.

21.2 VOLTAIC CELLS: USING SPONTANEOUS REACTIONS TO GENERATE ELECTRICAL ENERGY

When you put a strip of zinc metal in a solution of Cu^{2+} ion, the blue color of the solution fades and a brown-black crust of copper metal forms on the zinc strip (Figure 21.3). During this spontaneous reaction, Cu^{2+} ion is reduced to Cu metal, while Zn metal is oxidized to Zn^{2+} ion. The overall reaction consists of two half-reactions:

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) \quad \text{[reduction]}$$

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \quad \text{[oxidation]}$$

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s) \quad \text{[overall reaction]}$$

Let's examine this spontaneous reaction as the basis of a voltaic cell.

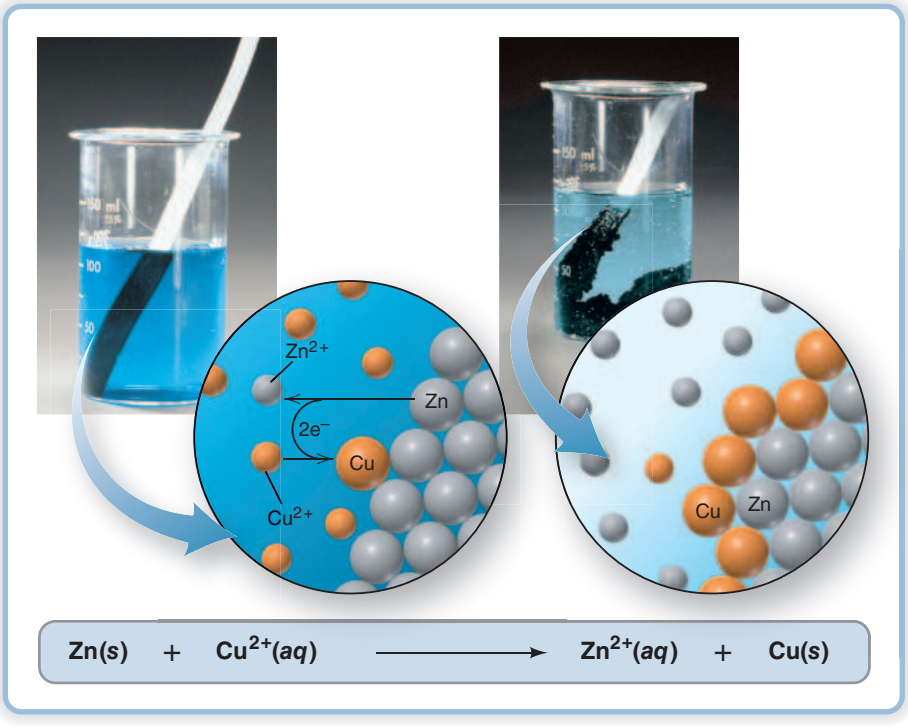

Figure 21.3 The spontaneous reaction between zinc and copper(II) ion. When zinc metal is placed in a solution of Cu^{2+} ion *(left)*, zinc is oxidized to Zn^{2+}, and Cu^{2+} is reduced to copper metal *(right)*. (The very finely divided Cu appears black.)

Construction and Operation of a Voltaic Cell

Electrons are being transferred in the Zn/Cu^{2+} reaction, but the system does not generate electrical energy because the oxidizing agent (Cu^{2+}) and the reducing agent (Zn) are in the *same* beaker. If, however, we physically separate the half-reactions and connect them by an external circuit, the electrons lost by the zinc produce an electric current as they travel through the circuit toward the copper ions that gain them.

Basis of the Voltaic Cell: Separation of Half-Reactions In any voltaic cell, the components of each half-reaction are placed in a separate container, or **half-cell,** which consists of one electrode dipping into an electrolyte solution (Figure 21.4A). The two half-cells are joined by the external circuit, and a voltmeter measures the voltage generated. A switch (not shown) closes (completes) or opens (breaks) the circuit. Here are some key points about the half-cells of the Zn/Cu^{2+} voltaic cell:

1. *Oxidation half-cell (anode compartment, always shown on the left).* The anode compartment consists of a bar of zinc (the anode) immersed in a Zn^{2+} electrolyte (such as aqueous zinc sulfate, $ZnSO_4$). Zinc metal is the reactant in the oxidation half-reaction, and the bar loses electrons *and* conducts them *out* of this half-cell.
2. *Reduction half-cell (cathode compartment, always shown on the right).* The cathode compartment consists of a bar of copper (the cathode) immersed in a Cu^{2+} electrolyte [such as aqueous copper(II) sulfate, $CuSO_4$]. Copper is the product in the reduction half-reaction, and the bar conducts electrons *into* its half-cell, where Cu^{2+} is reduced.

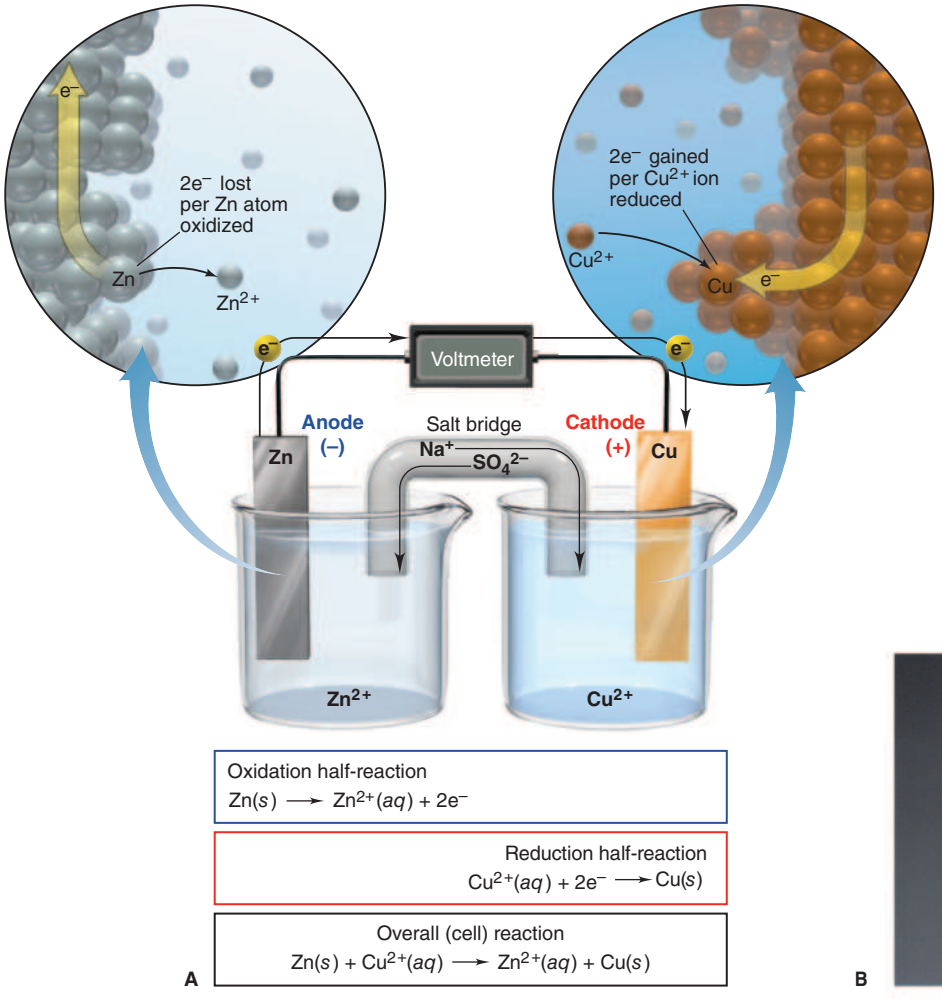

Figure 21.4 A voltaic cell based on the zinc-copper reaction. A, In the anode half-cell (oxidation; *left*), two electrons from a Zn atom move through the Zn bar as the Zn^{2+} ion enters the solution. In the cathode half-cell (reduction; *right*), the electrons reduce Cu^{2+} ions to Cu atoms. **B,** After several hours, the Zn anode weighs less and the Cu cathode weighs more.

Charges of the Electrodes The charges of the electrodes are determined by the *source of electrons* and the *direction of electron flow* through the circuit. In this cell, Zn atoms are oxidized at the anode to Zn^{2+} ions and are the source of electrons. The Zn^{2+} ions enter the half-cell's electrolyte, while the electrons move through the bar and into the wire. *The electrons flow left to right* through the wire to the cathode, where Cu^{2+} ions in this half-cell's electrolyte are reduced to Cu atoms. As the cell operates, electrons are continuously generated at the anode and consumed at the cathode. Therefore, the anode has an excess of electrons and the cathode has a deficit of electrons: *in any **voltaic** cell, the anode is negative relative to the cathode.*

Completing the Circuit with a Salt Bridge A cell cannot operate unless the circuit is complete. The oxidation half-cell initially contains a neutral solution of Zn^{2+} and SO_4^{2-} ions, but as Zn atoms in the bar lose electrons, the Zn^{2+} ions that form enter the solution and would give it a net positive charge. Similarly, in the reduction half-cell, the initial neutral solution of Cu^{2+} and SO_4^{2-} ions would develop a net negative charge as Cu^{2+} ions leave the solution and form Cu atoms. If allowed to occur, such a charge imbalance between the half-cells would stop cell operation.

This situation is avoided by use of a **salt bridge.** It joins the half-cells and acts like a "liquid wire," allowing ions to flow through both compartments and complete the circuit while keeping the electrolyte solutions neutral. The salt bridge is an inverted U tube containing nonreacting ions, such as Na^+ and SO_4^{2-}, dissolved in a gel, which does not flow out of the tube but allows ions to diffuse into or out of the half-cells:

- *Maintaining a neutral reduction half-cell (right; cathode compartment).* As Cu^{2+} ions change to Cu atoms, Na^+ ions move from the salt bridge into the electrolyte solution (and some SO_4^{2-} ions move from the solution into the salt bridge).
- *Maintaining a neutral oxidation half-cell (left; anode compartment).* As Zn atoms change to Zn^{2+} ions, SO_4^{2-} ions move from the salt bridge into the electrolyte solution (and some Zn^{2+} ions move from the solution into the salt bridge).

Thus, the wire and the salt bridge complete the circuit:

- *Electrons move left to right* through the wire.
- *Anions move right to left* through the salt bridge.
- *Cations move left to right* through the salt bridge.

Active vs. Inactive Electrodes The electrodes in the Zn/Cu^{2+} cell are *active* because the metals themselves are components of the half-reactions. As the cell operates, the mass of the zinc bar gradually decreases, as the $[Zn^{2+}]$ in the anode half-cell increases. At the same time, the mass of the copper bar increases as the $[Cu^{2+}]$ in the cathode half-cell decreases and the ions form atoms that "plate out" on the electrode (Figure 21.4B).

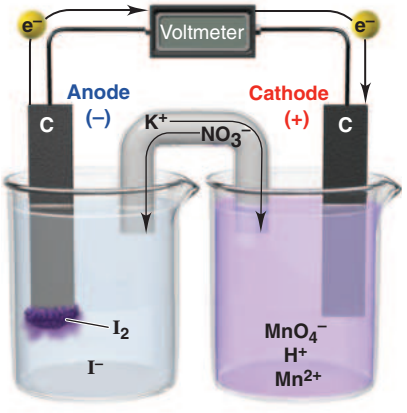
In many cases, however, there are no reaction components that can be physically used as an electrode, so *inactive* electrodes are used. Most commonly, inactive electrodes are rods of *graphite* or *platinum*. In a voltaic cell based on the following half-reactions, for instance, the reacting species cannot be made into electrodes:

$$2I^-(aq) \longrightarrow I_2(s) + 2e^- \quad \text{[anode; oxidation]}$$

$$MnO_4^-(aq) + 8H^+(aq) + 5e^- \longrightarrow Mn^{2+}(aq) + 4H_2O(l) \quad \text{[cathode; reduction]}$$

Each half-cell consists of an inactive electrode immersed in an electrolyte that contains *all the reactant species involved in that half-reaction* (Figure 21.5):

- In the *anode half-cell*, I^- ions are oxidized to solid I_2, and the released electrons flow into the graphite (C) electrode and through the wire.
- From the wire, the electrons enter the graphite electrode in the *cathode half-cell* and reduce MnO_4^- ions to Mn^{2+} ions. (A KNO_3 salt bridge is used.)



Oxidation half-reaction
$2I^-(aq) \longrightarrow I_2(s) + 2e^-$

Reduction half-reaction
$MnO_4^-(aq) + 8H^+(aq) + 5e^- \longrightarrow Mn^{2+}(aq) + 4H_2O(l)$

Overall (cell) reaction
$2MnO_4^-(aq) + 16H^+(aq) + 10I^-(aq) \longrightarrow 2Mn^{2+}(aq) + 5I_2(s) + 8H_2O(l)$

Figure 21.5 **A voltaic cell using inactive electrodes.**

Diagram of a Voltaic Cell As Figures 21.4A and 21.5 show, there are certain consistent features in the *diagram* of any voltaic cell:

- Components of the half-cells include electrode materials, electrolyte ions, and other species involved in the reaction.
- Electrode name (anode or cathode) and charge are shown. By convention, the anode compartment appears *on the left.*
- Each half-reaction and the overall cell reaction are given.
- Direction of electron flow in the external circuit is from left to right.
- Nature of ions and direction of ion flow in the salt bridge are shown, with cations moving right and anions moving left.

Notation for a Voltaic Cell

A useful shorthand notation describes the components of a voltaic cell. The notation for the Zn/Cu^{2+} cell is

$$Zn(s) \mid Zn^{2+}(aq) \parallel Cu^{2+}(aq) \mid Cu(s)$$

Key parts of the notation are as follows:

- The components of the anode compartment (oxidation half-cell) are written *to the left* of the components of the cathode compartment (reduction half-cell).
- A double vertical line indicates the half-cells are physically separated.
- A single vertical line represents a phase boundary. For example, $Zn(s) \mid Zn^{2+}(aq)$ indicates that *solid* Zn is a *different* phase from *aqueous* Zn^{2+}.
- A comma separates the half-cell components that are in the *same* phase. For example, the notation for the voltaic cell shown in Figure 21.5 is

  $$\text{graphite} \mid I^-(aq) \mid I_2(s) \parallel MnO_4^-(aq), H^+(aq), Mn^{2+}(aq) \mid \text{graphite}$$

  That is, in the cathode compartment, MnO_4^-, H^+, and Mn^{2+} ions are in an aqueous solution with solid graphite immersed in it.
- If needed, the concentrations of dissolved components are given in parentheses; for example, if the concentrations of Zn^{2+} and Cu^{2+} are 1 *M*, we write

  $$Zn(s) \mid Zn^{2+}(1\ M) \parallel Cu^{2+}(1\ M) \mid Cu(s)$$

- Half-cell components usually appear in the same order as in the half-reaction, and electrodes appear at the far left (anode) and far right (cathode) of the notation.
- Ions in the salt bridge are not part of the reaction so they are not in the notation.

SAMPLE PROBLEM 21.2 Describing a Voltaic Cell with Diagram and Notation

Problem Draw a diagram, show balanced half-cell and cell equations, and write the notation for a voltaic cell that consists of one half-cell with a Cr bar in a $Cr(NO_3)_3$ solution, another half-cell with an Ag bar in an $AgNO_3$ solution, and a KNO_3 salt bridge. Measurement indicates that the Cr electrode is negative relative to the Ag electrode.

Plan From the given contents of the half-cells, we write the half-reactions. To determine which is the anode compartment (oxidation) and which is the cathode (reduction), we note the relative electrode charges (which are based on the direction of the spontaneous redox reaction). Electrons are released into the anode during oxidation, so it has a negative charge. We are told that Cr is negative, so it is the anode and Ag is the cathode.

Solution Writing the balanced half-reactions. The Ag half-reaction consumes e^-:

$$Ag^+(aq) + e^- \longrightarrow Ag(s) \quad \text{[reduction; cathode]}$$

The Cr half-reaction releases e^-:

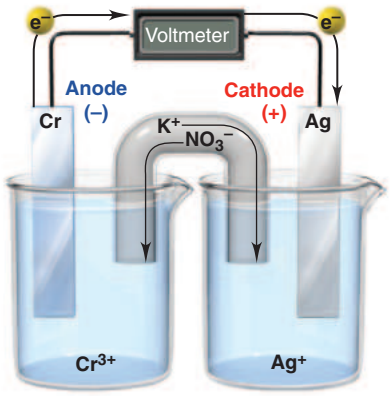
$$Cr(s) \longrightarrow Cr^{3+}(aq) + 3e^- \quad \text{[oxidation; anode]}$$

Writing the balanced overall cell equation. We triple the reduction half-reaction to balance e^- and combine the half-reactions:

$$Cr(s) + 3Ag^+(aq) \longrightarrow Cr^{3+}(aq) + 3Ag(s)$$

Determining direction of electron and ion flow. The released e^- in the Cr electrode (negative) flow through the external circuit to the Ag electrode (positive). As Cr^{3+} ions enter the anode electrolyte, NO_3^- ions enter from the salt bridge to maintain neutrality. As Ag^+ ions leave the cathode electrolyte and plate out on the Ag electrode, K^+ ions enter from the salt bridge to maintain neutrality. The cell diagram is shown in the margin. Writing the cell notation:

$$Cr(s) \mid Cr^{3+}(aq) \parallel Ag^+(aq) \mid Ag(s)$$



Check Always be sure that the half-reactions and the cell reaction are balanced, the half-cells contain *all* components of the half-reactions, and the electron and ion flow are shown. You should be able to write the half-reactions from the cell notation as a check.

Comment The diagram of a voltaic cell relies on the *direction of the spontaneous reaction* to give the oxidation (anode; negative) and reduction (cathode; positive) half-reactions.

FOLLOW-UP PROBLEMS

21.2A In one half-cell of a voltaic cell, a graphite rod dips into an acidic solution of $K_2Cr_2O_7$ and $Cr(NO_3)_3$; in the other half-cell, a tin bar dips into a $Sn(NO_3)_2$ solution. A KNO_3 salt bridge joins the half-cells. The tin electrode is negative relative to the graphite. Diagram the cell, and write the balanced half-cell and cell equations and the cell notation.

21.2B In one half-cell of a voltaic cell, a graphite rod dips into an acidic solution of $KClO_3$ and KCl; in the other half-cell, a nickel bar dips into a $Ni(NO_3)_2$ solution. A KNO_3 salt bridge joins the half-cells, and the graphite is positive relative to the nickel. Diagram the cell, and write balanced half-cell and cell equations and the cell notation.

SOME SIMILAR PROBLEMS 21.29–21.34

Why Does a Voltaic Cell Work?

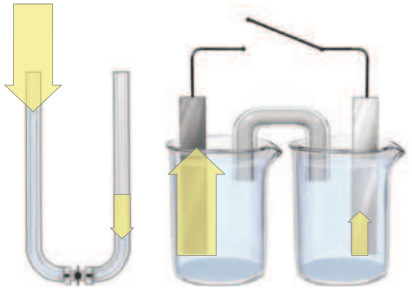
What principles explain *how* the Zn/Cu^{2+} cell reaction takes place and *why* electrons flow in the direction they do? Let's examine what is happening when the switch is open and no reaction is occurring. In each half-cell, the metal electrode is in equilibrium with the metal ions in the electrolyte and the electrons within the metal:

$$Zn(s) \rightleftharpoons Zn^{2+}(aq) + 2e^- \text{ (in Zn metal)}$$
$$Cu(s) \rightleftharpoons Cu^{2+}(aq) + 2e^- \text{ (in Cu metal)}$$

Given the direction of the overall spontaneous reaction, Zn gives up its electrons more easily than Cu does; that is, Zn is a stronger reducing agent. Therefore, the equilibrium position of the Zn half-reaction lies farther to the right. We can think of the electrons in the Zn electrode as being subject to a greater "pressure" than those in the Cu electrode, a greater potential energy (referred to as *electrical potential*) ready to "push" them through the circuit. Close the switch, and electrons flow from the Zn to the Cu electrode to equalize this difference in electrical potential. The flow disturbs the equilibrium at each electrode. The Zn half-reaction shifts to the right to restore the electrons flowing out, and the Cu half-reaction shifts to the left to remove the electrons flowing in. Thus, *the spontaneous reaction occurs as a result of the different abilities of these metals to give up their electrons.*

Electron Flow and Water Flow

Consider this analogy between electron "pressure" and water pressure. A U tube (cell) is separated into two arms (two half-cells) by a stopcock (switch), and the two arms contain water at different heights (the half-cells have different electrical potentials). Open the stopcock (close the switch), and the different heights (potential difference) become equal as water flows (electrons flow and current is generated).



Summary of Section 21.2

- A voltaic cell consists of oxidation (anode) and reduction (cathode) half-cells, connected by a wire to conduct electrons and a salt bridge to maintain charge neutrality.
- Electrons move from the anode (left) to the cathode (right), while cations move from the salt bridge into the cathode half-cell and anions move from the salt bridge into the anode half-cell.
- The cell notation shows the species and their phases in each half-cell, as well as the direction of current flow.
- A voltaic cell operates because species in the two half-cells differ in the tendency to lose electrons (strength as a reducing agent).

21.3 CELL POTENTIAL: OUTPUT OF A VOLTAIC CELL

A voltaic cell converts the free energy change of a spontaneous reaction into the kinetic energy of electrons moving through an external circuit (electrical energy). This electrical energy is proportional to the *difference in electrical potential between the two electrodes,* which is called the **cell potential (E_{cell}),** the **voltage** of the cell, or the **electromotive force (emf).**

Electrons flow spontaneously from the negative to the positive electrode, that is, toward the electrode with the more positive electrical potential. Thus, when the cell operates *spontaneously,* there is a *positive* cell potential:

$$E_{cell} > 0 \text{ for a spontaneous process} \qquad (21.1)$$

- $E_{cell} > 0$ for a spontaneous reaction. The more positive E_{cell} is, the more work the cell can do, and the farther the reaction proceeds to the right as written.
- $E_{cell} < 0$ for a *nonspontaneous* cell reaction.
- $E_{cell} = 0$ when the reaction has reached equilibrium, so the cell can do no more work. (We return to these ideas in Section 21.4.)

Standard Cell Potential (E°_{cell})

The SI unit of electrical potential is the **volt (V),** and the SI unit of electrical charge is the **coulomb (C).** By definition, if two electrodes differ by 1 volt of electrical potential, 1 joule of energy is released (that is, 1 joule of work can be done) for each coulomb of charge that moves between the electrodes. That is,

$$1 \text{ V} = 1 \text{ J/C} \qquad (21.2)$$

Table 21.1 lists the voltages of some commercial and natural voltaic cells.

Table 21.1 Voltages of Some Voltaic Cells

Voltaic Cell	Voltage (V)
Common alkaline flashlight battery	1.5
Lead-acid car battery (6 cells ≈ 12 V)	2.1
Calculator battery (mercury)	1.3
Lithium-ion laptop battery	3.7
Electric eel (~5000 cells in 6-ft eel = 750 V)	0.15
Nerve of giant squid (across cell membrane)	0.070

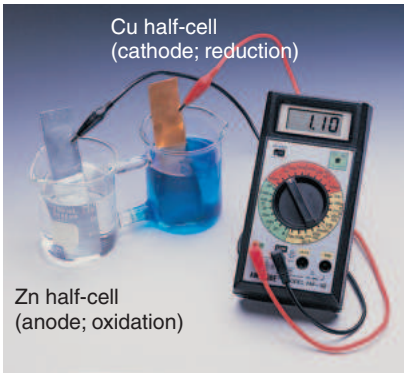


Figure 21.6 Measuring the standard cell potential of a zinc-copper cell.

The *measured* cell potential is affected by changes in concentration as the reaction proceeds and by energy losses from heating the cell and external circuit. Therefore, as with other thermodynamic quantities, to compare potentials of different cells, we obtain a **standard cell potential (E°_{cell}),** which is measured at a specified temperature (usually 298 K) with no current flowing* and *all components in their standard states:* 1 atm for gases, 1 *M* for solutions, the pure solid for electrodes. For example, the zinc-copper cell produces 1.10 V when it operates at 298 K with $[Zn^{2+}] = [Cu^{2+}] = 1\ M$ (Figure 21.6):

$$Zn(s) + Cu^{2+}(aq;\ 1\ M) \longrightarrow Zn^{2+}(aq;\ 1\ M) + Cu(s) \qquad E_{cell} = E^\circ_{cell} = 1.10 \text{ V}$$

Standard Electrode (Half-Cell) Potential ($E^\circ_{half\text{-}cell}$) Just as each half-reaction makes up part of the overall reaction, each half-cell (electrode) potential makes up a part of the overall cell potential. The **standard electrode potential ($E^\circ_{half\text{-}cell}$)** is the potential of a given half-reaction (half-cell compartment) with all components in their standard states.

By convention (and as they appear in reference tables), *a standard electrode potential refers to the half-reaction written as a* ***reduction.*** (A list of them, like that in Appendix D, is called an *emf series* or a *table of standard electrode potentials*.) For the zinc-copper reaction, both the zinc half-reaction (E°_{zinc}, anode compartment) and the copper half-reaction (E°_{copper}, cathode compartment) are written as reductions:

$$Zn^{2+}(aq) + 2e^- \longrightarrow Zn(s) \qquad E^\circ_{zinc}\ (E^\circ_{anode}) \qquad \text{[reduction]}$$
$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) \qquad E^\circ_{copper}\ (E^\circ_{cathode}) \qquad \text{[reduction]}$$

But, since the overall cell reaction involves the *oxidation* of zinc, not the *reduction* of Zn^{2+}, we can show what is actually occurring by reversing the zinc (anode) half-reaction:

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \qquad \text{[oxidation]}$$
$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) \qquad \text{[reduction]}$$

*The tiny current required to operate modern digital voltmeters makes a negligible difference in the value of E°_{cell}.

Calculating E°_{cell} from $E^\circ_{half\text{-}cell}$ The overall redox reaction for the zinc-copper cell is the sum of its half-reactions:

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$$

Because electrons flow spontaneously from the negative to the positive electrode, the copper electrode (cathode) has a more positive $E^\circ_{half\text{-}cell}$ than the zinc electrode (anode). As you'll see shortly, to obtain a positive E°_{cell} for this spontaneous redox reaction, we subtract E°_{zinc} from E°_{copper}:

$$E^\circ_{cell} = E^\circ_{copper} - E^\circ_{zinc}$$

We can generalize this result for any voltaic cell: *the standard cell potential is the standard electrode potential of the cathode (reduction) half-cell* ***minus*** *the standard electrode potential of the anode (oxidation) half-cell:*

$$E^\circ_{cell} = E^\circ_{cathode\ (reduction)} - E^\circ_{anode\ (oxidation)} \qquad \textbf{(21.3)}$$

For a *spontaneous* reaction at standard conditions, this calculation gives $E^\circ_{cell} > 0$.

SAMPLE PROBLEM 21.3 Using $E^\circ_{half\text{-}cell}$ to Find E°_{cell}

Problem Balance the following skeleton ionic reaction, and calculate E°_{cell} to decide whether the reaction is spontaneous:

$$Mn^{2+}(aq) + Br_2(l) \longrightarrow MnO_4^-(aq) + Br^-(aq) \qquad \text{[acidic solution]}$$

Plan We balance the skeleton reaction (see Sample Problem 21.1). Then, we look up the $E^\circ_{half\text{-}cell}$ values in Appendix D and use Equation 21.3 to find E°_{cell}. If E°_{cell} is positive, the reaction is spontaneous.

Solution Balancing the skeleton reaction:

$$2[Mn^{2+} + 4H_2O \longrightarrow MnO_4^- + 8H^+ + 5e^-] \qquad \text{[oxidation]}$$
$$5[Br_2 + 2e^- \longrightarrow 2Br^-] \qquad \text{[reduction]}$$
$$2Mn^{2+}(aq) + 5Br_2(l) + 8H_2O(l) \longrightarrow 2MnO_4^-(aq) + 10Br^-(aq) + 16H^+(aq) \qquad \text{[overall]}$$

Using $E^\circ_{half\text{-}cell}$ values to find E°_{cell}:

$$E^\circ_{cell} = E^\circ_{cathode\ (reduction)} - E^\circ_{anode\ (oxidation)} = 1.07\ V - 1.51\ V$$
$$= -0.44\ V; \text{ not spontaneous}$$

Check Rounding to check the calculation: 1.00 V − 1.50 V = −0.50 V. A negative E°_{cell} indicates a nonspontaneous reaction.

FOLLOW-UP PROBLEMS

21.3A Balance the following skeleton ionic reaction, and calculate E°_{cell} to decide whether the reaction is spontaneous:

$$Ag(s) + Cu^{2+}(aq) \longrightarrow Ag^+(aq) + Cu(s)$$

21.3B Balance the following skeleton ionic reaction, and calculate E°_{cell} to decide whether the reaction is spontaneous:

$$Cl_2(g) + Fe^{2+}(aq) \longrightarrow Cl^-(aq) + Fe^{3+}(aq)$$

SOME SIMILAR PROBLEMS 21.42–21.45

Determining $E^\circ_{half\text{-}cell}$ with the Standard Hydrogen Electrode To compare half-cell potentials, we need to know the portion of E°_{cell} contributed by each half-cell. But, how can we find individual half-cell potentials if we can measure only the potential of the overall cell? We can do so because half-cell potentials, such as E°_{zinc} and E°_{copper}, are measured *relative* to a standard reference half-cell, *which has a standard electrode potential defined as zero* ($E^\circ_{reference} \equiv 0.00$ V). To find an unknown standard electrode potential ($E^\circ_{unknown}$), we construct a voltaic cell consisting of this reference half-cell and the unknown half-cell. Since $E^\circ_{reference}$ is zero, the overall E°_{cell} gives $E^\circ_{unknown}$.

The **standard reference half-cell** is a **standard hydrogen electrode,** which consists of a platinum electrode that has H_2 gas at 1 atm bubbling through it and is

immersed in 1 *M* strong acid, which means 1 *M* $H^+(aq)$ [or $H_3O^+(aq)$]. Thus, the reference half-reaction is

$$2H^+(aq;\ 1\ M) + 2e^- \rightleftharpoons H_2(g;\ 1\ \text{atm}) \qquad E^\circ_{\text{reference}} = 0.00\ \text{V}$$

Depending on the unknown half-cell, the reference half-cell can be the anode or the cathode:

- When H_2 is oxidized, the reference half-cell is the anode, and so *reduction* occurs at the unknown half-cell:

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = E^\circ_{\text{unknown}} - E^\circ_{\text{reference}} = E^\circ_{\text{unknown}} - 0.00\ \text{V} = E^\circ_{\text{unknown}}$$

- When H^+ is reduced, the reference half-cell is the cathode, and so *oxidation* occurs at the unknown half-cell:

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = E^\circ_{\text{reference}} - E^\circ_{\text{unknown}} = 0.00\ \text{V} - E^\circ_{\text{unknown}} = -E^\circ_{\text{unknown}}$$

Figure 21.7 shows a voltaic cell that has the Zn/Zn^{2+} half-reaction in one compartment and the H^+/H_2 (or H_3O^+/H_2) half-reaction in the other. The zinc electrode is negative relative to the hydrogen electrode, so we know that the zinc is being oxidized and is the anode. The measured E°_{cell} is +0.76 V (reaction is spontaneous), and we use this value to find the unknown standard electrode potential, E°_{zinc}:

$$2H^+(aq) + 2e^- \longrightarrow H_2(g) \qquad E^\circ_{\text{reference}} = 0.00\ \text{V}\ [\text{cathode; reduction}]$$
$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \qquad E^\circ_{\text{zinc}} = ?\ \text{V}\ [\text{anode; oxidation}]$$
$$Zn(s) + 2H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2(g) \qquad E^\circ_{\text{cell}} = 0.76\ \text{V}$$
$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = E^\circ_{\text{reference}} - E^\circ_{\text{zinc}}$$

Solving for E°_{zinc}, the standard half-cell potential for $Zn^{2+} + 2e^- \longrightarrow Zn$, gives

$$E^\circ_{\text{zinc}} = E^\circ_{\text{reference}} - E^\circ_{\text{cell}} = 0.00\ \text{V} - 0.76\ \text{V} = -0.76\ \text{V}$$

Now we can return to the zinc-copper cell and use the measured E°_{cell} (1.10 V) and the value we just found for E°_{zinc} to calculate E°_{copper}:

$$E^\circ_{\text{cell}} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} = E^\circ_{\text{copper}} - E^\circ_{\text{zinc}}$$

and,
$$E^\circ_{\text{copper}} = E^\circ_{\text{cell}} + E^\circ_{\text{zinc}} = 1.10\ \text{V} + (-0.76\ \text{V}) = 0.34\ \text{V}$$

By continuing this process of constructing cells with one known and one unknown electrode potential, we find other standard electrode potentials.

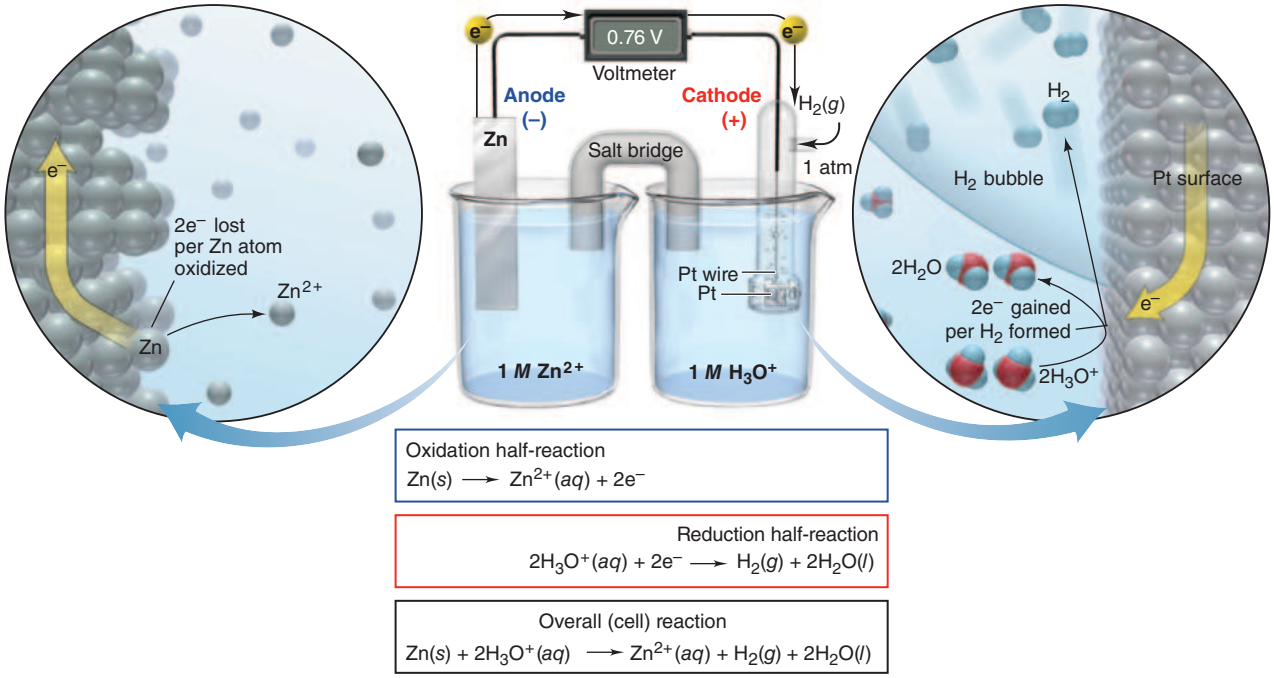

Figure 21.7 Determining an unknown $E^\circ_{\text{half-cell}}$ with the standard reference (hydrogen) electrode. The magnified view of the hydrogen half-reaction *(right)* shows two H_3O^+ ions being reduced to two H_2O molecules and an H_2 molecule, which enters the H_2 bubble.

SAMPLE PROBLEM 21.4 Calculating an Unknown $E^\circ_{\text{half-cell}}$ from E°_{cell}

Problem A voltaic cell houses the reaction between aqueous bromine and zinc metal:

$$Br_2(aq) + Zn(s) \longrightarrow Zn^{2+}(aq) + 2Br^-(aq) \qquad E^\circ_{cell} = 1.83\ V$$

Calculate $E^\circ_{bromine}$, given $E^\circ_{zinc} = -0.76$ V.

Plan E°_{cell} is positive, so the reaction is spontaneous as written. By dividing the reaction into half-reactions, we see that Br_2 is reduced and Zn is oxidized; thus, the zinc half-cell contains the anode. We use Equation 21.3 and the known E°_{zinc} to find $E^\circ_{unknown}$ ($E^\circ_{bromine}$).

Solution Dividing the reaction into half-reactions:

$$Br_2(aq) + 2e^- \longrightarrow 2Br^-(aq) \qquad E^\circ_{unknown} = E^\circ_{bromine} = ?\ V$$
$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \qquad E^\circ_{zinc} = -0.76\ V$$

Calculating $E^\circ_{bromine}$:

$$E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode} = E^\circ_{bromine} - E^\circ_{zinc}$$
$$E^\circ_{bromine} = E^\circ_{cell} + E^\circ_{zinc} = 1.83\ V + (-0.76\ V) = 1.07\ V$$

Check A good check is to make sure that calculating $E^\circ_{bromine} - E^\circ_{zinc}$ gives E°_{cell}: 1.07 V − (−0.76 V) = 1.83 V.

Comment Keep in mind that, whichever half-cell potential is unknown, reduction is the cathode half-reaction and oxidation is the anode half-reaction. *Always* subtract E°_{anode} from $E^\circ_{cathode}$ to get E°_{cell}. (We use $E^\circ_{bromine}$ in Follow-up Problem 21.4A.)

FOLLOW-UP PROBLEMS

21.4A A voltaic cell based on the reaction between aqueous Br_2 and vanadium(III) ions has $E^\circ_{cell} = 0.73$ V:

$$Br_2(aq) + 2V^{3+}(aq) + 2H_2O(l) \longrightarrow 2VO^{2+}(aq) + 4H^+(aq) + 2Br^-(aq)$$

What is $E^\circ_{vanadium}$, the standard electrode potential for the reduction of VO^{2+} to V^{3+}?

21.4B A voltaic cell based on the reaction between vanadium(III) and nitrate ions has $E^\circ_{cell} = 0.62$ V:

$$3V^{3+}(aq) + NO_3^-(aq) + H_2O(l) \longrightarrow 3VO^{2+}(aq) + NO(g) + 2H^+(aq)$$

Use the value for $E^\circ_{vanadium}$ you obtained in Follow-up Problem 21.4A to find $E^\circ_{nitrate}$, the standard electrode potential for the reduction of NO_3^- to NO.

SOME SIMILAR PROBLEMS 21.38 and 21.39

Relative Strengths of Oxidizing and Reducing Agents

We learn the relative strengths of oxidizing and reducing agents from measuring cell potentials. Three oxidizing agents we just discussed are Cu^{2+}, H^+, and Zn^{2+}. Let's rank, from high *(top)* to low *(bottom),* their relative oxidizing strengths by writing each half-reaction as a reduction (gain of electrons), with its corresponding standard electrode potential:

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) \qquad E^\circ = 0.34\ V$$
$$2H^+(aq) + 2e^- \longrightarrow H_2(g) \qquad E^\circ = 0.00\ V$$
$$Zn^{2+}(aq) + 2e^- \longrightarrow Zn(s) \qquad E^\circ = -0.76\ V$$

The more positive the E° value, the more readily the reaction (as written) occurs; thus, Cu^{2+} gains two e^- more readily than H^+, which gains them more readily than Zn^{2+}:

- Strength as an oxidizing agent *decreases* top to bottom: $Cu^{2+} > H^+ > Zn^{2+}$.
- Strength as a reducing agent *increases* top to bottom: $Zn > H_2 > Cu$.

By continuing this process with other half-cells, we create a list of reduction half-reactions in *decreasing* order of standard electrode potential (from most positive to most negative), as in Appendix D; a few examples are presented in Table 21.2 *(next page)*. There are several key points to keep in mind:

- All values are relative to the standard hydrogen (reference) electrode.
- Since the half-reactions are written as *reductions, reactants are oxidizing agents* and *products are reducing agents*.

Table 21.2 Selected Standard Electrode Potentials (298 K)

Half-Reaction	$E^\circ_{\text{half-cell}}$ (V)
$F_2(g) + 2e^- \rightleftharpoons 2F^-(aq)$	+2.87
$Cl_2(g) + 2e^- \rightleftharpoons 2Cl^-(aq)$	+1.36
$MnO_2(s) + 4H^+(aq) + 2e^- \rightleftharpoons Mn^{2+}(aq) + 2H_2O(l)$	+1.23
$NO_3^-(aq) + 4H^+(aq) + 3e^- \rightleftharpoons NO(g) + 2H_2O(l)$	+0.96
$Ag^+(aq) + e^- \rightleftharpoons Ag(s)$	+0.80
$Fe^{3+}(aq) + e^- \rightleftharpoons Fe^{2+}(aq)$	+0.77
$O_2(g) + 2H_2O(l) + 4e^- \rightleftharpoons 4OH^-(aq)$	+0.40
$Cu^{2+}(aq) + 2e^- \rightleftharpoons Cu(s)$	+0.34
$2H^+(aq) + 2e^- \rightleftharpoons H_2(g)$	**0.00**
$N_2(g) + 5H^+(aq) + 4e^- \rightleftharpoons N_2H_5^+(aq)$	−0.23
$Fe^{2+}(aq) + 2e^- \rightleftharpoons Fe(s)$	−0.44
$Zn^{2+}(aq) + 2e^- \rightleftharpoons Zn(s)$	−0.76
$2H_2O(l) + 2e^- \rightleftharpoons H_2(g) + 2OH^-(aq)$	−0.83
$Na^+(aq) + e^- \rightleftharpoons Na(s)$	−2.71
$Li^+(aq) + e^- \rightleftharpoons Li(s)$	−3.05

Strength of oxidizing agent ↑ (increases going up)

Strength of reducing agent ↓ (increases going down)

- The more positive the $E^\circ_{\text{half-cell}}$, the more readily the half-reaction occurs, as written.
- Half-reactions are shown with an equilibrium arrow because each can occur as a reduction (at the cathode) or an oxidation (at the anode), depending on the $E^\circ_{\text{half-cell}}$ of the other half-reaction. In calculations, *always* use $E^\circ_{\text{half-cell}}$ for the half-reaction *written as a reduction*.
- As Appendix D (or Table 21.2) is arranged, the strength of the oxidizing agent (reactant) *increases going up (bottom to top),* and the strength of the reducing agent (product) *increases going down (top to bottom).*

Thus, $F_2(g)$ is the strongest oxidizing agent (has the largest positive E°), which means $F^-(aq)$ is the weakest reducing agent. Similarly, $Li^+(aq)$ is the weakest oxidizing agent (has the most negative E°), which means $Li(s)$ is the strongest reducing agent: a *strong oxidizing agent forms a weak reducing agent,* and vice versa. Rely on your knowledge of the redox behavior of the elements (Section 8.4) if you forget the ranking in the table:

- F_2 is very electronegative and occurs naturally as F^-, so it is easily reduced (gains electrons) and must be a strong oxidizing agent (high, positive E°).
- Li metal has a low ionization energy and occurs naturally as Li^+, so it is easily oxidized (loses electrons) and must be a strong reducing agent (low, negative E°).

Using $E^\circ_{\text{half-cell}}$ Values to Write Spontaneous Redox Reactions

Every redox reaction is the sum of two half-reactions, so there is a reducing agent and an oxidizing agent on each side. In the zinc-copper reaction, for instance, Zn and Cu are the reducing agents, and Cu^{2+} and Zn^{2+} are the oxidizing agents. The stronger oxidizing and reducing agents react spontaneously to form the weaker oxidizing and reducing agents:

$$\underset{\substack{\text{stronger}\\\text{reducing agent}}}{Zn(s)} + \underset{\substack{\text{stronger}\\\text{oxidizing agent}}}{Cu^{2+}(aq)} \longrightarrow \underset{\substack{\text{weaker}\\\text{oxidizing agent}}}{Zn^{2+}(aq)} + \underset{\substack{\text{weaker}\\\text{reducing agent}}}{Cu(s)}$$

Based on the order of the E° values in Appendix D, and as we just saw for the Cu^{2+}/Cu, H^+/H_2, and Zn^{2+}/Zn redox pairs (or redox *couples*), *the stronger oxidizing agent (species on the left) has a half-reaction with a larger (more positive or less negative) E° value, and the stronger reducing agent (species on the right) has a half-reaction with a smaller (less positive or more negative) E° value*. Therefore, we can use Appendix D to choose a redox reaction for constructing a voltaic cell.

Writing a Spontaneous Reaction *With* Appendix D A spontaneous reaction ($E^\circ_{cell} > 0$) will occur between an oxidizing agent and any reducing agent that lies *below* it in the list of standard electrode potentials in Appendix D. In other words, *for a spontaneous reaction to occur, the half-reaction higher in the list proceeds at the cathode as written, and the half-reaction lower in the list proceeds at the anode in reverse*. This pairing ensures that the stronger oxidizing agent (higher on the left) and stronger reducing agent (lower on the right) will be the reactants. For example, two half-reactions in the order they appear in Appendix D are

$$Cl_2(g) + 2e^- \longrightarrow 2Cl^-(aq) \qquad E^\circ_{chlorine} = 1.36\ V$$
$$Ni^{2+}(aq) + 2e^- \longrightarrow Ni(s) \qquad E^\circ_{nickel} = -0.25\ V$$

Here are the steps we follow to write a spontaneous reaction between these reactants:

- Reverse the nickel half-reaction (it is lower in the list):

$$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^- \qquad E^\circ_{nickel} = -0.25\ V$$

  Note, however, that *we do **not** reverse the sign of* $E^\circ_{half\text{-}cell}$ because the arithmetic operation of subtraction in Equation 21.3 (cathode – anode) will do that.
- Make sure that e^- lost equals e^- gained; if not, multiply one or both half-reactions by a coefficient to accomplish this. In this case, both e^- lost and e^- gained are $2e^-$, so we skip this step.
- Add the half-reactions to get the balanced equation:

$$Cl_2(g) + Ni(s) \longrightarrow Ni^{2+}(aq) + 2Cl^-(aq)$$

- Apply Equation 21.3 to find E°_{cell}:

$$E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode} = E^\circ_{chlorine} - E^\circ_{nickel} = 1.36\ V - (-0.25\ V) = 1.61\ V$$

Writing a Spontaneous Reaction *Without* Appendix D Even when a list like Appendix D is not available, we can write a spontaneous redox reaction from a given pair of half-reactions. For example, here are two half-reactions:

$$Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s) \qquad E^\circ_{tin} = -0.14\ V$$
$$Ag^+(aq) + e^- \longrightarrow Ag(s) \qquad E^\circ_{silver} = 0.80\ V$$

Two steps are required:

1. Reverse one of the half-reactions into an oxidation step so that the difference of the electrode potentials (cathode *minus* anode) gives a *positive* E°_{cell}. (Remember that when we reverse the half-reaction, we do *not* reverse the sign of $E^\circ_{half\text{-}cell}$.)
2. Multiply by one or more coefficients to make e^- lost equal e^- gained, add the rearranged half-reactions to get a balanced overall equation, and cancel species common to both sides.

We want the reactants to be the stronger oxidizing and reducing agents:

- The larger (more positive) E° value for the silver half-reaction means that Ag^+ is a stronger oxidizing agent (gains electrons more readily) than Sn^{2+}.
- The smaller (more negative) E° value for the tin half-reaction means that Sn is a stronger reducing agent (loses electrons more readily) than Ag.

For step 1, we reverse the tin half-reaction (but *not* the sign of E°_{tin}):

$$Sn(s) \longrightarrow Sn^{2+}(aq) + 2e^- \qquad E^\circ_{tin} = -0.14\ V$$

because when we subtract $E^\circ_{half\text{-}cell}$ of the tin half-reaction (anode, oxidation) from $E^\circ_{half\text{-}cell}$ of the silver half-reaction (cathode, reduction), we get a positive E°_{cell}:

$$0.80\ V - (-0.14\ V) = 0.94\ V$$

For step 2, the number of electrons lost in the oxidation must equal the number gained in the reduction, so we double the silver (reduction) half-reaction. Adding the half-reactions and applying Equation 21.3 gives

$$2Ag^+(aq) + 2e^- \longrightarrow 2Ag(s) \qquad E^\circ_{silver} = 0.80\ V \quad [\text{reduction}]$$
$$Sn(s) \longrightarrow Sn^{2+}(aq) + 2e^- \qquad E^\circ_{tin} = -0.14\ V \quad [\text{oxidation}]$$
$$Sn(s) + 2Ag^+(aq) \longrightarrow Sn^{2+}(aq) + 2Ag(s)$$
$$E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode} = E^\circ_{silver} - E^\circ_{tin} = 0.94\ V$$

A *very important point* to note is that, when we double the coefficients of the silver half-reaction, we do *not* double its $E^\circ_{\text{half-cell}}$. *Changing the coefficients of a half-reaction does* ***not*** *change its* $E^\circ_{\textit{half-cell}}$ because a standard electrode potential is an *intensive* property, one that does *not* depend on the amount of substance. Let's see why. The potential is the *ratio* of energy to charge. When we change the coefficients to change the amounts, the energy *and* the charge change proportionately, so their ratio stays the same. (Similarly, density does not change with the amount of substance because the mass *and* the volume change proportionately.)

SAMPLE PROBLEM 21.5 Writing Spontaneous Redox Reactions and Ranking Oxidizing and Reducing Agents by Strength

Problem **(a)** Combine pairs of the balanced half-reactions (1), (2), and (3) into three spontaneous reactions A, B, and C, and calculate E°_{cell} for each.
(b) Rank the relative strengths of the oxidizing and reducing agents.

(1) $NO_3^-(aq) + 4H^+(aq) + 3e^- \longrightarrow NO(g) + 2H_2O(l)$ $\quad E^\circ = 0.96\ \text{V}$
(2) $N_2(g) + 5H^+(aq) + 4e^- \longrightarrow N_2H_5^+(aq)$ $\quad E^\circ = -0.23\ \text{V}$
(3) $MnO_2(s) + 4H^+(aq) + 2e^- \longrightarrow Mn^{2+}(aq) + 2H_2O(l)$ $\quad E^\circ = 1.23\ \text{V}$

Plan **(a)** To write spontaneous redox reactions, we combine the possible pairs of half-reactions: (1) and (2) give reaction A, (1) and (3) give B, and (2) and (3) give C. They are all written as reductions, so the oxidizing agents appear as reactants and the reducing agents appear as products. For each pair, we reverse the half-reaction that has the smaller (less positive or more negative) E° value to an oxidation (without changing the sign of E°) to obtain a positive E°_{cell}. We make e^- lost equal e^- gained (without changing the E° value), add the half-reactions together, and then apply Equation 21.3 to find E°_{cell}. **(b)** Because each reaction is spontaneous as written, the stronger oxidizing and reducing agents are the reactants. To obtain the overall ranking, we first rank the relative strengths within each equation and then compare them.

Solution **(a)** Combining half-reactions (1) and (2) gives equation A. The E° value for half-reaction (1) is larger (more positive) than that for (2), so we reverse (2) to obtain a positive E°_{cell}:

(1) $NO_3^-(aq) + 4H^+(aq) + 3e^- \longrightarrow NO(g) + 2H_2O(l)$ $\quad E^\circ = 0.96\ \text{V}$
(rev 2) $N_2H_5^+(aq) \longrightarrow N_2(g) + 5H^+(aq) + 4e^-$ $\quad E^\circ = -0.23\ \text{V}$

To make e^- lost equal e^- gained, we multiply (1) by four and the reversed (2) by three; then add half-reactions and cancel appropriate numbers of common species (H^+ and e^-):

$4NO_3^-(aq) + 16H^+(aq) + 12e^- \longrightarrow 4NO(g) + 8H_2O(l)$ $\quad E^\circ = 0.96\ \text{V}$
$3N_2H_5^+(aq) \longrightarrow 3N_2(g) + 15H^+(aq) + 12e^-$ $\quad E^\circ = -0.23\ \text{V}$

(A) $3N_2H_5^+(aq) + 4NO_3^-(aq) + H^+(aq) \longrightarrow 3N_2(g) + 4NO(g) + 8H_2O(l)$
$E^\circ_{\text{cell}} = 0.96\ \text{V} - (-0.23\ \text{V}) = 1.19\ \text{V}$

Combining half-reactions (1) and (3) gives equation B. Half-reaction (1) has a smaller E°, so it is reversed:

(rev 1) $NO(g) + 2H_2O(l) \longrightarrow NO_3^-(aq) + 4H^+(aq) + 3e^-$ $\quad E^\circ = 0.96\ \text{V}$
(3) $MnO_2(s) + 4H^+(aq) + 2e^- \longrightarrow Mn^{2+}(aq) + 2H_2O(l)$ $\quad E^\circ = 1.23\ \text{V}$

We multiply reversed (1) by two and (3) by three, then add and cancel:

$2NO(g) + 4H_2O(l) \longrightarrow 2NO_3^-(aq) + 8H^+(aq) + 6e^-$ $\quad E^\circ = 0.96\ \text{V}$
$3MnO_2(s) + 12H^+(aq) + 6e^- \longrightarrow 3Mn^{2+}(aq) + 6H_2O(l)$ $\quad E^\circ = 1.23\ \text{V}$

(B) $3MnO_2(s) + 4H^+(aq) + 2NO(g) \longrightarrow 3Mn^{2+}(aq) + 2H_2O(l) + 2NO_3^-(aq)$
$E^\circ_{\text{cell}} = 1.23\ \text{V} - 0.96\ \text{V} = 0.27\ \text{V}$

Combining half-reactions (2) and (3) gives equation C. Half-reaction (2) has a smaller E°, so it is reversed:

(rev 2) $N_2H_5^+(aq) \longrightarrow N_2(g) + 5H^+(aq) + 4e^-$ $\quad E^\circ = -0.23\ \text{V}$
(3) $MnO_2(s) + 4H^+(aq) + 2e^- \longrightarrow Mn^{2+}(aq) + 2H_2O(l)$ $\quad E^\circ = 1.23\ \text{V}$

We multiply reaction (3) by two, add the half-reactions, and cancel:

$$N_2H_5^+(aq) \longrightarrow N_2(g) + 5H^+(aq) + 4e^- \qquad E° = -0.23\ V$$
$$2MnO_2(s) + 8H^+(aq) + 4e^- \longrightarrow 2Mn^{2+}(aq) + 4H_2O(l) \qquad E° = 1.23\ V$$

(C) $N_2H_5^+(aq) + 2MnO_2(s) + 3H^+(aq) \longrightarrow N_2(g) + 2Mn^{2+}(aq) + 4H_2O(l)$

$E°_{cell} = 1.23\ V - (-0.23\ V) = 1.46\ V$

(b) Ranking the oxidizing and reducing agents within each reaction:

Equation A	Oxidizing agents: $NO_3^- > N_2$	Reducing agents: $N_2H_5^+ > NO$
Equation B	Oxidizing agents: $MnO_2 > NO_3^-$	Reducing agents: $NO > Mn^{2+}$
Equation C	Oxidizing agents: $MnO_2 > N_2$	Reducing agents: $N_2H_5^+ > Mn^{2+}$

Determining the overall ranking of oxidizing and reducing agents. Comparing the relative strengths from the three balanced equations gives

Oxidizing agents: $MnO_2 > NO_3^- > N_2$
Reducing agents: $N_2H_5^+ > NO > Mn^{2+}$

Check As always, check that atoms and charges balance on both sides of each equation. A good way to check the ranking and equations is to list the given half-reactions in order of decreasing $E°$ value:

$$MnO_2(s) + 4H^+(aq) + 2e^- \longrightarrow Mn^{2+}(aq) + 2H_2O(l) \qquad E° = 1.23\ V$$
$$NO_3^-(aq) + 4H^+(aq) + 3e^- \longrightarrow NO(g) + 2H_2O(l) \qquad E° = 0.96\ V$$
$$N_2(g) + 5H^+(aq) + 4e^- \longrightarrow N_2H_5^+(aq) \qquad E° = -0.23\ V$$

Then the oxidizing agents (reactants) decrease in strength going down the list, so the reducing agents (products) decrease in strength going up. Moreover, each of the equations for the spontaneous reactions (A, B, and C) should combine a reactant with a product that is lower down on this list.

FOLLOW-UP PROBLEMS

21.5A **(a)** Combine pairs of the balanced half-reactions (1), (2), and (3) into three spontaneous reactions A, B, and C, and calculate $E°_{cell}$ for each:

(1) $Ag_2O(s) + H_2O(l) + 2e^- \longrightarrow 2Ag(s) + 2OH^-(aq) \qquad E° = 0.34\ V$
(2) $BrO_3^-(aq) + 3H_2O(l) + 6e^- \longrightarrow Br^-(aq) + 6OH^-(aq) \qquad E° = 0.61\ V$
(3) $Zn(OH)_2(s) + 2e^- \longrightarrow Zn(s) + 2OH^-(aq) \qquad E° = -1.25\ V$

(b) Rank the relative strengths of the oxidizing and reducing agents.

21.5B Is the following reaction spontaneous as written?

$$3Fe^{2+}(aq) \longrightarrow Fe(s) + 2Fe^{3+}(aq)$$

If not, write the equation for the spontaneous reaction, calculate $E°_{cell}$, and rank the three species of iron in order of decreasing strength as a reducing agent.

SOME SIMILAR PROBLEMS 21.46–21.49

Explaining the Activity Series of the Metals

In Chapter 4, we discussed the activity series of the metals (see Figure 4.20, p. 177), which ranks metals by their ability to "displace" one another from aqueous solution. Now you'll see *why* this displacement occurs, as well as why many, but not all, metals react with acid to form H_2, and why a few metals form H_2 even in water.

1. *Metals that can displace H_2 from acid.* The standard hydrogen half-reaction represents the reduction of H^+ ions from an acid to H_2:

$$2H^+(aq) + 2e^- \longrightarrow H_2(g) \qquad E° = 0.00\ V$$

To see which metals reduce H^+ (referred to as "displacing H_2") from acids, choose a metal, write its half-reaction as an oxidation, combine this half-reaction with the hydrogen half-reaction, and see if $E°_{cell}$ is positive. We find that the metals Li through Pb, those

that lie *below* the standard hydrogen (reference) half-reaction in Appendix D, give a positive E°_{cell} when reducing H^+. Iron, for example, reduces H^+ from an acid to H_2:

$$\begin{array}{rll} Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^- & E^\circ = -0.44\ V & \text{[anode; oxidation]} \\ 2H^+(aq) + 2e^- \longrightarrow H_2(g) & E^\circ = 0.00\ V & \text{[cathode; reduction]} \\ \hline Fe(s) + 2H^+(aq) \longrightarrow H_2(g) + Fe^{2+}(aq) & E^\circ_{cell} = 0.00\ V - (-0.44\ V) = 0.44\ V & \end{array}$$

The lower the metal in the list, the stronger it is as a reducing agent; therefore, *if E°_{cell} for the reduction of H^+ is more positive with metal A than with metal B, metal A is a stronger reducing agent than metal B and a more* ***active*** *metal.*

2. *Metals that cannot displace H_2 from acid.* For metals that are *above* the standard hydrogen (reference) half-reaction, the E°_{cell} is negative when we reverse the metal half-reaction, so the reaction does not occur. For example, the coinage metals—copper, silver, and gold, which are in Group 1B(11)—are not strong enough reducing agents to reduce H^+ from acids:

$$\begin{array}{rll} Ag(s) \longrightarrow Ag^+(aq) + e^- & E^\circ = 0.80\ V & \text{[anode; oxidation]} \\ 2H^+(aq) + 2e^- \longrightarrow H_2(g) & E^\circ = 0.00\ V & \text{[cathode; reduction]} \\ \hline 2Ag(s) + 2H^+(aq) \longrightarrow 2Ag^+(aq) + H_2(g) & E^\circ_{cell} = 0.00\ V - 0.80\ V = -0.80\ V & \end{array}$$

The *higher* the metal in the list, the *more negative* is its E°_{cell} for the reduction of H^+ to H_2, the *lower* is its reducing strength, and the *less active* it is. Thus, gold is less active than silver, which is less active than copper.

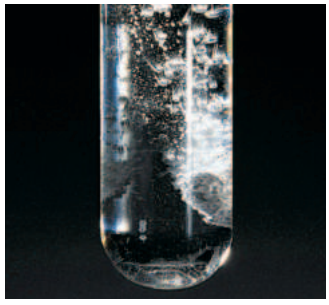
3. *Metals that can displace H_2 from water.* Metals active enough to reduce H_2O *lie below that half-reaction:*

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E^\circ = -0.83\ V$$

For example, consider the reaction of sodium in water (with the Na^+/Na half-reaction reversed and doubled):

$$\begin{array}{rll} 2Na(s) \longrightarrow 2Na^+(aq) + 2e^- & E^\circ = -2.71\ V & \text{[anode; oxidation]} \\ 2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) & E^\circ = -0.83\ V & \text{[cathode; reduction]} \\ \hline 2Na(s) + 2H_2O(l) \longrightarrow 2Na^+(aq) + H_2(g) + 2OH^-(aq) & & \\ \qquad E^\circ_{cell} = -0.83\ V - (-2.71\ V) = 1.88\ V & & \end{array}$$

The alkali metals [Group 1A(1)] and the larger alkaline earth metals [Group 2A(2)] can reduce water (displace H_2 from H_2O). Figure 21.8 shows calcium reducing H_2O to H_2.



Oxidation half-reaction
$Ca(s) \longrightarrow Ca^{2+}(aq) + 2e^-$

Reduction half-reaction
$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$

Overall (cell) reaction
$Ca(s) + 2H_2O(l) \longrightarrow Ca(OH)_2(aq) + H_2(g)$

Figure 21.8 The reaction of calcium in water.

4. *Metals that displace other metals from solution.* We can also predict whether one metal can reduce the aqueous ion of another metal. Any metal that is lower in the list in Appendix D can reduce the ion of a metal that is higher up, and thus displace that metal from solution. For example, zinc can displace iron from solution:

$$\begin{array}{rll} Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- & E^\circ = -0.76\ V & \text{[anode; oxidation]} \\ Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s) & E^\circ = -0.44\ V & \text{[cathode; reduction]} \\ \hline Zn(s) + Fe^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Fe(s) & E^\circ_{cell} = -0.44\ V - (-0.76\ V) = 0.32\ V & \end{array}$$

This particular reaction has tremendous economic importance in protecting iron from rusting, as we'll discuss in Section 21.6.

A common incident involving the reducing power of metals occurs when you bite down with a filled tooth on a scrap of aluminum foil left on a piece of food. The foil acts as an active anode ($E^\circ_{aluminum} = -1.66$ V), saliva as the electrolyte, and the filling (usually a silver/tin/mercury alloy) as an inactive cathode at which O_2 is reduced to water. The circuit between the foil and the filling creates a current that is sensed as pain by the nerve of the tooth (Figure 21.9).

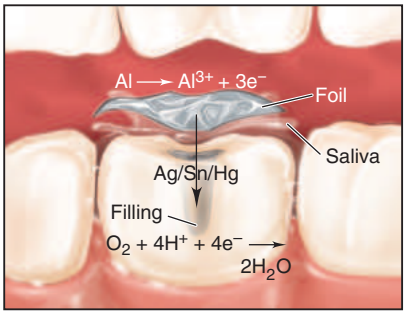


Figure 21.9 A dental "voltaic cell."

Summary of Section 21.3

- The output of a cell is the cell potential (E_{cell}), measured in volts (1 V = 1 J/C).
- With all substances in their standard states, the output is the standard cell potential (E°_{cell}).
- $E^\circ_{cell} > 0$ for a spontaneous reaction at standard-state conditions.
- By convention, a standard electrode potential ($E^\circ_{half\text{-}cell}$) refers to the *reduction* half-reaction.

- E°_{cell} equals $E^\circ_{half\text{-}cell}$ of the cathode *minus* $E^\circ_{half\text{-}cell}$ of the anode.
- Using a standard hydrogen (reference) electrode ($E^\circ_{reference} = 0$ V), $E^\circ_{half\text{-}cell}$ values can be measured and used to rank oxidizing (or reducing) agents.
- Spontaneous redox reactions combine stronger oxidizing and reducing agents to form weaker reducing and oxidizing agents, respectively.
- A metal can reduce another species (H^+, H_2O, or an ion of another metal) if E°_{cell} for the overall reaction is positive.

21.4 FREE ENERGY AND ELECTRICAL WORK

Following up on our discussion in Chapter 20, in this section, we examine the relationship of useful work, free energy, and the equilibrium constant in the context of electrochemical cells and see the effect of concentration on cell potential.

Standard Cell Potential and the Equilibrium Constant

The signs of ΔG and E_{cell} are *opposite* for a spontaneous reaction: a *negative* free energy change ($\Delta G < 0$; Section 20.3) and a *positive* cell potential ($E_{cell} > 0$). These two indicators of spontaneity are proportional to each other:

$$\Delta G \propto -E_{cell}$$

Let's determine this proportionality constant. The electrical work done (w, in joules) is the product of the potential (E_{cell}, in volts) and the charge that flows (in coulombs). Since E_{cell} is measured with no current flowing and, thus, no energy lost as heat, it is the maximum voltage possible, and, thus, determines the maximum work possible (w_{max}).* Work done *by* the cell *on* the surroundings has a negative sign:

$$w_{max} = -E_{cell} \times \text{charge}$$

The maximum work done *on* the surroundings is equal to ΔG (Equation 20.9, p. 896):

$$w_{max} = \Delta G = -E_{cell} \times \text{charge}$$

The charge that flows through the cell equals the amount (mol) of electrons transferred (n) times the charge of 1 mol of electrons (which has the symbol F):

$$\text{Charge} = \text{amount (mol) of } e^- \times \frac{\text{charge}}{\text{mol } e^-} \qquad \text{or} \qquad \text{charge} = nF$$

The charge of 1 mol of electrons is the **Faraday constant (*F*),** named for Michael Faraday, the 19th-century British scientist who pioneered the study of electrochemistry:

$$F = \frac{96{,}485 \text{ C}}{\text{mol } e^-}$$

Because 1 V = 1 J/C, we have 1 C = 1 J/V, and

$$F = 9.65\times10^4 \frac{\text{J}}{\text{V·mol } e^-} \quad (3 \text{ sf}) \tag{21.4}$$

Substituting for charge, the proportionality constant is nF:

$$\Delta G = -nFE_{cell} \tag{21.5}$$

And, when all components are in their standard states, we have

$$\Delta G^\circ = -nFE^\circ_{cell} \tag{21.6}$$

Using this relationship, we can relate the standard cell potential to the equilibrium constant of the redox reaction. Recall from Equation 20.12 that

$$\Delta G^\circ = -RT \ln K$$

*Recall from Chapter 20 that only a reversible process can do maximum work. For no current to flow and the process to be reversible, E_{cell} must be opposed by an equal potential in the measuring circuit: if the opposing potential is infinitesimally smaller, the cell reaction goes forward; if it is infinitesimally larger, the reaction goes backward.

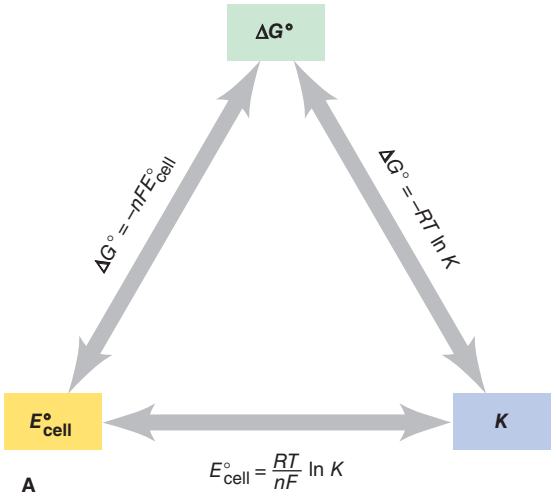

Figure 21.10 **The interrelationship of $\Delta G°$, $E°_{cell}$, and K. A,** Any one parameter can be used to find the other two. **B,** The signs of $\Delta G°$, K, and $E°_{cell}$ determine reaction direction.

Reaction Parameters at the Standard State

$\Delta G°$	K	$E°_{cell}$	Reaction at standard-state conditions
<0	>1	>0	Spontaneous
0	1	0	At equilibrium
>0	<1	<0	Nonspontaneous

B

Substituting for $\Delta G°$ from Equation 21.6 gives

$$-nFE°_{cell} = -RT \ln K$$

Solving for $E°_{cell}$ gives

$$E°_{cell} = \frac{RT}{nF} \ln K \qquad \textbf{(21.7)}$$

Figure 21.10 summarizes the interconnections among the standard free energy change, the equilibrium constant, and the standard cell potential. In Chapter 20, we determined K from $\Delta G°$, which we found either from $\Delta H°$ and $\Delta S°$ values or from $\Delta G°_f$ values. Now, for redox reactions, we have a direct *experimental* method for determining K *and* $\Delta G°$: measure $E°_{cell}$.

In calculations, we adjust Equation 21.7 as follows:

- Substitute 8.314 J/(mol rxn·K) for the constant R.
- Substitute 9.65×10^4 J/(V·mol e^-) for the constant F.
- Substitute 298.15 K for T, keeping in mind that the cell can run at other temperatures.
- Multiply by 2.303 to convert natural to common (base-10) logarithms. This conversion shows that a *10-fold change in K makes* $E°_{cell}$ *change by 1*.

Thus, when n moles of e^- are transferred per mole of reaction based on the balanced equation, we have

$$E°_{cell} = \frac{RT}{nF} \ln K = 2.303 \times \frac{8.314 \dfrac{\cancel{J}}{\text{mol rxn}\cdot\cancel{K}} \times 298.15\ \cancel{K}}{\dfrac{n\ \text{mol}\ \cancel{e^-}}{\text{mol rxn}}\left(9.65\times10^4 \dfrac{\cancel{J}}{\text{V}\cdot\text{mol}\ \cancel{e^-}}\right)} \log K$$

And this becomes

$$E°_{cell} = \frac{0.0592\ \text{V}}{n} \log K \quad \text{or} \quad \log K = \frac{nE°_{cell}}{0.0592\ \text{V}} \quad (\text{at } 298.15\ \text{K}) \qquad \textbf{(21.8)}$$

SAMPLE PROBLEM 21.6 Calculating K and $\Delta G°$ from $E°_{cell}$

Problem Silver occurs in trace amounts in some ores of lead, and lead can displace silver from solution:

$$Pb(s) + 2Ag^+(aq) \longrightarrow Pb^{2+}(aq) + 2Ag(s)$$

As a consequence, silver is a valuable byproduct in the industrial extraction of lead from its ores. Calculate K and $\Delta G°$ at 298.15 K for this reaction.

Plan We divide the spontaneous redox reaction into half-reactions and use values from Appendix D to calculate $E°_{cell}$. Then, we substitute this result into Equations 21.7 and 21.8 to find K and into Equation 21.6 to find $\Delta G°$.

Solution Writing the half-reactions with their $E°$ values:

(1) $Ag^+(aq) + e^- \longrightarrow Ag(s)$ $\quad E° = 0.80\ V$

(2) $Pb^{2+}(aq) + 2e^- \longrightarrow Pb(s)$ $\quad E° = -0.13\ V$

Calculating $E°_{cell}$: We double (1), reverse (2), add the half-reactions, and subtract $E°_{lead}$ from $E°_{silver}$:

$$2Ag^+(aq) + 2e^- \longrightarrow 2Ag(s) \qquad E° = 0.80\ V$$
$$Pb(s) \longrightarrow Pb^{2+}(aq) + 2e^- \qquad E° = -0.13\ V$$
$$Pb(s) + 2Ag^+(aq) \longrightarrow Pb^{2+}(aq) + 2Ag(s) \qquad E°_{cell} = 0.80\ V - (-0.13\ V) = 0.93\ V$$

Calculating K with Equations 21.7 and 21.8: The adjusted half-reactions show that 2 mol of e^- are transferred per mole of reaction as written, so $n = 2$. Then, performing the substitutions for R and F that we just discussed, changing to common logarithms, and running the cell at 25°C (298.15 K), we have

$$E°_{cell} = \frac{RT}{nF} \ln K = \frac{0.0592\ V}{2} \log K = 0.93\ V$$

So, $$\log K = \frac{0.93\ V \times 2}{0.0592\ V} = 31.42 \quad \text{and} \quad K = 2.6\times10^{31}$$

Calculating $\Delta G°$ (Equation 21.6):

$$\Delta G° = -nFE°_{cell} = -\frac{2\ mol\ e^-}{mol\ rxn} \times \frac{96.5\ kJ}{V\cdot mol\ e^-} \times 0.93\ V = -1.8\times10^2\ kJ/mol\ rxn$$

Check The three variables are consistent with the reaction being spontaneous at standard-state conditions: $E°_{cell} > 0$, $\Delta G° < 0$, and $K > 1$. Be sure to round and check the order of magnitude: to find $\Delta G°$, for instance, $\Delta G° \approx -2 \times 100 \times 1 = -200$, so the overall math seems right. Another check would be to obtain $\Delta G°$ directly from its relation with K:

$$\Delta G° = -RT \ln K = -8.314\ J/mol\ rxn\cdot K \times 298.15\ K \times \ln(2.6\times10^{31})$$
$$= -1.8\times10^5\ J/mol\ rxn = -1.8\times10^2\ kJ/mol\ rxn$$

FOLLOW-UP PROBLEMS

21.6A For the following reaction, $E°_{cell} = 0.25\ V$:

$$2MnO_4^-(aq) + 4H_2O(l) + 3Cu(s) \longrightarrow 2MnO_2(s) + 8OH^-(aq) + 3Cu^{2+}(aq)$$

Calculate K and $\Delta G°$ for this reaction at 298.15 K.

21.6B When cadmium metal reduces Cu^{2+} in solution, Cd^{2+} forms in addition to copper metal. Given that $\Delta G° = -143$ kJ/mol rxn, calculate K at 25°C. What is $E°_{cell}$ of a voltaic cell that uses this reaction?

SOME SIMILAR PROBLEMS 21.56–21.67

The Effect of Concentration on Cell Potential

So far, we've considered cells at standard-state conditions, but most cells don't start with those concentrations, and even if they did, concentrations change as the cell operates. Moreover, in all batteries, reactant concentrations are far from the standard state.

To determine E_{cell}, the cell potential under *nonstandard* conditions, we'll derive an expression for the relation between E_{cell} and concentration based on the relation between ΔG and concentration. Recall from Chapter 20 (Equation 20.13, p. 905) that

$$\Delta G = \Delta G° + RT \ln Q$$

ΔG is related to E_{cell} and $\Delta G°$ to $E°_{cell}$ (Equations 21.5 and 21.6); substituting, we get

$$-nFE_{cell} = -nFE°_{cell} + RT \ln Q$$

Dividing both sides by $-nF$, we obtain the equation developed by the great German chemist Walther Hermann Nernst when he was only 25 years old. (In his career, which culminated in the 1920 Nobel Prize, he also formulated the third law of thermodynamics and established the concept of the solubility product.) The **Nernst equation** says that E_{cell} depends on $E°_{cell}$ *and* a term for the potential at any ratio of concentrations:

$$E_{cell} = E°_{cell} - \frac{RT}{nF} \ln Q \qquad (21.9)$$

How do changes in Q affect cell potential? From Equation 21.9, we see that

- When $Q < 1$ and thus [reactant] $>$ [product], $\ln Q < 0$, so $E_{cell} > E^\circ_{cell}$.
- When $Q = 1$ and thus [reactant] $=$ [product], $\ln Q = 0$, so $E_{cell} = E^\circ_{cell}$.
- When $Q > 1$ and thus [reactant] $<$ [product], $\ln Q > 0$, so $E_{cell} < E^\circ_{cell}$.

As before, to obtain a form for calculations, we substitute known values of R and F, operate the cell at 298.15 K, and convert to common (base-10) logarithms:

$$E_{cell} = E^\circ_{cell} - \frac{RT}{nF}\ln Q$$

$$= E^\circ_{cell} - 2.303 \times \frac{8.314\ \dfrac{\cancel{J}}{\cancel{\text{mol rxn}}\cdot\cancel{K}} \times 298.15\ \cancel{K}}{\dfrac{n\ \cancel{\text{mol e}^-}}{\cancel{\text{mol rxn}}}\left(9.65\times10^4\ \dfrac{\cancel{J}}{\text{V}\cdot\cancel{\text{mol e}^-}}\right)}\log Q$$

We obtain

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ \text{V}}{n}\log Q \quad \text{(at 298.15 K)} \qquad \textbf{(21.10)}$$

Remember that the expression for Q *contains only those species with concentrations (and/or pressures) that can vary;* thus, solids do not appear, even when they are the electrodes. For example, in the reaction between cadmium and silver ion, the Cd and Ag electrodes do not appear in the expression for Q:

$$Cd(s) + 2Ag^+(aq) \longrightarrow Cd^{2+}(aq) + 2Ag(s) \qquad Q = \frac{[Cd^{2+}]}{[Ag^+]^2}$$

SAMPLE PROBLEM 21.7 Using the Nernst Equation to Calculate E_{cell}

Problem In a test of a new reference electrode, a chemist constructs a voltaic cell consisting of a Zn/Zn^{2+} half-cell and an H_2/H^+ half-cell under the following conditions:

$$[Zn^{2+}] = 0.010\ M \qquad [H^+] = 2.5\ M \qquad P_{H_2} = 0.30\ \text{atm}$$

Calculate E_{cell} at 298.15 K.

Plan To apply the Nernst equation and determine E_{cell}, we must know E°_{cell} and Q. We write the spontaneous reaction and calculate E°_{cell} from standard electrode potentials (Appendix D). To have consistent units, we convert the given pressure to molarity with the ideal gas law and find Q. Then we substitute into Equation 21.10.

Solution Determining the cell reaction and E°_{cell}:

$$2H^+(aq) + 2e^- \longrightarrow H_2(g) \qquad E^\circ = 0.00\ \text{V}$$
$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \qquad E^\circ = -0.76\ \text{V}$$
$$2H^+(aq) + Zn(s) \longrightarrow H_2(g) + Zn^{2+}(aq) \qquad E^\circ_{cell} = 0.00\ \text{V} - (-0.76\ \text{V}) = 0.76\ \text{V}$$

Converting pressure to molarity: $PV = nRT$, or

$$\frac{n}{V} = \frac{P}{RT} = \frac{0.30\ \text{atm}}{0.0821\ \dfrac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \times 298.15\ \text{K}} = 1.2\times10^{-2}\ \text{mol/L} = 0.012\ M$$

Calculating Q:

$$Q = \frac{[H_2] \times [Zn^{2+}]}{[H^+]^2} = \frac{0.012 \times 0.010}{2.5^2} = 1.9\times10^{-5}$$

Solving for E_{cell} at 25°C (298.15 K), with $n = 2$:

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ \text{V}}{n}\log Q$$

$$= 0.76\ \text{V} - \frac{0.0592\ \text{V}}{2}\log(1.9\times10^{-5}) = 0.76\ \text{V} - (-0.14\ \text{V}) = 0.90\ \text{V}$$

Check After you check the arithmetic, reason through the answer: $E_{cell} > E^\circ_{cell}$ (0.90 $>$ 0.76) because the log Q term was negative, which is consistent with $Q < 1$.

FOLLOW-UP PROBLEMS

21.7A A voltaic cell consists of a Cr/Cr^{2+} half-cell and an Sn/Sn^{2+} half-cell, with $[Sn^{2+}] = 0.20\ M$ and $[Cr^{2+}] = 1.60\ M$. Use Appendix D to calculate E_{cell} at 298.15 K.

21.7B Consider a voltaic cell based on the following reaction:

$$Fe(s) + Cu^{2+}(aq) \longrightarrow Fe^{2+}(aq) + Cu(s)$$

If $[Cu^{2+}] = 0.30\ M$, what must $[Fe^{2+}]$ be to increase E_{cell} by 0.25 V above E°_{cell} at 25°C?

SOME SIMILAR PROBLEMS 21.68 and 21.69

Following Changes in Potential During Cell Operation

As with any voltaic cell, the potential of a zinc-copper cell changes during cell operation because the concentrations of the components do. With both of the other components solids, the only variables are $[Cu^{2+}]$ and $[Zn^{2+}]$:

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s) \qquad Q = \frac{[Zn^{2+}]}{[Cu^{2+}]}$$

In this section, we follow the potential as the zinc-copper cell operates.

1. *Starting point of cell operation.* The positive E°_{cell} (1.10 V) means that this reaction proceeds *spontaneously* to the right at standard-state conditions, $[Zn^{2+}] = [Cu^{2+}] = 1\ M$ ($Q = 1$). But, if we start the cell when $[Zn^{2+}] < [Cu^{2+}]$ ($Q < 1$), for example, $[Zn^{2+}] = 1.0\times10^{-4}\ M$ and $[Cu^{2+}] = 2.0\ M$, the cell potential starts out *higher* than the standard cell potential, because $\log Q < 0$:

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ V}{2}\log\frac{[Zn^{2+}]}{[Cu^{2+}]} = 1.10\ V - \left(\frac{0.0592\ V}{2}\log\frac{1.0\times10^{-4}}{2.0}\right)$$

$$= 1.10\ V - \left[\frac{0.0592\ V}{2}(-4.30)\right] = 1.10\ V + 0.127\ V = 1.23\ V$$

2. *Key stages during cell operation.* Using Equation 21.10, we identify four key stages of operation. Figure 21.11A shows the first three. The main point is that *as the cell operates, its potential decreases.* As product concentration ([P] = $[Zn^{2+}]$) increases and reactant concentration ([R] = $[Cu^{2+}]$) decreases, Q becomes larger, the $[(0.0592\ V/n)\log Q]$ term becomes less negative (more positive), and E_{cell} decreases:

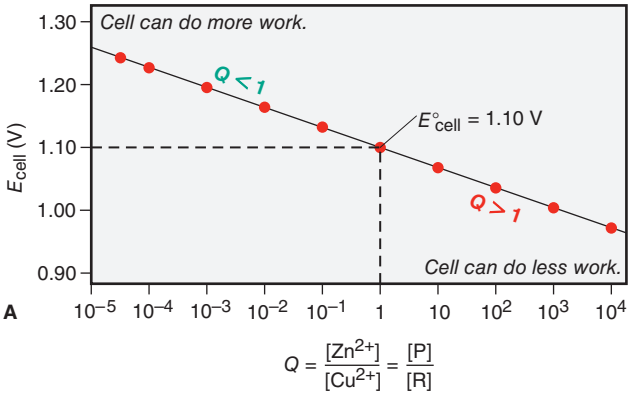
Stage 1. $E_{cell} > E^\circ_{cell}$ when $Q < 1$: When the cell begins operation, $[Cu^{2+}] > [Zn^{2+}]$, so $(0.0592\ V/n)\log Q < 0$ and $E_{cell} > E^\circ_{cell}$.

Stage 2. $E_{cell} = E^\circ_{cell}$ when $Q = 1$: At the point when $[Cu^{2+}] = [Zn^{2+}]$, $Q = 1$, so $(0.0592\ V/n)\log Q = 0$ and $E_{cell} = E^\circ_{cell}$.

Stage 3. $E_{cell} < E^\circ_{cell}$ when $Q > 1$: As the $[Zn^{2+}]/[Cu^{2+}]$ ratio continues to increase, $(0.0592\ V/n)\log Q > 0$, so $E_{cell} < E^\circ_{cell}$.

Stage 4. $E_{cell} = 0$ when $Q = K$: Eventually, $(0.0592\ V/n)\log Q$ becomes so large that it equals E°_{cell}, which means that E_{cell} is zero. This occurs *when the system reaches* ***equilibrium:*** *no more free energy is released, so the cell can do no more work.* At this point, we say that a battery is "dead."

Figure 21.11B summarizes these four key stages during operation of a voltaic cell.



A

Changes in E_{cell} and Concentration

Stage in cell operation	Q	Relative [P] and [R]	$\frac{0.0592\ V}{n}\log Q$
1. $E > E^\circ$	<1	[P] < [R]	<0
2. $E = E^\circ$	=1	[P] = [R]	=0
3. $E < E^\circ$	>1	[P] > [R]	>0
4. $E = 0$	$=K$	[P] ≫ [R]	$=E^\circ$

B

Figure 21.11 The relation between E_{cell} and log Q for the zinc-copper cell. A, A plot of E_{cell} vs. Q (on a logarithmic scale) decreases linearly. When $Q < 1$ *(left)*, the cell does relatively more work. When $Q = 1$, $E_{cell} = E^\circ_{cell}$. When $Q > 1$ *(right)*, the cell does relatively less work. **B,** A summary of the changes in E_{cell} as this or any voltaic cell operates. ($[Zn^{2+}]$ is [P] for [product], and $[Cu^{2+}]$ is [R] for [reactant].)

3. *Q/K and the work the cell can do.* At equilibrium, Equation 21.10 becomes

$$0 = E^\circ_{cell} - \frac{0.0592\ V}{n}\log K, \qquad \text{which rearranges to} \qquad E^\circ_{cell} = \frac{0.0592\ V}{n}\log K$$

Note that this result is identical to Equation 21.8, which we obtained from ΔG°. Solving for K of the zinc-copper cell ($E^\circ_{cell} = 1.10$ V),

$$\log K = \frac{2 \times E^\circ_{cell}}{0.0592\ V} \qquad \text{so} \qquad K = 10^{(2\times 1.10\ V)/0.0592\ V} = 10^{37.16} = 1.4\times 10^{37}$$

As you can see, this cell does work until $[Zn^{2+}]/[Cu^{2+}]$ is *very* high.

The three relations between initial Q/K and E_{cell} are

- If $Q/K < 1$, E_{cell} is positive for the reaction *as written*. The smaller Q/K is, the greater the value of E_{cell}, and the more electrical work the cell can do.
- If $Q/K = 1$, $E_{cell} = 0$. The cell is at equilibrium and can no longer do work.
- If $Q/K > 1$, E_{cell} is negative for the reaction as written. The reverse reaction will take place, and the cell will do work until Q/K equals 1 at equilibrium.

Concentration Cells

If you mix a concentrated solution of a substance with a dilute solution of it, the final solution has an intermediate concentration. A **concentration cell** employs this simple, spontaneous change to generate electrical energy: different concentrations of species involved in the same half-reaction are in separate half-cells, and the cell does work until the concentrations become equal.

Finding E_{cell} for a Concentration Cell Suppose a voltaic cell has the Cu/Cu^{2+} half-reaction in both compartments. The cell reaction is the sum of identical half-reactions, written in opposite directions. The *standard* cell potential, E°_{cell}, is zero because the *standard* electrode potentials are both based on 1 *M* Cu^{2+}, so they cancel. As we said, however, *in a concentration cell, the concentrations are* ***different.*** Thus, even though E°_{cell} is still zero, the *nonstandard* cell potential, E_{cell}, depends on the *ratio of concentrations,* so it is *not* zero.

For the final concentrations to be equal, a concentration cell must have the dilute solution in the anode compartment and the concentrated solution in the cathode compartment. For example, let's use 0.10 *M* Cu^{2+} in the anode half-cell and 1.0 *M* Cu^{2+}, a 10-fold higher concentration, in the cathode half-cell (Figure 21.12A):

$$Cu(s) \longrightarrow Cu^{2+}(aq;\ 0.10\ M) + 2e^- \qquad \text{[anode; oxidation]}$$
$$Cu^{2+}(aq;\ 1.0\ M) + 2e^- \longrightarrow Cu(s) \qquad \text{[cathode; reduction]}$$

The overall cell reaction is the sum of the half-reactions:

$$Cu^{2+}(aq;\ 1.0\ M) \longrightarrow Cu^{2+}(aq;\ 0.10\ M) \qquad E_{cell} = ?$$

The cell potential at the initial concentrations of 0.10 *M* (dilute) and 1.0 *M* (concentrated), with $n = 2$, is obtained from the Nernst equation:

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ V}{2}\log\frac{[Cu^{2+}]_{dil}}{[Cu^{2+}]_{conc}} = 0\ V - \left(\frac{0.0592\ V}{2}\log\frac{0.10\ M}{1.0\ M}\right)$$
$$= 0\ V - \left[\frac{0.0592\ V}{2}(-1.00)\right] = 0.0296\ V$$

Since E°_{cell} is zero, E_{cell} depends entirely on the $[(0.0592\ V/n)\log Q]$ term.

How a Concentration Cell Works Let's see what is happening as this cell operates:

- *In the anode (dilute) half-cell,* Cu atoms in the electrode give up electrons and the resulting Cu^{2+} ions enter the solution and make it *more* concentrated.
- *In the cathode (concentrated) half-cell,* Cu^{2+} ions gain the electrons and the resulting Cu atoms plate out on the electrode, which makes that solution *less* concentrated.

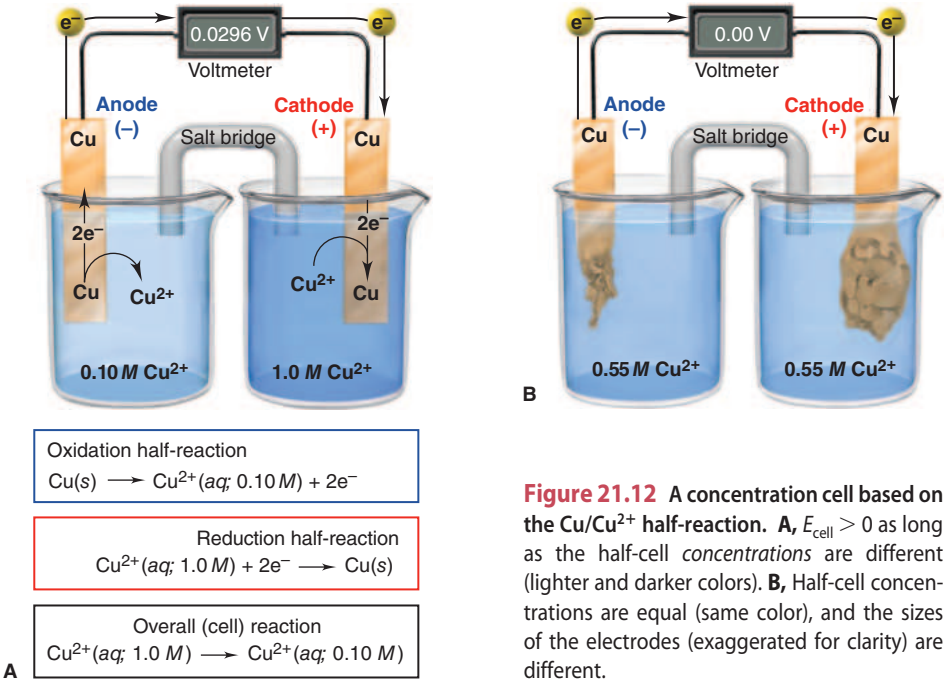


Figure 21.12 **A concentration cell based on the Cu/Cu²⁺ half-reaction.** **A,** $E_{cell} > 0$ as long as the half-cell *concentrations* are different (lighter and darker colors). **B,** Half-cell concentrations are equal (same color), and the sizes of the electrodes (exaggerated for clarity) are different.

As in any voltaic cell, E_{cell} decreases until equilibrium is attained, which happens when $[Cu^{2+}]$ is the same in both half-cells (Figure 21.12B). The same final concentration would result if we mixed the two solutions, but no electrical work would be done.

SAMPLE PROBLEM 21.8 Calculating the Potential of a Concentration Cell

Problem A voltaic cell consists of two Ag/Ag^+ half-cells. In half-cell A, the electrolyte is 0.010 *M* $AgNO_3$; in half-cell B, it is 4.0×10^{-4} *M* $AgNO_3$. What is E_{cell} at 298.15 K?

Plan The standard half-cell reactions are identical, so E°_{cell} is zero, and we find E_{cell} from the Nernst equation. Half-cell A has a higher $[Ag^+]$, so Ag^+ ions are reduced and plate out on electrode A. In half-cell B, Ag atoms of the electrode are oxidized and Ag^+ ions enter the solution. As in all voltaic cells, reduction occurs at the cathode, so it is positive.

Solution Writing the spontaneous reaction: The $[Ag^+]$ decreases in half-cell A and increases in half-cell B, so the spontaneous reaction is

$$Ag^+(aq; 0.010\ M)\ [\text{half-cell A}] \longrightarrow Ag^+(aq; 4.0\times10^{-4}\ M)\ [\text{half-cell B}]$$

Calculating E_{cell}, with $n = 1$:

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ \text{V}}{1}\log\frac{[Ag^+]_{dil}}{[Ag^+]_{conc}} = 0\ \text{V} - \left(0.0592\ \text{V}\log\frac{4.0\times10^{-4}}{0.010}\right)$$

$$= 0.083\ \text{V}$$

FOLLOW-UP PROBLEMS

21.8A A voltaic cell consists of two Ni/Ni^{2+} half-cells. In half-cell A, the electrolyte is 0.015 *M* $Ni(NO_3)_2$; in half-cell B, it is 0.40 *M* $Ni(NO_3)_2$. Calculate E_{cell} at 298.15 K.

21.8B A voltaic cell is built using two Au/Au^{3+} half-cells. In half-cell A, $[Au^{3+}] = 7.0\times10^{-4}$ *M*, and in half-cell B, $[Au^{3+}] = 2.5\times10^{-2}$ *M*. What is E_{cell}, and which electrode is negative?

SOME SIMILAR PROBLEMS 21.72 and 21.73

Applications of Concentration Cells The principle of a concentration cell has many applications. Here, we'll discuss three:

1. *Measuring pH.* The most important laboratory application of this principle is in measuring $[H^+]$. If we construct a concentration cell in which the cathode compartment is the standard hydrogen electrode and the anode compartment has the same apparatus dipping into a solution of unknown $[H^+]$, the half-reactions and overall reaction are

$$H_2(g;\ 1\ \text{atm}) \longrightarrow 2H^+(aq;\ \text{unknown}) + 2e^- \quad [\text{anode; oxidation}]$$
$$2H^+(aq;\ 1\ M) + 2e^- \longrightarrow H_2(g;\ 1\ \text{atm}) \quad [\text{cathode; reduction}]$$
$$2H^+(aq;\ 1\ M) \longrightarrow 2H^+(aq;\ \text{unknown}) \qquad E_{cell} = ?$$

E°_{cell} is zero, but E_{cell} is *not* because the half-cells differ in $[H^+]$. From the Nernst equation, with $n = 2$, we have

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ \text{V}}{2} \log \frac{[H^+]^2_{unknown}}{[H^+]^2_{standard}}$$

Substituting 1 M for $[H^+]_{standard}$ and 0 V for E°_{cell} gives

$$E_{cell} = 0\ \text{V} - \frac{0.0592\ \text{V}}{2} \log \frac{[H^+]^2_{unknown}}{1^2} = -\frac{0.0592\ \text{V}}{2} \log [H^+]^2_{unknown}$$

Because $\log x^2 = 2 \log x$ (see Appendix A), we obtain

$$E_{cell} = -\left[\frac{0.0592\ \text{V}}{2} (2 \log [H^+]_{unknown})\right] = -0.0592\ \text{V} \times \log [H^+]_{unknown}$$

Substituting $-\log [H^+] = \text{pH}$, we have

$$E_{cell} = 0.0592\ \text{V} \times \text{pH}$$

Thus, by measuring E_{cell}, we can find the pH.

For routine lab measurement of pH, a concentration cell made of two hydrogen electrodes is too bulky and difficult to maintain. Instead, we use a pH meter (Figure 21.13A). In a common, but older, design, two separate electrodes dip into the solution being tested:

- The *glass electrode* consists of an Ag/AgCl half-reaction immersed in HCl solution (usually 1.000 M) and enclosed by a thin (~0.05 mm) membrane made of a glass that is very sensitive to H^+ ions.
- The *reference electrode,* usually a *saturated calomel electrode,* consists of a platinum wire immersed in calomel (Hg_2Cl_2) paste, liquid Hg, and saturated KCl solution.

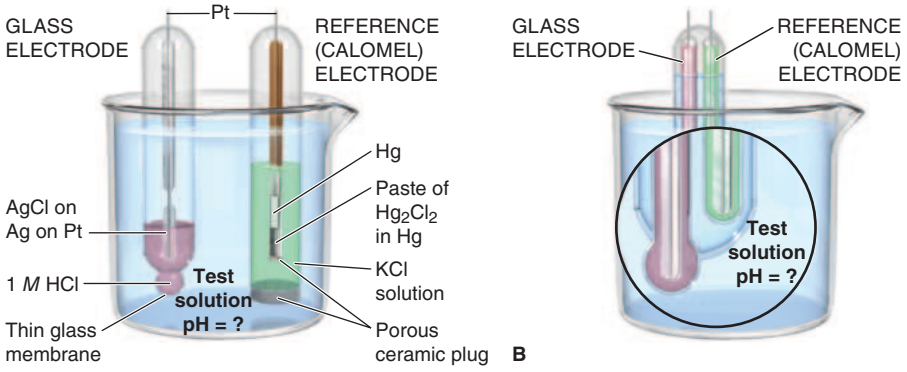

Figure 21.13 Laboratory measurement of pH. A, An older style pH meter includes a glass electrode *(left)* and a reference calomel electrode *(right).* **B,** Modern pH meters use a combination electrode.

The glass electrode monitors the solution's $[H^+]$ relative to its own fixed internal $[H^+]$, and the instrument converts the potential difference between the glass and reference electrodes into a measure of pH. In modern instruments, a *combination* electrode houses both electrodes in one tube (Figure 21.13B).

2. *Measuring ions selectively.* The pH electrode is one type of *ion-selective (or ion-specific) electrode.* These are designed with specialized membranes to selectively measure certain ion concentrations in a mixture of many ions, as in natural waters and soils. Biologists can implant a tiny ion-selective electrode in a single cell to study ion channels and receptors (Figure 21.14). Recent advances allow measurement in the femtomolar (10^{-15} *M*) range. Table 21.3 shows a few of the ions studied.

3. *Concentration cells in nerves.* A nerve cell membrane is embedded with enzyme "gates" that use the energy of one-third of the body's ATP to create an ion gradient of low $[Na^+]$ and high $[K^+]$ inside and high $[Na^+]$ and low $[K^+]$ outside. As a result of these differences, the outside of a nerve cell is more positive than the inside. (The 1997 Nobel Prize in chemistry was shared by Jens C. Skou for elucidating this mechanism.) When the nerve membrane is stimulated, an electrical impulse is created as Na^+ ions rush in spontaneously and the inside becomes more positive than the outside. This event is followed by K^+ ions spontaneously rushing out, and the outside becomes more positive again; the whole process takes about 0.002 s! These large changes in charge in one membrane region stimulate the neighboring region and the electrical impulse moves along the cell.

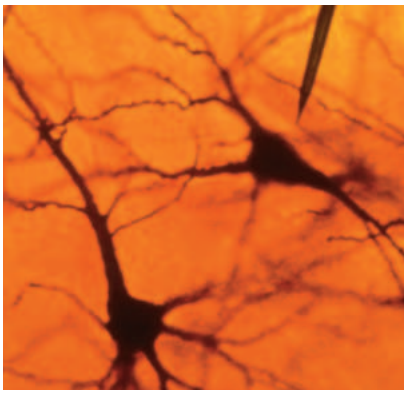

Figure 21.14 Minimicroanalysis. A microelectrode records electrical impulses of a single neuron in a monkey's visual cortex.

Table 21.3 Some Ions Measured with Ion-Specific Electrodes

Species Detected	Typical Sample
NH_3/NH_4^+	Industrial wastewater, seawater
CO_2/HCO_3^-	Blood, groundwater
F^-	Drinking water, urine, soil, industrial stack gases
Br^-	Grain, plant tissue
I^-	Milk, pharmaceuticals
NO_3^-	Soil, fertilizer, drinking water
K^+	Blood serum, soil, wine
H^+	Laboratory solutions, soil, natural waters

Summary of Section 21.4

- A spontaneous process has a negative ΔG and a positive E_{cell}, $\Delta G = -nFE_{cell}$. The ΔG of the cell reaction represents the maximum electrical work the cell can do.
- The standard free energy change, $\Delta G°$, is related to $E°_{cell}$ and to K.
- For nonstandard conditions, the Nernst equation shows that E_{cell} depends on $E°_{cell}$ and a correction term based on Q. E_{cell} is high when Q is small (high [reactant]), and it decreases as the cell operates. At equilibrium, ΔG and E_{cell} are zero, which means that $Q = K$.
- Concentration cells have identical half-reactions, but solutions of differing concentration. They generate electrical energy as the concentrations become equal.
- Ion-specific electrodes, such as the pH electrode, measure the concentration of one species.
- The principle of the concentration cell—spontaneous movement of ions "down" a concentration gradient—creates an electrical impulse in a nerve cell.

21.5 ELECTROCHEMICAL PROCESSES IN BATTERIES

Because of their compactness and mobility, batteries play a major role in everyday life, and in our increasingly wireless world, that role is growing. In general, a **battery** consists of self-contained voltaic cells arranged in series (plus-to-minus-to-plus, and so on), so that their individual voltages are added. In this section, we examine the three categories of batteries—primary, secondary, and fuel cells (flow batteries).

Primary (Nonrechargeable) Batteries

A *primary battery* cannot be recharged, so the initial amounts of reactants are as far from equilibrium as is practical. This type of battery is discarded when the cell reaction has reached equilibrium, that is, when the battery is "dead." We'll discuss the alkaline battery, mercury and silver "button" batteries, and the primary lithium battery.

Alkaline Battery Invented in the 1860s, the common dry cell was a familiar item into the 1970s, but has now been replaced by the ubiquitous alkaline battery. The electrode materials are zinc and manganese dioxide, and the electrolyte is a basic paste of KOH and water (Figure 21.15). The half-reactions are

Anode (oxidation): $Zn(s) + 2OH^-(aq) \longrightarrow ZnO(s) + H_2O(l) + 2e^-$

Cathode (reduction): $MnO_2(s) + 2H_2O(l) + 2e^- \longrightarrow Mn(OH)_2(s) + 2OH^-(aq)$

Overall (cell) reaction:

$$Zn(s) + MnO_2(s) + H_2O(l) \longrightarrow ZnO(s) + Mn(OH)_2(s) \quad E_{cell} = 1.5\ V$$

The alkaline battery powers portable radios, toys, flashlights, and so on, is safe, and comes in many sizes. It has no voltage drop, a long shelf life, and reliable performance in terms of power capability and stored energy.

Figure 21.15 Alkaline battery.

Mercury and Silver (Button) Batteries Both mercury and silver batteries use a zinc container as the anode (reducing agent) in a basic medium. The mercury battery employs HgO as the oxidizing agent, the silver uses Ag_2O, and both have a steel can around the cathode. The solid reactants are compacted with KOH and separated with moist paper. The half-reactions are

Anode (oxidation): $Zn(s) + 2OH^-(aq) \longrightarrow ZnO(s) + H_2O(l) + 2e^-$

Cathode (reduction) (mercury): $HgO(s) + H_2O(l) + 2e^- \longrightarrow Hg(l) + 2OH^-(aq)$

Cathode (reduction) (silver): $Ag_2O(s) + H_2O(l) + 2e^- \longrightarrow 2Ag(s) + 2OH^-(aq)$

Overall (cell) reaction (mercury):

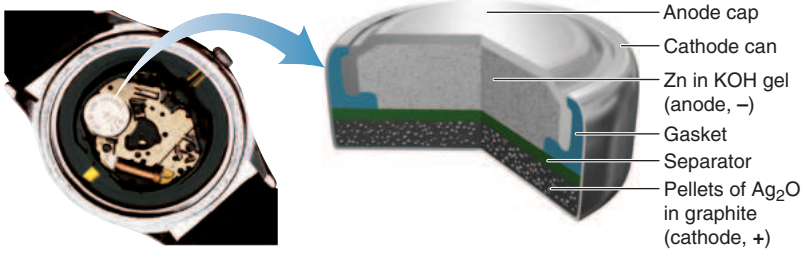
$$Zn(s) + HgO(s) \longrightarrow ZnO(s) + Hg(l) \qquad E_{cell} = 1.3\ V$$

Overall (cell) reaction (silver):

$$Zn(s) + Ag_2O(s) \longrightarrow ZnO(s) + 2Ag(s) \qquad E_{cell} = 1.6\ V$$

Both cells are manufactured as button-sized batteries. The mercury cell is used in calculators and the silver cell (Figure 21.16) in watches, cameras, heart pacemakers, and hearing aids because of its very steady output. Disadvantages are the toxicity of discarded mercury and the high cost of silver.

Figure 21.16 Silver button battery.



Primary Lithium Batteries The primary lithium battery is also widely used in watches and implanted medical products, and more recently in numerous remote-control devices. It offers an extremely high energy/mass ratio, producing 1 mol of e^- (1 *F*) from less than 7 g of metal ($\mathcal{M}$ of Li = 6.941 g/mol). The anode is lithium

foil in a nonaqueous electrolyte. The cathode is one of several metal oxides in which lithium ions lie between oxide layers. Some pacemakers have a silver vanadium oxide (SVO; $AgV_2O_{5.5}$) cathode and can provide power (1.5 to 3.5 V) for several years, but at a low rate because energy storage is limited (Figure 21.17). The half-reactions are

Anode (oxidation): $3.5Li(s) \longrightarrow 3.5Li^+ + 3.5e^-$

Cathode (reduction): $AgV_2O_{5.5} + 3.5Li^+ + 3.5e^- \longrightarrow Li_{3.5}AgV_2O_{5.5}$

Overall (cell) reaction: $AgV_2O_{5.5} + 3.5Li(s) \longrightarrow Li_{3.5}AgV_2O_{5.5}$

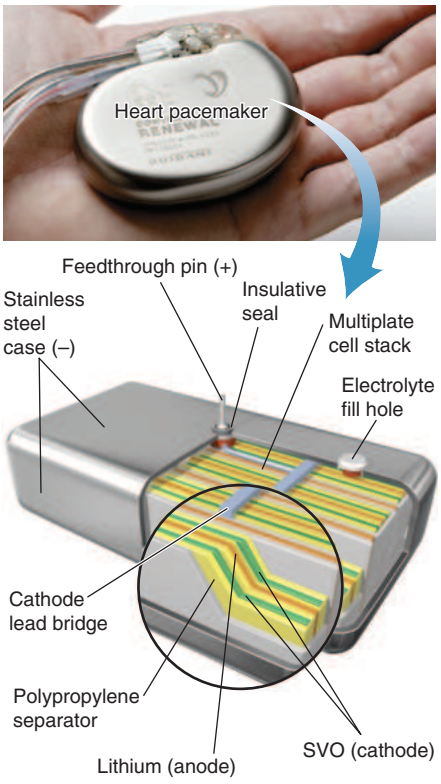


Figure 21.17 Lithium battery.

Secondary (Rechargeable) Batteries

In contrast to a primary battery, a *secondary battery* is *rechargeable;* when it runs down, *electrical energy is supplied to reverse the cell reaction* and form more reactant. In other words, in a secondary battery, the voltaic cells are periodically converted to electrolytic cells to restore the starting *nonequilibrium* concentrations of the cell components. We'll discuss the common car battery, the nickel–metal hydride battery, and the lithium-ion battery, a secondary lithium battery.

Lead-Acid Battery A typical lead-acid car battery has six cells connected in series, each of which delivers about 2.1 V for a total of about 12 V. Each cell contains two lead grids packed with high-surface-area (spongy) Pb in the anode and high-surface-area PbO_2 in the cathode. The grids are immersed in a solution of ~4.5 *M* H_2SO_4. Fiberglass sheets between the grids prevent shorting due to physical contact (Figure 21.18).

1. *Discharging.* When the cell discharges as a voltaic cell, it generates electrical energy:

Anode (oxidation): $Pb(s) + HSO_4^-(aq) \longrightarrow PbSO_4(s) + H^+ + 2e^-$

Cathode (reduction):

$$PbO_2(s) + 3H^+(aq) + HSO_4^-(aq) + 2e^- \longrightarrow PbSO_4(s) + 2H_2O(l)$$

Both half-reactions form Pb^{2+} ions, one through oxidation of Pb, the other through reduction of PbO_2. The Pb^{2+} forms $PbSO_4(s)$ at both electrodes by reacting with HSO_4^-.

Overall (cell) reaction (discharge):

$$PbO_2(s) + Pb(s) + 2H_2SO_4(aq) \longrightarrow 2PbSO_4(s) + 2H_2O(l) \qquad E_{cell} = 2.1\ V$$

2. *Recharging.* When the cell recharges as an electrolytic cell, it uses electrical energy and the half-cell and overall reactions are reversed.

Overall (cell) reaction (recharge):

$$2PbSO_4(s) + 2H_2O(l) \longrightarrow PbO_2(s) + Pb(s) + 2H_2SO_4(aq)$$

Car and truck owners have relied on the lead-acid battery for over a century to provide the large burst of current needed to start the engine—and to do so for years, in hot and cold weather. The main problems with the lead-acid battery are loss of capacity due to corrosion of the positive (Pb) grid, detachment of the active material due to normal mechanical bumping, and formation of large $PbSO_4$ crystals that hinder recharging.

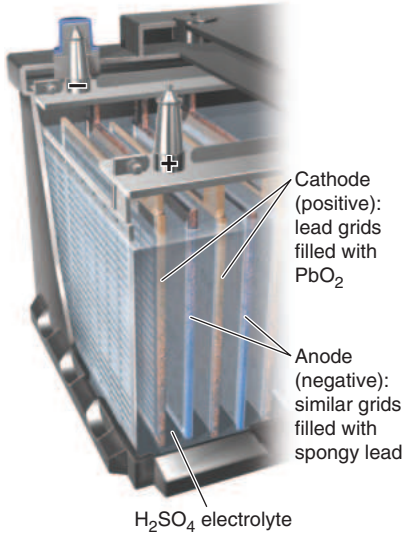

Figure 21.18 Lead-acid battery.

Nickel–Metal Hydride (Ni-MH) Battery Concerns about the toxicity of cadmium in the nickel-cadmium (nicad) battery have led to its replacement by the nickel–metal hydride battery. The anode half-reaction oxidizes the hydrogen absorbed within a metal alloy (such as $LaNi_5$; designated M) in a basic (KOH) electrolyte, while nickel(III) in the form of NiO(OH) is reduced at the cathode (Figure 21.19, *next page*):

Anode (oxidation): $MH(s) + OH^-(aq) \longrightarrow M(s) + H_2O(l) + e^-$

Cathode (reduction): $NiO(OH)(s) + H_2O(l) + e^- \longrightarrow Ni(OH)_2(s) + OH^-(aq)$

Overall (cell) reaction: $MH(s) + NiO(OH)(s) \longrightarrow M(s) + Ni(OH)_2(s)$

$E_{cell} = 1.4\ V$

The cell reaction is reversed during recharging. The Ni-MH battery is common in cordless razors, camera flash units, and power tools. It is lightweight, has high power, and is nontoxic, but it discharges significantly during storage.

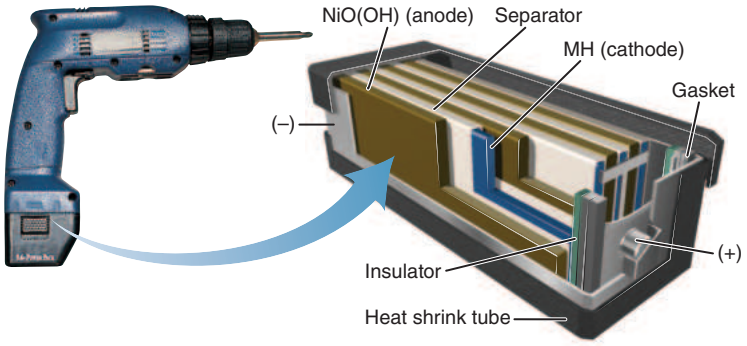

Figure 21.19 Nickel–metal hydride battery.

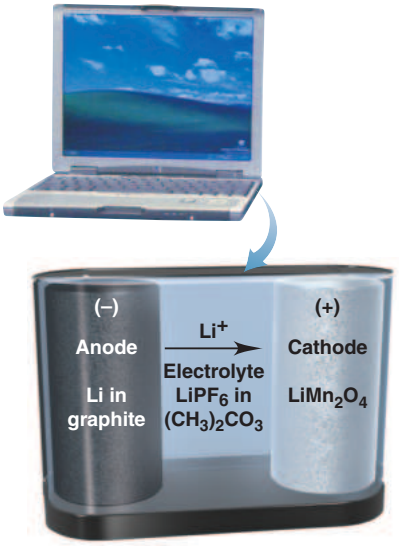

Figure 21.20 Lithium-ion battery.

Lithium-Ion Battery The secondary lithium-ion battery has an anode of Li atoms that lie between sheets of graphite (designated Li_xC_6). The cathode is a lithium metal oxide, such as $LiMn_2O_4$ or $LiCoO_2$, and a typical electrolyte is 1 *M* $LiPF_6$ in an organic solvent, such as dimethyl carbonate mixed with methylethyl carbonate. Electrons flow through the circuit, while solvated Li^+ ions flow from anode to cathode within the cell (Figure 21.20). The cell reactions are

Anode (oxidation): $Li_xC_6 \longrightarrow xLi^+ + xe^- + C_6(s)$

Cathode (reduction): $Li_{1-x}Mn_2O_4(s) + xLi^+ + xe^- \longrightarrow LiMn_2O_4(s)$

Overall (cell) reaction: $Li_xC_6 + Li_{1-x}Mn_2O_4(s) \longrightarrow LiMn_2O_4(s) + C_6(s)$

$E_{cell} = 3.7$ V

The cell reaction is reversed during recharging. The lithium-ion battery powers countless laptop computers, tablets, cell phones, and camcorders. Its key drawbacks are cost and flammability of the organic solvent.

Fuel Cells

In contrast to primary and secondary batteries, a **fuel cell,** sometimes called a *flow battery,* is not self-contained. The reactants (usually a fuel and oxygen) enter the cell, and the products leave, *generating electricity through controlled combustion* of the fuel. The fuel does not burn because, as in other voltaic cells, the half-reactions are separated, and the electrons move through an external circuit.

The most common fuel cell being developed for use in cars is the *proton exchange membrane (PEM) cell,* which uses H_2 as the fuel and has an operating temperature of around 80°C (Figure 21.21). The cell reactions are

Anode (oxidation): $2H_2(g) \longrightarrow 4H^+(aq) + 4e^-$

Cathode (reduction): $O_2(g) + 4H^+(aq) + 4e^- \longrightarrow 2H_2O(g)$

Overall (cell) reaction: $2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$ $\quad E_{cell} = 1.2$ V

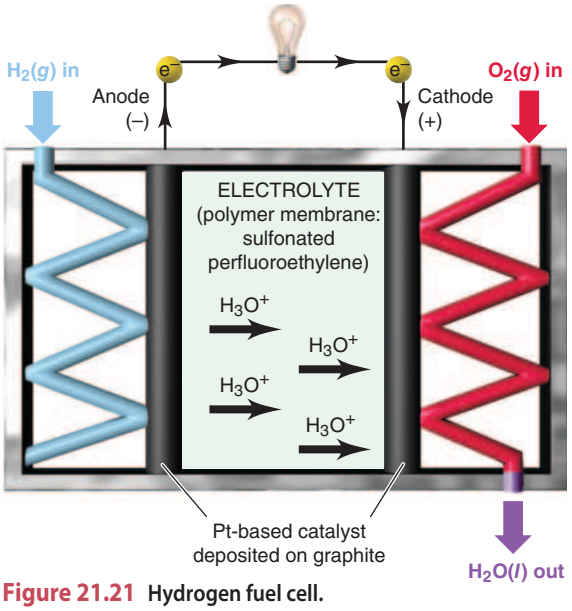

Figure 21.21 Hydrogen fuel cell.

How H_2 Fuel Cells Work Reaction rates are lower in fuel cells than in other batteries, so an *electrocatalyst* is used to decrease the activation energy (Section 16.7). The PEM cell's electrodes are made of a nanocomposite consisting of a Pt-based catalyst deposited on graphite. These are embedded in a polymer electrolyte membrane having a perfluoroethylene backbone ($-[F_2C-CF_2]_n-$) with attached sulfonic acid groups (RSO_3^-) that play a key role in ferrying protons from anode to cathode.

- *At the anode,* two H_2 molecules adsorb onto the catalyst and are split and oxidized. From each H_2, two e^- travel through the wire to the cathode, while two H^+ are hydrated and migrate through the electrolyte as H_3O^+.
- *At the cathode,* an O_2 molecule is believed to adsorb onto the catalyst, which provides an e^- to form O_2^-. One H_3O^+ donates its H^+ to the O_2^-, forming HO_2 (that is, HO—O). The O—O bond stretches and breaks as another H_3O^+ gives its H^+ and the catalyst provides another e^-: the first H_2O has formed. In similar fashion, a third H^+ and e^- attach to the freed O atom to form OH, and a fourth H^+ and e^- are transferred to form the second H_2O. Both water molecules desorb and leave the cell.

Applications of Fuel Cells Hydrogen fuel cells have been used for years to provide electricity *and* water during space flights. Similar ones have begun to supply electric power for residential needs, and every major car manufacturer has a fuel-cell model. Fuel cells produce no pollutants and convert about 75% of a fuel's bond energy into power, compared to 40% for a coal-fired power plant and 25% for a gasoline engine.

Summary of Section 21.5

- Batteries are voltaic cells arranged in series and are classified as primary (e.g., alkaline, mercury, silver, and lithium), secondary (e.g., lead-acid, nickel–metal hydride, and lithium-ion), or fuel cells.
- Supplying electricity to a rechargeable (secondary) battery reverses the redox reaction, re-forming reactant.
- Fuel cells generate a current through the controlled oxidation of a fuel such as H_2.

21.6 CORROSION: AN ENVIRONMENTAL VOLTAIC CELL

If you think all spontaneous electrochemical processes are useful, consider the problem of **corrosion,** which causes tens of billions of dollars of damage to cars, ships, buildings, and bridges each year. This natural process, which oxidizes metals to their oxides and sulfides, shares many similarities with the operation of a voltaic cell. We focus on the corrosion of iron, but several other metals, such as copper and silver, also corrode.

The Corrosion of Iron

The most common and economically destructive form of corrosion is the rusting of iron. About 25% of the steel produced in the United States each year is for replacing steel in which the iron has corroded. Rust is *not* a direct product of the reaction between iron and oxygen but arises through a complex electrochemical process. Let's look at the facts concerning iron corrosion and then use the features of a voltaic cell to explain them:

Fact 1. Iron does not rust in dry air; moisture must be present.
Fact 2. Iron does not rust in air-free water; oxygen must be present.
Fact 3. Iron loss and rust formation occur at *different* places on the *same* object.
Fact 4. Iron rusts more quickly at low pH (high $[H^+]$).
Fact 5. Iron rusts more quickly in ionic solutions.
Fact 6. Iron rusts more quickly in contact with a less active metal (such as Cu) and more slowly in contact with a more active metal (such as Zn).

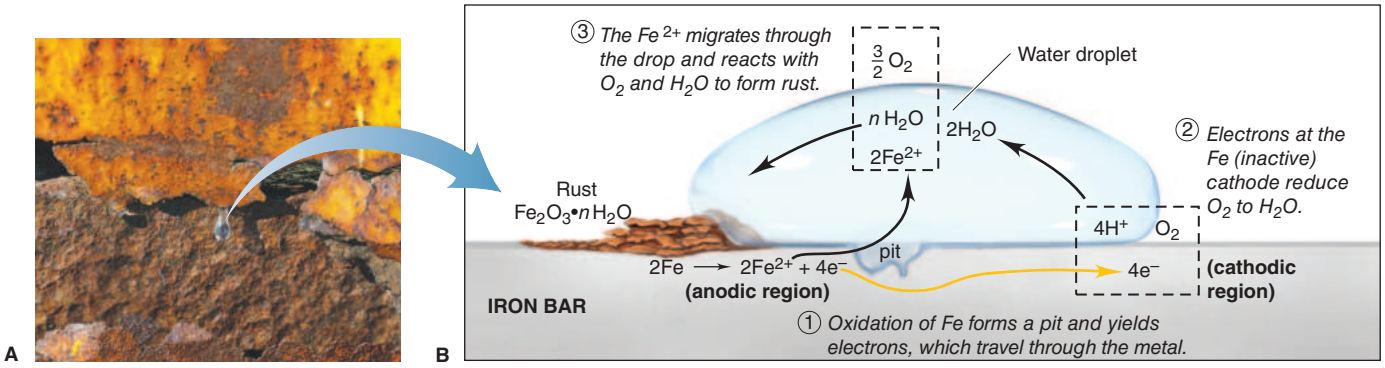

Figure 21.22 **The corrosion of iron.** **A,** Close-up view of an iron surface. Corrosion usually occurs at a surface irregularity. **B,** A small area of the surface, showing the steps in the corrosion process.

Two separate redox processes occur during corrosion:

1. *The loss of iron*. Picture the surface of a piece of iron (Figure 21.22). A strain, ridge, or dent in contact with water is typically the site of iron loss (fact 1). This site is called an *anodic region* because the following half-reaction occurs there:

$$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^- \qquad \text{[anodic region; oxidation]}$$

Once the iron atoms lose electrons, the damage to the object has been done, and a pit forms where the iron is lost.

The freed electrons move through the external circuit—the piece of iron itself—until they reach a region of relatively high $[O_2]$ (fact 2), usually the air near the edge of a water droplet that surrounds the newly formed pit. At this *cathodic region,* the electrons released from the iron atoms reduce O_2:

$$O_2(g) + 4H^+(aq) + 4e^- \longrightarrow 2H_2O(l) \qquad \text{[cathodic region; reduction]}$$

This portion of the corrosion process (the sum of these two half-reactions) occurs without any rust forming:

$$2Fe(s) + O_2(g) + 4H^+(aq) \longrightarrow 2Fe^{2+}(aq) + 2H_2O(l) \qquad \text{[overall]}$$

2. *The rusting process*. Rust forms in another redox reaction. The Fe^{2+} ions formed at the anodic region disperse through the water and react with O_2, often away from the pit, to form the Fe^{3+} in rust (fact 3). The overall reaction for this step is

$$2Fe^{2+}(aq) + \tfrac{1}{2}O_2(g) + (2 + n)H_2O(l) \longrightarrow Fe_2O_3 \cdot nH_2O(s) + 4H^+(aq)$$

[The coefficient n for H_2O appears because rust, $Fe_2O_3 \cdot nH_2O$, may have a variable number of waters of hydration.] The rust deposit is incidental to the real damage, which is the loss of iron that weakens the strength of the object. Adding the two previous equations gives the overall equation for the loss and rusting of iron:

$$2Fe(s) + \tfrac{3}{2}O_2(g) + nH_2O(l) + \cancel{4H^+(aq)} \longrightarrow Fe_2O_3 \cdot nH_2O(s) + \cancel{4H^+(aq)}$$

Other species ($2Fe^{2+}$ and $2H_2O$) also cancel, but we showed the canceled H^+ ions to emphasize that they act as a catalyst: they speed the process as they are used up in one step and created in another. For this reason, rusting is faster at low pH (high $[H^+]$) (fact 4). Ionic solutions speed rusting by improving the conductivity of the aqueous medium near the anodic and cathodic regions (fact 5). The effect of ions is especially evident on ocean-going vessels (Figure 21.23) and on the underbodies and around the wheel wells of cars driven in cold climates, where salts are used to melt ice on slippery roads. (We discuss fact 6 in the next subsection.)

Figure 21.23 **Enhanced corrosion at sea.** The high ion concentration of seawater enhances the corrosion of iron in hulls and anchors.

Thus, in some key ways, corrosion resembles the operation of a voltaic cell:

- Anodic and cathodic regions are physically separated.
- The regions are connected via an external circuit through which the electrons travel.
- In the anodic region, iron behaves like an active electrode, whereas in the cathodic region, it is inactive.
- The moisture surrounding the pit functions somewhat like an electrolyte and salt bridge, a solution of ions and a means for them to move and keep the solution neutral.

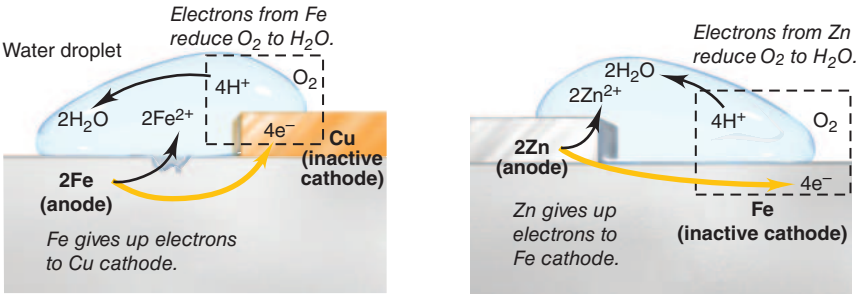

Figure 21.24 **The effect of metal-metal contact on the corrosion of iron. A,** Fe in contact with Cu corrodes faster. **B,** Fe in contact with Zn does not corrode. This method of preventing corrosion is known as *cathodic protection.*

Protecting Against the Corrosion of Iron

Corrosion is prevented by eliminating corrosive factors. Washing road salt off automobile bodies removes ions. Painting an object keeps out O_2 and moisture. Plating chromium on plumbing fixtures is a more permanent method, as is "blueing" of gun barrels and other steel objects, in which a coating of Fe_3O_4 (magnetite) is bonded to the surface.

The final point regarding corrosion (fact 6) concerns the relative activity of other metals in contact with iron. The essential idea is that *iron functions as both anode and cathode in the rusting process, but it is lost only at the anode.* Thus,

1. *Corrosion increases when iron behaves more like the anode.* When iron is in contact with a *less* active metal (weaker reducing agent), such as copper, it loses electrons more readily (its anodic function is enhanced; Figure 21.24A). For example, when iron plumbing is connected directly to copper plumbing, the iron pipe corrodes rapidly. Nonconducting rubber or plastic spacers are placed between the metals to avoid this problem.

2. *Corrosion decreases when iron behaves more like the cathode.* In *cathodic protection,* the most effective way to prevent corrosion, iron makes contact with a *more* active metal (stronger reducing agent), such as zinc. The iron becomes the cathode and remains intact, while the zinc acts as the anode and loses electrons (Figure 21.24B). Coating steel with a "sacrificial" layer of zinc is called *galvanizing*. In addition to blocking physical contact with H_2O and O_2, the zinc (or other active metal) is "sacrificed" (oxidized) instead of the iron. Sacrificial anodes are placed underwater and underground to protect iron and steel pipes, tanks, oil rigs, and so on. Magnesium and aluminum are often used because they are much more active than iron and, thus, act as the anode (Figure 21.25). Moreover, they form adherent oxide coatings, which slow their own corrosion.

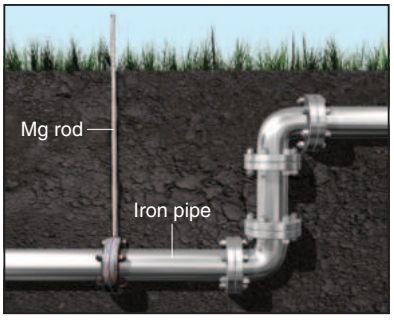

Figure 21.25 **The use of a sacrificial anode to prevent iron corrosion.** In cathodic protection, an active metal, such as zinc, magnesium, or aluminum, acts as the anode and is sacrificed instead of the iron.

Summary of Section 21.6

- Corrosion damages metal structures through a natural electrochemical process.
- Iron corrosion occurs in the presence of oxygen and moisture and is increased by high $[H^+]$, high [ion], or contact with a less active metal, such as Cu.
- Fe is oxidized and O_2 is reduced in one redox reaction, while Fe^{2+} is oxidized and O_2 is reduced to form rust (hydrated form of Fe_2O_3) in another redox reaction that often takes place at a different location.
- Because Fe functions as both anode and cathode in the corrosion process, an iron object can be protected by physically covering it or by joining it to a more active metal (such as Zn, Mg, or Al), which acts as the anode in place of the Fe.

21.7 ELECTROLYTIC CELLS: USING ELECTRICAL ENERGY TO DRIVE NONSPONTANEOUS REACTIONS

In contrast to a voltaic cell, which generates electrical energy from a spontaneous reaction, *an electrolytic cell requires electrical energy from an external source to drive a* ***non****spontaneous redox reaction.* (Industrial electrolysis is in Chapter 22.)

Construction and Operation of an Electrolytic Cell

Let's see how an electrolytic cell operates by constructing one from a voltaic cell. Consider a tin-copper voltaic cell (Figure 21.26A). The Sn anode will gradually be oxidized to Sn^{2+} ions, which enter the electrolyte, and the Cu^{2+} ions will gradually be reduced and plate out on the Cu cathode because the cell reaction is spontaneous in that direction:

For the voltaic cell,

$$\begin{array}{rll} Sn(s) \longrightarrow Sn^{2+}(aq) + 2e^- & & [\text{anode; oxidation}] \\ Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) & & [\text{cathode; reduction}] \\ \hline Sn(s) + Cu^{2+}(aq) \longrightarrow Sn^{2+}(aq) + Cu(s) & & E^\circ_{cell} = 0.48\ V \text{ and } \Delta G^\circ = -93\ kJ \end{array}$$

Therefore, the *reverse* cell reaction is *non*spontaneous and cannot happen on its own. But, we can make it happen by supplying an electric potential *greater than* E°_{cell} from an external source. In effect, we convert the voltaic cell into an electrolytic cell—anode becomes cathode, and cathode becomes anode (Figure 21.26B):

For the electrolytic cell,

$$\begin{array}{rll} Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^- & & [\text{anode; oxidation}] \\ Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s) & & [\text{cathode; reduction}] \\ \hline Cu(s) + Sn^{2+}(aq) \longrightarrow Cu^{2+}(aq) + Sn(s) & & E^\circ_{cell} = -0.48\ V \text{ and } \Delta G^\circ = 93\ kJ \end{array}$$

In an electrolytic cell, as in a voltaic cell, *oxidation takes place at the anode and reduction takes place at the cathode.* Note, however, that *the direction of electron flow and the signs of the electrodes are reversed.*

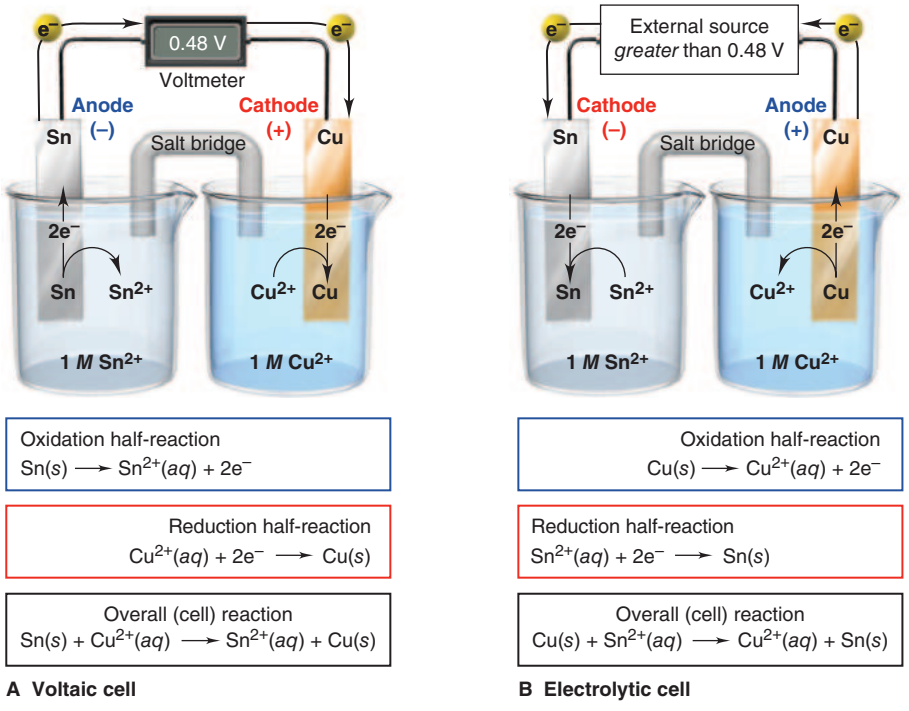

Figure 21.26 **The tin-copper reaction as the basis of a voltaic and an electrolytic cell. A,** The spontaneous reaction between Sn and Cu^{2+} generates 0.48 V in a voltaic cell. **B,** If more than 0.48 V is supplied, the nonspontaneous (reverse) reaction between Cu and Sn^{2+} occurs. Note the changes in electrode charges and direction of electron flow.

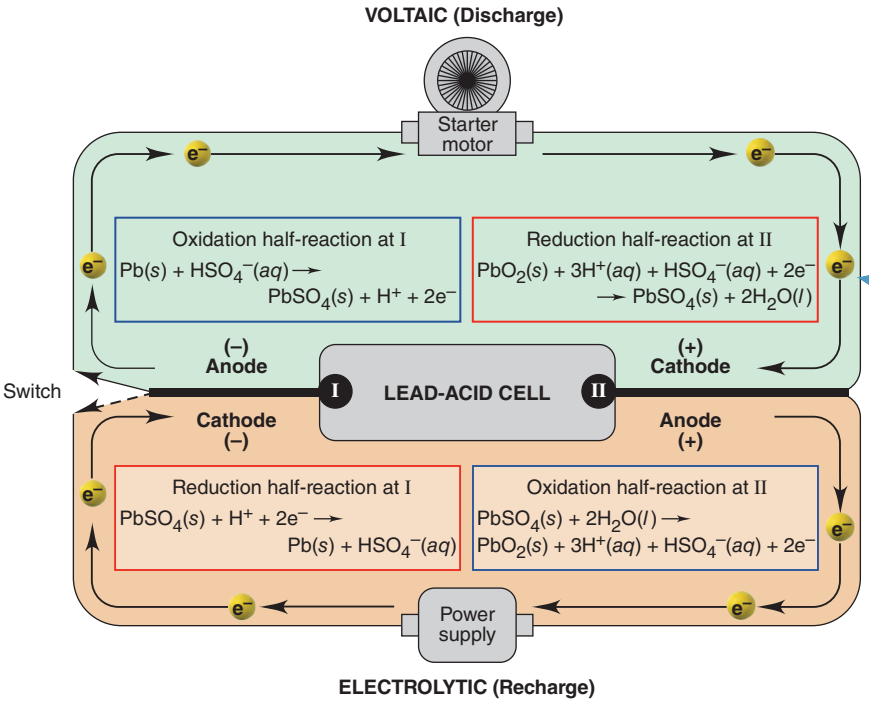

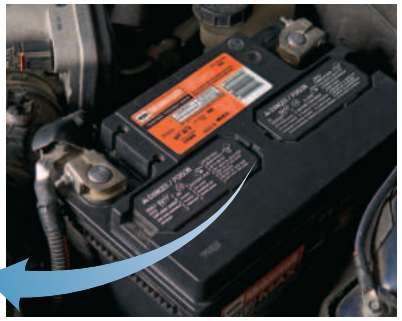

Figure 21.27 The processes occurring during the discharge *(top)* and recharge *(bottom)* of a lead-acid battery.

To understand these differences, we focus on the *cause* of the electron flow:

- In a voltaic cell, electrons are generated *in* the anode, so it is *negative,* and *removed from* the cathode, so it is *positive*.
- In an electrolytic cell, an external power source supplies electrons *to* the cathode, so it is *negative,* and removes them *from* the anode, so it is *positive*.

A rechargeable battery is a voltaic cell when it is discharging and an electrolytic cell when it is recharging. Let's compare these two functions in a lead-acid car battery (Figure 21.27; see also Figure 21.18):

- In the discharge mode (voltaic cell), oxidation occurs at electrode I, thus making the *negative* electrode the anode and the *positive* electrode (electrode II) the cathode.
- In the recharge mode (electrolytic cell), reduction occurs at electrode I, making the *negative* electrode the cathode and the *positive* electrode (electrode II) the anode.

Table 21.4 summarizes the processes and signs in the two types of cells.

Table 21.4 Comparison of Voltaic and Electrolytic Cells

			Electrode		
Cell Type	**ΔG**	**E_{cell}**	**Name**	**Process**	**Sign**
Voltaic	<0	>0	Anode	Oxidation	−
Voltaic	<0	>0	Cathode	Reduction	+
Electrolytic	>0	<0	Anode	Oxidation	+
Electrolytic	>0	<0	Cathode	Reduction	−

Predicting the Products of Electrolysis

Electrolysis is the splitting (lysing) of a substance by the input of electrical energy and is often used to decompose a compound into its elements, as you'll see for chlorine, aluminum, copper, and several others in Chapter 22. Water was first electrolyzed to H_2 and O_2 in 1800, and the process is still used to produce these gases in ultrahigh purity. The electrolyte in an electrolytic cell can be the pure compound (such as a molten salt), a mixture of molten salts, or an aqueous solution of a salt. As you'll see, the products depend on atomic properties and several other factors.

Electrolysis of Pure Molten Salts If the salt is pure, predicting the products is straightforward: *the cation will be reduced and the anion oxidized.* The electrolyte is the molten salt itself, and the ions are attracted by the oppositely charged electrodes.

Consider the electrolysis of molten (fused) calcium chloride. The two species present are Ca^{2+} and Cl^-, so Ca^{2+} ion is reduced and Cl^- ion is oxidized:

$$2Cl^-(l) \longrightarrow Cl_2(g) + 2e^- \quad \text{[anode; oxidation]}$$
$$Ca^{2+}(l) + 2e^- \longrightarrow Ca(s) \quad \text{[cathode; reduction]}$$
$$Ca^{2+}(l) + 2Cl^-(l) \longrightarrow Ca(s) + Cl_2(g) \quad \text{[overall]}$$

Calcium is prepared industrially this way, as are several other active metals, such as Na and Mg, and the halogens Cl_2 and Br_2.

Electrolysis of Mixed Molten Salts More typically, the electrolyte is a mixture of molten salts being electrolyzed to obtain one of the metals. How can we tell which species will react at which electrode? The general rule for all electrolytic cells is

- *The more easily reduced species (stronger oxidizing agent) reacts at the cathode.*
- *The more easily oxidized species (stronger reducing agent) reacts at the anode.*

Unfortunately, for molten salts, we *cannot* use $E°$ values to tell the relative strength of the oxidizing and reducing agents, because those values refer to the reduction of the *aqueous ion to the free element,* $M^{n+}(aq) + ne^- \longrightarrow M(s)$, under standard-state conditions. Instead, we use periodic trends of atomic properties to predict which ion gains or loses electrons more easily (Sections 8.3 and 9.5):

- If a metal holds its electrons *more* tightly than another, it has a higher ionization energy (IE). Thus, as a cation, it gains electrons more easily, so it is the stronger oxidizing agent and is reduced at the cathode.
- If a nonmetal holds its electrons *less* tightly than another, it has a lower electronegativity (EN). Thus, as an anion, it loses electrons more easily, so it is the stronger reducing agent and is oxidized at the anode.

SAMPLE PROBLEM 21.9 Predicting the Electrolysis Products of a Molten Salt Mixture

Problem A chemical engineer melts a naturally occurring mixture of NaBr and $MgCl_2$ and decomposes it in an electrolytic cell. Predict the substance formed at each electrode, and write balanced half-reactions and the overall cell reaction.

Plan We have to determine which metal and nonmetal will form more easily at each electrode. We list the ions as oxidizing or reducing agents and then use periodic trends to determine which metal ion is more easily reduced and which nonmetal ion more easily oxidized.

Solution Listing the ions as oxidizing or reducing agents:

The possible oxidizing agents are Na^+ and Mg^{2+}.

The possible reducing agents are Br^- and Cl^-.

Determining the cathode product (more easily reduced cation): Mg is to the right of Na in Period 3. IE increases from left to right, so it is harder to remove e^- from Mg. Thus, Mg^{2+} has a greater attraction for e^- and is more easily reduced (stronger oxidizing agent):

$$Mg^{2+}(l) + 2e^- \longrightarrow Mg(l) \quad \text{[cathode; reduction]}$$

Determining the anode product (more easily oxidized anion): Br is below Cl in Group 7A(17). EN decreases down the group, so Br accepts e^- less readily. Thus, Br^- loses its e^- more easily, so it is more easily oxidized (stronger reducing agent):

$$2Br^-(l) \longrightarrow Br_2(g) + 2e^- \quad \text{[anode; oxidation]}$$

Writing the overall cell reaction:

$$Mg^{2+}(l) + 2Br^-(l) \longrightarrow Mg(l) + Br_2(g) \quad \text{[overall]}$$

Comment The cell temperature must be high enough to keep the salt mixture molten. In this case, the temperature is greater than the melting point of Mg, so it appears as a liquid in the equation, and greater than the boiling point of Br_2, so it appears as a gas.

FOLLOW-UP PROBLEMS

21.9A The most ionic and least ionic of the common alkali halides are, respectively, CsF and LiI. A solid mixture of these compounds is melted and electrolyzed. Determine which metal and nonmetal form at the electrodes, and write the overall cell reaction.

21.9B A sample of $AlBr_3$ contaminated with KF is melted and electrolyzed. Determine the electrode products, and write the overall cell reaction.

SOME SIMILAR PROBLEMS 21.89–21.92

Electrolysis of Water and Nonstandard Half-Cell Potentials Before we analyze the electrolysis products of aqueous salt solutions, let's examine the electrolysis of water itself. Very pure water is difficult to electrolyze because so few ions are present to conduct a current. However, if we add a small amount of a salt that cannot be electrolyzed (such as Na_2SO_4), electrolysis proceeds rapidly. An electrolytic cell with separate compartments for H_2 and O_2 is used (Figure 21.28). At the anode, water is oxidized; note that the oxidation number (O.N.) of O changes from -2 in H_2O to 0 in O_2:

$$\overset{+1\ -2}{2H_2O(l)} \longrightarrow \overset{0}{O_2(g)} + \overset{+1}{4H^+(aq)} + 4e^- \qquad E = 0.82\ V \qquad \text{[anode; oxidation]}$$

At the cathode, water is reduced; note that the O.N. of H changes from $+1$ in H_2O to 0 in H_2:

$$\overset{+1\ -2}{2H_2O(l)} + 2e^- \longrightarrow \overset{0}{H_2(g)} + \overset{-2}{2OH^-(aq)} \qquad E = -0.42\ V \qquad \text{[cathode; reduction]}$$

Doubling the cathode half-reaction to make e^- loss equal e^- gain, adding the half-reactions (which involves combining the H^+ and OH^- into H_2O and canceling e^- and excess H_2O), and calculating E_{cell} gives the overall reaction:

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g) \qquad E_{cell} = -0.42\ V - 0.82\ V = -1.24\ V \qquad \text{[overall]}$$

Note that, because the $[H^+]$ and $[OH^-]$ are $1.0\times10^{-7}\ M$ rather than the standard-state value of 1 M, these electrode potentials are *not* standard electrode potentials and are designated with E, not $E°$. In aqueous ionic solutions, $[H^+]$ and $[OH^-]$ are also approximately $10^{-7}\ M$, so we use these nonstandard $E_{half\text{-}cell}$ values to predict electrode products.

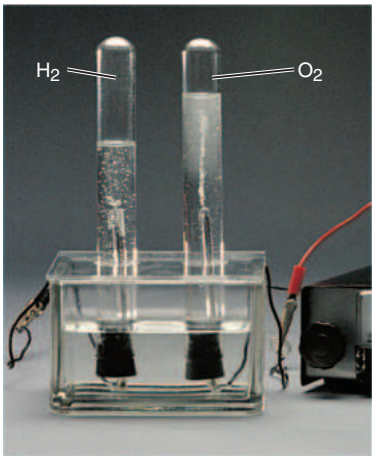

Figure 21.28 **The electrolysis of water.** Twice as much H_2 forms as O_2.

Electrolysis of Aqueous Salt Solutions and the Effect of Overvoltage Aqueous salt solutions are mixtures of ions *and* water, so we have to compare the electrode potentials of the ions and of water to predict the electrode products.

1. *Predicting the electrode products*. When two half-reactions are possible at an electrode,

- *The reduction with the less negative (more positive) electrode potential occurs.*
- *The oxidation with the less positive (more negative) electrode potential occurs.*

What happens, for instance, when a solution of potassium iodide is electrolyzed?

- The possible *oxidizing agents* are K^+ and H_2O; their reduction half-reactions are

$$K^+(aq) + e^- \longrightarrow K(s) \qquad E° = -2.93\ V$$

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E = -0.42\ V \qquad \text{[reduction]}$$

The less *negative* electrode potential for water means that it is much easier to reduce H_2O than K^+, so H_2 forms at the cathode.

- The possible *reducing agents* are I^- and H_2O; their oxidation half-reactions are

$$2I^-(aq) \longrightarrow I_2(s) + 2e^- \qquad E° = 0.53\ V \qquad \text{[oxidation]}$$
$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^- \qquad E = 0.82\ V$$

The less *positive* electrode potential for iodide ion means that it is easier to oxidize I^- than H_2O, so I_2 forms at the anode.

2. *The effect of overvoltage.* The products predicted from a comparison of electrode potentials are not always the actual products. For gases to be produced at metal electrodes, additional voltage is required. This increment above the expected voltage is the **overvoltage.** It is 0.4–0.6 V for $H_2(g)$ or $O_2(g)$ and is due to the large activation energy (Section 16.5) required for a gas to form at the electrode.

Overvoltage has major practical significance. A multibillion-dollar example is the industrial production of chlorine from concentrated NaCl solution. Water is easier to reduce than Na^+, so H_2 forms at the cathode, even *with* an overvoltage of 0.6 V:

$$Na^+(aq) + e^- \longrightarrow Na(s) \qquad E° = -2.71\ V$$
$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E = -0.42\ V\ (\approx -1\ V \text{ with overvoltage})$$
[reduction]

But Cl_2 *does* form at the anode, even though a comparison of the electrode potentials alone would lead us to predict that O_2 should form:

$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^- \qquad E = 0.82\ V\ (\sim 1.4\ V \text{ with overvoltage})$$
$$2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \qquad E° = 1.36\ V \qquad \text{[oxidation]}$$

An overvoltage of ~0.6 V for O_2 makes Cl_2 the product that is easier to form. Keeping $[Cl^-]$ high also favors its formation. Thus, Cl_2, one of the 10 most heavily produced chemicals, is formed from plentiful natural sources of aqueous sodium chloride (Chapter 22).

3. *A summary: which product at which electrode.* Experiments have shown the elements that can be prepared electrolytically from aqueous solutions of their salts:

- Cations of less active metals, including gold, silver, copper, chromium, platinum, and cadmium, *are* reduced to the metal.
- Cations of more active metals, including those in Groups 1A(1) and 2A(2) and Al from 3A(13), *are not* reduced. Water is reduced to H_2 and OH^- instead.
- Anions that *are* oxidized, because of overvoltage from O_2 formation, include the halides ($[Cl^-]$ must be high), except for F^-.
- Anions that *are not* oxidized include F^- and common oxoanions, such as SO_4^{2-}, CO_3^{2-}, NO_3^-, and PO_4^{3-}, because the central nonmetal in these oxoanions is already in its highest oxidation state. Water is oxidized to O_2 and H^+ instead.

SAMPLE PROBLEM 21.10 Predicting the Electrolysis Products of Aqueous Salt Solutions

Problem Use half-reactions to show which product forms at each electrode during the electrolysis of aqueous solutions of the following salts:
(a) KBr
(b) $AgNO_3$
(c) $MgSO_4$

Plan We identify the reacting ions and compare their electrode potentials with those of water, taking the additional 0.4–0.6 V overvoltage into account. The reduction half-reaction with the less negative electrode potential occurs at the cathode, and the oxidation half-reaction with the less positive electrode potential occurs at the anode.

Solution

(a)

$$K^+(aq) + e^- \longrightarrow K(s) \qquad E^\circ = -2.93\ V$$
$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E = -0.42\ V$$

Despite the overvoltage, which makes E for the reduction of water between -0.8 V and -1.0 V, H_2O is still easier to reduce than K^+, so $H_2(g)$ forms at the cathode.

$$2Br^-(aq) \longrightarrow Br_2(l) + 2e^- \qquad E^\circ = 1.07\ V$$
$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^- \qquad E = 0.82\ V$$

Because of the overvoltage, which makes E for the oxidation of water between 1.2 V and 1.4 V, Br^- is easier to oxidize than water, so $Br_2(l)$ forms at the anode *(see photo)*.

(b)

$$Ag^+(aq) + e^- \longrightarrow Ag(s) \qquad E^\circ = 0.80\ V$$
$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E = -0.42\ V$$

As the cation of an inactive metal, Ag^+ is a better oxidizing agent than H_2O, so $Ag(s)$ forms at the cathode. NO_3^- cannot be oxidized, because N is already in its highest (+5) oxidation state. Thus, $O_2(g)$ forms at the anode:

$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$$

(c)

$$Mg^{2+}(aq) + 2e^- \longrightarrow Mg(s) \qquad E^\circ = -2.37\ V$$

Like K^+ in part (a), Mg^{2+} cannot be reduced in the presence of water, so $H_2(g)$ forms at the cathode. The SO_4^{2-} ion cannot be oxidized because S is in its highest (+6) oxidation state. Thus, H_2O is oxidized, and $O_2(g)$ forms at the anode:

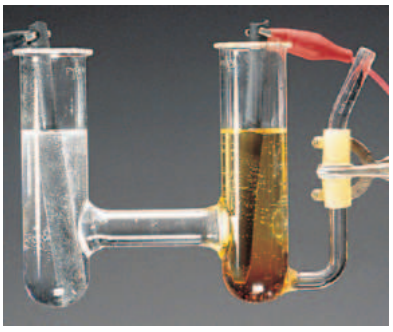
$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$$

FOLLOW-UP PROBLEMS

21.10A Use half-reactions to show which product forms at each electrode when an aqueous solution of lead(II) nitrate is electrolyzed.

21.10B Use half-reactions to show which product forms at each electrode in the electrolysis of aqueous $AuBr_3$.

SOME SIMILAR PROBLEMS 21.97–21.100



Electrolysis of aqueous KBr.

Stoichiometry of Electrolysis: The Relation Between Amounts of Charge and Products

Since charge flowing through an electrolytic cell yields products at the electrodes, it makes sense that more product forms when more charge flows. This relationship was first determined experimentally in the 1830s by Michael Faraday and is referred to as *Faraday's law of electrolysis: the amount of substance produced at each electrode is directly proportional to the quantity of charge flowing through the electrolytic cell.*

Each balanced half-reaction shows the amounts (mol) of reactant, electrons, and product involved in the change, so it contains the information we need to answer such questions as "How much material will form from a given quantity of charge?" or, conversely, "How much charge is needed to produce a given amount of material?"

Measuring Current to Find Charge We cannot measure charge directly, but we *can* measure *current,* the charge flowing per unit time. The SI unit of current is the **ampere (A),** which is defined as a charge of 1 coulomb (C) flowing through a conductor in 1 second (s):

$$\text{Current (A)} = \text{charge (C)/time (s)} \qquad \text{or} \qquad 1\ A = 1\ C/s \qquad (21.11)$$

Thus, the current multiplied by the time gives the charge:

$$\text{Current} \times \text{time} = \text{charge} \qquad \text{or} \qquad A \times s = \frac{C}{s} \times s = C$$

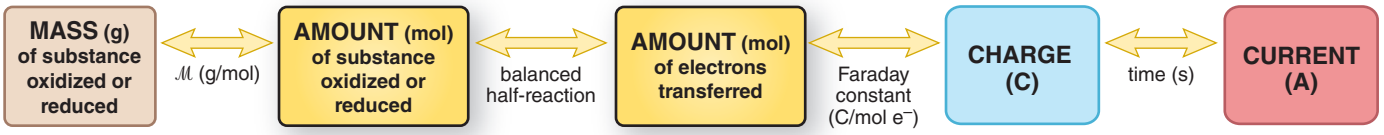


Figure 21.29 A summary diagram for the stoichiometry of electrolysis.

Therefore, by measuring the current *and* the time during which the current flows, we find the charge, which relates to the amount of product (Figure 21.29).

Faraday's Law and the Stoichiometry of Electrolysis Problems based on Faraday's law often ask you to calculate current, mass of material, or time. As we said, the electrode half-reaction provides the key to solving these problems because it relates the mass of product to a certain quantity of charge. To apply Faraday's law,

1. Balance the half-reaction to find the amount (mol) of electrons needed per mole of product.
2. Use the Faraday constant ($F = 9.65\times10^4$ C/mol e^-) to find the quantity of charge.
3. Depending on the question, do one of the following:
   a. Use the molar mass to find the charge needed for a given mass of product, or vice versa.
   b. Use the mass of product and the given current to find the time needed, or vice versa.

Here is a typical problem in practical electrolysis: how long does it take to produce 3.0 g of $Cl_2(g)$ by electrolysis of aqueous NaCl using a power supply with a current of 12 A? The problem asks for the time needed to produce a certain mass, so let's first relate mass to amount (mol) of electrons to find the charge needed. Then, we'll relate the charge to the current to find the time.

The half-reaction tells us that 2 mol of electrons are lost to form 1 mol of Cl_2 and we'll use this relationship as a conversion factor:

$$2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^-$$

We convert the given mass of Cl_2 to amount (mol) of Cl_2, use the conversion factor from the half-reaction, and multiply by the Faraday constant to find the total charge:

$$\text{Charge (C)} = 3.0 \text{ g } Cl_2 \times \frac{1 \text{ mol } Cl_2}{70.90 \text{ g } Cl_2} \times \frac{2 \text{ mol } e^-}{1 \text{ mol } Cl_2} \times \frac{9.65\times10^4 \text{ C}}{1 \text{ mol } e^-}$$
$$= 8.2\times10^3 \text{ C}$$

Now we use the relationship between charge and current to find the time needed:

$$\text{Time (s)} = \frac{\text{charge (C)}}{\text{current (A, or C/s)}} = 8.2\times10^3 \text{ C} \times \frac{1 \text{ s}}{12 \text{ C}}$$
$$= 6.8\times10^2 \text{ s } (\sim 11 \text{ min})$$

Note that the entire calculation follows Figure 21.29 until the last step, which asks for the time that the given current must flow:

grams of Cl_2 ⟹ moles of Cl_2 ⟹ moles of e^- ⟹ coulombs ⟹ seconds

Sample Problem 21.11 applies these ideas in an important industrial setting.

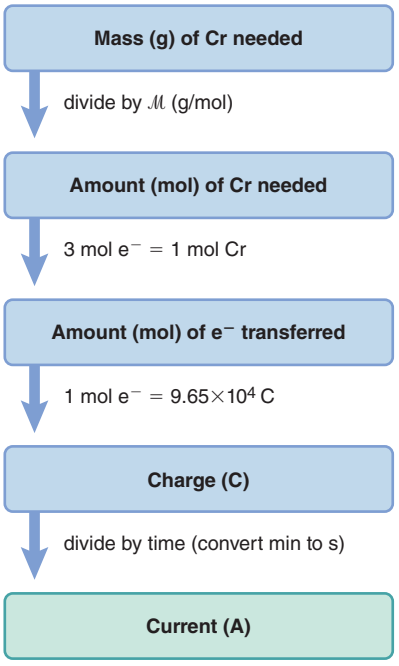
SAMPLE PROBLEM 21.11 Applying the Relationship Among Current, Time, and Amount of Substance

Problem A technician plates a faucet with 0.86 g of Cr metal by electrolysis of aqueous $Cr_2(SO_4)_3$. If 12.5 min is allowed for the plating, what current is needed?

Plan To find the current, we divide charge by time, so we need to find the charge. We write the half-reaction for the Cr^{3+} reduction to get the amount (mol) of e^- transferred

per mole of Cr. To find the charge, we convert the mass of Cr needed (0.86 g) to amount (mol) of Cr. Then, we use the Faraday constant (9.65×10^4 C/mol e^-) to find the charge and divide by the time (12.5 min, converted to seconds) to obtain the current (see the road map).

Road Map



Solution Writing the balanced half-reaction:

$$Cr^{3+}(aq) + 3e^- \longrightarrow Cr(s)$$

Combining steps to find amount (mol) of e^- transferred for the mass of Cr needed:

$$\text{Amount (mol) of } e^- \text{ transferred} = 0.86 \text{ g Cr} \times \frac{1 \text{ mol Cr}}{52.00 \text{ g Cr}} \times \frac{3 \text{ mol } e^-}{1 \text{ mol Cr}} = 0.050 \text{ mol } e^-$$

Calculating the charge:

$$\text{Charge (C)} = 0.050 \text{ mol } e^- \times \frac{9.65\times10^4 \text{ C}}{1 \text{ mol } e^-} = 4.8\times10^3 \text{ C}$$

Calculating the current:

$$\text{Current (A)} = \frac{\text{charge (C)}}{\text{time (s)}} = \frac{4.8\times10^3 \text{ C}}{12.5 \text{ min}} \times \frac{1 \text{ min}}{60 \text{ s}} = 6.4 \text{ C/s} = 6.4 \text{ A}$$

Check Rounding gives

$$(\sim 0.9 \text{ g})(1 \text{ mol Cr}/50 \text{ g})(3 \text{ mol } e^-/1 \text{ mol Cr}) = 5\times10^{-2} \text{ mol } e^-$$

then

$$(5\times10^{-2} \text{ mol } e^-)(\sim 1\times10^5 \text{ C/mol } e^-) = 5\times10^3 \text{ C}$$

and

$$(5\times10^3 \text{ C}/12 \text{ min})(1 \text{ min}/60 \text{ s}) = 7 \text{ A}$$

Comment In order to introduce Faraday's law, we have neglected some details about actual electroplating. In practice, electroplating chromium is only 30% to 40% efficient and must be run at a specific temperature range for the plate to appear bright. Nearly 10,000 metric tons (2×10^8 mol) of chromium are used annually for electroplating.

FOLLOW-UP PROBLEMS

21.11A Using a current of 4.75 A, how many minutes does it take to plate a sculpture with 1.50 g of Cu from a $CuSO_4$ solution?

21.11B To protect it from corrosion, a section of iron pipe is electrogalvanized with 1.25 g of zinc from a basic solution of $Na_2Zn(OH)_4$. The half-reaction is

$$Zn(OH)_4^{2-}(aq) + 2e^- \longrightarrow Zn(s) + 4OH^-(aq)$$

If the process takes 8.75 min, what current (in amperes) is needed?

SOME SIMILAR PROBLEMS 21.101–21.106

The following Chemical Connections essay links several themes of this chapter to the generation of energy in a living cell.

Summary of Section 21.7

- An electrolytic cell uses electrical energy to drive a nonspontaneous reaction.
- Oxidation occurs at the anode and reduction at the cathode, but the direction of electron flow and the charges of the electrodes are opposite those in voltaic cells.
- When two products can form at each electrode, the more easily oxidized substance forms at the anode and the more easily reduced substance forms at the cathode.
- Overvoltage causes the actual voltage required to be unexpectedly high (especially for gases, such as H_2 and O_2) and can affect the product that forms at each electrode.
- The amount of product that forms is proportional to the quantity of charge flowing through the cell, which is related to the time the charge flows and the current.
- Biological redox systems combine aspects of voltaic, concentration, and electrolytic cells to convert bond energy in food into electrochemical potential and then into the bond energy of ATP.

Cellular Electrochemistry and the Production of ATP

Biological cells apply the principles of electrochemical cells to generate energy. The complex multistep process can be divided into two parts:

1. Bond energy in food generates an electrochemical potential.
2. That potential creates the bond energy of ATP (see Chemical Connections, pp. 902–903).

These steps are part of the *electron-transport chain* (ETC), which lies on the inner membranes of *mitochondria,* the subcellular particles that produce energy (Figure B21.1).

The ETC is a series of large molecules (mostly proteins), each of which contains a *redox couple* (the oxidized and reduced forms of a species), such as Fe^{3+}/Fe^{2+}, that passes electrons along the chain. At three points in this chain, large potential differences supply enough free energy to convert adenosine diphosphate (ADP) into ATP.

Bond Energy to Electrochemical Potential

Cells utilize the energy in food by releasing it in controlled steps rather than all at once. The reaction that ultimately powers the ETC is the oxidation of hydrogen to form water: $H_2 + \frac{1}{2}O_2 \longrightarrow H_2O$. But, instead of H_2 gas, which does not occur in organisms, the hydrogen takes the form of two H^+ ions and two e^-. The biological oxidizing agent NAD^+ (*n*icotinamide *a*denine *d*inucleotide) acquires these protons and electrons in the process of oxidizing molecules in food. To show this process, we use this half-reaction (without canceling an H^+ on both sides):

$$NAD^+(aq) + 2H^+(aq) + 2e^- \longrightarrow NADH(aq) + H^+(aq)$$

At the mitochondrial inner membrane, the NADH and H^+ transfer the two e^- to the first redox couple of the ETC and release the two H^+. The electrons are transported down the chain of redox couples, where they finally reduce O_2. The overall process, with standard electrode potentials,* is

$$NADH(aq) + H^+(aq) \longrightarrow NAD^+(aq) + 2H^+(aq) + 2e^- \qquad E^{\circ\prime} = -0.315\ V$$

$$\tfrac{1}{2}O_2(aq) + 2e^- + 2H^+(aq) \longrightarrow H_2O(l) \qquad E^{\circ\prime} = 0.815\ V$$

$$NADH(aq) + H^+(aq) + \tfrac{1}{2}O_2(aq) \longrightarrow NAD^+(aq) + H_2O(l)$$

$$E^{\circ\prime}_{overall} = 0.815\ V - (-0.315\ V) = 1.130\ V$$

Thus, for every 2 mol of e^-, 1 mol of NADH enters the ETC, and the free energy equivalent of 1.130 V is available:

$$\begin{aligned}\Delta G^{\circ\prime} &= -nFE^{\circ\prime}\\ &= -(2\ mol\ e^-/mol\ NADH)(96.5\ kJ/V\cdot mol\ e^-)(1.130\ V)\\ &= -218\ kJ/mol\ NADH\end{aligned}$$

Note that this aspect of the process functions like a voltaic cell: a spontaneous reaction, the reduction of O_2 to H_2O, is used to generate a potential. In contrast to the operation of a voltaic cell, this process occurs in many small steps. Figure B21.2 is a highly simplified diagram showing the three steps in the ETC that generate a high enough potential to form ATP from ADP.

Each step consists of several components, in which electrons are passed from one redox couple to the next. Since most

*In biological systems, standard potentials are designated $E^{\circ\prime}$ and the standard states include a pH of 7.0 ($[H^+] = 1\times10^{-7}\ M$).

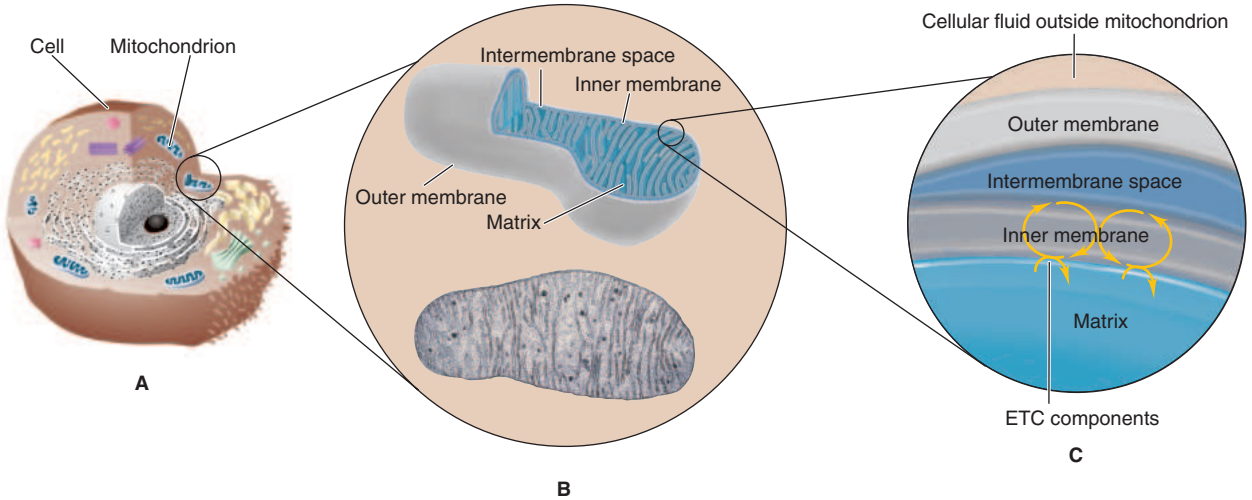


Figure B21.1 The mitochondrion. A, Mitochondria are subcellular particles outside the cell nucleus. **B,** They have a smooth outer membrane and a highly folded inner membrane, shown schematically and in an electron micrograph. **C,** The components of the electron-transport chain are attached to the inner membrane, which is in contact with the matrix, a relatively viscous aqueous mixture of small organic molecules, enzymes, and other macromolecules.

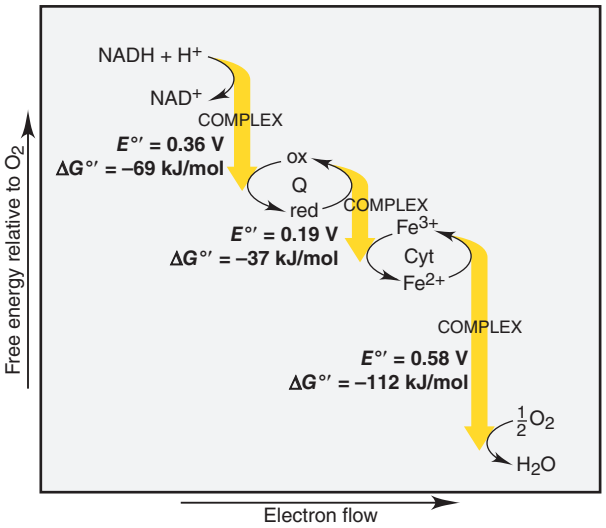

Figure B21.2 The main energy-yielding steps in the electron-transport chain (ETC). At the three points shown, $E°'$ (or $\Delta G°'$) is large enough to form ATP from ADP. (A complex consists of many components; Q is a large organic molecule; Cyt stands for a cytochrome, a protein that contains a metal-ion redox couple.)

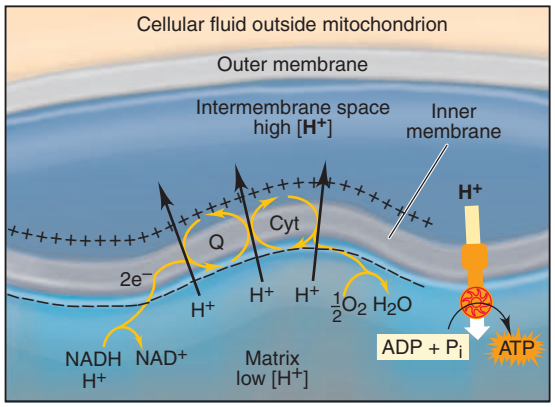

Figure B21.3 Coupling electron transport to proton transport to ATP synthesis. Electrons are transported along the ETC *(curved yellow arrows)*. Protons pumped into the intermembrane space create an $[H^+]$ difference that generates a potential across the inner membrane. When that difference is large enough, H^+ flows back into the inner space, and the free energy drives the formation of ATP.

of the ETC components are iron-containing proteins, the redox change consists of the oxidation of Fe^{2+} to Fe^{3+} in one component accompanied by the reduction of Fe^{3+} to Fe^{2+} in the other:

$$Fe^{2+}\ (\text{in A}) + Fe^{3+}\ (\text{in B}) \longrightarrow Fe^{3+}\ (\text{in A}) + Fe^{2+}\ (\text{in B})$$

In other words, metal ions bound within the ETC proteins are the actual species undergoing the redox reactions.

Electrochemical Potential to Bond Energy

Formation of ATP requires a lot of energy:

$$ADP^{3-}(aq) + HPO_4^{2-}(aq) + H^+(aq) \longrightarrow ATP^{4-}(aq) + H_2O(l)$$

$$\Delta G°' = 30.5\ \text{kJ/mol}$$

Note that, at each of the three points in Figure B21.2, the free energy *released* exceeds the 30.5 kJ needed to form 1 mol of ATP. Thus, as in an electrolytic cell, an electrochemical potential is supplied to drive a nonspontaneous reaction.

We've followed the flow of *electrons* through the ETC. To see how electrochemical potential is converted to bond energy in ATP, we focus on the released *protons*. The free energy released at the three key steps is used to force the H^+ ions into the intermembrane space; as a result, $[H^+]$ of the intermembrane space becomes higher than $[H^+]$ of the matrix, the aqueous mixture that fills the spaces between the folds of the inner membrane (Figure B21.3). This part of the process uses the free energy released by the three steps to *create an H^+ concentration cell across the inner membrane.*

When the $[H^+]$ difference across the inner membrane reaches a "trigger" point of about 2.5-fold, H^+ ions spontaneously flow back through the membrane (in effect, closing the switch and allowing the concentration cell to operate). The free energy released in this spontaneous process drives the nonspontaneous ATP formation via an enzyme-catalyzed mechanism.

Thus, the mitochondrion uses the "electron-motive force" of redox couples on the membrane to generate a "proton-motive force" across the membrane, which converts a potential difference into bond energy.

Problems

B21.1 In the final steps of the ETC, there is a large protein complex containing iron and copper ions that interact with each other. (a) Write balanced equations for the one-electron half-reactions of Fe^{3+} and of Cu^+.
(b) Write a balanced overall equation for this redox reaction.

B21.2 As the ETC proceeds, a difference in $[H^+]$ develops across the inner mitochondrial membrane. The "proton-motive force," which is used to form ATP, is based largely on this difference and is equivalent to an electrical potential of 0.224 V. What is the free energy change (in kJ/mol) associated with the "proton-motive force"?

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The meanings of *oxidation* and *reduction;* why an oxidizing agent is reduced and a reducing agent is oxidized (§21.1 and §4.5)
2. How the half-reaction method is used to balance redox reactions in acidic or basic solution (§21.1)
3. The distinction between voltaic and electrolytic cells in terms of the sign of ΔG (§21.1)
4. How voltaic cells use a spontaneous reaction to release electrical energy (§21.2)
5. The physical makeup of a voltaic cell: arrangement and composition of half-cells, relative charges of electrodes, and purpose of a salt bridge (§21.2)
6. How the difference in reducing strength of the electrodes determines the direction of electron flow (§21.2)
7. The correspondence between a positive E_{cell} and a spontaneous cell reaction (§21.3)
8. The usefulness and significance of standard electrode potentials ($E^\circ_{half\text{-}cell}$) (§21.3)
9. How $E^\circ_{half\text{-}cell}$ values are combined to give E°_{cell} (§21.3)
10. How the standard reference electrode is used to find an unknown $E^\circ_{half\text{-}cell}$ (§21.3)
11. How an emf series (e.g., Table 21.2 or Appendix D) is used to write spontaneous redox reactions (§21.3)
12. How the relative reactivity of a metal is determined by its reducing power and is related to the negative of its $E^\circ_{half\text{-}cell}$ (§21.3)
13. How E_{cell} (the nonstandard cell potential) is related to ΔG (maximum work) and the charge (moles of electrons times the Faraday constant) flowing through the cell (§21.4)
14. The interrelationship of ΔG°, E°_{cell}, and K (§21.4)
15. How E_{cell} changes as the cell operates (Q changes) (§21.4)
16. Why a voltaic cell can do work until $Q = K$ (§21.4)
17. How a concentration cell does work until the half-cell concentrations are equal (§21.4)
18. The distinction between primary (nonrechargeable) and secondary (rechargeable) batteries and the nature of fuel cells (§21.5)
19. How corrosion occurs and is prevented; the similarities between a corroding metal and a voltaic cell (§21.6)
20. How electrolytic cells use nonspontaneous redox reactions driven by an external source of electricity (§21.7)
21. How atomic properties (ionization energy and electronegativity) determine the products of the electrolysis of molten salt mixtures (§21.7)
22. How the electrolysis of water influences the products of aqueous electrolysis; the importance of overvoltage (§21.7)
23. The relationship between the quantity of charge flowing through the cell and the amount of product formed (§21.7)

Master These Skills

1. Balancing redox reactions by the half-reaction method (§21.1 and SP 21.1)
2. Diagramming and notating a voltaic cell (§21.2 and SP 21.2)
3. Combining $E^\circ_{half\text{-}cell}$ values to obtain E°_{cell} (§21.3 and SP 21.3)
4. Using E°_{cell} and a known $E^\circ_{half\text{-}cell}$ to find an unknown $E^\circ_{half\text{-}cell}$ (SP 21.4)
5. Manipulating half-reactions to write a spontaneous redox reaction and calculate its E°_{cell} (SP 21.5)
6. Ranking the relative strengths of oxidizing and reducing agents in a redox reaction (SP 21.5)
7. Predicting whether a metal can displace hydrogen or another metal from solution (§21.3)
8. Using the interrelationship of ΔG°, E°_{cell}, and K to calculate one of the three given the other two (§21.4 and SP 21.6)
9. Using the Nernst equation to calculate the nonstandard cell potential (E_{cell}) (SP 21.7)
10. Calculating E_{cell} of a concentration cell (SP 21.8)
11. Predicting the products of the electrolysis of a mixture of molten salts (SP 21.9)
12. Predicting the products of the electrolysis of aqueous salt solutions (SP 21.10)
13. Calculating the current (or time) needed to produce a given amount of product by electrolysis (SP 21.11)

Key Equations and Relationships

Page numbers appear in parentheses.

21.1 Relating the sponteneity of a process to the sign of the cell potential (930):

$$E_{cell} > 0 \text{ for a spontaneous process}$$

21.2 Relating electric potential to energy and charge in SI units (930):

$$\text{Potential} = \text{energy/charge} \quad \text{or} \quad 1\ \text{V} = 1\ \text{J/C}$$

21.3 Relating standard cell potential to standard electrode potentials in a voltaic cell (931):

$$E^\circ_{cell} = E^\circ_{cathode\ (reduction)} - E^\circ_{anode\ (oxidation)}$$

21.4 Defining the Faraday constant (939):

$$F = 9.65\times10^4\ \frac{\text{J}}{\text{V·mol e}^-} \quad (3\ \text{sf})$$

21.5 Relating the free energy change to the cell potential (939):

$$\Delta G = -nFE_{cell}$$

21.6 Finding the standard free energy change from the standard cell potential (939):

$$\Delta G^\circ = -nFE^\circ_{cell}$$

21.7 Finding the equilibrium constant from the standard cell potential (940):

$$E^\circ_{cell} = \frac{RT}{nF}\ln K$$

21.8 Substituting known values of R, F, and T into Equation 21.7 and converting to common logarithms (940):

$$E^\circ_{cell} = \frac{0.0592\ \text{V}}{n}\log K \quad \text{or} \quad \log K = \frac{nE^\circ_{cell}}{0.0592\ \text{V}} \quad (\text{at } 298.15\ \text{K})$$

21.9 Calculating the nonstandard cell potential (Nernst equation) (942):

$$E_{cell} = E^\circ_{cell} - \frac{RT}{nF}\ln Q$$

21.10 Substituting known values of R, F, and T into the Nernst equation and converting to common logarithms (942):

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ \text{V}}{n}\log Q \quad (\text{at } 298.15\ \text{K})$$

21.11 Relating current to charge and time (959):

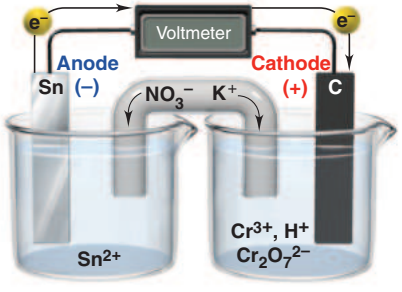
$$\text{Current (A)} = \text{charge (C)/time (s)} \quad \text{and} \quad 1\ \text{A} = 1\ \text{C/s}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

21.1A $6KMnO_4(aq) + 6KOH(aq) + KI(aq) \longrightarrow 6K_2MnO_4(aq) + KIO_3(aq) + 3H_2O(l)$

21.1B $2Cr(OH)_3(s) + NaIO_3(aq) + 4NaOH(aq) \longrightarrow 2Na_2CrO_4(aq) + NaI(aq) + 5H_2O(l)$

21.2A



$$Sn(s) \longrightarrow Sn^{2+}(aq) + 2e^- \quad \text{[anode; oxidation]}$$

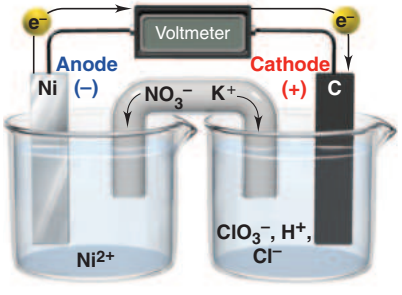
$$6e^- + 14H^+(aq) + Cr_2O_7^{2-}(aq) \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l) \quad \text{[cathode; reduction]}$$

$$3Sn(s) + Cr_2O_7^{2-}(aq) + 14H^+(aq) \longrightarrow 3Sn^{2+}(aq) + 2Cr^{3+}(aq) + 7H_2O(l) \quad \text{[overall]}$$

Cell notation:

$Sn(s) \mid Sn^{2+}(aq) \parallel H^+(aq), Cr_2O_7^{2-}(aq), Cr^{3+}(aq) \mid \text{graphite}$

21.2B



$$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^- \quad \text{[anode; oxidation]}$$

$$ClO_3^-(aq) + 6H^+(aq) + 6e^- \longrightarrow Cl^-(aq) + 3H_2O(l) \quad \text{[cathode; reduction]}$$

$$3Ni(s) + ClO_3^-(aq) + 6H^+(aq) \longrightarrow 3Ni^{2+}(aq) + Cl^-(aq) + 3H_2O(l) \quad \text{[overall]}$$

Cell notation:

$Ni(s) \mid Ni(aq) \parallel H^+(aq), ClO_3^-(aq), Cl^-(aq) \mid \text{graphite}$

21.3A $2Ag(s) + Cu^{2+}(aq) \longrightarrow 2Ag^+(aq) + Cu(s)$

$E^\circ_{cell} = E^\circ_{cathode\ (reduction)} - E^\circ_{anode\ (oxidation)} = 0.34\ \text{V} - 0.80\ \text{V}$
$= -0.46\ \text{V}$; not spontaneous

21.3B $Cl_2(g) + 2Fe^{2+}(aq) \longrightarrow 2Cl^-(aq) + 2Fe^{3+}(aq)$

$E^\circ_{cell} = E^\circ_{cathode\ (reduction)} - E^\circ_{anode\ (oxidation)} = 1.36\ \text{V} - 0.77\ \text{V}$
$= 0.59\ \text{V}$; spontaneous

21.4A $Br_2(aq) + 2e^- \longrightarrow 2Br^-(aq) \quad E^\circ_{bromine} = 1.07\ \text{V}$ [cathode]

$2V^{3+}(aq) + 2H_2O(l) \longrightarrow 2VO^{2+}(aq) + 4H^+(aq) + 2e^- \quad E^\circ_{vanadium} = ?$ [anode]

$E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode} = E^\circ_{bromine} - E^\circ_{vanadium}$

$E^\circ_{vanadium} = E^\circ_{bromine} - E^\circ_{cell} = 1.07\ \text{V} - 0.73\ \text{V} = 0.34\ \text{V}$

21.4B $V^{3+}(aq) + H_2O(l) \longrightarrow VO^{2+}(aq) + 2H^+(aq) + e^- \quad E^\circ_{vanadium} = 0.34\ \text{V}$ [anode]

$NO_3^-(aq) + 4H^+(aq) + 3e^- \longrightarrow NO(g) + 2H_2O(l) \quad E^\circ_{nitrate} = ?$ [cathode]

$E^\circ_{cell} = E^\circ_{cathode} - E^\circ_{anode} = E^\circ_{nitrate} - E^\circ_{vanadium} = 0.62\ \text{V}$

$E^\circ_{nitrate} = E^\circ_{cell} + E^\circ_{vanadium} = 0.62\ \text{V} + 0.34\ \text{V} = 0.96\ \text{V}$

21.5A (a) Combine (2) and reversed (1) to obtain equation A:

$BrO_3^-(aq) + 6Ag(s) \longrightarrow Br^-(aq) + 3Ag_2O(s)$

$E^\circ_{cell} = 0.61\ \text{V} - 0.34\ \text{V} = 0.27\ \text{V}$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS (continued)

Combine (1) and reversed (3) to obtain equation B:
$Ag_2O(s) + H_2O(l) + Zn(s) \longrightarrow 2Ag(s) + Zn(OH)_2(s)$
$E^\circ_{cell} = 0.34\ V - (-1.25\ V) = 1.59\ V$
Combine (2) and reversed (3) to obtain equation C:
$BrO_3^-(aq) + 3H_2O(l) + 3Zn(s) \longrightarrow Br^-(aq) + 3Zn(OH)_2(s)$
$E^\circ_{cell} = 0.61\ V - (-1.25\ V) = 1.86\ V$
(b) Oxidizing agents: $BrO_3^- > Ag_2O > Zn(OH)_2$
Reducing agents: $Zn > Ag > Br^-$

21.5B $Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s)$ $\quad E^\circ = -0.44\ V$
$2[Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-]$ $\quad E^\circ = 0.77\ V$
$3Fe^{2+}(aq) \longrightarrow 2Fe^{3+}(aq) + Fe(s)$
$E^\circ_{cell} = -0.44\ V - 0.77\ V = -1.21\ V$
The reaction is nonspontaneous. The spontaneous reaction is
$2Fe^{3+}(aq) + Fe(s) \longrightarrow 3Fe^{2+}(aq)$ $\quad E^\circ_{cell} = 1.21\ V$
$Fe > Fe^{2+} > Fe^{3+}$

21.6A We use Equations 21.6 and 21.8 with $E^\circ_{cell} = 0.25\ V$. To find n (moles of e^- transferred) from the balanced equation, we note that each Mn (O.N. = +7) gains $3e^-$ to become Mn (O.N. = +4), so two Mn gain $6e^-$; similarly, each Cu loses $2e^-$ to become Cu^{2+}, so three Cu lose $6e^-$. Therefore, n = 6 mol e^-/mol rxn.

$$\Delta G^\circ = -nFE^\circ_{cell} = -\frac{6\ mol\ e^-}{mol\ rxn} \times \frac{96.5\ kJ}{V \cdot mol\ e^-} \times 0.25\ V$$
$$= -1.4\times10^2\ kJ/mol\ rxn$$

$$E^\circ_{cell} = 0.25\ V = \frac{0.0592\ V}{6} \log K$$

$$\log K = \frac{0.25\ V \times 6}{0.0592\ V} = 25.34;\ K = 2.2\times10^{25}$$

21.6B $Cd(s) + Cu^{2+}(aq) \longrightarrow Cd^{2+}(aq) + Cu(s)$
$\Delta G^\circ = -RT \ln K = -8.314\ J/mol\ rxn \cdot K \times 298\ K \times \ln K$
$= -143\ kJ/mol\ rxn;\ K = 1.2\times10^{25}$

$$E^\circ_{cell} = \frac{0.0592\ V}{2} \log (1.2\times10^{25}) = 0.742\ V$$

21.7A From Appendix D,
$Cr^{2+}(aq) + 2e^- \longrightarrow Cr(s)$ $\quad E^\circ = -0.91\ V$
$Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s)$ $\quad E^\circ = -0.14\ V$
$Cr(s) + Sn^{2+}(aq) \longrightarrow Cr^{2+}(aq) + Sn(s)$
So, $E^\circ_{cell} = -0.14\ V - (-0.91\ V) = 0.77\ V$

$$Q = \frac{[Cr^{2+}]}{[Sn^{2+}]} = \frac{1.60}{0.20} = 8.0$$

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ V}{2} \log Q = 0.77\ V - \frac{0.0592\ V}{2} \log 8.0$$
$$= 0.74\ V$$

21.7B From Appendix D,
$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$ $\quad E^\circ = -0.44\ V$
$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$ $\quad E^\circ = 0.34\ V$
$Fe(s) + Cu^{2+}(aq) \longrightarrow Fe^{2+}(aq) + Cu(s)$
So, $E^\circ_{cell} = 0.34\ V - (-0.44\ V) = 0.78\ V$
Therefore, $E_{cell} = 0.78\ V + 0.25\ V = 1.03\ V$

$$1.03\ V = 0.78\ V - \frac{0.0592\ V}{2} \log \frac{[Fe^{2+}]}{[Cu^{2+}]}$$

$$\frac{[Fe^{2+}]}{[Cu^{2+}]} = 3.6\times10^{-9}$$
$$[Fe^{2+}] = 3.6\times10^{-9} \times 0.30\ M = 1.1\times10^{-9}\ M$$

21.8A The cell reaction is
$Ni^{2+}(aq;\ 0.40\ M)$ [half-cell B] $\longrightarrow$ $Ni^{2+}(aq;\ 0.015\ M)$ [half-cell A]

$$E_{cell} = E^\circ_{cell} - \frac{0.0592\ V}{2} \log \frac{[Ni^{2+}]_{dil}}{[Ni^{2+}]_{conc}}$$
$$= 0\ V - \frac{0.0592\ V}{2} \log \frac{0.015}{0.40} = 0.042\ V$$

21.8B The cell reaction is
$Au^{3+}(aq;\ 2.5\times10^{-2}\ M)$ [half-cell B] $\longrightarrow$ $Au^{3+}(aq;\ 7.0\times10^{-4}\ M)$ [half-cell A]

$$E_{cell} = 0\ V - \left(\frac{0.0592\ V}{3} \times \log \frac{7.0\times10^{-4}}{2.5\times10^{-2}}\right) = 0.031\ V$$

The electrode in A is negative, so it is the anode.

21.9A Oxidizing agents: Cs^+ and Li^+. Li, at the top of Group 1A(1), has a higher IE, so it is more easily reduced:
$Li^+ + e^- \longrightarrow Li$ [cathode; reduction]
Reducing agents: F^- and I^-. I, near the bottom of Group 7A(17), has a lower EN, so it is more easily oxidized:
$2I^- \longrightarrow I_2 + 2e^-$ [anode; oxidation]
$2Li^+(l) + 2I^-(l) \longrightarrow 2Li(l) + I_2(g)$ [overall]

21.9B Oxidizing agents: K^+ and Al^{3+}. Al is above and to the right of K in the periodic table, so it has a higher IE:
$Al^{3+}(l) + 3e^- \longrightarrow Al(s)$ [cathode; reduction]
Reducing agents: F^- and Br^-. Br is below F in Group 7A(17), so it has a lower EN:
$2Br^-(l) \longrightarrow Br_2(g) + 2e^-$ [anode; oxidation]
$2Al^{3+}(l) + 6Br^-(l) \longrightarrow 2Al(s) + 3Br_2(g)$ [overall]

21.10A The possible reduction (cathode) half-reactions are
$Pb^{2+}(aq) + 2e^- \longrightarrow Pb(s)$ $\quad E^\circ = -0.13\ V$
$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-$ $\quad E = -0.42\ V$
The possible oxidation (anode) half-reactions are
$NO_3^-(aq) \longrightarrow$ no reaction
$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$ $\quad E = 0.82\ V$
Thus, Pb^{2+} is reduced and Pb forms at the cathode, and H_2O is oxidized and O_2 forms at the anode.

21.10B The reduction with the more positive electrode potential is
$Au^{3+}(aq) + 3e^- \longrightarrow Au(s)$ $\quad E^\circ = 1.50\ V$ [cathode; reduction]
Because of overvoltage, O_2 will not form at the anode, so Br_2 will form:
$2Br^-(aq) \longrightarrow Br_2(l) + 2e^-$ $\quad E^\circ = 1.07\ V$ [cathode; oxidation]

21.11A $Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$; therefore,
$2\ mol\ e^-/1\ mol\ Cu = 2\ mol\ e^-/63.55\ g\ Cu$

$$\text{Time (min)} = 1.50\ g\ Cu \times \frac{2\ mol\ e^-}{63.55\ g\ Cu} \times \frac{9.65\times10^4\ C}{1\ mol\ e^-} \times \frac{1\ s}{4.75\ C} \times \frac{1\ min}{60\ s}$$
$$= 16.0\ min$$

21.11B The half-reaction shows 2 mol e^-/1 mol Zn. Thus,

$$\text{Amount (mol) of } e^- \text{ transferred} = 1.25 \text{ g Zn} \times \frac{1 \text{ mol Zn}}{65.38 \text{ g Zn}} \times \frac{2 \text{ mol } e^-}{1 \text{ mol Zn}} = 0.0382 \text{ mol } e^-$$

$$\text{Charge (C)} = 0.0382 \text{ mol } e^- \times \frac{9.65\times10^4 \text{ C}}{1 \text{ mol } e^-} = 3.69\times10^3 \text{ C}$$

$$\text{Currrent (A)} = \frac{3.69\times10^3 \text{ C}}{8.75 \text{ min}} \times \frac{1 \text{ min}}{60 \text{ s}} = 7.03 \text{ A}$$

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Note: Unless stated otherwise, all problems refer to systems at 298 K (25°C).

Redox Reactions and Electrochemical Cells

(Sample Problem 21.1)

Concept Review Questions

21.1 Define *oxidation* and *reduction* in terms of electron transfer and change in oxidation number.

21.2 Why must an electrochemical process involve a redox reaction?

21.3 Can one half-reaction in a redox process take place independently of the other? Explain.

21.4 Water is used to balance O atoms in the half-reaction method. Why can't O^{2-} ions be used instead?

21.5 During the redox balancing process, what step is taken to ensure that e^- loss equals e^- gain?

21.6 How are protons removed when balancing a redox reaction in basic solution?

21.7 Are spectator ions used to balance the half-reactions of a redox reaction? At what stage might spectator ions enter the balancing process?

21.8 Which type of electrochemical cell has $\Delta G_{sys} < 0$? Which type shows an increase in free energy?

21.9 Which statements are true? Correct any that are false.
(a) In a voltaic cell, the anode is negative relative to the cathode.
(b) Oxidation occurs at the anode of a voltaic or electrolytic cell.
(c) Electrons flow into the cathode of an electrolytic cell.
(d) In a voltaic cell, the surroundings do work on the system.
(e) A metal that plates out of an electrolytic cell appears on the cathode.
(f) In an electrochemical cell, the electrolyte provides a solution of mobile electrons.

Skill-Building Exercises (grouped in similar pairs)

21.10 Consider the following balanced redox reaction:

$$16H^+(aq) + 2MnO_4^-(aq) + 10Cl^-(aq) \longrightarrow 2Mn^{2+}(aq) + 5Cl_2(g) + 8H_2O(l)$$

(a) Which species is being oxidized?
(b) Which species is being reduced?
(c) Which species is the oxidizing agent?
(d) Which species is the reducing agent?
(e) From which species to which does electron transfer occur?
(f) Write the balanced molecular equation, with K^+ and SO_4^{2-} as the spectator ions.

21.11 Consider the following balanced redox reaction:

$$2CrO_2^-(aq) + 2H_2O(l) + 6ClO^-(aq) \longrightarrow 2CrO_4^{2-}(aq) + 3Cl_2(g) + 4OH^-(aq)$$

(a) Which species is being oxidized?
(b) Which species is being reduced?
(c) Which species is the oxidizing agent?
(d) Which species is the reducing agent?
(e) From which species to which does electron transfer occur?
(f) Write the balanced molecular equation, with Na^+ as the spectator ion.

21.12 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $ClO_3^-(aq) + I^-(aq) \longrightarrow I_2(s) + Cl^-(aq)$ [acidic]
(b) $MnO_4^-(aq) + SO_3^{2-}(aq) \longrightarrow MnO_2(s) + SO_4^{2-}(aq)$ [basic]
(c) $MnO_4^-(aq) + H_2O_2(aq) \longrightarrow Mn^{2+}(aq) + O_2(g)$ [acidic]

21.13 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $O_2(g) + NO(g) \longrightarrow NO_3^-(aq)$ [acidic]
(b) $CrO_4^{2-}(aq) + Cu(s) \longrightarrow Cr(OH)_3(s) + Cu(OH)_2(s)$ [basic]
(c) $AsO_4^{3-}(aq) + NO_2^-(aq) \longrightarrow AsO_2^-(aq) + NO_3^-(aq)$ [basic]

21.14 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $Cr_2O_7^{2-}(aq) + Zn(s) \longrightarrow Zn^{2+}(aq) + Cr^{3+}(aq)$ [acidic]
(b) $Fe(OH)_2(s) + MnO_4^-(aq) \longrightarrow MnO_2(s) + Fe(OH)_3(s)$ [basic]
(c) $Zn(s) + NO_3^-(aq) \longrightarrow Zn^{2+}(aq) + N_2(g)$ [acidic]

21.15 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $BH_4^-(aq) + ClO_3^-(aq) \longrightarrow H_2BO_3^-(aq) + Cl^-(aq)$ [basic]
(b) $CrO_4^{2-}(aq) + N_2O(g) \longrightarrow Cr^{3+}(aq) + NO(g)$ [acidic]
(c) $Br_2(l) \longrightarrow BrO_3^-(aq) + Br^-(aq)$ [basic]

21.16 Balance the following skeleton reactions and identify the oxidizing and reducing agents:

(a) $Sb(s) + NO_3^-(aq) \longrightarrow Sb_4O_6(s) + NO(g)$ [acidic]

(b) $Mn^{2+}(aq) + BiO_3^-(aq) \longrightarrow MnO_4^-(aq) + Bi^{3+}(aq)$ [acidic]

(c) $Fe(OH)_2(s) + Pb(OH)_3^-(aq) \longrightarrow Fe(OH)_3(s) + Pb(s)$ [basic]

21.17 Balance the following skeleton reactions and identify the oxidizing and reducing agents:

(a) $NO_2(g) \longrightarrow NO_3^-(aq) + NO_2^-(aq)$ [basic]

(b) $Zn(s) + NO_3^-(aq) \longrightarrow Zn(OH)_4^{2-}(aq) + NH_3(g)$ [basic]

(c) $H_2S(g) + NO_3^-(aq) \longrightarrow S_8(s) + NO(g)$ [acidic]

21.18 Balance the following skeleton reactions and identify the oxidizing and reducing agents:

(a) $As_4O_6(s) + MnO_4^-(aq) \longrightarrow AsO_4^{3-}(aq) + Mn^{2+}(aq)$ [acidic]

(b) $P_4(s) \longrightarrow HPO_3^{2-}(aq) + PH_3(g)$ [acidic]

(c) $MnO_4^-(aq) + CN^-(aq) \longrightarrow MnO_2(s) + CNO^-(aq)$ [basic]

21.19 Balance the following skeleton reactions and identify the oxidizing and reducing agents:

(a) $SO_3^{2-}(aq) + Cl_2(g) \longrightarrow SO_4^{2-}(aq) + Cl^-(aq)$ [basic]

(b) $Fe(CN)_6^{3-}(aq) + Re(s) \longrightarrow Fe(CN)_6^{4-}(aq) + ReO_4^-(aq)$ [basic]

(c) $MnO_4^-(aq) + HCOOH(aq) \longrightarrow Mn^{2+}(aq) + CO_2(g)$ [acidic]

Problems in Context

21.20 In many residential water systems, the aqueous Fe^{3+} concentration is high enough to stain sinks and turn drinking water light brown. The iron content is analyzed by first reducing the Fe^{3+} to Fe^{2+} and then titrating with MnO_4^- in acidic solution. Balance the skeleton reaction of the titration step:

$$Fe^{2+}(aq) + MnO_4^-(aq) \longrightarrow Mn^{2+}(aq) + Fe^{3+}(aq)$$

21.21 *Aqua regia,* a mixture of concentrated HNO_3 and HCl, was developed by alchemists as a means to "dissolve" gold. The process is a redox reaction with this simplified skeleton reaction:

$$Au(s) + NO_3^-(aq) + Cl^-(aq) \longrightarrow AuCl_4^-(aq) + NO_2(g)$$

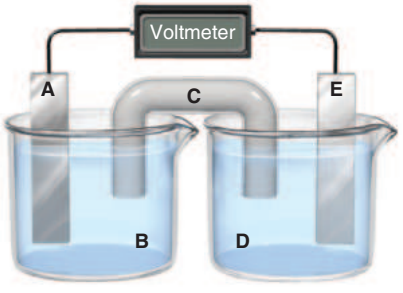
(a) Balance the reaction by the half-reaction method.
(b) What are the oxidizing and reducing agents?
(c) What is the function of HCl in aqua regia?

Voltaic Cells: Using Spontaneous Reactions to Generate Electrical Energy

(Sample Problem 21.2)

Concept Review Questions

21.22 Consider the following general voltaic cell:



Identify the following:
(a) Anode
(b) Cathode
(c) Salt bridge
(d) Electrode from which e^- leave the cell
(e) Electrode with a positive charge
(f) Electrode that gains mass as the cell operates (assuming that a metal plates out)

21.23 Why does a voltaic cell not operate unless the two compartments are connected through an external circuit?

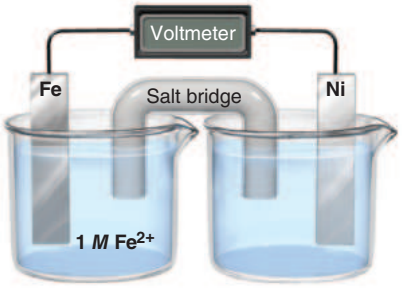
21.24 What purpose does the salt bridge serve in a voltaic cell, and how does it accomplish this purpose?

21.25 What is the difference between an active and an inactive electrode? Why are inactive electrodes used? Name two substances commonly used for inactive electrodes.

21.26 When a piece of metal A is placed in a solution containing ions of metal B, metal B plates out on the piece of A.
(a) Which metal is being oxidized?
(b) Which metal is being displaced?
(c) Which metal would you use as the anode in a voltaic cell incorporating these two metals?
(d) If bubbles of H_2 form when B is placed in acid, will they form if A is placed in acid? Explain.

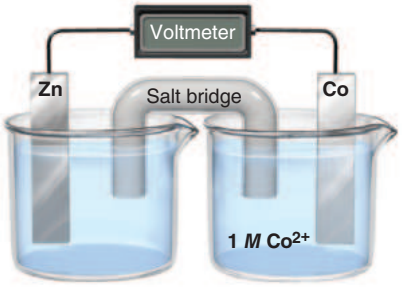
Skill-Building Exercises (grouped in similar pairs)

21.27 Consider the following voltaic cell:



(a) In which direction do electrons flow in the external circuit?
(b) In which half-cell does oxidation occur?
(c) In which half-cell do electrons enter the cell?
(d) At which electrode are electrons consumed?
(e) Which electrode is negatively charged?
(f) Which electrode decreases in mass during cell operation?
(g) Suggest a solution for the electrolyte in the cathode compartment.
(h) Suggest a pair of ions for the salt bridge.
(i) For which electrode could you use an inactive material?
(j) In which direction do anions within the salt bridge move to maintain charge neutrality?
(k) Write balanced half-reactions and the overall cell reaction.

21.28 Consider the following voltaic cell:



(a) In which direction do electrons flow in the external circuit?
(b) In which half-cell does reduction occur?
(c) In which half-cell do electrons leave the cell?
(d) At which electrode are electrons generated?
(e) Which electrode is positively charged?
(f) Which electrode increases in mass during cell operation?
(g) Suggest a solution you can use as the electrolyte in the anode compartment.
(h) Suggest a pair of ions for the salt bridge.
(i) For which electrode could you use an inactive material?
(j) In which direction do cations within the salt bridge move to maintain charge neutrality?
(k) Write balanced half-reactions and the overall cell reaction.

21.29 A voltaic cell is constructed with an Sn/Sn^{2+} half-cell and a Zn/Zn^{2+} half-cell. The zinc electrode is negative.
(a) Write balanced half-reactions and the overall cell reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

21.30 A voltaic cell is constructed with an Ag/Ag^{+} half-cell and a Pb/Pb^{2+} half-cell. The silver electrode is positive.
(a) Write balanced half-reactions and the overall cell reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

21.31 A voltaic cell is constructed with an Fe/Fe^{2+} half-cell and an Mn/Mn^{2+} half-cell. The iron electrode is positive.
(a) Write balanced half-reactions and the overall cell reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

21.32 A voltaic cell is constructed with a Cu/Cu^{2+} half-cell and an Ni/Ni^{2+} half-cell. The nickel electrode is negative.
(a) Write balanced half-reactions and the overall cell reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.

21.33 Write the cell notation for the voltaic cell that incorporates each of the following redox reactions:
(a) $Al(s) + Cr^{3+}(aq) \longrightarrow Al^{3+}(aq) + Cr(s)$
(b) $Cu^{2+}(aq) + SO_2(g) + 2H_2O(l) \longrightarrow Cu(s) + SO_4^{2-}(aq) + 4H^{+}(aq)$

21.34 Write a balanced equation from each cell notation:
(a) $Mn(s) \mid Mn^{2+}(aq) \parallel Cd^{2+}(aq) \mid Cd(s)$
(b) $Fe(s) \mid Fe^{2+}(aq) \parallel NO_3^{-}(aq) \mid NO(g) \mid Pt(s)$

Cell Potential: Output of a Voltaic Cell

(Sample Problems 21.3 to 21.5)

Concept Review Questions

21.35 How is a standard reference electrode used to determine unknown $E^\circ_{\text{half-cell}}$ values?

21.36 What does a negative E°_{cell} indicate about a redox reaction? What does it indicate about the reverse reaction?

21.37 The standard cell potential is a thermodynamic state function. How are E° values treated similarly to ΔH°, ΔG°, and S° values? How are they treated differently?

Skill-Building Exercises (grouped in similar pairs)

21.38 In basic solution, Se^{2-} and SO_3^{2-} ions react spontaneously:

$$2Se^{2-}(aq) + 2SO_3^{2-}(aq) + 3H_2O(l) \longrightarrow 2Se(s) + 6OH^{-}(aq) + S_2O_3^{2-}(aq) \qquad E^\circ_{\text{cell}} = 0.35\ \text{V}$$

(a) Write balanced half-reactions for the process.
(b) If E°_{sulfite} is -0.57 V, calculate $E^\circ_{\text{selenium}}$.

21.39 In acidic solution, O_3 and Mn^{2+} ions react spontaneously:

$$O_3(g) + Mn^{2+}(aq) + H_2O(l) \longrightarrow O_2(g) + MnO_2(s) + 2H^{+}(aq) \qquad E^\circ_{\text{cell}} = 0.84\ \text{V}$$

(a) Write the balanced half-reactions.
(b) Using Appendix D to find E°_{ozone}, calculate $E^\circ_{\text{manganese}}$.

21.40 Use the emf series (Appendix D) to arrange the species.
(a) In order of *decreasing* strength as *oxidizing* agents: Fe^{3+}, Br_2, Cu^{2+}
(b) In order of *increasing* strength as *oxidizing* agents: Ca^{2+}, $Cr_2O_7^{2-}$, Ag^{+}

21.41 Use the emf series (Appendix D) to arrange the species.
(a) In order of *decreasing* strength as *reducing* agents: SO_2, $PbSO_4$, MnO_2
(b) In order of *increasing* strength as *reducing* agents: Hg, Fe, Sn

21.42 Balance each skeleton reaction, use Appendix D to calculate E°_{cell}, and state whether the reaction is spontaneous:
(a) $Co(s) + H^{+}(aq) \longrightarrow Co^{2+}(aq) + H_2(g)$
(b) $Hg_2^{2+}(aq) \longrightarrow Hg^{2+}(aq) + Hg(l)$

21.43 Balance each skeleton reaction, use Appendix D to calculate E°_{cell}, and state whether the reaction is spontaneous:
(a) $Mn^{2+}(aq) + Co^{3+}(aq) \longrightarrow MnO_2(s) + Co^{2+}(aq)$ [acidic]
(b) $AgCl(s) + NO(g) \longrightarrow Ag(s) + Cl^{-}(aq) + NO_3^{-}(aq)$ [acidic]

21.44 Balance each skeleton reaction, use Appendix D to calculate E°_{cell}, and state whether the reaction is spontaneous:
(a) $Cd(s) + Cr_2O_7^{2-}(aq) \longrightarrow Cd^{2+}(aq) + Cr^{3+}(aq)$
(b) $Ni^{2+}(aq) + Pb(s) \longrightarrow Ni(s) + Pb^{2+}(aq)$

21.45 Balance each skeleton reaction, use Appendix D to calculate E°_{cell}, and state whether the reaction is spontaneous:
(a) $Cu^{+}(aq) + PbO_2(s) + SO_4^{2-}(aq) \longrightarrow PbSO_4(s) + Cu^{2+}(aq)$ [acidic]
(b) $H_2O_2(aq) + Ni^{2+}(aq) \longrightarrow O_2(g) + Ni(s)$ [acidic]

21.46 Use the following half-reactions to write three spontaneous reactions, calculate E°_{cell} for each reaction, and rank the strengths of the oxidizing and reducing agents:
(1) $Al^{3+}(aq) + 3e^{-} \longrightarrow Al(s) \qquad E^\circ = -1.66\ \text{V}$
(2) $N_2O_4(g) + 2e^{-} \longrightarrow 2NO_2^{-}(aq) \qquad E^\circ = 0.867\ \text{V}$
(3) $SO_4^{2-}(aq) + H_2O(l) + 2e^{-} \longrightarrow SO_3^{2-}(aq) + 2OH^{-}(aq) \qquad E^\circ = 0.93\ \text{V}$

21.47 Use the following half-reactions to write three spontaneous reactions, calculate E°_{cell} for each reaction, and rank the strengths of the oxidizing and reducing agents:
(1) $Au^{+}(aq) + e^{-} \longrightarrow Au(s) \qquad E^\circ = 1.69\ \text{V}$
(2) $N_2O(g) + 2H^{+}(aq) + 2e^{-} \longrightarrow N_2(g) + H_2O(l) \qquad E^\circ = 1.77\ \text{V}$
(3) $Cr^{3+}(aq) + 3e^{-} \longrightarrow Cr(s) \qquad E^\circ = -0.74\ \text{V}$

21.48 Use the following half-reactions to write three spontaneous reactions, calculate E°_{cell} for each reaction, and rank the strengths of the oxidizing and reducing agents:

(1) $2HClO(aq) + 2H^+(aq) + 2e^- \longrightarrow Cl_2(g) + 2H_2O(l)$ $\quad E^\circ = 1.63$ V

(2) $Pt^{2+}(aq) + 2e^- \longrightarrow Pt(s)$ $\quad E^\circ = 1.20$ V

(3) $PbSO_4(s) + 2e^- \longrightarrow Pb(s) + SO_4^{2-}(aq)$ $\quad E^\circ = -0.31$ V

21.49 Use the following half-reactions to write three spontaneous reactions, calculate E°_{cell} for each reaction, and rank the strengths of the oxidizing and reducing agents:

(1) $I_2(s) + 2e^- \longrightarrow 2I^-(aq)$ $\quad E^\circ = 0.53$ V

(2) $S_2O_8^{2-}(aq) + 2e^- \longrightarrow 2SO_4^{2-}(aq)$ $\quad E^\circ = 2.01$ V

(3) $Cr_2O_7^{2-}(aq) + 14H^+(aq) + 6e^- \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l)$ $\quad E^\circ = 1.33$ V

Problems in Context

21.50 When metal A is placed in a solution of a salt of metal B, the surface of metal A changes color. When metal B is placed in acid solution, gas bubbles form on the surface of the metal. When metal A is placed in a solution of a salt of metal C, no change is observed in the solution or on the surface of metal A.

(a) Will metal C cause formation of H_2 when placed in acid solution?

(b) Rank metals A, B, and C in order of *decreasing* reducing strength.

21.51 When a clean iron nail is placed in an aqueous solution of copper(II) sulfate, the nail becomes coated with a brownish black material.

(a) What is the material coating the iron?

(b) What are the oxidizing and reducing agents?

(c) Can this reaction be made into a voltaic cell?

(d) Write the balanced equation for the reaction.

(e) Calculate E°_{cell} for the process.

Free Energy and Electrical Work

(Sample Problems 21.6 to 21.8)

Concept Review Questions

21.52 (a) How do the relative magnitudes of Q and K relate to the signs of ΔG and E_{cell}? Explain.

(b) Can a cell do work when $Q/K > 1$ or $Q/K < 1$? Explain.

21.53 A voltaic cell consists of A/A^+ and B/B^+ half-cells, where A and B are metals and the A electrode is negative. The initial $[A^+]/[B^+]$ is such that $E_{cell} > E^\circ_{cell}$.

(a) How do $[A^+]$ and $[B^+]$ change as the cell operates?

(b) How does E_{cell} change as the cell operates?

(c) What is $[A^+]/[B^+]$ when $E_{cell} = E^\circ_{cell}$? Explain.

(d) Is it possible for E_{cell} to be less than E°_{cell}? Explain.

21.54 Explain whether E_{cell} of a voltaic cell will increase or decrease with each of the following changes:

(a) Decrease in cell temperature

(b) Increase in [active ion] in the anode compartment

(c) Increase in [active ion] in the cathode compartment

(d) Increase in pressure of a gaseous reactant in the cathode compartment

21.55 In a concentration cell, is the more concentrated electrolyte in the cathode or the anode compartment? Explain.

Skill-Building Exercises (grouped in similar pairs)

21.56 What is the value of the equilibrium constant for the reaction between each pair at 25°C?

(a) Ni(*s*) and $Ag^+(aq)$ (b) Fe(*s*) and $Cr^{3+}(aq)$

21.57 What is the value of the equilibrium constant for the reaction between each pair at 25°C?

(a) Al(*s*) and $Cd^{2+}(aq)$ (b) $I_2(s)$ and $Br^-(aq)$

21.58 What is the value of the equilibrium constant for the reaction between each pair at 25°C?

(a) Ag(*s*) and $Mn^{2+}(aq)$ (b) $Cl_2(g)$ and $Br^-(aq)$

21.59 What is the value of the equilibrium constant for the reaction between each pair at 25°C?

(a) Cr(*s*) and $Cu^{2+}(aq)$ (b) Sn(*s*) and $Pb^{2+}(aq)$

21.60 Calculate ΔG° for each of the reactions in Problem 21.56.

21.61 Calculate ΔG° for each of the reactions in Problem 21.57.

21.62 Calculate ΔG° for each of the reactions in Problem 21.58.

21.63 Calculate ΔG° for each of the reactions in Problem 21.59.

21.64 What are E°_{cell} and ΔG° of a redox reaction at 25°C for which $n = 1$ and $K = 5.0\times10^4$?

21.65 What are E°_{cell} and ΔG° of a redox reaction at 25°C for which $n = 1$ and $K = 5.0\times10^{-6}$?

21.66 What are E°_{cell} and ΔG° of a redox reaction at 25°C for which $n = 2$ and $K = 65$?

21.67 What are E°_{cell} and ΔG° of a redox reaction at 25°C for which $n = 2$ and $K = 0.065$?

21.68 A voltaic cell consists of a standard reference half-cell and a Cu/Cu^{2+} half-cell. Calculate $[Cu^{2+}]$ when E_{cell} is 0.22 V.

21.69 A voltaic cell consists of an Mn/Mn^{2+} half-cell and a Pb/Pb^{2+} half-cell. Calculate $[Pb^{2+}]$ when $[Mn^{2+}]$ is 1.4 *M* and E_{cell} is 0.44 V.

21.70 A voltaic cell with Ni/Ni^{2+} and Co/Co^{2+} half-cells has the following initial concentrations: $[Ni^{2+}] = 0.80$ *M*; $[Co^{2+}] = 0.20$ *M*.

(a) What is the initial E_{cell}?

(b) What is $[Ni^{2+}]$ when E_{cell} reaches 0.03 V?

(c) What are the equilibrium concentrations of the ions?

21.71 A voltaic cell with Mn/Mn^{2+} and Cd/Cd^{2+} half-cells has the following initial concentrations: $[Mn^{2+}] = 0.090$ *M*; $[Cd^{2+}] = 0.060$ *M*.

(a) What is the initial E_{cell}?

(b) What is E_{cell} when $[Cd^{2+}]$ reaches 0.050 *M*?

(c) What is $[Mn^{2+}]$ when E_{cell} reaches 0.055 V?

(d) What are the equilibrium concentrations of the ions?

21.72 A voltaic cell consists of two H_2/H^+ half-cells. Half-cell A has H_2 at 0.95 atm bubbling into 0.10 *M* HCl. Half-cell B has H_2 at 0.60 atm bubbling into 2.0 *M* HCl. Which half-cell houses the anode? What is the voltage of the cell?

21.73 A voltaic cell consists of two Sn/Sn^{2+} half-cells, A and B. The electrolyte in A is 0.13 *M* $Sn(NO_3)_2$. The electrolyte in B is 0.87 *M* $Sn(NO_3)_2$. Which half-cell houses the cathode? What is the voltage of the cell?

Electrochemical Processes in Batteries

Concept Review Questions

21.74 What is the direction of electron flow with respect to the anode and the cathode in a battery? Explain.

21.75 In the everyday batteries used in flashlights, toys, and so forth, no salt bridge is evident. What is used in these cells to separate the anode and cathode compartments?

21.76 Both a D-sized and an AAA-sized alkaline battery have an output of 1.5 V. What property of the cell potential allows this to occur? What is different about these two batteries?

Problems in Context

21.77 Many common electrical devices require the use of more than one battery.
(a) How many alkaline batteries must be placed in series to light a flashlight with a 6.0-V bulb?
(b) What is the voltage requirement of a camera that uses six silver batteries?
(c) How many volts can a car battery deliver if two of its anode/cathode cells are shorted?

Corrosion: An Environmental Voltaic Cell

Concept Review Questions

21.78 During reconstruction of the Statue of Liberty, Teflon spacers were placed between the iron skeleton and the copper plates that cover the statue. What purpose do these spacers serve?

21.79 Why do steel bridge-supports rust at the waterline but not above or below it?

21.80 After the 1930s, chromium replaced nickel for corrosion resistance and appearance on car bumpers and trim. How does chromium protect steel from corrosion?

21.81 Which of the following metals are suitable for use as sacrificial anodes to protect against corrosion of underground iron pipes? If any are not suitable, explain why:
(a) Aluminum (b) Magnesium (c) Sodium (d) Lead
(e) Nickel (f) Zinc (g) Chromium

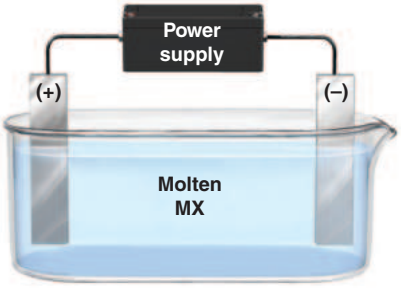
Electrolytic Cells: Using Electrical Energy to Drive Nonspontaneous Reactions

(Sample Problems 21.9 to 21.11)

Concept Review Questions

Note: Unless stated otherwise, assume that the electrolytic cells in the following problems operate at 100% efficiency.

21.82 Consider the following general electrolytic cell:



(a) At which electrode does oxidation occur?
(b) At which electrode does elemental M form?
(c) At which electrode are electrons being released by ions?
(d) At which electrode are electrons entering the cell?

21.83 A voltaic cell consists of Cr/Cr^{3+} and Cd/Cd^{2+} half-cells with all components in their standard states. After 10 minutes of operation, a thin coating of cadmium metal has plated out on the cathode. Describe what will happen if you attach the negative terminal of a dry cell (1.5 V) to the cell cathode and the positive terminal to the cell anode.

21.84 Why are $E_{\text{half-cell}}$ values for the oxidation and reduction of water different from $E^{\circ}_{\text{half-cell}}$ values for the same processes?

21.85 In an aqueous electrolytic cell, nitrate ions never react at the anode, but nitrite ions do. Explain.

21.86 How does overvoltage influence the products in the electrolysis of aqueous salts?

Skill-Building Exercises (grouped in similar pairs)

21.87 In the electrolysis of molten NaBr,
(a) What product forms at the anode?
(b) What product forms at the cathode?

21.88 In the electrolysis of molten BaI_2,
(a) What product forms at the negative electrode?
(b) What product forms at the positive electrode?

21.89 In the electrolysis of a molten mixture of KI and MgF_2, identify the product that forms at the anode and at the cathode.

21.90 In the electrolysis of a molten mixture of CsBr and $SrCl_2$, identify the product that forms at the negative electrode and at the positive electrode.

21.91 In the electrolysis of a molten mixture of NaCl and $CaBr_2$, identify the product that forms at the anode and at the cathode.

21.92 In the electrolysis of a molten mixture of RbF and $CaCl_2$, identify the product that forms at the negative electrode and at the positive electrode.

21.93 Which of the following elements can be prepared by electrolysis of their aqueous salts: copper, barium, aluminum, bromine?

21.94 Which of the following elements can be prepared by electrolysis of their aqueous salts: strontium, gold, tin, chlorine?

21.95 Which of the following elements can be prepared by electrolysis of their aqueous salts: lithium, iodine, zinc, silver?

21.96 Which of the following elements can be prepared by electrolysis of their aqueous salts: fluorine, manganese, iron, cadmium?

21.97 Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts: (a) LiF; (b) $SnSO_4$.

21.98 Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts: (a) $ZnBr_2$; (b) $Cu(HCO_3)_2$.

21.99 Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts: (a) $Cr(NO_3)_3$; (b) $MnCl_2$.

21.100 Write a balanced half-reaction for the product that forms at each electrode in the aqueous electrolysis of the following salts: (a) FeI_2; (b) K_3PO_4.

21.101 Electrolysis of molten $MgCl_2$ is the final production step in the isolation of magnesium from seawater by the Dow process (Section 22.4). Assuming that 45.6 g of Mg metal forms,
(a) How many moles of electrons are required?
(b) How many coulombs are required?
(c) How many amps will produce this amount in 3.50 h?

21.102 Electrolysis of molten NaCl in a Downs cell is the major isolation step in the production of sodium metal (Section 22.4). Assuming that 215 g of Na metal forms,
(a) How many moles of electrons are required?
(b) How many coulombs are required?
(c) How many amps will produce this amount in 9.50 h?

21.103 How many grams of radium can form by passing 235 C through an electrolytic cell containing a molten radium salt?

21.104 How many grams of aluminum can form by passing 305 C through an electrolytic cell containing a molten aluminum salt?

21.105 How many seconds does it take to deposit 65.5 g of Zn on a steel gate when 21.0 A is passed through a $ZnSO_4$ solution?

21.106 How many seconds does it take to deposit 1.63 g of Ni on a decorative drawer handle when 13.7 A is passed through a $Ni(NO_3)_2$ solution?

Problems in Context

21.107 A professor adds Na_2SO_4 to water to facilitate its electrolysis in a lecture demonstration. (a) What is the purpose of the Na_2SO_4? (b) Why is the water electrolyzed instead of the salt?

21.108 Subterranean brines in parts of the United States are rich in iodides and bromides and serve as an industrial source of these elements. In one recovery method, the brines are evaporated to dryness and then melted and electrolyzed. Which halogen is more likely to form from this treatment? Why?

21.109 Zinc plating (galvanizing) is an important means of corrosion protection. Although the process is done customarily by dipping the object into molten zinc, the metal can also be electroplated from aqueous solutions. How many grams of zinc can be deposited on a steel tank from a $ZnSO_4$ solution when a 0.855-A current flows for 2.50 days?

Comprehensive Problems

21.110 The MnO_2 used in alkaline batteries can be produced by an electrochemical process of which one half-reaction is

$$Mn^{2+}(aq) + 2H_2O(l) \longrightarrow MnO_2(s) + 4H^+(aq) + 2e^-$$

If a current of 25.0 A is used, how many hours are needed to produce 1.00 kg of MnO_2? At which electrode is the MnO_2 formed?

21.111 Car manufacturers are developing engines that use H_2 as fuel. In Iceland, Sweden, and other parts of Scandinavia, where hydroelectric plants produce inexpensive electric power, the H_2 can be made industrially by the electrolysis of water.
(a) How many coulombs are needed to produce 3.5×10^6 L of H_2 gas at 12.0 atm and 25°C? (Assume that the ideal gas law applies.)
(b) If the coulombs are supplied at 1.44 V, how many joules are produced?
(c) If the combustion of oil yields 4.0×10^4 kJ/kg, what mass of oil must be burned to yield the number of joules in part (b)?

21.112 The overall cell reaction occurring in an alkaline battery is

$$Zn(s) + MnO_2(s) + H_2O(l) \longrightarrow ZnO(s) + Mn(OH)_2(s)$$

(a) How many moles of electrons flow per mole of reaction?
(b) If 4.50 g of zinc is oxidized, how many grams of manganese dioxide and of water are consumed?
(c) What is the total mass of reactants consumed in part (b)?
(d) How many coulombs are produced in part (b)?
(e) In practice, voltaic cells of a given capacity (coulombs) are heavier than the calculation in part (c) indicates. Explain.

21.113 An inexpensive and accurate method of measuring the quantity of electricity flowing through a circuit is to pass the current through a solution of a metal ion and weigh the metal deposited. A silver electrode immersed in an Ag^+ solution weighs 1.7854 g before the current has passed and weighs 1.8016 g after the current has passed. How many coulombs have passed?

21.114 Brass, an alloy of copper and zinc, can be produced by simultaneously electroplating the two metals from a solution containing their 2+ ions. If 65.0% of the total current is used to plate copper, while 35.0% goes to plating zinc, what is the mass percent of copper in the brass?

21.115 A thin circular-disk earring 4.00 cm in diameter is plated with a coating of gold 0.25 mm thick from an Au^{3+} bath.
(a) How many days does it take to deposit the gold on one side of one earring if the current is 0.013 A (d of gold = 19.3 g/cm^3)?
(b) How many days does it take to deposit the gold on both sides of the pair of earrings?
(c) If the price of gold is \$1595 per troy ounce (31.10 g), what is the total cost of the gold plating?

21.116 (a) How many minutes does it take to form 10.0 L of O_2 measured at 99.8 kPa and 28°C from water if a current of 1.3 A passes through the electrolytic cell?
(b) What mass of H_2 forms?

21.117 Trains powered by electricity, including subways, use direct current. One conductor is the overhead wire (or "third rail" for subways), and the other is the rails upon which the wheels run. The rails are on supports in contact with the ground. To minimize corrosion, should the overhead wire or the rails be connected to the positive terminal? Explain.

21.118 A silver button battery used in a watch contains 0.75 g of zinc and can run until 80% of the zinc is consumed.
(a) For how many days can the battery produce a current of 0.85 microamps (10^{-6} amps)?
(b) When the battery dies, 95% of the Ag_2O has been consumed. How many grams of Ag were used to make the battery?
(c) If Ag costs \$23.00 per troy ounce (31.10 g), what is the cost of the Ag consumed each day the watch runs?

21.119 Like any piece of apparatus, an electrolytic cell operates at less than 100% efficiency. A cell depositing Cu from a Cu^{2+} bath operates for 10 h with an average current of 5.8 A. If 53.4 g of copper is deposited, at what efficiency is the cell operating?

21.120 Commercial electrolysis is performed on both molten NaCl and aqueous NaCl solutions. Identify the anode product, cathode product, species reduced, and species oxidized for the (a) molten electrolysis and (b) aqueous electrolysis.

21.121 To examine the effect of ion removal on cell voltage, a chemist constructs two voltaic cells, each with a standard hydrogen electrode in one compartment. One cell also contains a Pb/Pb^{2+} half-cell; the other contains a Cu/Cu^{2+} half-cell.
(a) What is $E°$ of each cell at 298 K?
(b) Which electrode in each cell is negative?
(c) When Na_2S solution is added to the Pb^{2+} electrolyte, solid PbS forms. What happens to the cell voltage?
(d) When sufficient Na_2S is added to the Cu^{2+} electrolyte, CuS forms and $[Cu^{2+}]$ drops to 1×10^{-16} M. Find the cell voltage.

21.122 Electrodes used in electrocardiography are disposable, and many of them incorporate silver. The metal is deposited in a thin layer on a small plastic "button," and then some is converted to AgCl:

$$Ag(s) + Cl^-(aq) \rightleftharpoons AgCl(s) + e^-$$

(a) If the surface area of the button is 2.0 cm^2 and the thickness of the silver layer is 7.5×10^{-6} m, calculate the volume (in cm^3) of Ag used in one electrode.
(b) The density of silver metal is 10.5 g/cm^3. How many grams of silver are used per electrode?
(c) If Ag is plated on the button from an Ag^+ solution with a current of 12.0 mA, how many minutes does the plating take?
(d) If bulk silver costs \$28.93 per troy ounce (31.10 g), what is the cost (in cents) of the silver in one disposable electrode?

21.123 Commercial aluminum production is done by electrolysis of a bath containing Al_2O_3 dissolved in molten Na_3AlF_6. Why isn't it done by electrolysis of an aqueous $AlCl_3$ solution?

21.124 Comparing the standard electrode potentials ($E°$) of the Group 1A(1) metals Li, Na, and K with the negative of their first ionization energies reveals a discrepancy:

Ionization process reversed: $M^+(g) + e^- \rightleftharpoons M(g)$ $(-IE)$

Electrode reaction: $M^+(aq) + e^- \rightleftharpoons M(s)$ $(E°)$

Metal	−IE (kJ/mol)	$E°$ (V)
Li	−520	−3.05
Na	−496	−2.71
K	−419	−2.93

Note that the electrode potentials do not decrease smoothly down the group, while the ionization energies do. You might expect that if it is more difficult to remove an electron from an atom to form a gaseous ion (larger IE), then it would be less difficult to add an electron to an aqueous ion to form an atom (smaller $E°$), yet $Li^+(aq)$ is *more* difficult to reduce than $Na^+(aq)$. Applying Hess's law, use an approach similar to a Born-Haber cycle to break down the process occurring at the electrode into three steps and label the energy involved in each step. How can you account for the discrepancy?

21.125 In Appendix D, standard electrode potentials range from about +3 V to −3 V. Thus, it might seem possible to use a half-cell from each end of this range to construct a cell with a voltage of approximately 6 V. However, most commercial aqueous voltaic cells have $E°$ values of 1.5–2 V. Why are there no aqueous cells with significantly higher potentials?

21.126 Tin is used to coat "tin" cans used for food storage. If the tin is scratched and the iron of the can exposed, will the iron corrode more or less rapidly than if the tin were not present? Inside the can, the tin itself is coated with a clear varnish. Explain.

21.127 Commercial electrolytic cells for producing aluminum operate at 5.0 V and 100,000 A.
(a) How long does it take to produce exactly 1 metric ton (1000 kg) of aluminum?
(b) How much electrical power (in kilowatt-hours, kW·h) is used (1 W = 1 J/s; 1 kW·h = 3.6×10^3 kJ)?
(c) If electricity costs \$0.123 per kW·h and cell efficiency is 90.%, what is the cost of electricity to produce exactly 1 lb of aluminum?

21.128 Magnesium bars are connected electrically to underground iron pipes to serve as sacrificial anodes.
(a) Do electrons flow from the bar to the pipe or the reverse?
(b) A 12-kg Mg bar is attached to an iron pipe, and it takes 8.5 yr for the Mg to be consumed. What is the average current flowing between the Mg and the Fe during this period?

21.129 Bubbles of H_2 form when metal D is placed in hot H_2O. No reaction occurs when D is placed in a solution of a salt of metal E, but D is discolored and coated immediately when placed in a solution of a salt of metal F. What happens if E is placed in a solution of a salt of metal F? Rank metals D, E, and F in order of *increasing* reducing strength.

21.130 In addition to reacting with gold (see Problem 21.21), aqua regia is used to bring other precious metals into solution. Balance the skeleton equation for the reaction with Pt:

$$Pt(s) + NO_3^-(aq) + Cl^-(aq) \longrightarrow PtCl_6^{2-}(aq) + NO(g)$$

21.131 The following reactions are used in batteries:

I $2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$ $E_{cell} = 1.23$ V

II $Pb(s) + PbO_2(s) + 2H_2SO_4(aq) \longrightarrow 2PbSO_4(s) + 2H_2O(l)$ $E_{cell} = 2.04$ V

III $2Na(l) + FeCl_2(s) \longrightarrow 2NaCl(s) + Fe(s)$ $E_{cell} = 2.35$ V

Reaction I is used in fuel cells, II in the automobile lead-acid battery, and III in an experimental high-temperature battery for powering electric vehicles. The aim is to obtain as much work as possible from a cell, while keeping its weight to a minimum.
(a) In each cell, find the moles of electrons transferred and ΔG.
(b) Calculate the ratio, in kJ/g, of w_{max} to mass of reactants for each of the cells. Which has the highest ratio, which the lowest, and why? (*Note:* For simplicity, ignore the masses of cell components that do not appear in the cell as reactants, including electrode materials, electrolytes, separators, cell casing, wiring, etc.)

21.132 A current is applied to two electrolytic cells in series. In the first, silver is deposited; in the second, a zinc electrode is consumed. How much Ag is plated out if 1.2 g of Zn dissolves?

21.133 You are investigating a particular chemical reaction. State all the types of data available in standard tables that enable you to calculate the equilibrium constant for the reaction at 298 K.

21.134 In an electric power plant, personnel monitor the O_2 content of boiler feed water to prevent corrosion of the boiler tubes. Why does Fe corrode faster in steam and hot water than in cold water?

21.135 A voltaic cell using Cu/Cu^{2+} and Sn/Sn^{2+} half-cells is set up at standard conditions, and each compartment has a volume of 345 mL. The cell delivers 0.17 A for 48.0 h. (a) How many grams of Cu(s) are deposited? (b) What is the $[Cu^{2+}]$ remaining?

21.136 If the E_{cell} of the following cell is 0.915 V, what is the pH in the anode compartment?

$$Pt(s) \mid H_2(1.00\ atm) \mid H^+(aq) \parallel Ag^+(0.100\ M) \mid Ag(s)$$

21.137 From the skeleton equations below, create a list of balanced half-reactions in which the strongest oxidizing agent is on top and the weakest is on the bottom:

$$U^{3+}(aq) + Cr^{3+}(aq) \longrightarrow Cr^{2+}(aq) + U^{4+}(aq)$$
$$Fe(s) + Sn^{2+}(aq) \longrightarrow Sn(s) + Fe^{2+}(aq)$$
$$Fe(s) + U^{4+}(aq) \longrightarrow \text{no reaction}$$
$$Cr^{3+}(aq) + Fe(s) \longrightarrow Cr^{2+}(aq) + Fe^{2+}(aq)$$
$$Cr^{2+}(aq) + Sn^{2+}(aq) \longrightarrow Sn(s) + Cr^{3+}(aq)$$

21.138 You are given the following three half-reactions:
(1) $Fe^{3+}(aq) + e^- \rightleftharpoons Fe^{2+}(aq)$
(2) $Fe^{2+}(aq) + 2e^- \rightleftharpoons Fe(s)$
(3) $Fe^{3+}(aq) + 3e^- \rightleftharpoons Fe(s)$
(a) Use $E^\circ_{\text{half-cell}}$ values for (1) and (2) to find $E^\circ_{\text{half-cell}}$ for (3).
(b) Calculate ΔG° for (1) and (2) from their $E^\circ_{\text{half-cell}}$ values.
(c) Calculate ΔG° for (3) from (1) and (2).
(d) Calculate $E^\circ_{\text{half-cell}}$ for (3) from its ΔG°.
(e) What is the relationship between the $E^\circ_{\text{half-cell}}$ values for (1) and (2) and the $E^\circ_{\text{half-cell}}$ value for (3)?

21.139 Use the half-reaction method to balance the equation for the conversion of ethanol to acetic acid in acid solution:

$$CH_3CH_2OH + Cr_2O_7^{2-} \longrightarrow CH_3COOH + Cr^{3+}$$

21.140 When zinc is refined by electrolysis, the desired half-reaction at the cathode is

$$Zn^{2+}(aq) + 2e^- \longrightarrow Zn(s)$$

A competing reaction, which lowers the yield, is the formation of hydrogen gas:

$$2H^+(aq) + 2e^- \longrightarrow H_2(g)$$

If 91.50% of the current flowing results in zinc being deposited, while 8.50% produces hydrogen gas, how many liters of H_2, measured at STP, form per kilogram of zinc?

21.141 A chemist designs an ion-specific probe for measuring $[Ag^+]$ in an NaCl solution saturated with AgCl. One half-cell has an Ag-wire electrode immersed in the unknown AgCl-saturated NaCl solution. It is connected through a salt bridge to the other half-cell, which has a calomel reference electrode [a platinum wire immersed in a paste of mercury and calomel (Hg_2Cl_2)] in a saturated KCl solution. The measured E_{cell} is 0.060 V.
(a) Given the following standard half-reactions, calculate $[Ag^+]$.

Calomel: $Hg_2Cl_2(s) + 2e^- \longrightarrow 2Hg(l) + 2Cl^-(aq)$ $\quad E^\circ = 0.24$ V

Silver: $Ag^+(aq) + e^- \longrightarrow Ag(s)$ $\quad E^\circ = 0.80$ V

(*Hint:* Assume that $[Cl^-]$ is so high that it is essentially constant.)
(b) A mining engineer wants an ore sample analyzed with the Ag^+-selective probe. After pretreating the ore sample, the chemist measures the cell voltage as 0.53 V. What is $[Ag^+]$?

21.142 Use Appendix D to calculate the K_{sp} of AgCl.

21.143 Black-and-white photographic film is coated with silver halides. Because silver is expensive, the manufacturer monitors the Ag^+ content of the waste stream, $[Ag^+]_{\text{waste}}$, from the plant with an Ag^+-selective electrode at 25°C. A stream of known Ag^+ concentration, $[Ag^+]_{\text{standard}}$, is passed over the electrode in turn with the waste stream and the data recorded by a computer.
(a) Write the equations relating the nonstandard cell potential to the standard cell potential and $[Ag^+]$ for each solution.
(b) Combine these into a single equation to find $[Ag^+]_{\text{waste}}$.
(c) Rewrite the equation from part (b) to find $[Ag^+]_{\text{waste}}$ in ng/L.
(d) If E_{waste} is 0.003 V higher than E_{standard}, and the standard solution contains 1000. ng/L, what is $[Ag^+]_{\text{waste}}$?
(e) Rewrite the equation from part (b) to find $[Ag^+]_{\text{waste}}$ for a system in which T changes and T_{waste} and T_{standard} may be different.

21.144 Calculate the K_f of $Ag(NH_3)_2^+$ from

$Ag^+(aq) + e^- \rightleftharpoons Ag(s)$ $\quad E^\circ = 0.80$ V

$Ag(NH_3)_2^+(aq) + e^- \rightleftharpoons Ag(s) + 2NH_3(aq)$ $\quad E^\circ = 0.37$ V

21.145 Even though the toxicity of cadmium has become a concern, nickel-cadmium (nicad) batteries are still used commonly in many devices. The overall cell reaction is

$$Cd(s) + 2NiO(OH)(s) + 2H_2O(l) \longrightarrow 2Ni(OH)(s) + Cd(OH)_2(s)$$

A certain nicad battery weighs 18.3 g and has a capacity of 300. mA·h (that is, the cell can store charge equivalent to a current of 300. mA flowing for 1 h).
(a) What is the capacity of this cell in coulombs?
(b) What mass of reactants is needed to deliver 300. mA·h?
(c) What percentage of the cell mass consists of reactants?

21.146 The zinc-air battery is a less expensive alternative to silver batteries for use in hearing aids. The cell reaction is

$$2Zn(s) + O_2(g) \longrightarrow 2ZnO(s)$$

A new battery weighs 0.275 g. The zinc accounts for exactly $\frac{1}{10}$ of the mass, and the oxygen does not contribute to the mass because it is supplied by the air.
(a) How much electricity (in C) can the battery deliver?
(b) How much free energy (in J) is released if E_{cell} is 1.3 V?

21.147 Use Appendix D to create an activity series of Mn, Fe, Ag, Sn, Cr, Cu, Ba, Al, Na, Hg, Ni, Li, Au, Zn, and Pb. Rank these metals in order of decreasing reducing strength, and divide them into three groups: those that displace H_2 from water, those that displace H_2 from acid, and those that cannot displace H_2.

21.148 Both Ti and V are reactive enough to displace H_2 from water. The difference in their $E^\circ_{\text{half-cell}}$ values is 0.43 V. Given

$$V(s) + Cu^{2+}(aq) \longrightarrow V^{2+}(aq) + Cu(s) \quad \Delta G^\circ = -298 \text{ kJ/mol}$$

use Appendix D to calculate the $E^\circ_{\text{half-cell}}$ values for V and Ti.

21.149 For the reaction

$$S_4O_6^{2-}(aq) + 2I^-(aq) \longrightarrow I_2(s) + S_2O_3^{2-}(aq) \quad \Delta G^\circ = 87.8 \text{ kJ/mol}$$

(a) Identify the oxidizing and reducing agents. (b) Calculate E°_{cell}.
(c) For the reduction half-reaction, write a balanced equation, give the oxidation number of each element, and calculate $E^\circ_{\text{half-cell}}$.

21.150 Two concentration cells are prepared, both with 90.0 mL of 0.0100 *M* $Cu(NO_3)_2$ and a Cu bar in each half-cell.
(a) In the first concentration cell, 10.0 mL of 0.500 *M* NH_3 is added to one half-cell; the complex ion $Cu(NH_3)_4^{2+}$ forms, and E_{cell} is 0.129 V. Calculate K_f for the formation of the complex ion.
(b) Calculate E_{cell} when an additional 10.0 mL of 0.500 *M* NH_3 is added.
(c) In the second concentration cell, 10.0 mL of 0.500 *M* NaOH is added to one half-cell; the precipitate $Cu(OH)_2$ forms ($K_{sp} = 2.2\times10^{-20}$). Calculate E°_{cell}.
(d) What would the molarity of NaOH have to be for the addition of 10.0 mL to result in an E°_{cell} of 0.340 V?

21.151 Two voltaic cells are to be joined so that one will run the other as an electrolytic cell. In the first cell, one half-cell has Au foil in 1.00 *M* $Au(NO_3)_3$, and the other half-cell has a Cr bar in 1.00 *M* $Cr(NO_3)_3$. In the second cell, one half-cell has a Co bar in 1.00 *M* $Co(NO_3)_2$, and the other half-cell has a Zn bar in 1.00 *M* $Zn(NO_3)_2$.
(a) Calculate E°_{cell} for each cell.
(b) Calculate the total potential if the two cells are connected as voltaic cells in series.
(c) When the electrode wires are switched in one of the cells, which cell will run as the voltaic cell and which as the electrolytic cell?
(d) Which metal ion is being reduced in each cell?
(e) If 2.00 g of metal plates out in the voltaic cell, how much metal ion plates out in the electrolytic cell?

21.152 A voltaic cell has one half-cell with a Cu bar in a 1.00 *M* Cu^{2+} salt, and the other half-cell with a Cd bar in the same volume of a 1.00 *M* Cd^{2+} salt.
(a) Find E°_{cell}, ΔG°, and *K*.
(b) As the cell operates, $[Cd^{2+}]$ increases; find E_{cell} and ΔG when $[Cd^{2+}]$ is 1.95 *M*.
(c) Find E_{cell}, ΔG, and $[Cu^{2+}]$ at equilibrium.

21.153 Gasoline is a mixture of hydrocarbons, but the heat released when it burns is close to that of octane, $C_8H_{18}(l)$ ($\Delta H^\circ_f = -250.1$ kJ/mol). Research is underway to use H_2 from the electrolysis of water in fuel cells to power cars instead of gasoline.
(a) Calculate ΔH° when 1.00 gal of gasoline ($d = 0.7028$ g/mL) burns to produce carbon dioxide gas and water vapor.
(b) How many liters of H_2 at 25°C and 1.00 atm must burn to produce this quantity of energy?
(c) How long would it take to produce this amount of H_2 by electrolysis with a current of 1.00×10^3 A at 6.00 V?
(d) How much power in kilowatt-hours (kW·h) is required to generate this amount of H_2? (1 W = 1 J/s, 1 J = 1 C·V, and 1 kW·h = 3.6×10^6 J.)
(e) If the cell is 88.0% efficient and electricity costs \$0.123 per kW·h, what is the cost of producing the amount of H_2 equivalent to 1.00 gal of gasoline?

Concepts and Skills to Review Before You Study This Chapter

- trends in atomic properties (Sections 8.3, 8.4, 9.2, and 9.5)
- catalysts and reaction rate (Section 16.7)
- Le Châtelier's principle (Section 17.6)
- acid-base equilibria (Sections 18.3 and 18.4)
- solubility and complex-ion equilibria (Sections 19.3 and 19.4)
- temperature and reaction spontaneity (Section 20.3)
- free energy and equilibrium (Section 20.4)
- standard electrode potentials (Section 21.3)
- electrolysis of molten salts and aqueous salt solutions (Section 21.7)

Humans have been removing elements from Earth since prehistoric times. One far more recent example of such extraction is the Bingham Canyon Open Pit Copper Mine *(photo)*, southwest of Salt Lake City, Utah, which has grown since 1906 to become one of the largest mineral mines in the world: it is readily visible from space! Every year, this mine produces approximately 275,000 metric tons (t; 1 t = 1000 kg) of copper, along with 12.5 t of gold, 125 t of silver, and 9,100 t of molybdenum.

In this chapter, we return to the periodic table, but now we consider these practical questions about the elements: how much of an element is present in nature, in what form does it occur, how do organisms affect its distribution, and how do we isolate and use it?

IN THIS CHAPTER . . . *We examine the distribution of elements on Earth and the natural cycles of three key elements. Then, we apply concepts of kinetics, equilibrium, thermodynamics, and electrochemistry from previous chapters to explain the methods we have developed to extract, purify, and utilize several important elements.*

- We identify the abundances and sources of elements in the various regions of Earth.
- We consider how three essential elements—carbon, nitrogen, and phosphorus—cycle through the environment and focus on how humans influence these processes.
- We focus on the isolation and purification of metals, discussing general redox and metallurgical procedures for extracting an element from its ore.
- We examine in detail the isolation and uses of seven key elements: sodium, potassium, iron, copper, aluminum, magnesium, and hydrogen.
- We take a close look at two of the most important processes in chemical manufacturing: the production of sulfuric acid and the isolation of chlorine.

22.1 HOW THE ELEMENTS OCCUR IN NATURE

To begin our examination of how we use the elements, let's take inventory of our elemental stock—the distribution and relative amounts of the elements on Earth, especially that thin outer portion of our planet that we can reach.

Earth's Structure and the Abundance of the Elements

Any attempt to isolate an element must begin with a knowledge of its **abundance,** the amount of the element in a particular region of the natural world. The abundances of the elements result from details of our planet's evolution.

Formation and Layering of Earth About 4.5 billion years ago, vast clouds of cold gases and interstellar debris from exploded older stars gradually coalesced into the Sun and planets. At first, Earth was a cold, solid sphere of uniformly distributed elements and simple compounds. In the next billion years or so, heat from radioactive decay and continuous meteor impacts raised the planet's temperature to around 10^4 K, sufficient to form an enormous molten mass. Any remaining gaseous elements, such as the cosmically abundant, very light hydrogen and helium, were lost to space.

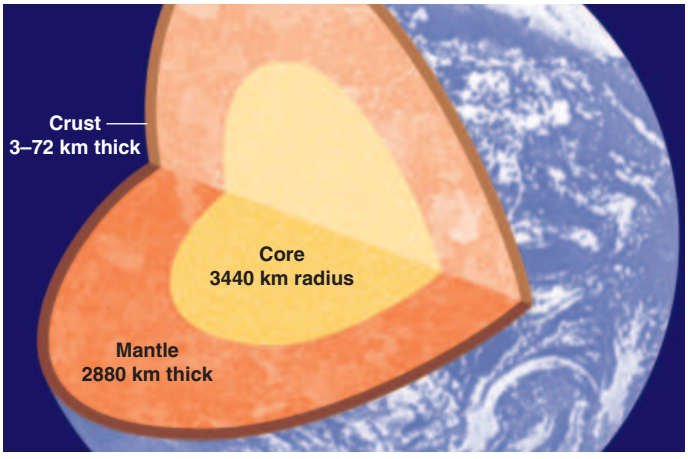

Figure 22.1 The layered internal structure of Earth.

As Earth cooled, chemical and physical processes resulted in its **differentiation,** the formation of regions of different composition and density. Differentiation gave Earth an internal structure consisting of three layers (Figure 22.1):

- The dense **core** (d = 10–15 g/cm^3) is composed of a molten outer core and a solid Moon-sized inner core. Remarkably, the inner core is nearly as hot as the surface of the Sun and spins within the molten outer core slightly faster than Earth itself does!
- The thick, homogeneous **mantle** lying around the core has an overall density of 4–6 g/cm^3.
- A thin, homogeneous **crust** lies on top of the mantle. The average density of the crust, on which all the comings and goings of life take place, is 2.8 g/cm^3.

Table 22.1 compares the abundance of some key elements in the universe, the whole Earth (actually core plus mantle only, which account for more than 99% of Earth's mass), and Earth's three regions. (Because the deepest terrestrial sampling can penetrate only a few kilometers into the crust, some of these data represent extrapolations from meteor samples and from seismic studies of earthquakes.) Several points stand out:

- Cosmic and whole-Earth abundances are very different, particularly for H and He; these two elements account for the majority of the mass of the universe but are not abundant in elemental form on Earth.

Table 22.1 Cosmic and Terrestrial Abundances (Mass %) of Selected Elements*

Element	Universe	Earth	Crust	Mantle	Core
O	1.07	29.5	49.5	43.7	—
Si	0.06	15.2	25.7	21.6	—
Al	—	1.1	7.5	1.8	—
Fe	0.19	34.6	4.7	13.3	88.6
Ca	0.007	1.1	3.4	2.1	—
Mg	0.06	12.7	2.8	16.6	—
Na	—	0.6	2.6	0.8	—
K	—	0.07	2.4	0.2	—
H	73.9	—	0.87	—	—
Ti	—	0.05	0.58	0.18	0.01
Cl	—	—	0.19	—	—
P	—	—	0.12	—	—
Mn	—	—	0.09	—	—
C	0.46	—	0.08	—	—
S	0.04	1.9	0.06	>2	—
Ni	0.006	2.4	0.008	0.3	8.5
Co	—	0.13	0.003	0.04	0.6
He	24.0	—	—	—	—

*A missing abundance value indicates either that reliable data are not available or that the value is less than 0.001% by mass.

- The elements O, Si, Fe, and Mg are abundant both cosmically and on Earth. Together, they account for more than 90% of Earth's mass.
- The core is particularly rich in the dense Group 8B(8) through 8B(10) metals: Co, Ni, and especially Fe, the most abundant element in the whole Earth.
- Crustal abundances are very different from whole-Earth abundances. The crust makes up only 0.4% of Earth's mass, but has the largest share of nonmetals, metalloids, and light, active metals: Al, Ca, Na, and K. The mantle contains much smaller proportions of these, and the core has none. Oxygen is the most abundant element in the crust and mantle but is absent from the core.

These differences in Earth's major layers arose from the effects of thermal energy. When Earth was molten, gravity and convection caused more dense materials to sink and less dense materials to rise, yielding several compositional *phases:*

- Most of the Fe sank to form the core, or *iron phase.*
- In the light outer phase, oxygen combined with Si, Al, Mg, and some Fe to form silicates, the material of rocks. This *silicate phase* later separated into the mantle and crust.
- The *sulfide phase,* intermediate in density and insoluble in the other two, consisted mostly of iron sulfide and mixed with parts of the silicate phase above and the iron phase below.
- The thin, primitive atmosphere, probably a mixture of water vapor (which gave rise to the oceans), carbon monoxide, and nitrogen (or ammonia), was produced by *outgassing* (the expulsion of trapped gases).

The distribution of the remaining elements (discussed here using only the new periodic table group numbers) was controlled by their chemical affinity for one of the three phases. In general terms, as Figure 22.2 shows:

- Elements with low or high electronegativity—active metals (those in Groups 1 through 5, Cr, and Mn) and nonmetals (O, lighter members of Groups 13 to 15, and all of Group 17)—tended to congregate in the silicate phase as ionic compounds.
- Metals with intermediate electronegativities (many from Groups 6 to 10) dissolved in the iron phase.
- Lower-melting transition metals and many metals and metalloids in Groups 11 to 16 became concentrated in the sulfide phase.

B Fossil of early multicellular organism

Figure 22.3 Ancient effects of an O_2-rich atmosphere.

The Impact of Life on Crustal Abundances At present, the crust is the only physically accessible portion of Earth, so only crustal abundances have practical significance. The crust is divided into the **lithosphere** (the solid region of the crust), **hydrosphere** (the liquid region), and **atmosphere** (the gaseous region). Over billions of years, weathering and volcanic upsurges have dramatically altered the composition of the crust. The **biosphere,** which consists of the living systems that have inhabited the planet, has been another *major influence on crustal element composition and distribution.*

When the earliest rocks were forming and the ocean basins were filling with water, binary inorganic molecules in the atmosphere were reacting to form first simple, and then more complex, organic molecules. The energy for these (mostly) endothermic changes was supplied by lightning, solar radiation, geologic heating, and meteoric impact. In an amazingly short period of time, probably no more than 500 million years, the first organisms appeared. It took less than another billion years for these to evolve into simple algae that could derive metabolic energy from photosynthesis, converting CO_2 and H_2O into organic molecules and releasing O_2 as a byproduct.

Let's look at some of the essential ways the evolution of organisms affected the chemistry of the crust:

1. *Increase in O_2.* Due to photosynthesis, the atmosphere gradually became richer in O_2 over the 300 million years following the emergence of algae. Thus, *oxidation became the major source of free energy in the crust and biosphere*. As a result of this oxidizing environment, the predominating Fe(II)-containing minerals were oxidized to Fe(III)-containing minerals, such as hematite, Fe_2O_3, shown in Figure 22.3A in ancient banded-iron formations (red beds). The increase in oxygen also led to an explosion of O_2-utilizing life forms, a few of which evolved into the organisms of today. Figure 22.3B shows a fossil of one of the multicellular organisms whose appearance coincided with the increase in O_2.

2. *K^+ vs. Na^+.* The K^+ concentration of the oceans is much lower than the Na^+ concentration. Forming over eons from outgassed water vapor condensing into rain and streaming over the land, the oceans became complex ionic solutions with 30 times as much Na^+ as K^+. One reason for this is that plants require K^+ for growth, so they absorbed dissolved K^+ that would otherwise have washed down to the sea.

3. *Buried organic carbon*. Enormous subterranean deposits of organic carbon formed when ancient plants, buried deeply and decomposing under high pressure and temperature in the absence of free O_2, gradually turned into coal. Animals buried under similar conditions turned into petroleum. Crustal deposits of this organic carbon provide the fuels that move our cars, heat our homes, and electrify our cities.

Dolomite Mountains, Italy.

4. *Fossilized $CaCO_3$.* Carbon and oxygen, together with calcium, the fifth most abundant element in the crust, occur in vast sedimentary deposits all over the world as limestone, dolomite *(see photo),* marble, and chalk, all of which are the fossilized skeletal remains of countless early marine organisms.

Table 22.2 compares selected elemental abundances in the whole crust, the three crustal regions, and the human body, a representative portion of the biosphere. Note the quantities of the four major elements of life—O, C, H, and N. Oxygen is either the first or second most abundant element in all cases. The biosphere contains large amounts of carbon in its biomolecules and large amounts of hydrogen as water. Nitrogen is abundant in the atmosphere as free N_2 and in organisms as part of their proteins. Phosphorus and sulfur also occur in high amounts in organisms.

One striking difference among the lithosphere, hydrosphere, and biosphere (human) is in the abundances of the transition metals vanadium through zinc. Their relatively insoluble oxides and sulfides make them much scarcer in water than on land. Yet organisms, which evolved in the seas, developed the ability to concentrate the trace amounts of these elements present in their aqueous environment. In every case, the biological concentration is at least 100 times the concentration in the hydrosphere, with Mn increasing about 1000-fold, and Cu, Zn, and Fe even more. These elements perform essential roles in living systems (see Chemical Connections, pp. 1043–1044).

Table 22.2 Abundances of Selected Elements in the Crust, Its Regions, and the Human Body as Representative of the Biosphere (Mass %)

		Crustal Regions			
Element	**Crust**	**Lithosphere**	**Hydrosphere**	**Atmosphere**	**Human**
O	49.5	45.5	85.8	23.0	65.0

Sources of the Elements

Given an element's abundance in a region of the crust, we must determine its **occurrence,** or **source,** the form(s) in which the element exists. Practical considerations often determine the commercial source. Oxygen, for example, is abundant in all three crustal regions, but the atmosphere is its primary industrial source because it occurs there as the free element. Nitrogen and the noble gases (except helium) are also obtained from the atmosphere. Several other elements occur uncombined, formed in large deposits by prehistoric biological action, such as sulfur in caprock salt domes and nearly pure carbon in coal. The relatively unreactive elements gold and platinum also occur in an uncombined *(native)* state.

The overwhelming majority of elements, however, occur in **ores,** natural compounds or mixtures from which an element can be extracted economically *(see photo): the financial costs of mining, isolating, and purifying must be considered when choosing a process to obtain an element.*

Figure 22.4 on the next page shows the most useful sources of the elements. Note that elements with the same types of ores tend to be grouped together in the periodic table:

- Alkali metal halides are ores for both of their component groups of elements, Group 1A(1) and Group 7A(17).
- Group 2A(2) metals occur as carbonates in the marble and limestone of mountain ranges, although magnesium is very abundant in seawater (making that the preferred source, as we discuss later).
- Even though many elements occur as silicates, most of these compounds are very stable thermodynamically. Thus, the cost that would be required to process them prohibits their use—aside from silicon, only lithium and beryllium are obtained from their silicates.
- The ores of most industrially important metals are either oxides, which dominate the left half of the transition series, or sulfides, which dominate the right half of the transition series and a few of the main groups beyond.

Deposit of borate (tufa), the ore of boron.

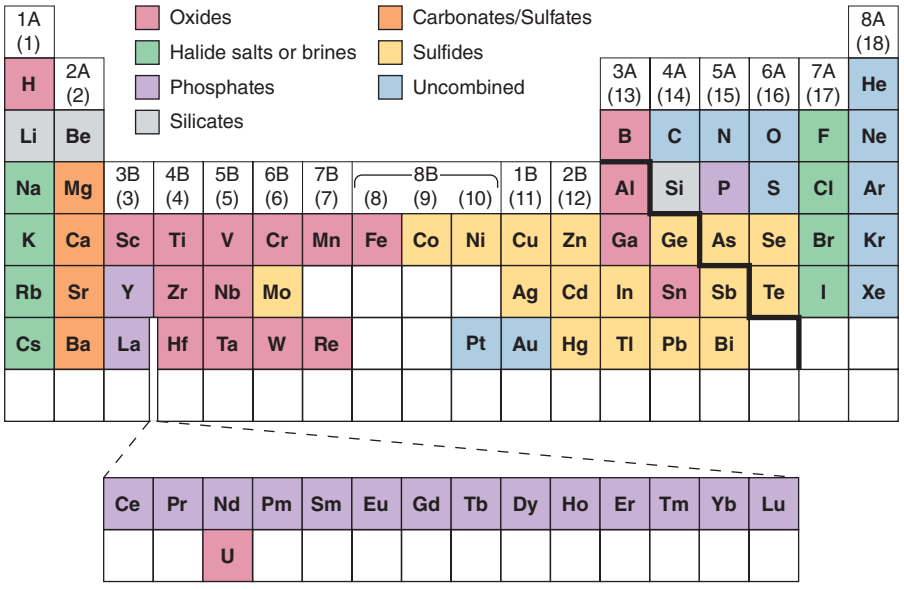

Figure 22.4 Sources of the elements.

The reasons for the prominence of oxide and sulfide ores of metallic elements are complex and include weathering processes, selective precipitation (Section 19.3), and relative solubilities. Certain atomic properties are relevant as well. Metals toward the left side of the periodic table have lower ionization energies and electronegativities, so they tend to give up electrons or hold them loosely in bonds. The O^{2-} ion is small enough to approach a metal cation closely, which results in a high lattice energy for the oxide. In contrast, metals toward the right side have higher ionization energies and electronegativities. Thus, they tend to form bonds that are more covalent, which suits the larger, more polarizable S^{2-} ion.

Summary of Section 22.1

- As the young Earth cooled, the elements became differentiated into a dense metallic core, a silicate-rich mantle, and a low-density crust.
- High abundances of light metals, metalloids, and nonmetals are concentrated in the crust, which consists of three regions: lithosphere (solid), hydrosphere (liquid), and atmosphere (gaseous).
- The biosphere (living systems) profoundly affected crustal chemistry by producing free O_2, and thus an oxidizing environment.
- Some elements occur in their native state, but most are combined in ores. The ores of most important metallic elements are oxides or sulfides.

22.2 THE CYCLING OF ELEMENTS THROUGH THE ENVIRONMENT

The distributions of many elements change at widely differing rates. The physical, chemical, and biological paths that atoms of an element take through the three regions of the crust—atmosphere, hydrosphere, and lithosphere—constitute the element's **environmental cycle.** In this section, we consider the cycles for carbon, nitrogen, and phosphorus and highlight the effects of humans on them.

The Carbon Cycle

Carbon is one of a handful of elements that appear in all three portions of Earth's crust. In the lithosphere, it occurs in elemental form as graphite and diamond, in fully oxidized form in carbonate minerals, in fully reduced form in petroleum hydrocarbons,

and in complex mixtures, such as coal and living matter. In the hydrosphere, it occurs in living matter, in carbonate minerals formed by the action of coral-reef organisms, and in dissolved CO_2 and related oxoanions. In the atmosphere, it occurs principally in gaseous CO_2, a minor (0.04%) but essential component that exists in equilibrium with the aqueous fraction.

Key Interactions Within the Cycle Figure 22.5 depicts the complex interplay of sources and the effect of the biosphere on carbon's environmental cycle. It provides an estimate of the size of each source and, where possible, the amount of carbon moving annually between sources. Note these key points:

- The portions of the cycle are linked by the atmosphere—one link between oceans and air, the other between land and air. The 2.6×10^{12} metric tons of CO_2 in air cycles through the oceans and atmosphere about once every 300 years but spends a much longer time in carbonate minerals.
- Atmospheric CO_2 accounts for only 0.04% of crustal carbon but moves the element through the other regions. A CO_2 molecule spends, on average, 3.5 years in the atmosphere.
- The land and oceans are in contact with the largest sources of carbon, immobilized as carbonates, coal, and oil in rocky sediment beneath the soil.

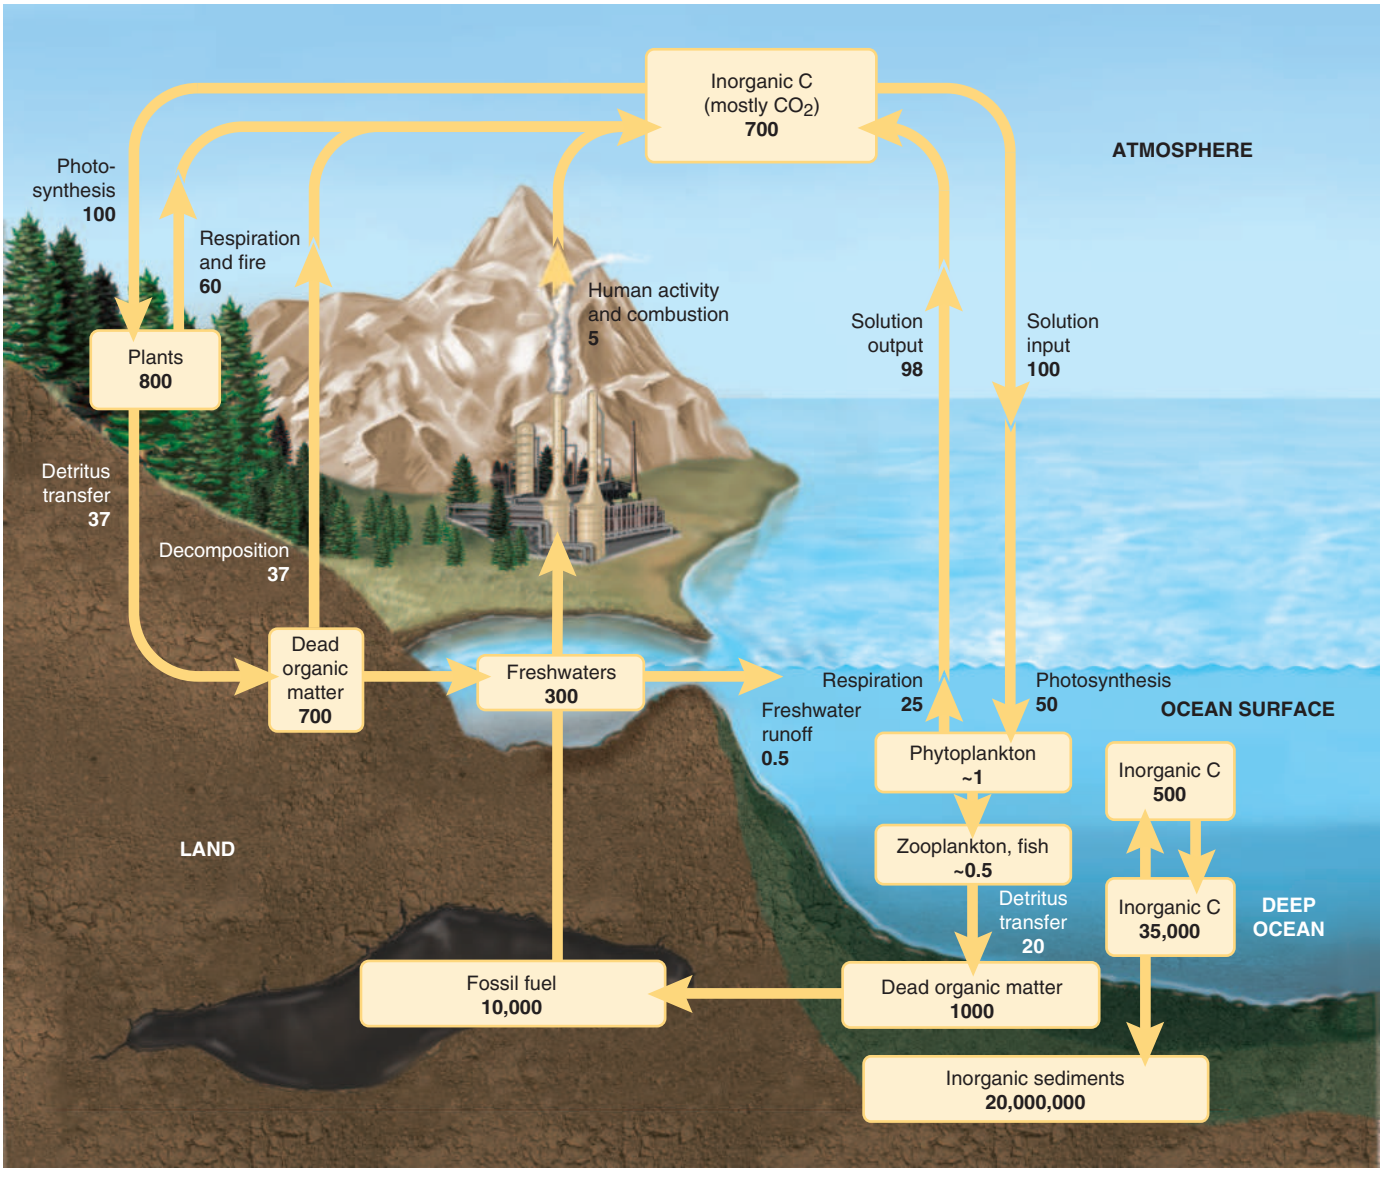

Figure 22.5 The carbon cycle. Numbers in boxes refer to the size of the source; numbers along arrows refer to the annual movement of the element from source to source. Both sets of values are in 10^9 t of C (1 t = 1000 kg = 1.1 tons).

- *Photosynthesis, respiration,* and *decomposition* are major factors in the cycle. **Fixation** is the process of converting a gaseous substance into a condensed form. Via photosynthesis, marine plankton and terrestrial plants use sunlight to fix atmospheric CO_2 into carbohydrates. Plants release CO_2 by respiration at night and, much more slowly, when they decompose. Animals eat the plants and release CO_2 by respiration and decomposition.
- Fires and volcanoes also release CO_2 into the air.

Buildup of CO_2 and Global Warming For hundreds of millions of years, the cycle maintained a relatively constant amount of atmospheric CO_2, resulting in a relatively constant planetary temperature range. But over the past century and a half, and especially since World War II, atmospheric CO_2 has increased. The principal cause is the combustion of coal, wood, and oil for fuel and for the decomposition of limestone to make cement, coupled with the clearing of forest and jungle for lumber, paper, and agriculture. And the principal effect is climate change. The 1990s and 2000s were the hottest decades ever recorded, and 2011 and 2012 continued this trend. Overwhelming evidence is showing that these activities have led to global warming through the greenhouse effect (see Chemical Connections, pp. 273–277). Higher temperatures, alterations in dry and rainy seasons, melting of polar ice, and increasing ocean acidity, with associated changes in carbonate equilibria, are clearly occurring. Nearly all science policy experts are pressing for programs that combine conservation of carbon-based fuels, an end to deforestation, and development of alternative energy sources.

The Nitrogen Cycle

In contrast to the carbon cycle, the nitrogen cycle includes a *direct* interaction between land and sea (Figure 22.6). All nitrites and nitrates are soluble, so rain and runoff

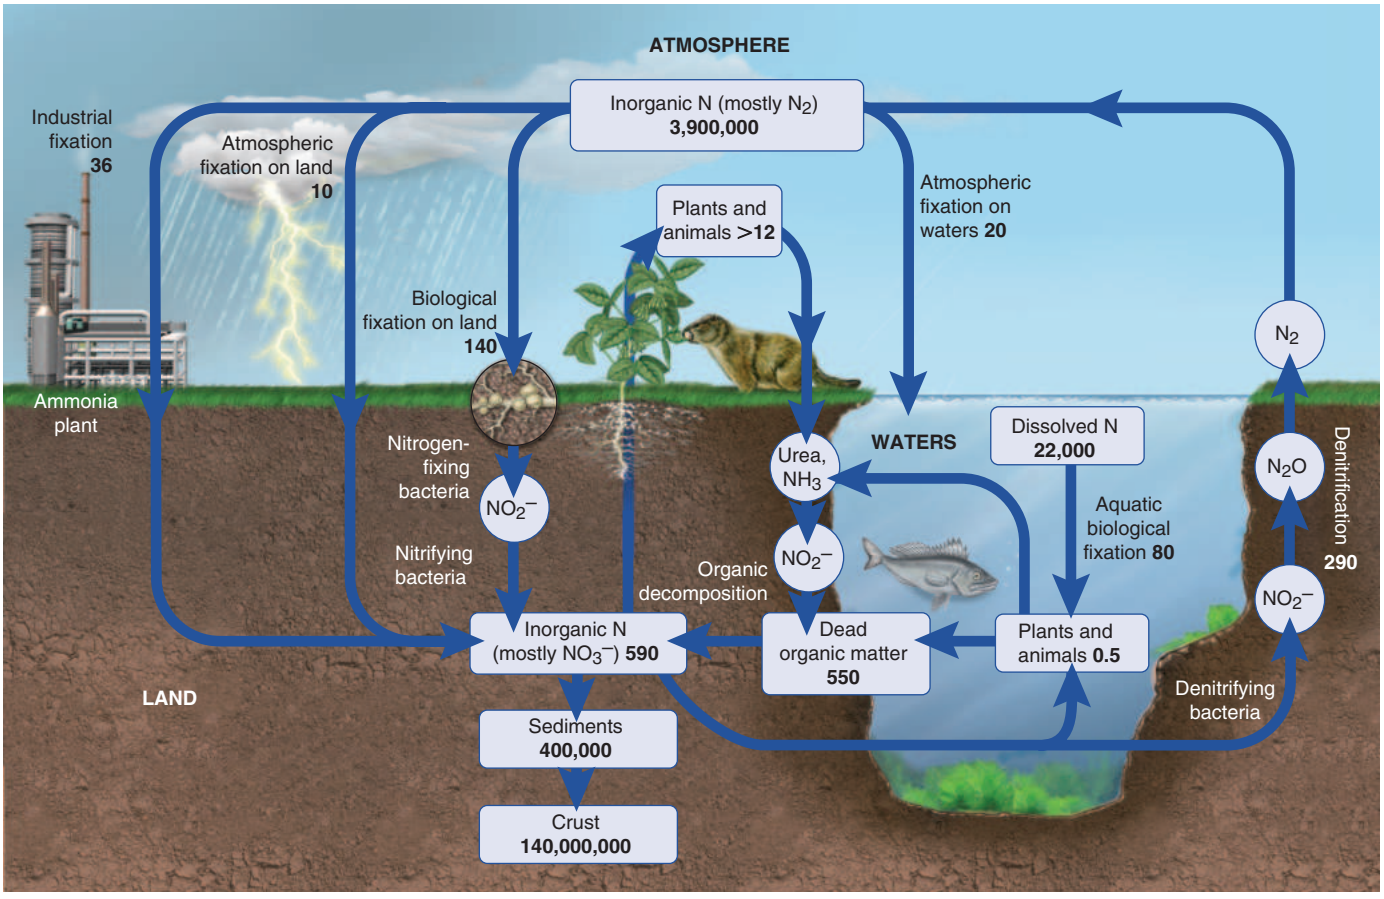

Figure 22.6 The nitrogen cycle. Numbers in boxes are in 10^9 metric tons of N and refer to the size of the source; numbers along arrows are in 10^6 metric tons of N and refer to the annual movement of the element between sources.

from the land contribute huge amounts of nitrogen to lakes, rivers, and oceans. Human activity, through the use of fertilizer, plays a major role in this cycle.

Like carbon dioxide, atmospheric nitrogen must be fixed. However, whereas CO_2 can be incorporated by plants in either its gaseous or aqueous form, the great stability of N_2 prevents plants from using it directly. Fixation of N_2 requires a great deal of energy and occurs through atmospheric, industrial, and biological processes.

Atmospheric Fixation Lightning causes the high-temperature endothermic reaction of N_2 and O_2 to form NO, which is then oxidized by ozone exothermically to NO_2:

$$N_2(g) + O_2(g) \longrightarrow 2NO(g) \qquad \Delta H^\circ = 180.6 \text{ kJ}$$
$$NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g) \qquad \Delta H^\circ = -200.1 \text{ kJ}$$

During the day, NO_2 reacts with hydroxyl radical to form HNO_3:

$$NO_2(g) + HO\cdot(g) \longrightarrow HNO_3(g)$$

At night, a multistep reaction between NO_2 and ozone is involved. In either case, rain dissociates the nitric acid, and $NO_3^-(aq)$ enters both sea and land to be utilized by plants.

Industrial Fixation Most human-caused fixation occurs industrially during ammonia synthesis via the Haber process (Chapter 17, pp. 763–764):

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$$

The process takes place on an enormous scale and NH_3 ranks first, on a mole basis, among compounds produced industrially. Some of this NH_3 is converted to HNO_3 in the Ostwald process (Chapter 14, p. 593), but most is used as fertilizer, either directly or in the form of urea and ammonium salts (sulfate, phosphate, and nitrate), which enter the biosphere when taken up by plants (as discussed in the next subsection).

In recent decades, high-temperature combustion in electric power plants and in car, truck, and plane engines has become an important contributor to total fixed nitrogen. High engine operating temperatures mimic lightning to form NO from the N_2 and O_2 in the air taken in to burn the hydrocarbon fuel. The NO in exhaust gases reacts to form nitric acid in the atmosphere, which adds to the nitrate load that reaches the ground.

The overuse of fertilizers *and* automobiles presents an increasingly serious water pollution problem in many areas. Leaching of the land by rain causes nitrate from fertilizer use and vehicle operation to enter lakes, rivers, and coastal estuaries and leads to *eutrophication,* the depletion of O_2 and the death of aquatic animal life from excessive algal and plant growth and decomposition. Excess nitrate also spoils nearby drinkable water.

Biological Fixation The biological fixation of atmospheric N_2 occurs in blue-green algae and in nitrogen-fixing bacteria that live on the roots of leguminous plants (such as peas, alfalfa, and clover). These microbial processes dwarf the previous two, fixing more than seven times as much nitrogen as the atmosphere and six times as much as industry. Root bacteria fix N_2 by enzymatically reducing it to NH_3 and NH_4^+. Enzymes in other soil bacteria catalyze the multistep oxidation of NH_4^+ to NO_2^- and finally NO_3^-, which the plants reduce again to make proteins. When the plants die, still other soil bacteria oxidize the proteins to NO_3^-.

Animals eat the plants, break down the plant proteins to make their own proteins, and excrete nitrogenous wastes, such as urea $[(H_2N)_2C{=}O]$. The nitrogen in the proteins is released when the animals die and decompose, and is converted by soil bacteria to NO_2^- and NO_3^- again. This central pool of inorganic nitrate has three main fates: some enters marine and terrestrial plants, some enters the enormous sediment store of mineral nitrates, and some is reduced by denitrifying bacteria to NO_2^- and then reduced further to N_2O and N_2, which re-enter the atmosphere to complete the cycle.

The Phosphorus Cycle

Virtually all the mineral sources of phosphorus contain the phosphate group, PO_4^{3-}. The most commercially important ores are **apatites,** compounds of general formula $Ca_5(PO_4)_3X$, where X is usually F, Cl, or OH. The cycling of phosphorus through the environment involves three interlocking subcycles (Figure 22.7). Two rapid biological cycles—a land-based cycle *(yellow arrows in figure)* completed in a matter of years and a water-based cycle *(blue arrows)* completed in weeks to years—are superimposed on an inorganic cycle *(pink arrows)* that takes millions of years to complete. Unlike the carbon and nitrogen cycles, the phosphorus cycle has no gaseous component and thus does *not* involve the atmosphere.

The Inorganic Cycle Although most phosphorus occurs in phosphate rock formed when Earth's lithosphere solidified, a sizeable amount has come from outer space in meteorites. About 100 metric tons of meteorites enter Earth's atmosphere every day, and with an average P content of 0.1% by mass, they have contributed about 10^{11} metric tons of phosphorus to the crust over Earth's lifetime. The most important components of phosphate rock are nearly insoluble phosphate salts:

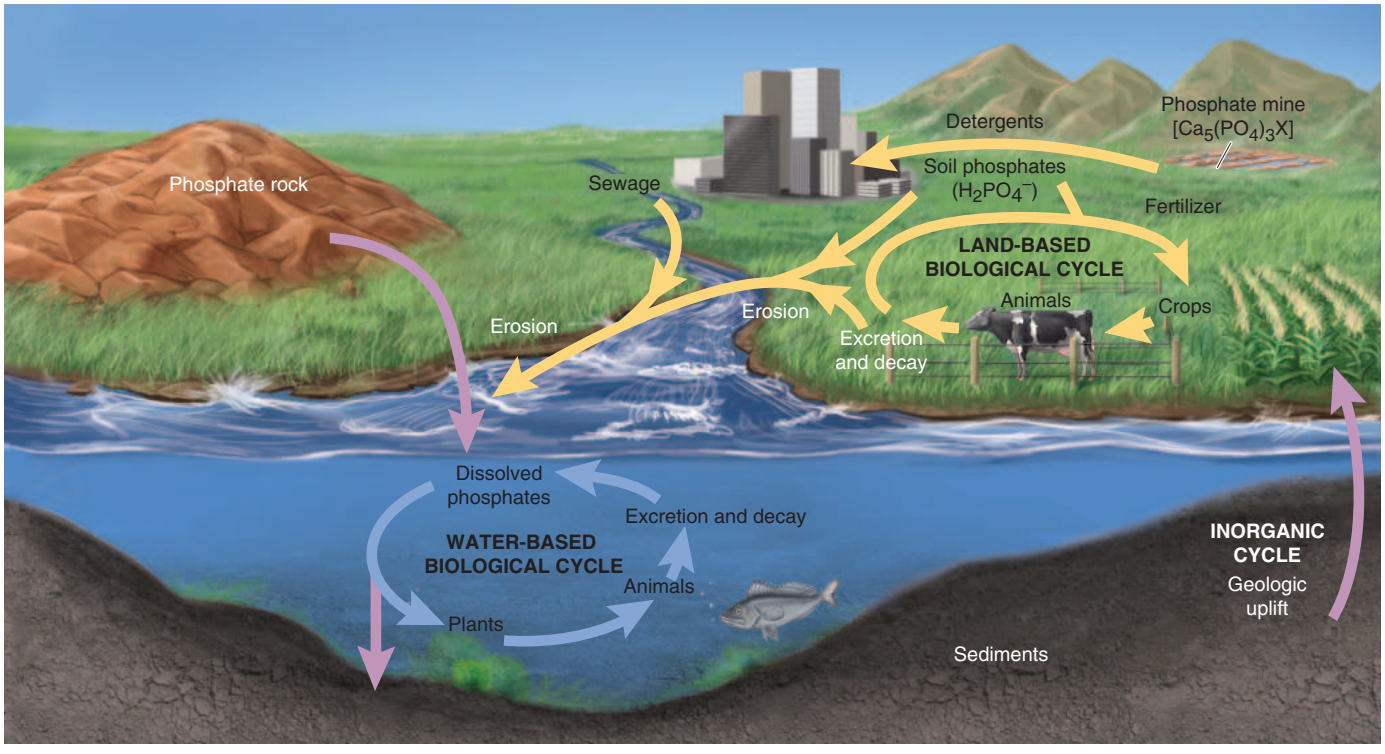
$$K_{sp} \text{ of } Ca_3(PO_4)_2 \approx 10^{-29}$$
$$K_{sp} \text{ of } Ca_5(PO_4)_3OH \approx 10^{-51}$$
$$K_{sp} \text{ of } Ca_5(PO_4)_3F \approx 10^{-60}$$

Weathering slowly leaches phosphates from the soil and carries the ions through rivers to the sea. Plants in the land-based biological cycle speed this process. In the ocean, some phosphate is absorbed by organisms in the water-based biological cycle, but the majority is precipitated again by Ca^{2+} ion and deposited on the continental shelf. Geologic activity lifts the continental shelves, returning the phosphate to the land.

The Land-Based Biological Cycle The biological cycles involve the incorporation of phosphate into organisms (biomolecules, bones, teeth, and so forth) and the release of phosphate through their excretion and decomposition. In the land-based cycle, plants continually remove phosphate from the inorganic cycle. Recall that there are three phosphate oxoanions, which exist in equilibrium in aqueous solution:

$$H_2PO_4^- \rightleftharpoons HPO_4^{2-} \rightleftharpoons PO_4^{3-}$$
$$+ H^+ \qquad + H^+$$

Figure 22.7 The phosphorus cycle.



In topsoil, phosphates occur as insoluble compounds of Ca^{2+}, Fe^{3+}, and Al^{3+}. Because they can absorb only the water-soluble dihydrogen phosphate, plants have evolved the ability to secrete acids near their roots to convert the insoluble salts gradually into the soluble ion:

$$Ca_3(PO_4)_2(s;\ \text{soil}) + 4H^+(aq;\ \text{secreted by plants}) \longrightarrow 3Ca^{2+}(aq) + 2H_2PO_4^-(aq;\ \text{absorbed by plants})$$

Animals that eat the plants excrete soluble phosphate, which is used by newly growing plants. As plants and animals excrete, die, and decompose, some phosphate is washed into rivers and the oceans. Most of the 2 million metric tons of phosphate that washes from land to sea each year comes from this biological source. Thus, the biosphere greatly increases the movement of phosphate from lithosphere to hydrosphere.

The Water-Based Biological Cycle Various phosphate oxoanions continually enter the aquatic environment. Studies that incorporate trace amounts of radioactive phosphorus into $H_2PO_4^-$ and monitor its uptake show that, within 1 minute, 50% of the ion is taken up by photosynthetic algae, which use it to synthesize their biomolecules (denoted by the top curved arrow in the equation, which shows the overall process):

$$106CO_2(g) + 16NO_3^-(aq) + H_2PO_4^-(aq) + 122H_2O(l) + 17H^+(aq) \underset{\text{decomposition}}{\overset{\text{synthesis}}{\rightleftharpoons}} C_{106}H_{263}O_{110}N_{16}P(aq;\ \text{in algal cell fluid}) + 138O_2(g)$$

(The complex formula on the right represents the total composition of algal biomolecules, not some particular compound.)

As on land, animals eat the plants and are eaten by other animals, and they all excrete phosphate, die, and decompose (denoted by the bottom curved arrow in the preceding equation). Some of the released phosphate is used by other aquatic organisms, and some returns to the land when fish-eating animals (mostly humans and birds) excrete phosphate, die, and decompose. In addition, some aquatic phosphate precipitates with Ca^{2+}, sinks to the seabed, and returns to the long-term mineral deposits of the inorganic cycle.

Human Effects on Phosphorus Movement From prehistoric through preindustrial times, these interlocking phosphorus cycles were balanced. Modern human activity, however, alters the movement of phosphorus considerably. Annually, we use more than 100 million tons of phosphate rock. Figure 22.8 shows the major end products, with box height proportional to the mass % of phosphate rock used annually. Removal

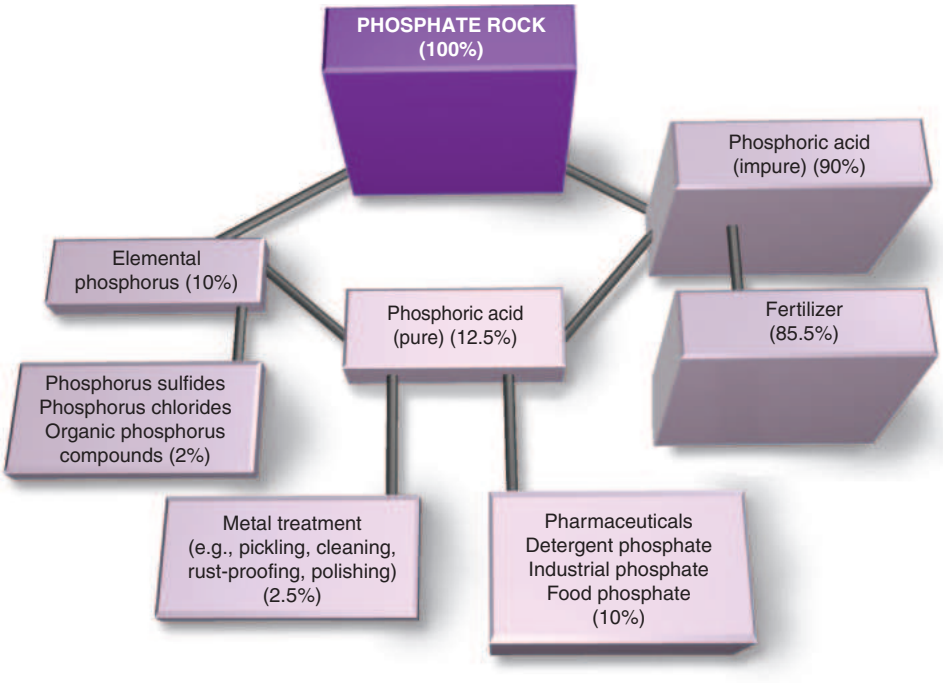


Figure 22.8 Industrial uses of phosphorus.

of phosphate rock has minimal influence on the inorganic cycle, but the end products have unbalanced the two biological cycles.

The imbalance arises from our overuse of *soluble phosphate fertilizers,* such as $Ca(H_2PO_4)_2$ and $NH_4H_2PO_4$, the end products from about 85% of the phosphate rock mined. Some fertilizer finds its way into rivers, lakes, and oceans to enter the water-based cycle. Much larger pollution sources, however, are the crops grown with the fertilizer and the detergents made from phosphate rock. The great majority of this phosphate arrives eventually in cities as crops, as animals that were fed crops, and as consumer products, such as the tripolyphosphates in detergents. Human garbage, excrement, wash water with detergents, and industrial wastewater containing phosphate are carried through sewers to the aquatic system. This human contribution equals the natural contribution—another 2 million metric tons of phosphate per year. The increased concentration in rivers and lakes causes eutrophication, which robs the water of O_2 so that it cannot support life. Such "dead" rivers and lakes are no longer usable for fishing, drinking, or recreation.

A century ago, in 1912, Lake Zurich in Switzerland had been choked with algae and become devoid of fish. Treatment with $FeCl_3$ precipitated enough phosphate to gradually return the lake to its natural state. Soluble aluminum compounds have the same effect:

$$FeCl_3(aq) + PO_4^{3-}(aq) \longrightarrow FePO_4(s) + 3Cl^-(aq)$$

$$KAl(SO_4)_2 \cdot 12H_2O(aq) + PO_4^{3-}(aq) \longrightarrow AlPO_4(s) + K^+(aq) + 2SO_4^{2-}(aq) + 12H_2O(l)$$

Summary of Section 22.2

- The environmental distribution of many elements changes cyclically with time and is affected in major ways by organisms.
- Carbon occurs in all three regions of Earth's crust, with atmospheric CO_2 linking the other two regions. Photosynthesis and decomposition of organisms alter the amount of carbon in the land and oceans. Human activity has increased atmospheric CO_2, leading to climate change.
- Nitrogen is fixed by lightning, by industry, and primarily by microorganisms. When plants or animals decompose, bacteria convert proteins to nitrites and nitrates and eventually to N_2, which returns to the atmosphere. Through extensive use of fertilizers, humans have added excess nitrogen to freshwaters.
- The phosphorus cycle has no gaseous component. Inorganic phosphates leach slowly into land and water, where biological cycles interact. When plants and animals decompose, they release phosphate to natural waters, where it is then absorbed by other plants and animals. Through overuse of phosphate fertilizers and detergents, humans double the amount of phosphorus entering the aqueous environment.

22.3 METALLURGY: EXTRACTING A METAL FROM ITS ORE

Metallurgy is the branch of materials science concerned with the extraction and utilization of metals. In this section, we discuss the general procedures for isolating metals and, occasionally, the nonmetals that are found in their ores. The extraction process applies one or more of these three types of metallurgy:

- *Pyrometallurgy* uses heat to obtain the metal.
- *Electrometallurgy* employs an electrochemical step.
- *Hydrometallurgy* relies on the metal's aqueous solution chemistry.

The extraction of an element begins with *mining the ore.* Most ores consist of a mineral attached to gangue. The **mineral** contains the element; it is defined as a naturally occurring, homogeneous, crystalline inorganic solid, with a well-defined composition. The **gangue** is the portion of the ore with no commercial value, such as sand, rock, and clay. Table 22.3 lists the common mineral sources of some metals.

Humans have been removing metals for thousands of years, so most of the concentrated sources are gone, and, in many cases, ores contain very low mass percents

Table 22.3 Common Mineral Sources of Some Elements

Element	Mineral, Formula
Al	Gibbsite (in bauxite), $Al(OH)_3$
Ba	Barite, $BaSO_4$
Be	Beryl, $Be_3Al_2Si_6O_{18}$
Ca	Limestone, $CaCO_3$
Fe	Hematite, Fe_2O_3
Hg	Cinnabar, HgS
Na	Halite, NaCl
Pb	Galena, PbS
Sn	Cassiterite, SnO_2
Zn	Sphalerite, ZnS

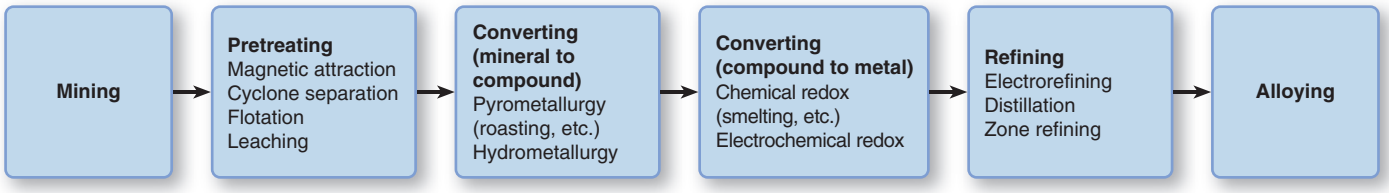

Figure 22.9 Steps in metallurgy.

of a metal. The general procedure for extracting most metals (and some nonmetals) involves a few basic steps, described in the upcoming subsections (Figure 22.9).

Pretreating the Ore

Following a crushing, grinding, or pulverizing step, which can be very expensive, pretreatment uses some physical or chemical difference to separate mineral from gangue. The following are common pretreatment techniques:

- *Magnetic attraction.* For magnetic minerals, such as magnetite (Fe_3O_4), a magnet can remove the mineral and leave the gangue behind.
- *Density separation.* When large density differences exist, a *cyclone separator* blows high-pressure air through the pulverized mixture to separate the particles. The lighter silicate-rich gangue is blown away, while the denser mineral-rich particles hit the walls of the separator and fall through the open bottom (Figure 22.10).
- *Flotation.* In **flotation,** an oil-detergent mixture is stirred with the pulverized ore in water to form a slurry (Figure 22.11). The surfaces of mineral and of gangue become wet to different extents with water and detergent. Rapid mixing with air produces an oily, mineral-rich froth that floats, while the silicate particles sink. Skimming, followed by solvent removal, isolates the concentrated mineral fraction.
- *Leaching.* Some metals are extracted by a hydrometallurgical process known as **leaching,** usually accomplished via formation of a complex ion. The modern extraction of gold is a good example of this technique. The crushed ore, which often contains as little as 25 ppm of gold, is contained in a plastic-lined pool, treated with a cyanide ion solution, and aerated. In the presence of CN^-, the O_2 in air oxidizes gold metal to gold(I) ion, Au^+, which forms the soluble complex ion, $Au(CN)_2^-$:

$$4Au(s) + O_2(g) + 8CN^-(aq) + 2H_2O(l) \longrightarrow 4Au(CN)_2^-(aq) + 4OH^-(aq)$$

(This method is controversial because cyanide enters streams and lakes, where it poisons fish and birds.)

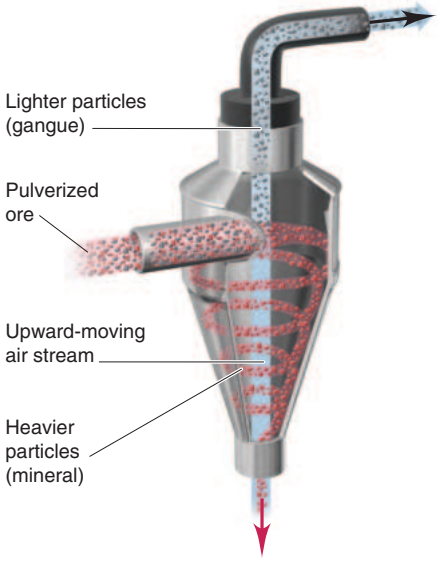

Figure 22.10 The cyclone separator.

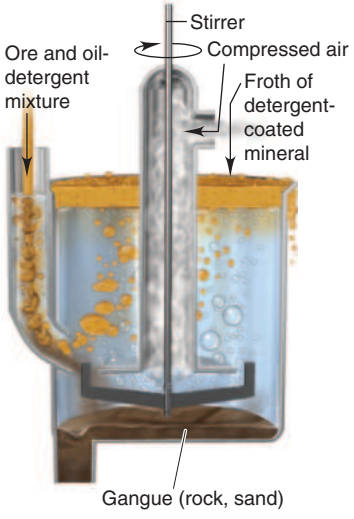

Figure 22.11 The flotation process.

Converting Mineral to Element

After the mineral has been freed of debris and concentrated, it may undergo several chemical steps during its conversion to the element.

Converting the Mineral to Another Compound First, the mineral is often converted to another compound, one that has different solubility properties, is easier to reduce, or is free of an impurity. Conversion to an oxide is common because oxides can be reduced easily. Carbonates are heated to convert them to the oxide:

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$$

Metal sulfides, such as ZnS, can be converted to oxides by **roasting** in air:

$$2ZnS(s) + 3O_2(g) \xrightarrow{\Delta} 2ZnO(s) + 2SO_2(g)$$

In most countries, hydrometallurgical methods are now used to avoid the atmospheric release of SO_2 from roasting. One way of processing copper, for example, is by bubbling air through an acidic slurry of insoluble Cu_2S, which completes both the pretreatment and conversion steps:

$$2Cu_2S(s) + 5O_2(g) + 4H^+(aq) \longrightarrow 4Cu^{2+}(aq) + 2SO_4^{2-}(aq) + 2H_2O(l)$$

Converting Compound to Element Through Chemical Redox The next step converts the new mineral form (usually an oxide) to the free element by either chemical or electrochemical redox methods. Let's consider the chemical methods first. In these processes, a reducing agent reacts directly with the compound. The most common reducing agents are carbon, hydrogen, and a more active metal.

1. *Reduction with carbon.* Because of its low cost and ready availability, carbon, in the form of coke (a porous material obtained from incomplete combustion of coal) or charcoal, is a common reducing agent. Heating an oxide with a reducing agent such as coke to obtain the metal is called **smelting.** Many metal oxides, such as zinc oxide and tin(IV) oxide, are smelted with carbon to free the metal, which then may need to be condensed and solidified (note the physical states of the metal products):

$$ZnO(s) + C(s) \longrightarrow Zn(g) + CO(g)$$
$$SnO_2(s) + 2C(s) \longrightarrow Sn(l) + 2CO(g)$$

Several nonmetals that occur with positive oxidation states in minerals can be reduced with carbon as well. Phosphorus, for example, is produced from calcium phosphate:

$$2Ca_3(PO_4)_2(s) + 10C(s) + 6SiO_2(s) \longrightarrow 6CaSiO_3(s) + 10CO(g) + P_4(s)$$

(Metallic calcium is a much stronger reducing agent than carbon, so it is not formed.)

- *Thermodynamic considerations.* Thermodynamic principles explain why carbon is often such an effective reducing agent. Consider the standard free energy change (ΔG°) for the reduction of tin(IV) oxide:

  $$SnO_2(s) + 2C(s) \longrightarrow Sn(s) + 2CO(g) \qquad \Delta G^\circ = 245 \text{ kJ at } 25^\circ\text{C } (298 \text{ K})$$

  The magnitude and sign of ΔG° indicate a highly *non*spontaneous reaction at standard-state conditions and 298 K. However, because solid C becomes gaseous CO, the standard molar entropy change is very positive ($\Delta S^\circ \approx 380$ J/K). Therefore, *the $-T\Delta S^\circ$ term of ΔG° becomes more negative with higher temperature* (Section 20.3). As the temperature increases, ΔG° decreases, and at a high enough temperature, the reaction becomes spontaneous ($\Delta G^\circ < 0$). At 1000°C (1273 K), for example, $\Delta G^\circ = -62.8$ kJ. The actual process is carried out at a temperature of around 1250°C (1523 K), so ΔG° is even more negative. In effect, the nonspontaneous reduction of SnO_2 is coupled to the spontaneous oxidation of C.
- *Multistep nature of the process.* As you know, overall reactions often actually occur through several intermediate steps. For instance, the reduction of tin(IV) oxide involves formation of tin(II) oxide:

  $$SnO_2(s) + C(s) \longrightarrow \cancel{SnO(s)} + CO(g)$$
  $$\cancel{SnO(s)} + C(s) \longrightarrow Sn(l) + CO(g)$$

[Molten tin (mp = 232 K) is obtained at this temperature.] The second step is thought to be composed of others, in which CO, not C, is the actual reducing agent:

$$SnO(s) + \cancel{CO(g)} \longrightarrow Sn(l) + \cancel{CO_2(g)}$$
$$\cancel{CO_2(g)} + C(s) \rightleftharpoons \cancel{2}CO(g)$$

Other pyrometallurgical processes are similarly complex. For instance, shortly you'll see that the overall reaction for the smelting of iron is

$$2Fe_2O_3(s) + 3C(s) \longrightarrow 4Fe(l) + 3CO_2(g)$$

However, the actual process is a multistep one with CO as the reducing agent. The advantage of CO over C is the far greater physical contact the gaseous reducing agent can make with the other reactant, which speeds the process.

2. *Reduction with hydrogen*. For oxides of some metals, especially some members of Groups 6B(6) and 7B(7), reduction with carbon forms metal carbides that are difficult to convert further, so hydrogen is used as the reducing agent instead, especially for less active metals, such as tungsten:

$$WO_3(s) + 3H_2(g) \longrightarrow W(s) + 3H_2O(g)$$

One step in the purification of the metalloid germanium also uses hydrogen:

$$GeO_2(s) + 2H_2(g) \longrightarrow Ge(s) + 2H_2O(g)$$

3. *Reduction with a more active metal.* If a metal oxide forms both an undesirable carbide and hydride, it is reduced by a more active metal. In the *thermite reaction,* aluminum powder reduces the metal oxide in a spectacular exothermic reaction to give the molten metal (Figure 22.12). The reaction for chromium is

$$Cr_2O_3(s) + 2Al(s) \longrightarrow 2Cr(l) + Al_2O_3(s) \qquad \Delta H^\circ << 0$$

Reduction by an active metal is also used when the mineral of the element is not an oxide. In the extraction of gold, after the pretreatment by leaching, the gold(I) complex ion is reduced with zinc:

$$2Au(CN)_2^-(aq) + Zn(s) \longrightarrow 2Au(s) + Zn(CN)_4^{2-}(aq)$$

In some cases, an active metal, such as calcium, is used to recover an even more active metal, such as rubidium, from its molten salt:

$$Ca(l) + 2RbCl(l) \longrightarrow CaCl_2(l) + 2Rb(g)$$

A similar process (detailed in Section 22.4) is used to recover sodium.

4. *Oxidation to obtain a nonmetal.* Just as *reduction* of a mineral is used to obtain the metal, *oxidation* of a mineral can be used to obtain a nonmetal. A stronger oxidizing agent removes electrons from the nonmetal anion to give the free nonmetal, as in the production of iodine from concentrated brines:

$$2I^-(aq) + Cl_2(g) \longrightarrow 2Cl^-(aq) + I_2(s)$$

Figure 22.12 The thermite reaction.

Converting Compound to Element Through Electrochemical Redox In these processes, the minerals are converted to the elements in an electrolytic cell (Section 21.7). Sometimes, the *pure* mineral, in the form of the molten halide or oxide, is used to prevent unwanted side reactions. The cation is reduced to the metal at the cathode, and the anion is oxidized to the nonmetal at the anode:

$$BeCl_2(l) \longrightarrow Be(s) + Cl_2(g)$$

High-purity hydrogen gas is prepared by electrochemical reduction:

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g)$$

Specially designed cells separate the products to prevent recombination. An inexpensive source of electricity is used for large-scale methods. The current and voltage requirements depend on the electrochemical potential and any necessary overvoltage (Section 21.7).

Figure 22.13 on the next page shows the most common redox step used in obtaining each free element from its mineral.

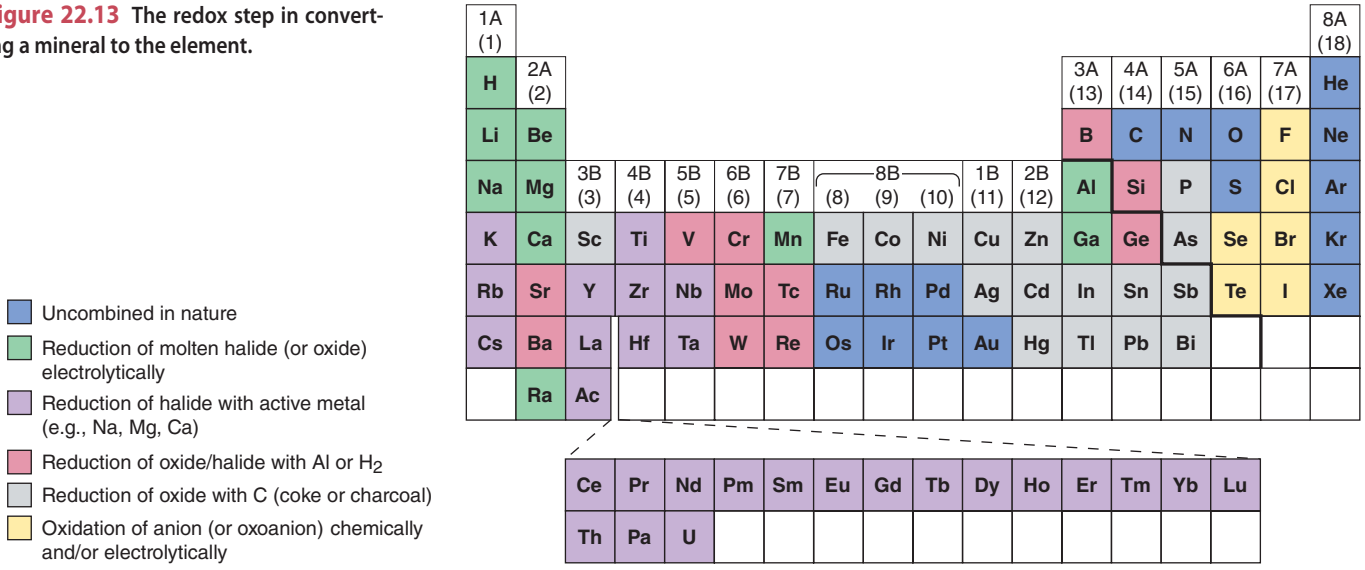

Figure 22.13 The redox step in converting a mineral to the element.

Refining and Alloying the Element

After being isolated, the element typically still contains impurities, so it must be refined to purify it further. Then, metallic elements are often alloyed to improve their properties.

Refining (Purifying) the Element Refining is often carried out by one of three common methods:

1. *Electrorefining.* An electrolytic cell is employed in **electrorefining,** in which the *impure metal acts as the anode and the pure metal as the cathode.* As the reaction proceeds, the anode disintegrates, and the metal ions are reduced to deposit on the cathode. In some cases (as with copper, discussed shortly), impurities that fall beneath the anode are the source of several valuable and less abundant elements.

2. *Distillation.* Metals with relatively low boiling points, such as zinc and mercury, are refined by *distillation.*

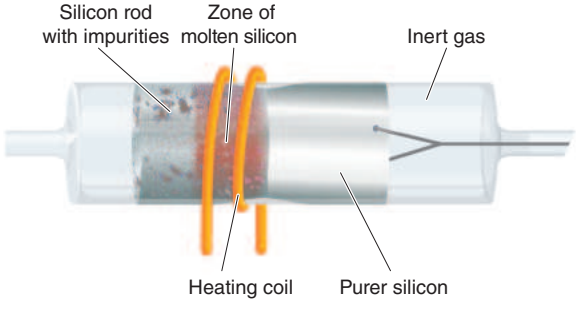

Figure 22.14 Zone refining of silicon.

3. *Zone refining.* In the process of **zone refining,** a rod of an impure metal or metalloid (such as silicon) is passed slowly through a heating coil in an inert atmosphere. The first narrow zone of the impure solid melts, and as the next zone melts, the dissolved impurites from the first zone lower the freezing point, so the solvent (purer solid of first zone) refreezes. The process continues, zone by zone, for the entire rod. After several passes through the coil, in which each zone's impurities move into the adjacent zone, the refrozen solid at the end of the rod becomes extremely pure (Figure 22.14). Metalloids used in electronic semiconductors, such as silicon and germanium, are zone refined to greater than 99.999999% purity.

Alloying the Purified Element An **alloy** is a metal-like mixture consisting of solid phases of two or more pure elements (a solid solution) or, in some cases, distinct intermediate phases (these alloys are sometimes referred to as *intermetallic compounds*) that are so finely divided they can only be distinguished microscopically. Alloying a metal with other metals (and, in some cases, nonmetals) is done to alter the metal's melting point and to enhance properties such as luster, conductivity, malleability, ductility, and strength.

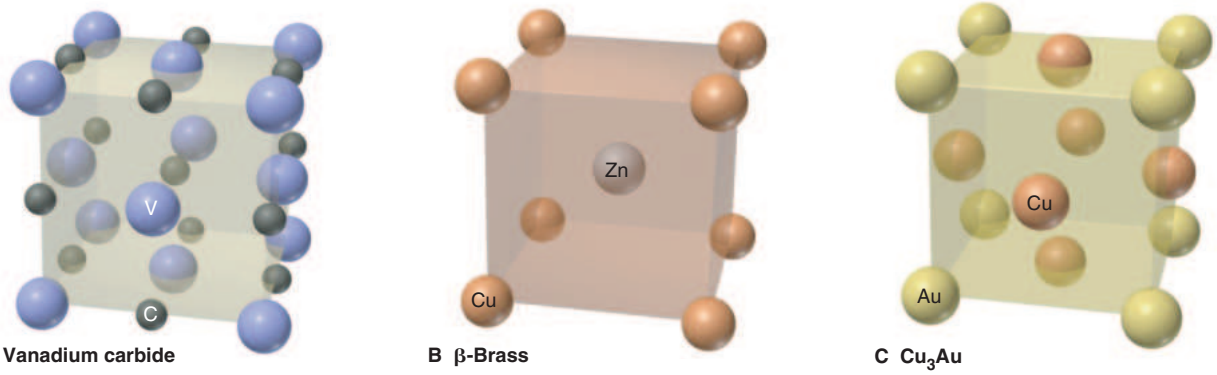
Table 22.4 Some Important Alloys and Their Composition

Name	Composition (Mass %)	Uses
Mostly Fe		
Stainless steel	73–79 Fe, 14–18 Cr, 7–9 Ni	Cutlery, instruments
Nickel steel	96–98 Fe, 2–4 Ni	Cables, gears
High-speed steels	80–94 Fe, 14–20 W (or 6–12 Mo)	Cutting tools
Mostly Cu		
Bronzes	70–95 Cu, 1–25 Zn, 1–18 Sn	Statues, castings
Brasses	50–80 Cu, 20–50 Zn	Plating, ornamental objects
Mostly precious metals		
Sterling silver	92.5 Ag, 7.5 Cu	Jewelry, tableware
14-carat gold	58 Au, 4–28 Ag, 14–28 Cu	Jewelry
18-carat white gold	75 Au, 12.5 Ag, 12.5 Cu	Jewelry
Dental amalgam	69 Ag, 18 Sn, 12 Cu, 1 Zn (dissolved in Hg)	Dental fillings
Other		
Permalloy	78 Ni, 22 Fe	Ocean cables
Typical tin solder	67 Pb, 33 Sn	Electrical connections

Iron is used only when alloyed. In pure form, it is soft and corrodes easily. However, when alloyed with carbon and other metals, such as Mo for hardness and Cr and Ni for corrosion resistance, it forms various steels. Copper stiffens when zinc is added to make brass. Mercury solidifies when alloyed with sodium, and vanadium becomes extremely tough with some carbon added. Table 22.4 shows the composition and uses of some common alloys.

The simplest alloys, called *binary alloys,* contain only two elements, which can combine in two ways:

- *The added element enters interstices,* spaces between the parent metal atoms in its crystal structure (Section 12.6). In vanadium carbide, for instance, carbon atoms occupy holes of a face-centered cubic vanadium unit cell (Figure 22.15A).
- The *added element substitutes for atoms of the parent.* In many types of brass, for example, relatively few zinc atoms substitute randomly for copper atoms in the face-centered cubic copper unit cell (see Figure 13.4A, p. 522). On the other hand, β-brass is an intermediate phase that crystallizes as the Zn/Cu ratio approaches 1/1 in a body-centered cubic structure with a central Zn atom surrounded by eight Cu atoms (Figure 22.15B). In one alloy of copper and gold, Cu atoms occupy the faces of a face-centered cube, and Au atoms lie at the corners (Figure 22.15C).



A Vanadium carbide **B** β-Brass **C** Cu_3Au

Figure 22.15 Three binary alloys.

Atomic properties, including size, electron configuration, and number of valence electrons, determine which metals form stable alloys. For example, transition metals from the left half of the *d* block [Groups 3B(3) to 5B(5)] often form alloys with metals from the right half [Groups 8B(9) to 1B(11)]: electron-poor Zr, Nb, and Ta form strong alloys with electron-rich Ir, Pt, and Au; an example is the very stable $ZrPt_3$.

Summary of Section 22.3

- Metallurgy involves mining an ore, separating it from debris, pretreating it to concentrate the mineral source, converting the mineral to another compound that is easier to process further, reducing this compound to the metal, purifying the metal, and in many cases, alloying it to obtain a more useful material.

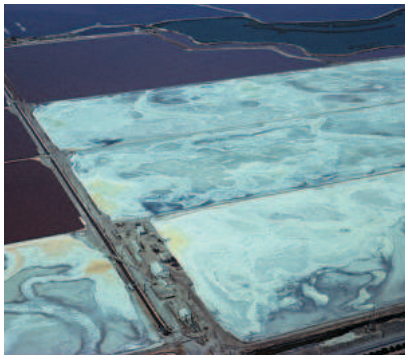
22.4 TAPPING THE CRUST: ISOLATION AND USES OF SELECTED ELEMENTS

The isolation process depends on the physical and chemical properties of the source: we isolate an element that occurs uncombined in the air differently from one dissolved in the sea or one found in a rocky ore. In this section, we detail methods for recovering some important elements.

Producing the Alkali Metals: Sodium and Potassium

The alkali metals are among the most reactive elements and thus are always found as ions in nature, either in solid minerals or in aqueous solution. The two most important of these metals are sodium and potassium. Their abundant, water-soluble compounds are used throughout industry and research, and the Na^+ and K^+ ions are essential to organisms.

Industrial Production of Sodium and Potassium Different methods are employed in the industrial production of these two metals:



Evaporative salt beds near San Francisco Bay.

1. *Production of sodium.* The sodium ore is *halite* (largely NaCl), which is obtained either by evaporation of concentrated salt solutions called *brines (see photo)* or by mining vast salt deposits formed from the evaporation of prehistoric seas. The Cheshire salt field in Britain, for example, is 60 km by 24 km by 400 m thick and contains more than 90% NaCl. Other large deposits occur in New Mexico, Michigan, New York, and Kansas.

The brine is evaporated and the solid crushed and fused (melted) for use in an electrolytic apparatus called the **Downs cell** (Figure 22.16). To reduce heating costs, 1 part NaCl (mp = 801°C) is mixed with $1\frac{1}{2}$ parts $CaCl_2$ to form a mixture that melts at only 580°C. Reduction of the metal ions to Na and Ca takes place at a cylindrical steel cathode, with the molten metals floating on the denser molten salt mixture. As they rise through a short collecting pipe, the liquid Na is siphoned off, while a higher melting Na/Ca alloy solidifies and falls back into the molten electrolyte. Chloride ions are oxidized to Cl_2 gas at a large anode within an inverted cone-shaped chamber that separates the metals from the Cl_2 to prevent their explosive recombination. The Cl_2 is purified and sold as a valuable byproduct.

2. *Production of potassium.* Sylvite (mostly KCl) is the major ore of potassium. The metal is too soluble in molten KCl to be obtained by a method similar to that used for sodium. Instead, chemical reduction of K^+ ions by Na is based on atomic properties and the nature of equilibrium systems. An Na atom is smaller than a K atom, so it holds its outer electron more tightly: IE_1 of Na = 496 kJ/mol; IE_1 of K = 419 kJ/mol. Thus, based on this atomic property, Na would not be effective at reducing K^+ because the equilibrium constant would favor reactants. However, the reduction is carried out at 850°C, which is above the boiling point of K, so the equilibrium mixture contains *gaseous* K:

$$Na(l) + K^+(l) \rightleftharpoons Na^+(l) + K(g)$$

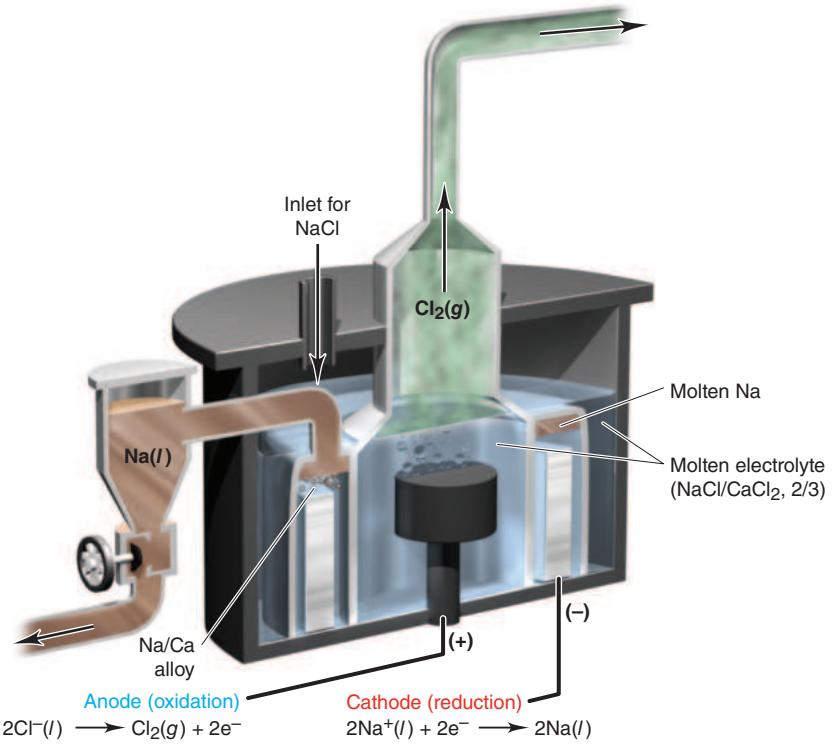


Figure 22.16 The Downs cell for production of sodium.

As the K gas is removed, Le Châtelier's principle predicts that the reaction shifts to the right and produces more K. The gas is then condensed and purified by fractional distillation. The same general method (with Ca as the reducing agent) is used to produce rubidium and cesium.

Uses of Sodium and Potassium The compounds of Na and K (and indeed, of all the alkali metals) have many more uses than the elements themselves. Nevertheless, there are some interesting uses of the metals that take advantage of their strong reducing power:

1. *Uses of sodium.* Large amounts of Na were used as an alloy with lead to make gasoline antiknock additives, such as tetraethyllead:

$$4C_2H_5Cl(g) + 4Na(s) + Pb(s) \longrightarrow (C_2H_5)_4Pb(l) + 4NaCl(s)$$

The toxic effects of environmental lead have limited this use to aviation fuel in the United States. Moreover, although leaded gasoline is still used in several developing countries, the global market for tetraethyllead is declining more than 15% annually.

If certain types of nuclear reactors, called *breeder reactors* (Chapter 24), become a practical way to generate energy in the United States, Na production would increase enormously. Its low melting point, viscosity, and interaction with neutrons, combined with its high thermal conductivity and heat capacity, make it perfect for cooling the reactor and exchanging heat to the steam generator.

2. *Uses of potassium.* The major use of potassium at present is in an alloy with sodium for use as a heat exchanger in chemical and nuclear reactors. Another application relies on production of its superoxide, which it forms by direct contact with O_2:

$$K(s) + O_2(g) \longrightarrow KO_2(s)$$

This material is employed as an emergency source of O_2 in breathing masks for miners, divers, submarine crews, and firefighters *(see photo):*

$$4KO_2(s) + 4CO_2(g) + 2H_2O(g) \longrightarrow 4KHCO_3(s) + 3O_2(g)$$

Firefighter with KO_2 breathing mask.

The Indispensable Three: Iron, Copper, and Aluminum

Their innumerable applications make iron (in the form of steel), copper, and aluminum indispensable metals in an industrial society.

Table 22.5 Important Minerals of Iron

Mineral Type	Mineral, Formula
Oxide	Hematite, Fe_2O_3
	Magnetite, Fe_3O_4
	Ilmenite, $FeTiO_3$
Carbonate	Siderite, $FeCO_3$
Sulfide	Pyrite, FeS_2
	Pyrrhotite, FeS

Metallurgy of Iron: From Ore to Pig Iron Although people have practiced iron smelting for more than 3000 years, it was not even 250 years ago that iron assumed its current dominant role. In 1773, an inexpensive process to convert coal to carbon in the form of coke was discovered, and the coke process made iron smelting cheap and efficient and led to large-scale iron production, which ushered in the Industrial Revolution.

Modern society rests, quite literally, on the various alloys of iron known as **steel.** Although steel production has obviously grown enormously since the 18th century, the process of recovering iron from its ores still employs *reduction by carbon in a blast furnace.* The most abundant minerals of iron are listed in Table 22.5. Only the first four are used for steelmaking, because traces of sulfur from the sulfide minerals make steel brittle.

The conversion from ore to metal involves a series of redox and acid-base reactions that appear simple, even though their detailed chemistry is not completely understood even today. A modern **blast furnace** (Figure 22.17) is a tower made of brick, about 14 m wide by 40 m high. The *charge,* which usually consists of hematite, coke, and limestone, is fed through the top. More coke is burned in air at the bottom. The charge falls and meets a *blast* of rapidly rising hot air created by the burning coke:

$$2C(s) + O_2(g) \longrightarrow 2CO(g) + \textit{heat}$$

At the bottom of the furnace, the temperature exceeds 2000°C, while at the top, it reaches only 200°C. Because the blast of hot air passes through the entire furnace in only 10 s, the various gas-solid reactions do *not* reach equilibrium, and many inter-

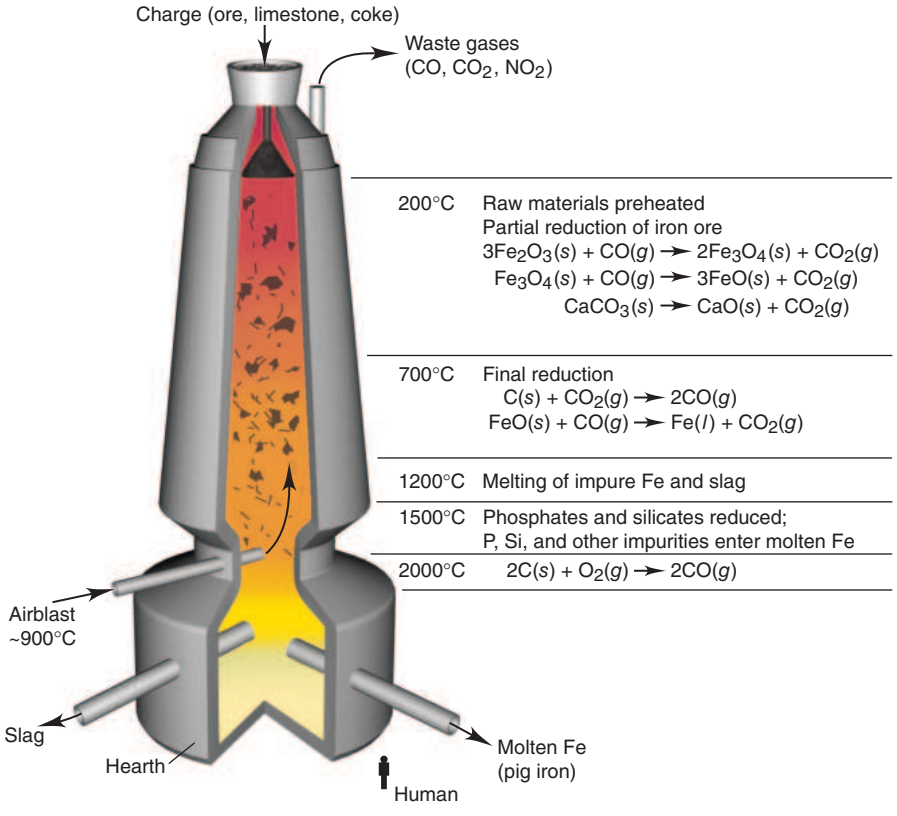

Figure 22.17 The major reactions in a blast furnace.

mediate products form. As a result, different stages of the overall reaction process occur at different heights:

1. In the upper part of the furnace (200°C to 700°C), the charge is preheated, and a *partial reduction* occurs. The hematite (Fe_2O_3) is reduced to magnetite (Fe_3O_4) and then to iron(II) oxide (FeO) by CO, which is the actual reducing agent. Carbon dioxide is formed as well. Limestone ($CaCO_3$) also decomposes to form CO_2 and the basic oxide CaO.
2. Lower down, at 700°C to 1200°C, a *final reduction* step occurs, as some of the coke reduces CO_2 to form more CO, which reduces the FeO to Fe.
3. At temperatures between 1200°C and 1500°C, the iron melts and drips to the bottom of the furnace. Acidic silica particles from the gangue react with the CaO in a Lewis acid-base reaction to form a molten waste product called **slag:**

$$CaO(s) + SiO_2(s) \longrightarrow CaSiO_3(l)$$

   The slag drips down and floats on the denser iron.
4. Some unwanted reactions occur between 1500°C and 2000°C. Any remaining phosphates and silicates are reduced to P and Si, and some Mn and traces of S dissolve into the molten iron along with carbon. The resulting impure product is called *pig iron* and contains about 3% to 4% C. A small amount of pig iron is used to make *cast iron,* but most is purified and alloyed to make various kinds of steel.

Metallurgy of Iron: From Pig Iron to Steel Pig iron is converted to steel in a separate furnace by means of the **basic-oxygen process** (Figure 22.18). High-pressure O_2 is blown over and through the molten iron, so that impurities (C, Si, P, Mn, and S) are oxidized rapidly. The highly negative standard enthalpies of formation of the carbon and silicon oxides (ΔH_f° of $CO_2 = -394$ kJ/mol; ΔH_f° of $SiO_2 = -911$ kJ/mol) raise the temperature, which speeds the reaction. A lime (CaO) flux is added, which converts the oxides to a molten slag [primarily $CaSiO_3$ and $Ca_3(PO_4)_2$] that is decanted from the molten steel. The product is **carbon steel,** which contains 1% to 1.5% C and other impurities. It is alloyed with metals that prevent corrosion and increase its strength or flexibility.

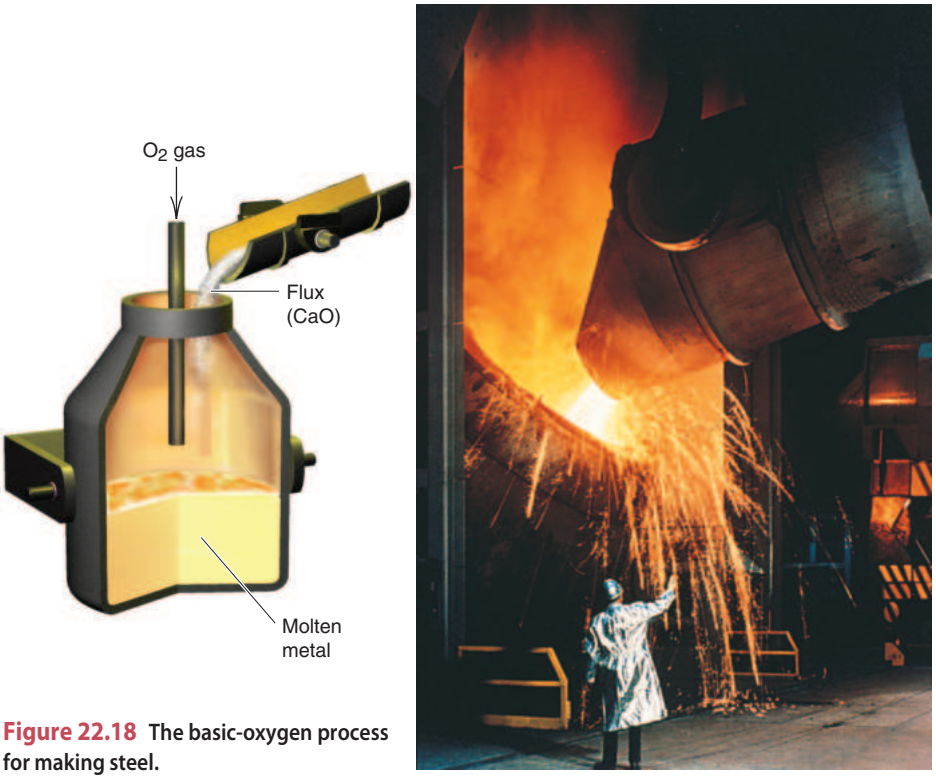

Figure 22.18 The basic-oxygen process for making steel.

Mining chalcopyrite.

Metallurgy of Copper: From Ore to Impure Metal After many centuries of being mined to make bronze and brass, copper ores have become much less plentiful and rich in copper. Despite this, more than 2.5 billion pounds of copper is produced in the United States annually. The most common ore is chalcopyrite, $CuFeS_2$, a mixed sulfide of FeS and CuS *(see photo)*. Most remaining deposits contain less than 0.5% Cu by mass. To "win" this small amount of copper requires several metallurgical steps:

1. *Flotation.* The low copper content in chalcopyrite must be enriched by removing the iron. The first step is pretreatment by flotation (see Figure 22.11, p. 989), which concentrates the ore to around 15% Cu by mass.

2. *Roasting.* The next step in many processing plants is a controlled roasting step, which oxidizes the FeS but not the CuS:

$$2FeCuS_2(s) + 3O_2(g) \longrightarrow 2CuS(s) + 2FeO(s) + 2SO_2(g)$$

3. *Heating with sand.* To remove the FeO and convert the CuS to a more convenient form, the mixture is heated to 1100°C with sand and more of the concentrated ore. Several reactions occur in this step. The FeO reacts with sand to form a molten slag:

$$FeO(s) + SiO_2(s) \longrightarrow FeSiO_3(l)$$

The CuS is thermodynamically unstable at the elevated temperature and decomposes to yield Cu_2S, which is drawn off as a liquid.

4. *Smelting.* In the final smelting step, the Cu_2S is roasted in air, which converts some of it to Cu_2O:

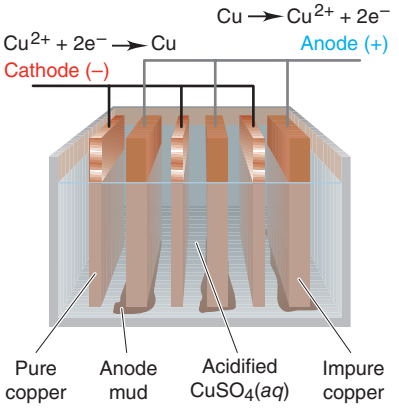
$$2Cu_2S(s) + 3O_2(g) \longrightarrow 2Cu_2O(s) + 2SO_2(g)$$

The two copper(I) compounds then react, with sulfide ion acting as the reducing agent:

$$Cu_2S(s) + 2Cu_2O(s) \longrightarrow 6Cu(l) + SO_2(g)$$

The copper obtained at this stage is usable for plumbing, but it must be purified further for electrical wiring applications by removal of the unwanted Fe and Ni as well as the valuable byproducts Ag, Au, and Pt.

Metallurgy of Copper: Electrorefining Achieving the desired 99.99% purity needed for wiring (copper's most important use) is accomplished by *electrorefining,* which involves the oxidation of Cu to form Cu^{2+} ions in solution, followed by their reduction and the plating out of Cu metal (Figure 22.19). The impure copper obtained from smelting is cast into plates to be used as anodes, and cathodes are made from already



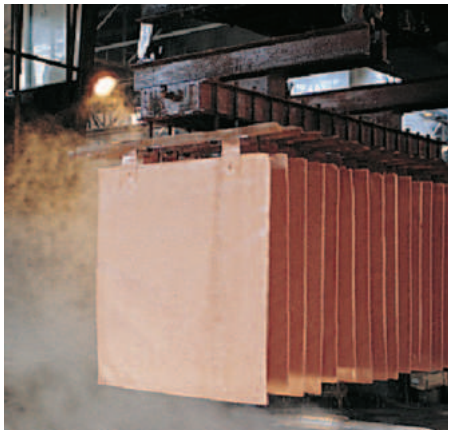


Figure 22.19 The electrorefining of copper.

purified copper. The electrodes are immersed in acidified $CuSO_4$ solution, and a voltage is applied that accomplishes two tasks simultaneously:

- Copper and the more active impurities (Fe, Ni) are oxidized to their cations, while the less active ones (Ag, Au, Pt) are not. As the anode slabs react, these unoxidized metals fall off as valuable "anode mud" and are purified separately. Sale of the precious metals in the anode mud nearly offsets the cost of electricity to operate the cell, making Cu wire inexpensive.
- Because Cu is much less active than the Fe and Ni impurities, Cu^{2+} ions are reduced at the cathode, but Fe^{2+} and Ni^{2+} ions remain in solution:

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) \qquad E^\circ = 0.34\ V$$
$$Ni^{2+}(aq) + 2e^- \longrightarrow Ni(s) \qquad E^\circ = -0.25\ V$$
$$Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s) \qquad E^\circ = -0.44\ V$$

Metallurgy of Aluminum: From Ore to Metal Aluminum is the most abundant metal in Earth's crust by mass and the third most abundant element (after O and Si). It is found in numerous aluminosilicate minerals, such as feldspars, micas, and clays, and in the rare gems garnet, beryl, spinel, and turquoise. Corundum, pure aluminum oxide (Al_2O_3), is extremely hard; mixed with traces of transition metals, it exists as ruby and sapphire. Impure Al_2O_3 is used in sandpaper and other abrasives.

Through eons of weathering, certain clays became *bauxite,* the major ore of aluminum. This mixed oxide-hydroxide occurs in enormous surface deposits in Mediterranean and tropical regions *(see photo),* but with world aluminum production near 100 million tons annually, it may someday be scarce. In addition to hydrated Al_2O_3 (about 75%), industrial-grade bauxite also contains Fe_2O_3, SiO_2, and TiO_2, which are removed during the extraction. The overall two-step process combines hydro- and electrometallurgical techniques:

Mining bauxite.

1. *Isolating Al_2O_3 from bauxite.* After mining, bauxite is pretreated by boiling in 30% NaOH in the *Bayer process,* which involves acid-base, solubility, and complex-ion equilibria. The acidic SiO_2 and the amphoteric Al_2O_3 dissolve in the base, but the basic Fe_2O_3 and TiO_2 do not:

$$SiO_2(s) + 2NaOH(aq) + 2H_2O(l) \longrightarrow Na_2Si(OH)_6(aq)$$
$$Al_2O_3(s) + 2NaOH(aq) + 3H_2O(l) \longrightarrow 2NaAl(OH)_4(aq)$$
$$Fe_2O_3(s) + NaOH(aq) \longrightarrow \text{no reaction}$$
$$TiO_2(s) + NaOH(aq) \longrightarrow \text{no reaction}$$

Further heating precipitates the $Na_2Si(OH)_6$ as an aluminosilicate, which is filtered out with the insoluble Fe_2O_3 and TiO_2 ("red mud").

Acidifying the filtrate precipitates Al^{3+} as $Al(OH)_3$. Recall that the aluminate ion, $Al(OH)_4^-(aq)$, is actually the complex ion $Al(H_2O)_2(OH)_4^-$ (see Figure 19.17, p. 860). Weakly acidic CO_2 is added to produce a small amount of H^+ ion, which reacts with this complex ion to form $Al(H_2O)_3(OH)_3$. Cooling supersaturates the solution, and the solid that forms is filtered out:

$$CO_2(g) + H_2O(l) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$
$$Al(H_2O)_2(OH)_4^-(aq) + H^+(aq) \longrightarrow Al(H_2O)_3(OH)_3(s)$$

[Recall that we usually write $Al(H_2O)_3(OH)_3$ more simply as $Al(OH)_3$.]

Drying at high temperature converts the hydroxide to the oxide:

$$2Al(H_2O)_3(OH)_3(s) \xrightarrow{\Delta} Al_2O_3(s) + 9H_2O(g)$$

2. *Converting Al_2O_3 to the free metal: the Hall-Heroult process.* Aluminum is an active metal, much too strong a reducing agent to be formed at the cathode from aqueous solution (Section 21.7), so the oxide itself is electrolyzed.

The melting point of Al_2O_3 is very high (2030°C), so it is dissolved in molten *cryolite* (Na_3AlF_6) to give a mixture that electrolyzes at ~1000°C. Using cryolite

provides a major energy (and thus, cost) savings, but the only sizeable cryolite mines cannot supply enough of the mineral, so production of synthetic cryolite has become a major subsidiary industry in aluminum manufacture.

The electrolytic step, called the *Hall-Heroult process,* takes place in a graphite-lined furnace, with the lining itself acting as the cathode. Anodes of graphite dip into the molten Al_2O_3-Na_3AlF_6 mixture (Figure 22.20). The cell typically operates at a moderate voltage of 4.5 V, but with an enormous current flow of 1.0×10^5 to 2.5×10^5 A.

The process is complex and its details are still not entirely known. The specific reactions shown below are among several other possibilities. Molten cryolite contains several ions (including AlF_6^{3-}, AlF_4^-, and F^-), which react with Al_2O_3 to form fluoro-oxy ions (including $AlOF_3^{2-}$, $Al_2OF_6^{2-}$, and $Al_2O_2F_4^{2-}$) that dissolve in the mixture. For example,

$$2Al_2O_3(s) + 2AlF_6^{3-}(l) \longrightarrow 3Al_2O_2F_4^{2-}(l)$$

Al forms at the cathode (reduction), shown here with AlF_6^{3-} as reactant:

$$AlF_6^{3-}(l) + 3e^- \longrightarrow Al(l) + 6F^-(l) \qquad \text{[cathode; reduction]}$$

The graphite anodes are oxidized and form carbon dioxide gas. Using one of the fluoro-oxy species as an example, the anode reaction is

$$Al_2O_2F_4^{2-}(l) + 8F^-(l) + C(\text{graphite}) \longrightarrow 2AlF_6^{3-}(l) + CO_2(g) + 4e^-$$

[anode; oxidation]

Thus, the *graphite anodes themselves are consumed* in this half-reaction and must be replaced frequently.

Combining the three preceding equations and making sure that e^- gained at the cathode equal e^- lost at the anode gives the overall reaction:

$$2Al_2O_3(\text{in } Na_3AlF_6) + 3C(\text{graphite}) \longrightarrow 4Al(l) + 3CO_2(g) \qquad \text{[overall (cell) reaction]}$$

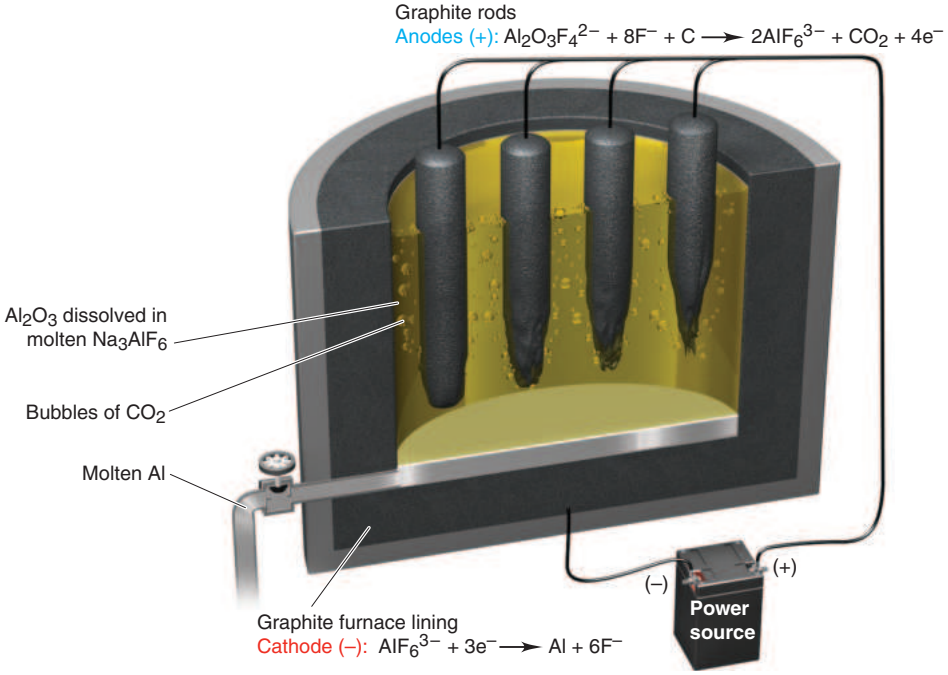

Figure 22.20 **The electrolytic cell in the manufacture of aluminum.**

3. *Energy considerations.* The Hall-Heroult process uses an enormous quantity of energy: aluminum production accounts for more than 5% of total U.S. electrical usage. The most basic reason for such high energy consumption is the electron configuration of Al ([Ne] $3s^23p^1$). Each Al^{3+} ion needs $3e^-$ to form an Al atom, and the atomic mass of Al is so low (~27 g/mol) that 1 mol of e^- (96,500 C) produces only 9 g of Al. An aluminum-air battery can turn this disadvantage around. Once produced, Al

represents a concentrated form of electrical energy that can deliver a high output per gram: 1 mol of e^- for every 9 g of Al consumed in the battery.

Metallurgy of Aluminum: Uses and Recycling Aluminum is a superb decorative, functional, and structural metal. It is lightweight, attractive, easy to work, and forms strong alloys. Although Al is very active, it does not corrode readily because of an adherent oxide layer that forms rapidly in air and prevents more O_2 from penetrating. Nevertheless, when it is in contact with less active metals such as Fe, Cu, and Pb, aluminum becomes the anode in a voltaic-like arrangement and deteriorates rapidly (Section 21.6). To prevent this, aluminum objects are often *anodized,* that is, made to act as the anode in an electrolytic cell that coats them with an oxide layer. The object is immersed in a 20% H_2SO_4 bath and connected to a graphite cathode:

$$6H^+(aq) + 6e^- \longrightarrow 3H_2(g) \quad \text{[cathode; reduction]}$$
$$2Al(s) + 3H_2O(l) \longrightarrow Al_2O_3(s) + 6H^+(aq) + 6e^- \quad \text{[anode; oxidation]}$$
$$2Al(s) + 3H_2O(l) \longrightarrow Al_2O_3(s) + 3H_2(g) \quad \text{[overall (cell) reaction]}$$

The Al_2O_3 layer deposited is typically from 10 μ to 100 μ thick, depending on the object's intended use. Figure 22.21 presents a breakdown of the many uses of aluminum.

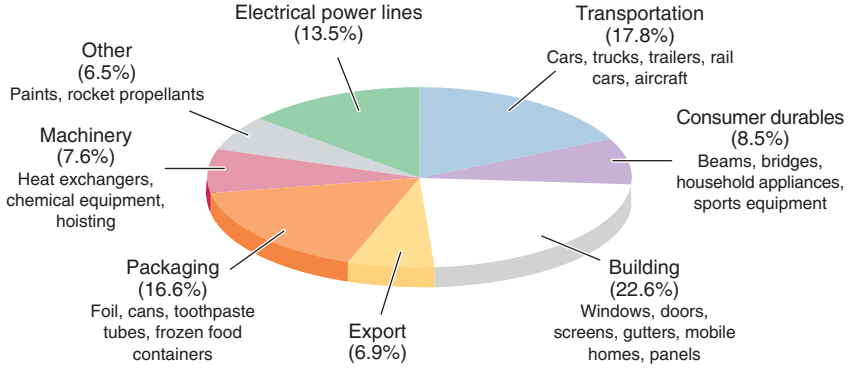

Figure 22.21 **The many familiar and essential uses of aluminum.**

More than 4.0 billion pounds (1.8 million metric tons) of aluminum cans and packaging are discarded each year—a waste of one of the most useful materials in the world *and* the energy used to make it. A quick calculation of the energy needed to prepare 1 mol of Al from *purified* Al_2O_3, compared with the energy needed for recycling, conveys a clear message. For the overall cell reaction in the Hall-Heroult process, $\Delta H^\circ = 2272$ kJ and $\Delta S^\circ = 635.4$ J/K. If we consider *only* the standard free energy change of the reaction at 1000.°C, for 1 mol of Al, we obtain

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = \frac{2272 \text{ kJ}}{4 \text{ mol Al}} - \left(1273 \text{ K} \times \frac{0.6354 \text{ kJ/K}}{4 \text{ mol Al}}\right) = 365.8 \text{ kJ/mol Al}$$

The molar mass of Al is nearly 2.5 times the mass of a soft-drink or beer can, so the electrolysis step requires nearly 150 kJ of energy for each can!

When aluminum is recycled, the major energy input (which is for melting the cans and foil) has been calculated as ~26 kJ/mol Al. The ratio of these energy inputs is

$$\frac{\text{Energy to recycle 1 mol Al}}{\text{Energy for electrolysis of 1 mol Al}} = \frac{26 \text{ kJ}}{365.8 \text{ kJ}} = 0.071$$

Based on just these portions of the process, recycling uses about 7% as much energy as electrolysis. Recent energy estimates for the entire manufacturing process (including mining, pretreating, maintaining operating conditions, electrolyzing, and so forth) are about 6000 kJ/mol Al, which means recycling requires less than 1% as much energy as manufacturing. The economic advantages, not to mention the environmental ones, are obvious, and recycling of aluminum has become common in the United States *(see photo).*

Crushed aluminum cans ready for recycling.

Mining the Sea for Magnesium

As terrestrial sources of certain elements become scarce or too costly to mine, the oceans will become an important source. In fact, despite the abundant distribution of magnesium on land, it is already obtained from the sea.

Isolation of Magnesium The *Dow process* for isolating magnesium from the sea involves steps similar to those used for rocky ores (Figure 22.22):

1. *Mining.* Intake of seawater and straining the debris are the "mining" steps. No pretreatment is needed.

2. *Converting to mineral.* The dissolved Mg^{2+} ion is converted to the mineral $Mg(OH)_2$ with $Ca(OH)_2$, which is generated on-site (at the plant). Seashells ($CaCO_3$) are crushed, decomposed with heat to CaO, and mixed with water to make slaked lime [$Ca(OH)_2$]. This is pumped into the intake tank to precipitate the Mg^{2+} as the hydroxide ($K_{sp} \approx 10^{-9}$):

$$Ca(OH)_2(aq) + Mg^{2+}(aq) \longrightarrow Mg(OH)_2(s) + Ca^{2+}(aq)$$

3. *Converting to compound.* The solid $Mg(OH)_2$ is filtered and mixed with excess HCl, which is also made on-site, to form aqueous $MgCl_2$:

$$Mg(OH)_2(s) + 2HCl(aq) \longrightarrow MgCl_2(aq) + 2H_2O(l)$$

The water is evaporated in stages to give solid, hydrated $MgCl_2 \cdot nH_2O$.

4. *Electrochemical redox.* Heating above 700°C drives off the water of hydration and melts the $MgCl_2$. Electrolysis gives chlorine gas and the molten metal, which floats on the denser molten salt:

$$MgCl_2(l) \longrightarrow Mg(l) + Cl_2(g)$$

The Cl_2 that forms is recycled to make the HCl used in step 3.

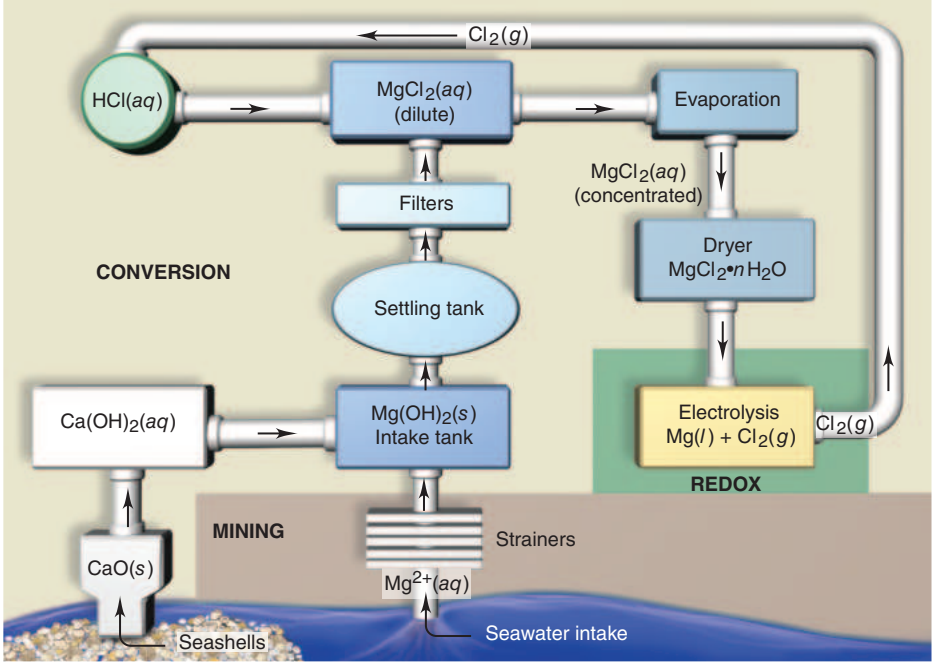

Figure 22.22 The Dow process for isolation of elemental Mg from seawater.

Uses of Magnesium Magnesium is the lightest structural metal available (about one-half the density of Al and one-fifth that of steel). Although Mg is quite reactive, it forms an extremely adherent, high-melting oxide layer (MgO) that prevents further reaction with the free metal beneath it; thus, magnesium finds many uses in metal

alloys and can be machined into any form. Magnesium alloys occur in everything from aircraft bodies to camera bodies, and from luggage to auto engine blocks. The pure metal is a strong reducing agent, which makes it useful for sacrificial anodes (Section 21.6) and in the metallurgical extraction of other metals, such as Be, Ti, Zr, Hf, and U. For example, titanium, an essential component of jet engines *(see photo),* is made from its major ore, ilmenite, in two steps:

(1) $2FeTiO_3(s) + 7Cl_2(g) + 6C(s) \longrightarrow 2TiCl_4(l) + 2FeCl_3(s) + 6CO(g)$

(2) $TiCl_4(l) + 2Mg(l) \longrightarrow Ti(s) + 2MgCl_2(l)$

Jet engine assembly.

The Sources and Uses of Hydrogen

Although hydrogen accounts for 90% of the atoms in the universe, it makes up only 15% of the atoms in Earth's crust. Moreover, hydrogen exists elsewhere in the universe mostly as H_2 molecules and free H atoms, but virtually all hydrogen in the crust is combined with other elements, either oxygen in natural waters or carbon in biomass and petroleum.

Industrial Production of Hydrogen Hydrogen gas (H_2) is produced on an industrial scale worldwide: 250,000 metric tons (3×10^{12} L at STP; equivalent to $\sim1\times10^{11}$ mol) are produced annually in the United States alone. All production methods are energy intensive, so the choice is determined by energy costs. In Scandinavia, where hydroelectric power is plentiful, electrolysis is used; on the other hand, where natural gas from oil refineries is plentiful, as in the United States and Great Britain, thermal methods are used.

1. *Electrolysis.* Very pure H_2 is prepared through electrolysis of water with Pt (or Ni) electrodes:

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \qquad E = -0.42\text{ V} \quad \text{[cathode; reduction]}$$
$$H_2O(l) \longrightarrow \tfrac{1}{2}O_2(g) + 2H^+(aq) + 2e^- \qquad E = 0.82\text{ V} \quad \text{[anode; oxidation]}$$
$$H_2O(l) \longrightarrow H_2(g) + \tfrac{1}{2}O_2(g) \qquad E_{cell} = -0.42\text{ V} - 0.82\text{ V} = -1.24\text{ V}$$

Overvoltage makes the cell potential about −2 V (Section 21.7). Therefore, under typical operating conditions, it takes about 400 kJ of energy to produce 1 mol of H_2:

$$\Delta G = -nFE = (-2\text{ mol e}^-)\left(\frac{96.5\text{ kJ}}{\text{V}\cdot\text{mol e}^-}\right)(-2\text{ V}) = 4\times10^2\text{ kJ/mol H}_2$$

High-purity O_2 is a valuable byproduct of this process that offsets some of the costs of isolating H_2.

2. *Thermal methods.* The most common thermal methods use water and a simple alkane like methane, which has the highest H/C atom ratio of any hydrocarbon. The reactants are heated to around 1000°C over a nickel-based catalyst in the endothermic *steam-reforming process:*

$$CH_4(g) + H_2O(g) \longrightarrow CO(g) + 3H_2(g) \qquad \Delta H^\circ = 206\text{ kJ}$$

Heat is supplied by burning methane. To generate more H_2, the product mixture (called *water gas*) is heated with steam at 400°C over an iron or cobalt oxide catalyst in the exothermic *water-gas shift reaction,* and the CO reacts (see also p. 273):

$$H_2O(g) + CO(g) \rightleftharpoons CO_2(g) + H_2(g) \qquad \Delta H^\circ = -41\text{ kJ}$$

The reaction mixture is recycled several times, which decreases the CO to around 0.2% by volume. Passing the mixture through liquid water removes the more soluble CO_2 (solubility = 0.034 mol/L), leaving a higher proportion of H_2 (solubility < 0.001 mol/L). Calcium oxide can also be used to remove CO_2 by formation of $CaCO_3$. By removing CO_2, these steps shift the equilibrium position to the right and produce H_2 that is about 98% pure. To filter out nearly all molecules larger than H_2 and attain greater purity (~99.9%), the gas mixture is passed through a *synthetic zeolite*. This material is an aluminosilicate whose framework of polyhedra contains small cavities of various sizes that trap some molecules and allow others to pass through.

Industrial Uses of Hydrogen Typically, an industrial plant produces H_2 to make some other product. More than 95% of H_2 produced is consumed in ammonia or petrochemical facilities.

1. *Ammonia synthesis.* In a plant that synthesizes NH_3, the reactant gases, N_2 and H_2, are formed through a series of reactions that involve methane. Here is a typical reaction series in an ammonia plant:

- The steam-reforming reaction is performed with excess CH_4, which depletes the reaction mixture of H_2O:

$$CH_4(g; \text{excess}) + H_2O(g) \longrightarrow CO(g) + 3H_2(g)$$

- An excess of the product mixture (CH_4, CO, and H_2) is burned in an amount of air ($N_2 + O_2$) that is insufficient for complete combustion, but is enough to consume the O_2, heat the mixture to 1100°C, and form additional H_2O:

$$4CH_4(g; \text{excess}) + 7O_2(g) \longrightarrow 2CO_2(g) + 2CO(g) + 8H_2O(g)$$
$$2H_2(g; \text{excess}) + O_2(g) \longrightarrow 2H_2O(g)$$
$$2CO(g; \text{excess}) + O_2(g) \longrightarrow 2CO_2(g)$$

- Any remaining CH_4 reacts by the steam-reforming reaction, the remaining CO reacts by the water-gas shift reaction ($H_2O + CO \rightleftharpoons CO_2 + H_2$) to form more H_2, and then the CO_2 is removed with CaO ($CaO + CO_2 \longrightarrow CaCO_3$).
- The amounts are carefully adjusted to produce a final mixture that contains a 1/3 mole ratio of N_2 (from the added air) to H_2 (with traces of CH_4, Ar, and CO). This mixture is used directly in the synthesis of ammonia (Section 17.6).

2. *Hydrogenation.* A second major use of H_2 is *hydrogenation* of C═C bonds in liquid oils to form C—C bonds in solid fats and margarine. The process uses H_2 in contact with transition metal catalysts, such as powdered nickel (see Figure 16.25, p. 714). Solid fats are also used in commercial baked goods. Look at the list of ingredients on most packages of bread, cake, and cookies, and you'll see the "partially hydrogenated vegetable oils" made by this process.

3. *Bulk chemicals and energy production.* Hydrogen is also essential in the manufacture of numerous "bulk" chemicals, those produced in large amounts because they have many further uses. One application that has been gaining great attention is the production of methanol. In this process, carbon monoxide reacts with hydrogen over a copper–zinc oxide catalyst:

$$CO(g) + 2H_2(g) \xrightarrow{\text{Cu-ZnO catalyst}} CH_3OH(l)$$

Methanol is already being used as a gasoline additive. As less expensive sources become available, hydrogen will also be used increasingly in fuel cells on a major scale (Section 21.5).

Production and Uses of Deuterium; Kinetic Isotope Effect In addition to ordinary hydrogen (^1H), or protium, there are two other naturally occurring isotopes of significantly lower abundance. Deuterium (^2H or D) has one neutron, and rare, radioactive tritium (^3H or T) has two. Like H_2, both occur as diatomic molecules: D_2 (or $^2H_2$) and T_2 (or $^3H_2$). Table 22.6 compares some of their molecular and physical properties. As you can see from these data, the heavier the isotope is and, thus, the higher the molar mass of the molecule, the higher the melting point, boiling point, and heats of phase change.

Because hydrogen is so light, the relative difference in mass of its isotopes is enormous compared with that of isotopes of other common, heavier elements. For example, ^2H has 2 times the mass of ^1H, whereas ^{13}C has only 1.08 times the mass of ^{12}C. *The mass difference leads to different bond energies, which affect reactivity.* As a result, an H atom bonded to a given atom vibrates at a higher frequency than a D atom does, so the bond to H is higher in energy. Thus, *it is weaker and easier to break*. Therefore, any reaction that includes breaking a bond to H or D in the rate-determining step occurs *faster with H than with D*. This phenomenon, called a *kinetic isotope effect,* is also used to isolate deuterium.

Table 22.6 Some Molecular and Physical Properties of Diatomic Protium, Deuterium, and Tritium

Property	H_2	D_2	T_2
Molar mass (g/mol)	2.016	4.028	6.032
Bond length (pm)	74.14	74.14	74.14
Melting point (K)	13.96	18.73	20.62
Boiling point (K)	20.39	23.67	25.04
ΔH°_{fus} (kJ/mol)	0.117	0.197	0.250
ΔH°_{vap} (kJ/mol)	0.904	1.226	1.393
Bond energy (kJ/mol at 298 K)	432	443	447

Deuterium and its compounds are produced from D_2O (heavy water), which is present as a minor component (0.016 mol %) in normal water and is isolated on the multiton scale by *electrolytic enrichment*. Due to the kinetic isotope effect, there is a *higher rate of bond breaking for O—H bonds compared to O—D bonds,* and thus a higher rate of electrolysis of H_2O compared with D_2O.

For example, with Pt electrodes, H_2O is electrolyzed about 14 times faster than D_2O. As some of the liquid decomposes to the elemental gases, the remainder becomes enriched in D_2O. Thus, by the time the volume of water has been reduced to 1/20,000 of its original volume, the remaining water is around 99% D_2O. By combining samples and repeating the electrolysis, more than 99.9% D_2O is obtained.

Deuterium gas is produced by electrolysis of D_2O or by any of the chemical reactions that produce hydrogen gas from water, such as

$$2Na(s) + 2D_2O(l) \longrightarrow 2Na^+(aq) + 2OD^-(aq) + D_2(g)$$

Compounds containing deuterium (or tritium) are produced from reactions that give rise to the corresponding hydrogen-containing compound; for example,

$$SiCl_4(l) + 2D_2O(l) \longrightarrow SiO_2(s) + 4DCl(g)$$

Compounds with acidic protons undergo hydrogen/deuterium exchange:

$$CH_3COOH(l) + D_2O(l; \text{excess}) \longrightarrow CH_3COOD(l) + DHO(l; \text{small amount})$$

We discuss the natural and synthetic formation of tritium in Chapter 24.

Summary of Section 22.4

Production highlights of key elements are as follows:

- Na is isolated by electrolysis of molten NaCl in the Downs process; Cl_2 is a byproduct.
- K is produced by reduction with Na in a thermal process.
- Fe is produced through a multistep high-temperature process in a blast furnace. The crude pig iron is converted to carbon steel in the basic-oxygen process and then alloyed with other metals to make different steels.
- Cu is produced by concentration of the ore through flotation, reduction to the metal by smelting, and purification by electrorefining. The metal has extensive electrical and plumbing uses.
- Al is extracted from bauxite by pretreating the ore with concentrated base, followed by electrolysis of the product Al_2O_3 mixed with molten cryolite. Al alloys are widely used in homes and industry. The total energy required to extract Al from its ore is over 100 times that needed for recycling it.
- The Mg^{2+} in seawater is converted to $Mg(OH)_2$ and then to $MgCl_2$, which is electrolyzed to obtain the metal; Mg forms strong, lightweight alloys.
- H_2 is produced by electrolysis of water or in the formation of gaseous fuels from hydrocarbons. It is used in NH_3 production, in hydrogenation of vegetable oils, and in energy production. The isotopes of hydrogen differ significantly in atomic mass and thus in the rate at which their bonds to other atoms break (kinetic isotope effect). This difference is used to obtain D_2O from water.

22.5 CHEMICAL MANUFACTURING: TWO CASE STUDIES

In this final section, we examine the interplay of theory and practice in two of the most important processes in the inorganic chemical industry: the contact process for the production of sulfuric acid and the chlor-alkali process for the production of chlorine.

Sulfuric Acid, the Most Important Chemical

Because it has countless uses, sulfuric acid is produced throughout the world on a gigantic scale—more than 150 million tons a year. The modern **contact process** is based on the *catalyzed oxidation of* SO_2. Here are the key steps.

1. *Obtaining sulfur.* In most countries today, the production of sulfuric acid starts with the production of elemental sulfur, often by the *Claus process,* in which the H_2S in "sour" natural gas that has been chemically separated is oxidized:

$$2H_2S(g) + 2O_2(g) \xrightarrow{\text{low temperature}} \tfrac{1}{8}S_8(g) + SO_2(g) + 2H_2O(g)$$

$$2H_2S(g) + SO_2(g) \xrightarrow{Fe_2O_3\ \text{catalyst}} \tfrac{3}{8}S_8(g) + 2H_2O(g)$$

Where natural deposits of sulfur are found, it is obtained by a nonchemical method called the *Frasch process.* A hole is drilled to the deposit, and superheated water (about 160°C) is pumped down two outer concentric pipes to melt the sulfur (Figure 22.23A). Then, a combination of the hydrostatic pressure in an outermost pipe and the pressure of compressed air sent through a narrow inner pipe forces the sulfur to the surface (Figure 22.23B and C). The costs of drilling, pumping, and supplying water (5×10^6 gallons per day) are balanced somewhat by the purity of the product (~99.7%

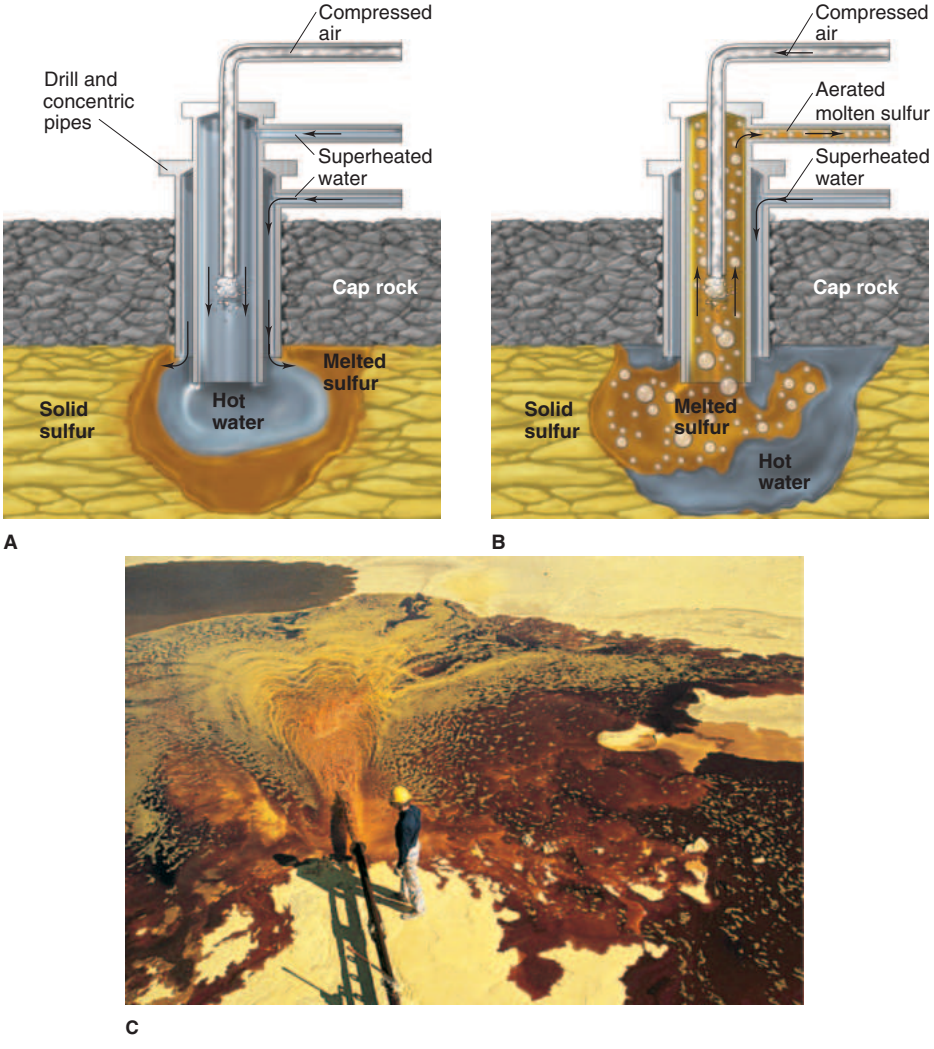

Figure 22.23 The Frasch process for mining elemental sulfur.

sulfur). About 90% of processed sulfur is used in making sulfur dioxide for production of sulfuric acid. Indeed, this end product is so important that a nation's level of sulfur production is a reliable indicator of its overall industrial capacity: the United States, Canada, China, Russia, Japan, and Germany are the top six sulfur producers.

2. *From sulfur to sulfur dioxide.* The sulfur is burned in air to form SO_2:

$$\tfrac{1}{8}S_8(s) + O_2(g) \longrightarrow SO_2(g) \qquad \Delta H^\circ = -297 \text{ kJ}$$

Some SO_2 is also obtained by roasting metal sulfide ores and from the Claus process.

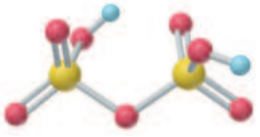
3. *From sulfur dioxide to trioxide.* The *contact process* oxidizes SO_2 to SO_3:

$$SO_2(g) + \tfrac{1}{2}O_2(g) \rightleftharpoons SO_3(g) \qquad \Delta H^\circ = -99 \text{ kJ}$$

The reaction is *exothermic* and very *slow* at room temperature. From Le Châtelier's principle (Section 17.6), the yield of SO_3 can be increased by (1) changing the temperature, (2) increasing the pressure (more moles of gas are on the left than on the right), or (3) adjusting the concentrations (adding excess O_2 and removing SO_3). In this case, the pressure effect is small and economically not worth exploiting. Let's examine the other two effects:

- *Effect of changing the temperature.* Adding heat (raising the temperature) increases the frequency and energy of SO_2–O_2 collisions and thus increases the *rate* of SO_3 formation. However, because the formation is exothermic, removing heat (lowering the temperature) shifts the equilibrium position to the right and thus increases the *yield* of SO_3. This is a classic situation that calls for use of a catalyst. By lowering the activation energy, *a catalyst allows equilibrium to be reached more quickly and at a lower temperature;* thus, rate *and* yield are optimized (Section 16.7). The catalyst in the contact process is V_2O_5 on inert silica, which is active between 400°C and 600°C.
- *Effect of changing the concentration.* Providing an excess of O_2 as a 5/1 mixture of air to SO_2, which is about 1/1 O_2 to SO_2, supplies about twice as much O_2 as in the balanced equation. The mixture is passed over catalyst beds in four stages, and the SO_3 is removed to shift the reaction toward more SO_3 formation. The overall yield of SO_3 is 99.5%.

4. *From sulfur trioxide to acid.* Sulfur trioxide is the anhydride of sulfuric acid. However, SO_3 cannot be added to water because, at the operating temperature, it would first meet water vapor, which catalyzes its polymerization to $(SO_3)_x$, and results in a smoke of solid particles that yields little acid (reaction 1). To avoid this, previously formed H_2SO_4 absorbs the SO_3 (reaction 2) and forms pyrosulfuric acid (or disulfuric acid, $H_2S_2O_7$; *see margin*), which is then hydrolyzed with sufficient water (reaction 3):



disulfuric acid

$$\text{(1)} \quad SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(l) \qquad \text{[lower yield]}$$
$$\text{(2)} \quad SO_3(g) + H_2SO_4(l) \longrightarrow H_2S_2O_7(l)$$
$$\text{(3)} \quad H_2S_2O_7(l) + H_2O(l) \longrightarrow 2H_2SO_4(l) \qquad \text{[higher yield]}$$

The industrial uses of sulfuric acid are legion, as Figure 22.24 indicates.

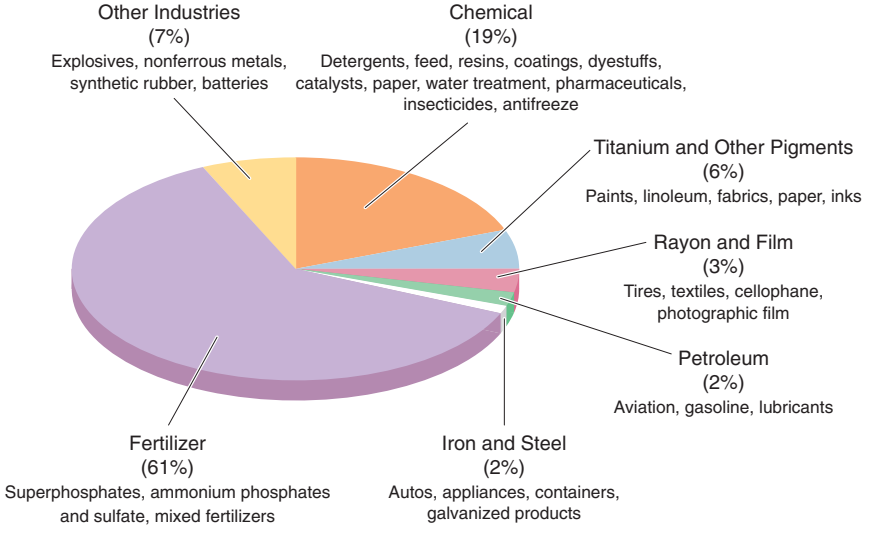


Figure 22.24 **The many indispensable applications of sulfuric acid.**

Sulfuric acid is remarkably inexpensive (about \$150/ton), largely because each step in the process is exothermic—burning S ($\Delta H^\circ = -297$ kJ/mol), oxidizing SO_2 ($\Delta H^\circ = -99$ kJ/mol), hydrating SO_3 ($\Delta H^\circ = -132$ kJ/mol)—and the heat is a valuable byproduct. Three-quarters of the heat is sold as steam, and the rest of it is used to pump gases through the plant. A typical plant making 825 tons of H_2SO_4 per day produces enough steam to generate 7×10^6 watts of electric power.

The Chlor-Alkali Process

Chlorine is produced and used in amounts many times greater than all the other halogens combined, ranking among the top 10 chemicals produced in the United States. The **chlor-alkali process,** which forms the basis of one of the largest inorganic chemical industries, *electrolyzes concentrated aqueous NaCl to produce Cl_2,* and several other important chemicals are also produced. There are three versions of this process.

Diaphragm-Cell Method As you learned in Section 21.7, the electrolysis of aqueous NaCl does not yield both of the component elements. Because of the overvoltage, Cl^- ions rather than H_2O molecules are oxidized at the anode. However, Na^+ ions are not reduced at the cathode because the half-cell potential (−2.71 V) is much more negative than that for reduction of H_2O (−0.42 V), even with the normal overvoltage (around −0.6 V). Therefore, the half-reactions for electrolysis of aqueous NaCl are

$$2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \qquad E^\circ = 1.36\text{ V} \quad \text{[anode; oxidation]}$$

$$2H_2O(l) + 2e^- \longrightarrow 2OH^-(aq) + H_2(g) \qquad E \approx -1.0\text{ V} \quad \text{[cathode; reduction]}$$

$$2Cl^-(aq) + 2H_2O(l) \longrightarrow 2OH^-(aq) + H_2(g) + Cl_2(g) \qquad E_{cell} = -1.0\text{ V} - 1.36\text{ V} = -2.4\text{ V}$$

To obtain commercially meaningful amounts of Cl_2, however, a voltage almost twice this value and a current in excess of 3×10^4 A are used.

When we include the spectator ion Na^+, the total ionic equation shows that the process yields another important product, NaOH:

$$2Na^+(aq) + 2Cl^-(aq) + 2H_2O(l) \longrightarrow 2Na^+(aq) + 2OH^-(aq) + H_2(g) + Cl_2(g)$$

As Figure 22.25 shows, the sodium salts in the cathode compartment exist as an aqueous mixture of NaCl and NaOH; the NaCl is removed by fractional crystallization. Thus, in this version of the chlor-alkali process, which uses an *asbestos diaphragm* to separate the anode and cathode compartments, electrolysis of NaCl brines yields Cl_2, H_2, and industrial-grade NaOH, a useful base. Like other reactive products, H_2 and Cl_2 are kept apart to prevent explosive recombination. Note the higher liquid level in the anode *(left)* compartment. This slight hydrostatic pressure difference minimizes

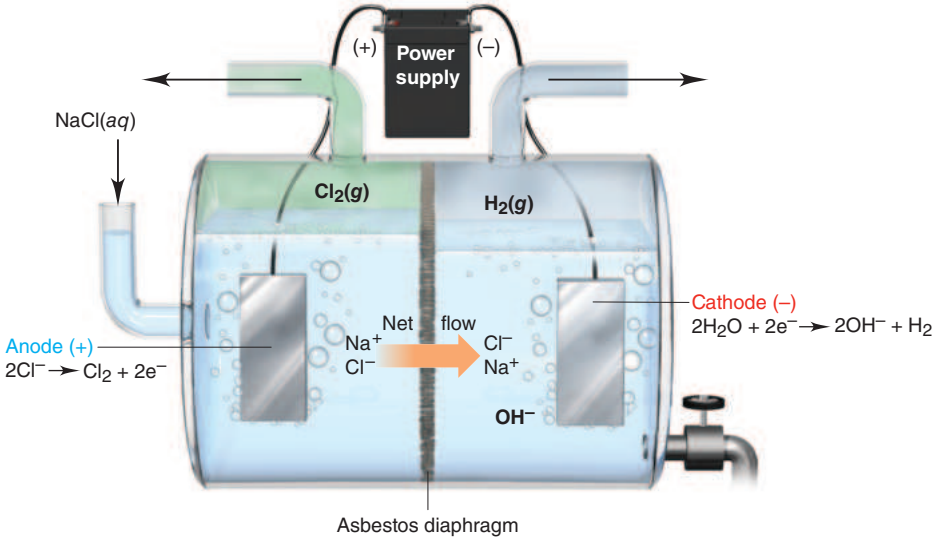

Figure 22.25 A diaphragm cell for the chlor-alkali process.

backflow of NaOH, which prevents the disproportionation reactions of Cl_2 that occur in the presence of OH^- (Section 14.9), such as

$$Cl_2(g) + 2OH^-(aq) \longrightarrow Cl^-(aq) + ClO^-(aq) + H_2O(l)$$

Mercury-Cell Method If high-purity NaOH is desired, a slightly different version, called the *chlor-alkali mercury-cell process,* is employed. Mercury is used as the cathode, which creates such a large overvoltage for reduction of H_2O to H_2 that the process *does* favor reduction of Na^+. The sodium dissolves in the mercury to form sodium amalgam, Na(Hg). In the mercury-cell version, the half-reactions are

$$2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \quad \text{[anode; oxidation]}$$
$$2Na^+(aq) + 2e^- \xrightarrow{Hg} 2Na(Hg) \quad \text{[cathode; reduction]}$$

To obtain sodium hydroxide, the sodium amalgam is pumped out of the system and treated with H_2O, which is reduced by the Na:

$$2Na(Hg) + 2H_2O(l) \xrightarrow{-Hg} 2Na^+(aq) + 2OH^-(aq) + H_2(g)$$

The mercury released in this step is recycled back to the electrolysis bath. Therefore, *the products are the same in both versions* of the chlor-alkali process, but the purity of NaOH from the mercury-cell method is much higher.

The mercury-cell method is being steadily phased out because, as the mercury is recycled, small amounts are lost in the industrial wastewater. On average, 200 g of Hg is lost per ton of Cl_2 produced. In the 1980s, annual U.S. production via the mercury-cell method was 2.75 million tons of Cl_2; thus, during that decade, 550,000 kg of mercury, a toxic heavy metal, was flowing into U.S. waterways each year!

Membrane-Cell Method The *chlor-alkali membrane-cell process* replaces the diaphragm with a polymeric membrane to separate the cell compartments. The membrane allows only cations to move through it and only from anode to cathode compartments. Thus, as Cl^- ions are removed at the anode through oxidation to Cl_2, Na^+ ions in the anode compartment move through the membrane to the cathode compartment and form an NaOH solution. In addition to forming purer NaOH than the older diaphragm-cell method, the membrane-cell method uses less electricity and eliminates the problem of Hg pollution. As a result, it has been adopted throughout much of the industrialized world.

Summary of Section 22.5

- Sulfuric acid production starts with the extraction of sulfur, either by the oxidation of H_2S or the mining of sulfur deposits. The sulfur is roasted to SO_2 and oxidized to SO_3 by the catalyzed contact process, which optimizes the yield at lower temperatures. Absorption of the SO_3 into H_2SO_4, followed by hydration, forms sulfuric acid.
- In the diaphragm-cell chlor-alkali process, aqueous NaCl is electrolyzed to form Cl_2, H_2, and low-purity NaOH. The mercury-cell method produces high-purity NaOH but has been almost completely phased out because of mercury pollution. The membrane-cell method requires less electricity and does not use Hg.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) numbers appear in parentheses.

Understand These Concepts

1. How gravity, thermal convection, and elemental properties led to the silicate, sulfide, and iron phases and the predominance of certain elements in Earth's crust, mantle, and core (§22.1)
2. How organisms affect crustal abundances of elements, especially oxygen, carbon, calcium, and some transition metals; the onset of oxidation as an energy source (§22.1)
3. How atomic properties influence which elements have oxide ores and which have sulfide ores (§22.1)
4. The central role of CO_2 and the importance of photosynthesis, respiration, and decomposition in the carbon cycle (§22.2)
5. The central role of N_2 and the importance of atmospheric, industrial, and biological fixation in the nitrogen cycle (§22.2)

Learning Objectives (continued)

Relevant section (§) numbers appear in parentheses.

6. The absence of a gaseous component, the interactions of the inorganic and biological cycles, and the impact of humans on the phosphorus cycle (§22.2)
7. How pyro-, electro-, and hydrometallurgical processes are employed to extract a metal from its ore; the importance of the reduction step from compound to metal; refining and alloying processes (§22.3)
8. Functioning of the Downs cell for Na production and the application of Le Châtelier's principle to K production (§22.4)
9. How iron ore is reduced in a blast furnace and how pig iron is purified by the basic-oxygen process (§22.4)
10. How Fe is removed from copper ore and impure Cu is electrorefined (§22.4)
11. The importance of amphoterism in the Bayer process for isolating Al_2O_3 from bauxite; the significance of cryolite in the electrolytic step; the energy advantage of Al recycling (§22.4)
12. The steps in the Dow process for the extraction of Mg from seawater (§22.4)
13. How H_2 production, whether by chemical or electrolytic means, is tied to NH_3 production (§22.4)
14. How the kinetic isotope effect is applied to produce deuterium (§22.4)
15. How the Frasch process is used to obtain sulfur from natural deposits (§22.5)
16. The importance of equilibrium and kinetic factors in H_2SO_4 production (§22.5)
17. How overvoltage allows electrolysis of aqueous NaCl to form Cl_2 gas in the chlor-alkali process; coproduction of NaOH; comparison of diaphragm-cell, mercury-cell, and membrane-cell methods (§22.5)

Key Terms

Page numbers appear in parentheses.

Section 22.1
abundance (977)
differentiation (978)
core (978)
mantle (978)
crust (978)
lithosphere (980)
hydrosphere (980)
atmosphere (980)
biosphere (980)
occurrence (source) (981)
ore (981)

Section 22.2
environmental cycle (982)
fixation (984)
apatites (986)

Section 22.3
metallurgy (988)
mineral (988)
gangue (988)
flotation (989)
leaching (989)
roasting (990)
smelting (990)
electrorefining (992)
zone refining (992)
alloy (992)

Section 22.4
Downs cell (994)
steel (996)
blast furnace (996)
slag (997)
basic-oxygen process (997)
carbon steel (997)

Section 22.5
contact process (1006)
chlor-alkali process (1008)

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and offer Concept Review Questions and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

How the Elements Occur in Nature

Concept Review Questions

22.1 Hydrogen is by far the most abundant element cosmically. In interstellar space, it exists mainly as H_2. In contrast, on Earth, it exists very rarely as H_2 and is ninth in abundance in the crust. Why is hydrogen so abundant in the universe? Why is hydrogen so rare as a diatomic gas in Earth's atmosphere?

22.2 Metallic elements can be recovered from ores that are oxides, carbonates, halides, or sulfides. Give an example of each type.

22.3 The location of elements in the regions of Earth has enormous practical importance. (a) Define *differentiation*, and explain which physical property of a substance is primarily responsible for this process. (b) What are the four most abundant elements in the crust? (c) Which element is abundant in the crust and mantle but not the core?

22.4 How does the position of a metal in the periodic table relate to whether it occurs primarily as an oxide or as a sulfide?

Problems in Context

22.5 What material is the source for commercial production of each of the following elements: (a) aluminum; (b) nitrogen; (c) chlorine; (d) calcium; (e) sodium?

22.6 Aluminum is widely distributed throughout the world in the form of aluminosilicates. What property of these minerals prevents them from being a source of aluminum?

22.7 Describe two ways in which the biosphere has influenced the composition of Earth's crust.

The Cycling of Elements Through the Environment

Concept Review Questions

22.8 Use atomic and molecular properties to explain why life is based on carbon rather than some other element, such as silicon.

22.9 Define *fixation*. Name two elements that undergo environmental fixation. What natural forms of them are fixed?

22.10 Carbon dioxide enters the atmosphere by natural processes and from human activity. Why is the latter a cause of concern?

22.11 Diagrams of environmental cycles are simplified to omit minor contributors. For example, the production of lime from limestone is not shown in the cycle for carbon (Figure 22.5, p. 983). Which labeled category in the figure includes this process? Name two other processes that contribute to this category.

22.12 Describe three pathways for the utilization of atmospheric nitrogen. Is human activity a significant factor? Explain.

22.13 Why don't the N-containing species in Figure 22.6 (p. 984) include rings or long chains with N—N bonds?

22.14 (a) Which region of Earth's crust is not involved in the phosphorus cycle? (b) Name two roles organisms play in the cycle.

Problems in Context

22.15 Nitrogen fixation requires a great deal of energy because the N_2 bond is strong. (a) How do the processes of atmospheric and industrial fixation reflect this energy requirement? (b) How do the thermodynamics of the two processes differ? (*Hint:* Examine the respective heats of formation.) (c) In view of the mild conditions for biological fixation, what must be the source of the "great deal of energy"? (d) What would be the most obvious environmental result of a low activation energy for N_2 fixation?

22.16 The following steps are *unbalanced* half-reactions involved in the nitrogen cycle. Balance each half-reaction to show the number of electrons lost or gained, and state whether it is an oxidation or a reduction (all occur in acidic conditions):

(a) $N_2(g) \longrightarrow NO(g)$ (b) $N_2O(g) \longrightarrow NO_2(g)$

(c) $NH_3(aq) \longrightarrow NO_2^-(aq)$ (d) $NO_3^-(aq) \longrightarrow NO_2^-(aq)$

(e) $N_2(g) \longrightarrow NO_3^-(aq)$

22.17 The use of silica to form slag in the production of phosphorus from phosphate rock was introduced by Robert Boyle more than 300 years ago. When fluorapatite [$Ca_5(PO_4)_3F$] is used in phosphorus production, most of the fluorine atoms appear in the slag, but some end up in the toxic and corrosive gas SiF_4.

(a) If 15% by mass of the fluorine in 100. kg of $Ca_5(PO_4)_3F$ forms SiF_4, what volume of this gas is collected at 1.00 atm and the industrial furnace temperature of 1450.°C?

(b) In some facilities, the SiF_4 is used to produce sodium hexafluorosilicate (Na_2SiF_6) which is sold for water fluoridation:

$$2SiF_4(g) + Na_2CO_3(s) + H_2O(l) \longrightarrow Na_2SiF_6(aq) + SiO_2(s) + CO_2(g) + 2HF(aq)$$

How many cubic meters of drinking water can be fluoridated to a level of 1.0 ppm of F^- using the SiF_4 produced in part (a)?

22.18 An impurity sometimes found in $Ca_3(PO_4)_2$ is Fe_2O_3, which is removed during the production of phosphorus as *ferrophosphorus* (Fe_2P). (a) Why is this impurity troubling from an economic standpoint? (b) If 50. metric tons of crude $Ca_3(PO_4)_2$ contains 2.0% Fe_2O_3 by mass and the overall yield of phosphorus is 90.%, how many metric tons of P_4 can be isolated?

Metallurgy: Extracting a Metal from Its Ore

Concept Review Questions

22.19 Define: (a) ore; (b) mineral; (c) gangue; (d) brine.

22.20 Define: (a) roasting; (b) smelting; (c) flotation; (d) refining.

22.21 What factors determine which reducing agent is selected for producing a specific metal?

22.22 Use atomic properties to explain the reduction of a less active metal by a more active one: (a) in aqueous solution; (b) in the molten state. Give a specific example of each process.

22.23 What class of element is obtained by oxidation of a mineral? What class of element is obtained by reduction of a mineral?

Problems in Context

22.24 Which set of elements gives each of the following alloys: (a) brass; (b) stainless steel; (c) bronze; (d) sterling silver?

1. Cu, Ag 2. Cu, Sn, Zn 3. Ag, Au
4. Fe, Cr, Ni 5. Fe, V 6. Cu, Zn

Tapping the Crust: Isolation and Uses of Selected Elements

Concept Review Questions

22.25 How are each of the following involved in iron metallurgy: (a) slag; (b) pig iron; (c) steel; (d) basic-oxygen process?

22.26 What are the distinguishing features of each extraction process: pyrometallurgy, electrometallurgy, and hydrometallurgy? Explain briefly how the types of metallurgy are used in the production of (a) Fe; (b) Na; (c) Au; (d) Al.

22.27 What property allows copper to be purified in the presence of iron and nickel impurities? Explain.

22.28 Why is cryolite used in the electrolysis of aluminum oxide?

22.29 (a) What is a kinetic isotope effect?

(b) Do compounds of hydrogen exhibit a relatively large or small kinetic isotope effect? Explain.

(c) Carbon compounds also exhibit a kinetic isotope effect. How do you expect it to compare in magnitude with that for hydrogen compounds? Why?

22.30 How is Le Châtelier's principle involved in the production of elemental potassium?

Problems in Context

22.31 Elemental Li and Na are prepared by electrolysis of a molten salt, whereas K, Rb, and Cs are prepared by chemical reduction.

(a) In general terms, explain why the alkali metals cannot be prepared by electrolysis of their aqueous salt solutions.

(b) Use ionization energies (see the Family Portraits, pp. 575 and 578) to explain why calcium should *not* be able to isolate Rb from molten RbX (X = halide).

(c) Use physical properties to explain why calcium *is* used to isolate Rb from molten RbX.

(d) Can Ca be used to isolate Cs from molten CsX? Explain.

22.32 A Downs cell operating at 77.0 A produces 31.0 kg of Na.

(a) What volume of $Cl_2(g)$ is produced at 1.0 atm and 540.°C?

(b) How many coulombs were passed through the cell?

(c) How long did the cell operate?

22.33 (a) In the industrial production of iron, what is the reducing substance loaded into the blast furnace?

(b) In addition to furnishing the reducing power, what other function does this substance serve?

(c) What is the formula of the active reducing agent in the process?

(d) Write equations for the stepwise reduction of Fe_2O_3 to iron in the furnace.

22.34 One of the substances loaded into a blast furnace is limestone, which produces lime in the furnace.

(a) Give the chemical equation for the reaction forming lime.

(b) Explain the purpose of lime in the furnace. The term *flux* is often used as a label for a substance acting as the lime does. What is the derivation of this word, and how does it relate to the function of the lime?

(c) Write a chemical equation describing the action of lime flux.

22.35 The last step in the Dow process for the production of magnesium metal involves electrolysis of molten $MgCl_2$.
(a) Why isn't the electrolysis carried out with aqueous $MgCl_2$? What are the products of this aqueous electrolysis?
(b) Do the high temperatures required to melt $MgCl_2$ favor products or reactants? (*Hint:* Consider the ΔH_f° of $MgCl_2$.)

22.36 Iodine is the only halogen that occurs in a positive oxidation state, in $NaIO_3$ impurities within Chile saltpeter, $NaNO_3$.
(a) Is this mode of occurrence consistent with iodine's location in the periodic table? Explain.
(b) In the production of I_2, IO_3^- reacts with HSO_3^-:

$$IO_3^-(aq) + HSO_3^-(aq) \longrightarrow HSO_4^-(aq) + SO_4^{2-}(aq) + H_2O(l) + I_2(s) \quad \text{[unbalanced]}$$

Identify the oxidizing and reducing agents.
(c) If 0.78 mol % of an $NaNO_3$ deposit is $NaIO_3$, how much I_2 (in g) can be obtained from 1.000 ton (2000. lb) of the deposit?

22.37 Selenium is prepared by the reaction of H_2SeO_3 with gaseous SO_2.
(a) What redox process does the sulfur dioxide undergo? What is the oxidation state of sulfur in the product?
(b) Given that the reaction occurs in acidic aqueous solution, what is the formula of the sulfur-containing species?
(c) Write the balanced redox equation for the process.

22.38 F_2 and Cl_2 are produced by electrolytic oxidation, whereas Br_2 and I_2 are produced by chemical oxidation of the halide ions in a concentrated aqueous solution (brine) by a more electronegative halogen. Give two reasons why Cl_2 isn't prepared this way.

22.39 Silicon is prepared by the reduction of K_2SiF_6 with Al. Write the equation for this reaction. (*Hint:* Can F^- be oxidized in this reaction? Can K^+ be reduced?)

22.40 What is the mass percent of iron in each of the following iron ores: Fe_2O_3, Fe_3O_4, FeS_2?

22.41 Phosphorus is one of the impurities present in pig iron that is removed in the basic-oxygen process. Assuming that phosphorus is present as P atoms, write equations for its oxidation and subsequent reaction in the basic slag.

22.42 The final step in the smelting of $FeCuS_2$ is

$$Cu_2S(s) + 2Cu_2O(s) \longrightarrow 6Cu(l) + SO_2(g)$$

(a) Give the oxidation states of copper in Cu_2S, Cu_2O, and Cu.
(b) What are the oxidizing and reducing agents in this reaction?

22.43 Use equations to show how acid-base properties are used to separate Fe_2O_3 and TiO_2 from Al_2O_3 in the Bayer process.

22.44 A piece of Al with a surface area of 2.5 m^2 is anodized to produce a film of Al_2O_3 that is 23 μm (23×10^{-6} m) thick. (a) How many coulombs flow through the cell in this process (assume that the density of the Al_2O_3 layer is 3.97 g/cm^3)? (b) If it takes 18 min to produce this film, what current must flow through the cell?

22.45 The production of H_2 gas by the electrolysis of water typically requires about 400 kJ of energy per mole.
(a) Use the relationship between work and cell potential (Section 21.4) to calculate the minimum work needed to form 1.0 mol of H_2 gas at a cell potential of 1.24 V.
(b) What is the energy efficiency of the cell operation?
(c) Find the cost of producing 500. mol of H_2 if electricity is \$0.06 per kilowatt-hour (1 watt-second = 1 joule).

22.46 (a) What are the components of the reaction mixture following the water-gas shift reaction? (b) Explain how zeolites are used to purify the H_2 formed.

22.47 Metal sulfides are often first converted to oxides by roasting in air and then reduced with carbon to produce the metal. Why aren't the metal sulfides reduced directly by carbon to yield CS_2? Give a thermodynamic analysis of both processes for ZnS.

Chemical Manufacturing: Two Case Studies

Concept Review Questions

22.48 Explain in detail why a catalyst is used to produce SO_3.

22.49 Among the exothermic steps in the manufacture of sulfuric acid is the process of hydrating SO_3. (a) Write two chemical reactions that show this process. (b) Why is the direct reaction of SO_3 with water not feasible?

22.50 Why is commercial H_2SO_4 so inexpensive?

22.51 (a) What are the three commercial products formed in the chlor-alkali process?
(b) State an advantage and a disadvantage of the mercury-cell method for this process.

Problems in Context

22.52 Consider the reaction of SO_2 to form SO_3 at standard conditions.
(a) Calculate ΔG° at 25°C. Is the reaction spontaneous?
(b) Why is the reaction not performed at 25°C?
(c) Is the reaction spontaneous at 500.°C? (Assume that ΔH° and ΔS° are constant with changing T.)
(d) Compare K at 500.°C and at 25°C.
(e) What is the highest T at which the reaction is spontaneous?

22.53 If a chlor-alkali cell used a current of 3×10^4 A, how many pounds of Cl_2 would be produced in a typical 8-h operating day?

22.54 The products of the chlor-alkali process, Cl_2 and NaOH, are kept separated.
(a) Why is this necessary when Cl_2 is the desired product?
(b) ClO^- or ClO_3^- may form by disproportionation of Cl_2 in basic solution. What determines which product forms?
(c) What mole ratio of Cl_2 to OH^- will produce ClO^-? ClO_3^-?

Comprehensive Problems

22.55 The key step in the manufacture of sulfuric acid is the oxidation of sulfur dioxide in the presence of a catalyst, such as V_2O_5. At 727°C, 0.010 mol of SO_2 is injected into an empty 2.00-L container ($K_p = 3.18$).
(a) What is the equilibrium pressure of O_2 that is needed to maintain a 1/1 mole ratio of SO_3 to SO_2?
(b) What is the equilibrium pressure of O_2 needed to maintain a 95/5 mole ratio of SO_3 to SO_2?

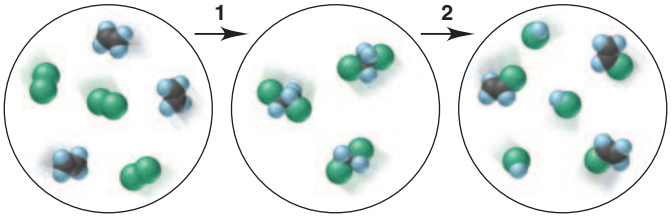
22.56 Tetraphosphorus decoxide (P_4O_{10}) is made from phosphate rock and used as a drying agent in the laboratory.
(a) Write a balanced equation for its reaction with water.
(b) What is the pH of a solution formed from the addition of 8.5 g of P_4O_{10} in sufficient water to form 0.750 L? (See Table 18.5, p. 797, for additional information.)

22.57 Heavy water (D_2O) is used to make deuterated chemicals.
(a) What major species, aside from the starting compounds, do you expect to find in a solution of CH_3OH and D_2O?

(b) Write equations to explain how these various species arise. (*Hint:* Consider the autoionization of both components.)

22.58 A blast furnace uses Fe_2O_3 to produce 8400. t of Fe per day.
(a) What mass of CO_2 is produced each day?
(b) Compare this amount of CO_2 with that produced by 1.0 million automobiles, each burning 5.0 gal of gasoline a day. Assume that gasoline has the formula C_8H_{18} and a density of 0.74 g/mL, and that it burns completely. (Note that U.S. gasoline consumption is over 4×10^8 gal/day.)

22.59 A major use of Cl_2 is in the manufacture of vinyl chloride, the monomer of poly(vinyl chloride). The two-step sequence for formation of vinyl chloride is depicted below.



(a) Write a balanced equation for each step.
(b) Write the overall equation.
(c) What type of organic reaction is shown in step 1?
(d) What type of organic reaction is shown in step 2?
(e) If each molecule depicted in the initial reaction mixture represents 0.15 mol of substance, what mass (in g) of vinyl chloride forms?

22.60 In the production of magnesium, $Mg(OH)_2$ is precipitated by using $Ca(OH)_2$, which itself is "insoluble." (a) Use K_{sp} values to show that $Mg(OH)_2$ can be precipitated from seawater in which $[Mg^{2+}]$ is initially 0.052 *M*. (b) If the seawater is saturated with $Ca(OH)_2$, what fraction of the Mg^{2+} is precipitated?

22.61 Step 1 of the Ostwald process for nitric acid production is

$$4NH_3(g) + 5O_2(g) \xrightarrow{\text{Pt/Rh catalyst}} 4NO(g) + 6H_2O(g)$$

An unwanted side reaction for this step is

$$4NH_3(g) + 3O_2(g) \longrightarrow 2N_2(g) + 6H_2O(g)$$

(a) Calculate K_p for these two NH_3 oxidations at 25°C.
(b) Calculate K_p for these two NH_3 oxidations at 900.°C.
(c) The Pt/Rh catalyst is one of the most efficient in the chemical industry, achieving 96% yield in 1 millisecond of contact with the reactants. However, at normal operating conditions (5 atm and 850°C), about 175 mg of Pt is lost per metric ton (t) of HNO_3 produced. If the annual U.S. production of HNO_3 is 1.01×10^7 t and the market price of Pt is $1557/troy oz, what is the annual cost of the lost Pt (1 kg = 32.15 troy oz)?
(d) Because of the high price of Pt, a filtering unit composed of ceramic fiber is often installed, which recovers as much as 75% of the lost Pt. What is the value of the Pt captured by a recovery unit with 72% efficiency?

22.62 Several transition metals are prepared by reduction of the metal halide with magnesium. Titanium is prepared by the Kroll method, in which ore (ilmenite) is converted to the gaseous chloride, which is then reduced to Ti metal by molten Mg (see p. 1003). Assuming yields of 84% for step 1 and 93% for step 2, and an excess of the other reactants, what mass of Ti metal can be prepared from 21.5 metric tons of ilmenite?

22.63 The production of S_8 from the $H_2S(g)$ found in natural gas deposits occurs through the Claus process (Section 22.5):
(a) Use these two unbalanced steps to write an overall balanced equation for this process:
(1) $H_2S(g) + O_2(g) \longrightarrow S_8(g) + SO_2(g) + H_2O(g)$
(2) $H_2S(g) + SO_2(g) \longrightarrow S_8(g) + H_2O(g)$
(b) Write the overall reaction with Cl_2 as the oxidizing agent instead of O_2. Use thermodynamic data to show whether $Cl_2(g)$ can be used to oxidize $H_2S(g)$.
(c) Why is oxidation by O_2 preferred to oxidation by Cl_2?

22.64 Acid mine drainage (AMD) occurs when geologic deposits containing pyrite (FeS_2) are exposed to oxygen and moisture. AMD is generated in a multistep process catalyzed by acidophilic (acid-loving) bacteria. Balance each step and identify those that increase acidity:
(1) $FeS_2(s) + O_2(g) \longrightarrow Fe^{2+}(aq) + SO_4^{2-}(aq)$
(2) $Fe^{2+}(aq) + O_2(g) \longrightarrow Fe^{3+}(aq) + H_2O(l)$
(3) $Fe^{3+}(aq) + H_2O(l) \longrightarrow Fe(OH)_3(s) + H^+(aq)$
(4) $FeS_2(s) + Fe^{3+}(aq) \longrightarrow Fe^{2+}(aq) + SO_4^{2-}(aq)$

22.65 Below 912°C, pure iron crystallizes in a body-centered cubic structure (ferrite) with $d = 7.86$ g/cm^3; from 912°C to 1394°C, it adopts a face-centered cubic structure (austenite) with $d = 7.40$ g/cm^3. Both types of iron form interstitial alloys with carbon. The maximum amount of carbon is 0.0218 mass % in ferrite and 2.08 mass % in austenite. Calculate the density of each alloy.

22.66 Why isn't nitric acid produced by oxidizing N_2 as follows?

$$\begin{aligned}
&(1)\quad N_2(g) + 2O_2(g) \longrightarrow 2NO_2(g)\\
&(2)\quad 3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(aq) + NO(g)\\
&(3)\quad 2NO(g) + O_2(g) \longrightarrow 2NO_2(g)\\
&\overline{\qquad\qquad 3N_2(g) + 6O_2(g) + 2H_2O(l) \longrightarrow 4HNO_3(aq) + 2NO(g)}
\end{aligned}$$

(*Hint:* Evaluate the thermodynamics of each step.)

22.67 Before the development of the Downs cell, the Castner cell was used for the industrial production of Na metal. The Castner cell was based on the electrolysis of molten NaOH.
(a) Write balanced cathode and anode half-reactions for this cell.
(b) A major problem with this cell was that the water produced at one electrode diffused to the other and reacted with the Na. If all the water produced reacted with Na, what would be the maximum efficiency of the Castner cell expressed as moles of Na produced per mole of electrons flowing through the cell?

22.68 When gold ores are leached with CN^- solutions, gold forms a complex ion, $Au(CN)_2^-$. (a) Find E_{cell} for the oxidation in air ($P_{O_2} = 0.21$) of Au to Au^+ in basic (pH 13.55) solution with $[Au^+] = 0.50$ *M*. Is the reaction $Au^+(aq) + e^- \longrightarrow Au(s)$, $E° = 1.68$ V, spontaneous? (b) How does formation of the complex ion change $E°$ so that the oxidation can be accomplished?

22.69 Nitric oxide occurs in the tropospheric nitrogen cycle, but it destroys ozone in the stratosphere.
(a) Write equations for its reaction with ozone and for the reverse reaction.
(b) Given that the forward and reverse steps are first order in each component, write general rate laws for them.
(c) Calculate $\Delta G°$ for this reaction at 280. K, the average temperature in the stratosphere. (Assume that the $\Delta H°$ and $S°$ values in Appendix B do not change with temperature.)
(d) What ratio of rate constants is consistent with K at this temperature?

22.70 A key part of the carbon cycle is the fixation of CO_2 by photosynthesis to produce carbohydrates and oxygen gas.
(a) Using the formula $(CH_2O)_n$ to represent a carbohydrate, write a balanced equation for the photosynthetic reaction.
(b) If a tree fixes 48 g of CO_2 per day, what volume of O_2 gas measured at 1.0 atm and 78°F does the tree produce per day?
(c) What volume of air (0.040 mol % CO_2) at the same conditions contains this amount of CO_2?

22.71 Farmers use ammonium sulfate as a fertilizer. In the soil, nitrifying bacteria oxidize NH_4^+ to NO_3^-, a groundwater contaminant that causes methemoglobinemia ("blue baby" syndrome). The World Health Organization standard for maximum $[NO_3^-]$ in groundwater is 45 mg/L. A farmer adds 210. kg of $(NH_4)_2SO_4$ to a field and 37% is oxidized to NO_3^-. What is the groundwater $[NO_3^-]$ (in mg/L) if 1000. m^3 of the water is contaminated?

22.72 The key reaction (unbalanced) in the manufacture of synthetic cryolite for aluminum electrolysis is

$$HF(g) + Al(OH)_3(s) + NaOH(aq) \longrightarrow Na_3AlF_6(aq) + H_2O(l)$$

Assuming a 95.6% yield of dried, crystallized product, what mass (in kg) of cryolite can be obtained from the reaction of 365 kg of $Al(OH)_3$, 1.20 m^3 of 50.0% by mass aqueous NaOH (d = 1.53 g/mL), and 265 m^3 of gaseous HF at 305 kPa and 91.5°C? (Assume that the ideal gas law holds.)

22.73 Because of their different molar masses, H_2 and D_2 effuse at different rates (Section 5.5).
(a) If it takes 16.5 min for 0.10 mol of H_2 to effuse, how long does it take for 0.10 mol of D_2 to do so in the same apparatus at the same T and P?
(b) How many effusion steps does it take to separate an equimolar mixture of D_2 and H_2 to 99 mol % purity?

22.74 The disproportionation of CO to graphite and CO_2 is thermodynamically favored but slow.
(a) What does this mean in terms of the magnitudes of the equilibrium constant (K), rate constant (k), and activation energy (E_a)?
(b) Write a balanced equation for the disproportionation of CO.
(c) Calculate K_c at 298 K. (d) Calculate K_p at 298 K.

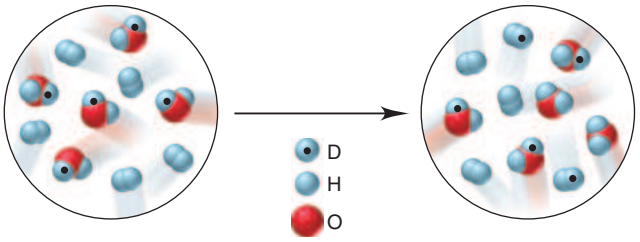
22.75 The overall cell reaction for aluminum production is

$$2Al_2O_3(\text{in } Na_3AlF_6) + 3C(\text{graphite}) \longrightarrow 4Al(l) + 3CO_2(g)$$

(a) Assuming 100% efficiency, how many metric tons (t) of Al_2O_3 are consumed per metric ton of Al produced?
(b) Assuming 100% efficiency, how many metric tons of the graphite anode are consumed per metric ton of Al produced?
(c) Actual conditions in an aluminum plant require 1.89 t of Al_2O_3 and 0.45 t of graphite per metric ton of Al. What is the percent yield of Al with respect to Al_2O_3?
(d) What is the percent yield of Al with respect to graphite?
(e) What volume of CO_2 (in m^3) is produced per metric ton of Al at operating conditions of 960.°C and exactly 1 atm?

22.76 World production of chromite ($FeCr_2O_4$), the main ore of chromium, was 1.97×10^7 metric tons in 2006. To isolate chromium, a mixture of chromite and sodium carbonate is heated in air to form sodium chromate, iron(III) oxide, and carbon dioxide. The sodium chromate is dissolved in water, and this solution is acidified with sulfuric acid to produce the less soluble sodium dichromate. The sodium dichromate is filtered out and reduced with carbon to produce chromium(III) oxide, sodium carbonate, and carbon monoxide. The chromium(III) oxide is then reduced to chromium with aluminum metal.
(a) Write balanced equations for each step.
(b) What mass of chromium (in kg) could be prepared from the 2006 world production of chromite?

22.77 Like heavy water (D_2O), so-called "semi-heavy water" (HDO) undergoes H/D exchange. The molecular scenes depict an initial mixture of HDO and H_2 reaching equlibrium.



(a) Write the balanced equation for the reaction.
(b) Is the value of K greater or less than 1?
(c) If each molecule depicted represents 0.10 M, calculate K.

22.78 Even though most metal sulfides are sparingly soluble in water, their solubilities differ by several orders of magnitude. This difference is sometimes used to separate the metals by controlling the pH. Use the following data to find the pH at which you can separate 0.10 M Cu^{2+} and 0.10 M Ni^{2+}:

Saturated H_2S = 0.10 M

K_{a1} of $H_2S = 9\times10^{-8}$ $\quad$ K_{a2} of $H_2S = 1\times10^{-17}$

K_{sp} of $NiS = 1.1\times10^{-18}$ $\quad$ K_{sp} of $CuS = 8\times10^{-34}$

22.79 Ores with as little as 0.25% by mass of copper are used as sources of the metal.
(a) How many kilograms of such an ore would be needed to construct another Statue of Liberty, which contains 2.0×10^5 lb of copper?
(b) If the mineral in the ore is chalcopyrite ($FeCuS_2$), what is the mass % of chalcopyrite in the ore?

22.80 How does acid rain affect the leaching of phosphate into groundwater from terrestrial phosphate rock? Calculate the solubility of $Ca_3(PO_4)_2$ in each of the following:
(a) Pure water, pH 7.0 (Assume that PO_4^{3-} does not react with water.)
(b) Moderately acidic rainwater, pH 4.5 (*Hint:* Assume that all the phosphate exists in the form that predominates at this pH.)

22.81 The lead(IV) oxide used in car batteries is prepared by coating the electrode plate with PbO and then oxidizing it to lead dioxide (PbO_2). Despite its name, PbO_2 has a nonstoichiometric mole ratio of lead to oxygen of about 1/1.98. In fact, the holes in the PbO_2 crystal structure due to missing O atoms are responsible for the oxide's conductivity.
(a) What is the mole % of O missing from the PbO_2 structure?
(b) What is the molar mass of the nonstoichiometric compound?

22.82 Chemosynthetic bacteria reduce CO_2 by "splitting" $H_2S(g)$ instead of the $H_2O(g)$ used by photosynthetic organisms. Compare the free energy change for splitting H_2S with that for splitting H_2O. Is there an advantage to using H_2S instead of H_2O?

22.83 Silver has a face-centered cubic structure with a unit cell edge length of 408.6 pm. Sterling silver is a substitutional alloy that contains 7.5% copper atoms. Assuming the unit cell remains the same, find the density of silver and of sterling silver.

22.84 Earth's mass is estimated to be 5.98×10^{24} kg, and titanium represents 0.05% by mass of this total.
(a) How many moles of Ti are present?
(b) If half of the Ti is found as ilmenite ($FeTiO_3$), what mass of ilmenite is present?
(c) If the airline and auto industries use 1.00×10^5 tons of Ti per year, how many years will it take to use up all the Ti (1 ton = 2000 lb)?

22.85 In 1790, Nicolas Leblanc found a way to form Na_2CO_3 from NaCl. His process, now obsolete, consisted of three steps:

$$2NaCl(s) + H_2SO_4(aq) \longrightarrow Na_2SO_4(aq) + 2HCl(g)$$
$$Na_2SO_4(s) + 2C(s) \longrightarrow Na_2S(s) + 2CO_2(g)$$
$$Na_2S(s) + CaCO_3(s) \longrightarrow Na_2CO_3(s) + CaS(s)$$

(a) Write a balanced overall equation for the process.
(b) Calculate the ΔH_f° of CaS if ΔH_{rxn}° is 351.8 kJ/mol.
(c) Is the overall process spontaneous at standard-state conditions and 298 K?
(d) How many grams of Na_2CO_3 form from 250. g of NaCl if the process is 73% efficient?

22.86 Limestone ($CaCO_3$) is the second most abundant mineral on Earth after SiO_2. For many uses, it is first decomposed thermally to quicklime (CaO). MgO is prepared similarly from $MgCO_3$.
(a) At what T is each decomposition spontaneous?
(b) Quicklime reacts with SiO_2 to form a slag ($CaSiO_3$), a byproduct of steelmaking. In 2010, the total steelmaking capacity of the U.S. steel industry was 2,236,000 tons per week, but only 84% of this capacity was utilized. If 50. kg of slag is produced per ton of steel, what mass (in kg) of limestone was used to make slag in 2010?

- Lewis acid-base concepts (Section 18.9)
- complex-ion formation (Section 19.4)
- redox behavior and standard electrode potentials (Section 21.3)

Though almost at the end of the text, we still haven't discussed the majority of the elements *and* some of the most familiar. The **transition elements** *(transition metals)* make up the *d* block (B groups) and *f* block *(inner transition elements)* (Figure 23.1, *next page*) and have crucial uses in industry and biology.

Aside from essential copper and iron (Chapter 22), some other indispensable transition elements are chromium (plumbing fixtures), gold and silver (jewelry and electronics), platinum (automobile catalytic converters), titanium (bicycle and aircraft parts and artificial joints), nickel (coins and catalysts), and zinc (batteries), to mention a few of the better known ones. There are also the lesser known zirconium (nuclear-reactor liners), vanadium (axles and crankshafts), molybdenum (boiler plates), tantalum (organ-replacement parts), palladium (telephone-relay contacts)—the list goes on and on.

Transition metal cations occupy the centers of many complex ions. In addition to providing fundamental insights into bonding and structure, these species play vital roles in organisms *and* give color to gems—Cr^{3+} ions make emeralds green and rubies red, and a mixture of Fe^{2+}, Fe^{3+}, and Ti^{4+} ions makes sapphires blue. Stained glass *(see photo)* gets its vivid colors from compounds of Co, Mn, Cu, Cr, Fe, and Ni.

IN THIS CHAPTER . . . *We focus on the transition metals and their properties, and especially on the bonding and structure of their coordination compounds.*

- We discuss key atomic, physical, and chemical properties of transition and inner transition elements—with attention to the effects of filling inner sublevels—and contrast them with properties of the main-group elements.
- For most of the chapter, we concentrate on the nomenclature, structure, and isomerism of transition elements' coordination compounds, species that contain complex ions.
- We use valence bond theory to explain the bonding and molecular shape of complex ions.
- We use crystal field theory to explain the colors and magnetic properties of coordination compounds, which relate directly to structure.
- We end with some examples of transition metal ions in biochemistry.

23.1 PROPERTIES OF THE TRANSITION ELEMENTS

The transition elements differ considerably in physical and chemical behavior from the main-group elements:

- *All transition elements are metals,* whereas main-group elements in each period change from metal to nonmetal.
- *Many transition metal compounds are colored and paramagnetic,* whereas most main-group ionic compounds are colorless and diamagnetic.

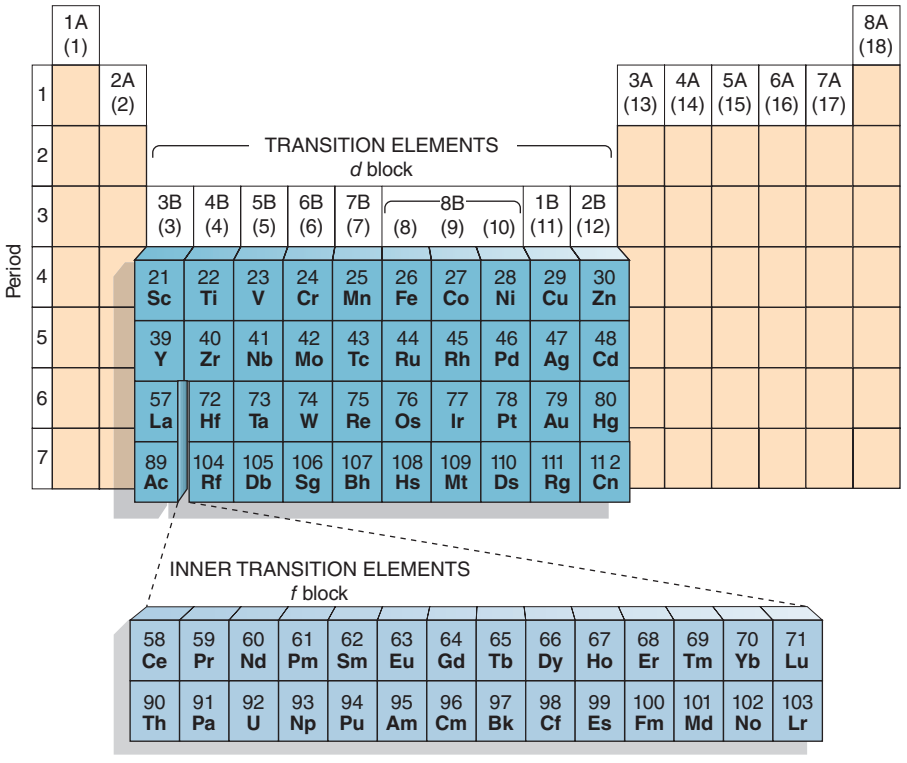

Figure 23.1 **The transition elements (*d* block) and inner transition elements (*f* block) in the periodic table.**

We first discuss electron configurations of the atoms and ions, and then examine key properties of transition elements to see how they contrast with the same properties among the main-group elements.

Electron Configurations of the Transition Metals and Their Ions

As with all the elements, the properties of the transition elements and their compounds arise largely from the electron configurations of their atoms (Section 8.2) and ions (Section 8.4). As Figure 23.1 shows, *d*-block (B-group) elements occur in four series that lie within Periods 4 through 7 between the last *ns*-block element [Group 2A(2)] and the first *np*-block element [Group 3A(13)]. Each of the four series contains ten elements based on the filling of five *d* orbitals, for a total of 40 transition elements. Lying between the first and second members of the series in Periods 6 and 7 are the inner transition elements, in which *f* orbitals are filled. Several points are important to review:

1. *Electron configurations of the atoms*. Despite several exceptions, in general, the *condensed* ground-state electron configuration for the atoms in each *d*-block series is

$$[\text{noble gas}]\, ns^2(n-1)d^x, \text{ with } n = 4 \text{ to } 7 \text{ and } x = 1 \text{ to } 10$$

In Periods 6 and 7, the condensed configuration includes the *f* sublevel:

$$[\text{noble gas}]\, ns^2(n-2)f^{14}(n-1)d^x, \text{ with } n = 6 \text{ or } 7$$

Figure 23.2 **The Period 4 transition metals.** The ten elements appear in periodic-table order across pp. 1018–1019.

Scandium, Sc; 3B(3)

Titanium, Ti; 4B(4)

Vanadium, V; 5B(5)

Chromium, Cr; 6B(6)

Manganese, Mn; 7B(7)

Table 23.1 Orbital Occupancy of the Period 4 Transition Metals

Element	Partial Orbital Diagram (4s / 3d / 4p)	Unpaired Electrons
Sc	↑↓ / ↑	1
Ti	↑↓ / ↑ ↑	2
V	↑↓ / ↑ ↑ ↑	3
Cr	↑ / ↑ ↑ ↑ ↑ ↑	6
Mn	↑↓ / ↑ ↑ ↑ ↑ ↑	5
Fe	↑↓ / ↑↓ ↑ ↑ ↑	4
Co	↑↓ / ↑↓ ↑↓ ↑	3
Ni	↑↓ / ↑↓ ↑↓ ↑↓	2
Cu	↑ / ↑↓ ↑↓ ↑↓ ↑↓	1
Zn	↑↓ / ↑↓ ↑↓ ↑↓ ↑↓	0

The *partial* (valence-level) electron configuration for the *d*-block elements excludes the noble gas core and the filled inner *f* sublevel:

$$ns^2(n-1)d^x$$

2. *Filling pattern in Period 4*. The first (Period 4) transition series consists of scandium (Sc) through zinc (Zn) (Figure 23.2 and Table 23.1). Scandium has the electron configuration [Ar] $4s^2 3d^1$, and the addition of one electron at a time first half-fills, then fills, the 3*d* orbitals, up to zinc. Recall that chromium and copper are exceptions to this pattern: the 4*s* and 3*d* orbitals in Cr are half-filled to give [Ar] $4s^1 3d^5$, and the 4*s* orbital in Cu is half-filled to give [Ar] $4s^1 3d^{10}$. These exceptions are due to the relative energies of the 4*s* and 3*d* sublevels as electrons are added and the unusual stability of half-filled and filled sublevels (see Figure 8.26, p. 348).

3. *Electron configurations of the ions*. Transition metal ions form through *the loss of ns electrons before (n − 1)d electrons.* Thus, the electron configuration of Ti^{2+} is [Ar] $3d^2$, *not* [Ar] $4s^2$, and Ti^{2+} is referred to as a d^2 ion. Ions of different metals with the same configuration often have similar properties. For example, Mn^{2+} and Fe^{3+} are d^5 ions: both have pale colors in solution and form complex ions with similar magnetic properties.

Table 23.1 shows partial orbital box diagrams for the Period 4 elements. In general for all periods, the number of *unpaired* electrons (or half-filled orbitals) *increases in the first half* of the series and, when pairing begins, *decreases in the second half.* A key point to note in upcoming discussions is that the electron configuration of the *atom* (O.N. = 0) correlates with the physical properties of the *element,* whereas the

Iron, Fe; 8B(8)

Cobalt, Co; 8B(9)

Nickel, Ni; 8B(10)

Copper, Cu; 1B(11)

Zinc, Zn; 2B(12)

electron configuration of the *ion* (and other species of higher O.N.) correlates with the chemical properties of the *compounds.*

SAMPLE PROBLEM 23.1 **Writing Electron Configurations of Transition Metal Atoms and Ions**

Problem Write *condensed* electron configurations for the following: **(a)** Zr; **(b)** V^{3+}; **(c)** Mo^{3+}. (Assume that elements in higher periods behave like those in Period 4.)

Plan We locate the element in the periodic table and count its position in the respective transition series. These elements are in Periods 4 and 5, so the general configuration is [noble gas] $ns^2(n-1)d^x$. For the ions, we recall that *ns* electrons are lost first.

Solution **(a)** Zr is the second element in the 4*d* series: [Kr] $5s^24d^2$.
(b) V is the third element in the 3*d* series: [Ar] $4s^23d^3$. In forming V^{3+}, three electrons are lost (two 4*s* and one 3*d*), so V^{3+} is a d^2 ion: [Ar] $3d^2$.
(c) Mo lies below Cr in Group 6B(6), so we expect the same exception as for Cr. Thus, Mo is [Kr] $5s^14d^5$. To form the ion, Mo loses the one 5*s* and two of the 4*d* electrons, so Mo^{3+} is a d^3 ion: [Kr] $4d^3$.

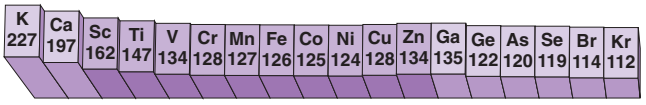
Check Figure 8.10 (p. 333) shows we're correct for the atoms. Be sure that charge plus number of *d* electrons in the ion equals the sum of outer *s* and *d* electrons in the atom.

FOLLOW-UP PROBLEMS
Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*
23.1A Write *partial* electron configurations (no noble gas core or filled inner sublevels) for the following: **(a)** Ag^+; **(b)** Cd^{2+}; **(c)** Ir^{3+}.
23.1B Find the charge of each of the following ions, given the *condensed* electron configuration: **(a)** Ta^{x+}: [Xe] $4f^{14}5d^2$; **(b)** Mn^{x+}: [Ar] $3d^3$; **(c)** Os^{x+}: [Xe] $4f^{14}5d^5$.
SOME SIMILAR PROBLEMS 23.10–23.15

Atomic and Physical Properties of the Transition Elements

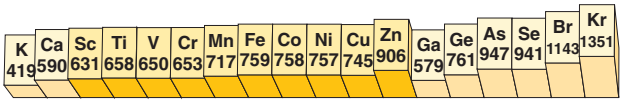
Properties of the transition elements contrast in several ways with properties of the main-group elements.

Trends Across a Period Consider the variations in atomic size, electronegativity, and ionization energy across Period 4 (Figure 23.3):



A Atomic radius (pm)

B Electronegativity



C First ionization energy (kJ/mol)

Figure 23.3 **Trends in key atomic properties of Period 4 elements.** Atomic radius **(A),** electronegativity **(B),** and first ionization energy **(C)** of all Period 4 elements are shown as heights of posts, with darker shading for the transition series.

- *Atomic size.* Atomic size decreases overall across the period (Figure 23.3A). There is a smooth, steady decrease across the main groups because the electrons are added to *outer ns* or *np* orbitals, which shield the increasing nuclear charge poorly. This decrease is not steady in the transition series, where *atomic size decreases at first but then remains relatively constant.* The reason is that the *d* electrons fill *inner* orbitals, so they shield outer electrons very efficiently, and so, the outer 4*s* electrons are *not* pulled closer.
- *Electronegativity (EN).* Electronegativity generally increases across the period, but, once again, the main groups show a steady, steep increase between the metal potassium (0.8) and the nonmetal bromine (2.8), whereas the transition elements have *relatively constant EN* (Figure 23.3B), consistent with their relatively constant size. The transition elements all have intermediate electronegativity values, much like the large, metallic members of Groups 3A(13) to 5A(15).
- *Ionization energy (IE_1).* The ionization energies of the Period 4 main-group elements rise steeply from left to right, more than tripling from potassium (419 kJ/mol) to krypton (1351 kJ/mol), as electrons become more difficult to remove from the poorly shielded, increasing nuclear charge. In the transition metals, IE_1 *values increase relatively little* because the inner 3*d* electrons shield more effectively (Figure 23.3C). [Recall from Section 8.3 that the drop at Group 3A(13) occurs because it is relatively easy to remove the first electron from the outer *np* orbital.]

Trends Within a Group Vertical trends for transition elements are also different from main-group trends.

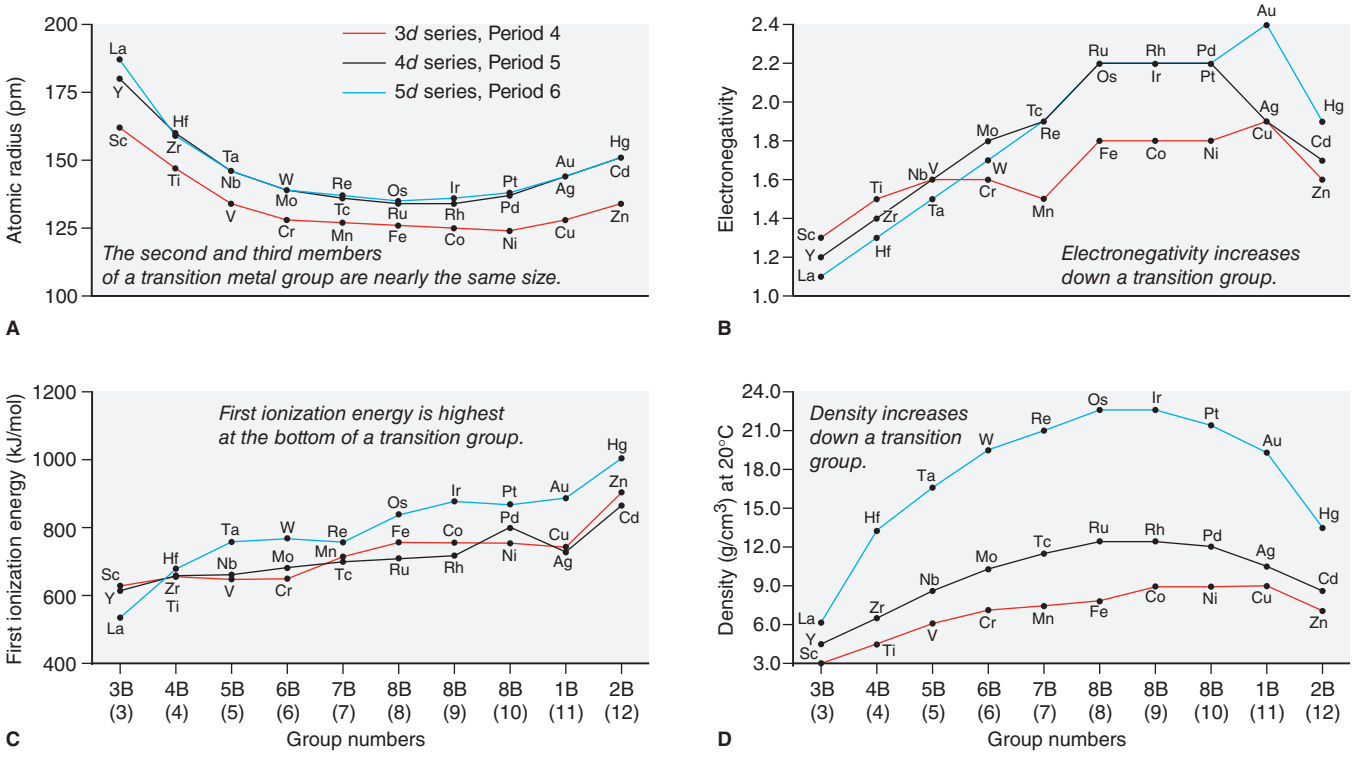
1. *Atomic size.* As expected, atomic size increases from Period 4 to 5, as it does for the main-group elements, but there is virtually *no size increase from Period 5 to 6* (Figure 23.4A). Since the lanthanides, with their buried 4*f* sublevel, appear between the 4*d* (Period 5) and 5*d* (Period 6) series, an element in Period 6 is separated from the one above it by 32 elements (ten 4*d*, six 5*p*, two 6*s*, and fourteen 4*f* electrons) instead of just 18. The fourteen 4*f* electrons shield the outer electrons poorly from the increase in nuclear charge due to fourteen additional protons, resulting in a shrinkage in atomic size called the **lanthanide contraction.** By coincidence, this size *decrease* is about equal to the normal *increase* between periods, so Periods 5 and 6 transition elements have about the same atomic sizes.

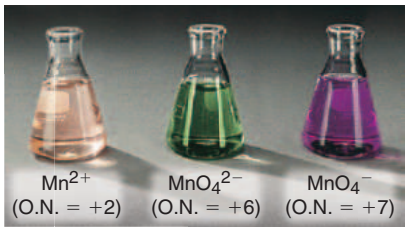
2. *Electronegativity.* The vertical trend in electronegativity is opposite the decreasing trend in the main groups. Electronegativity *increases* from Period 4 to Period 5, but there is no further increase in Period 6 (Figure 23.4B). The heavier elements, especially gold (EN = 2.4), become quite electronegative, with values higher than most metalloids and even some nonmetals (e.g., EN of Te and of P = 2.1). (In fact, with very electropositive cesium EN = 0.7, gold forms the saltlike CsAu.) Although atomic size increases slightly from top to bottom in a group, the nuclear charge increases much more. Therefore, the heavier transition metals form bonds with more covalent character because they attract electrons more strongly than do main-group metals.

3. *Ionization energy.* The small increase in size combined with the large increase in nuclear charge also explains why *IE_1 values generally increase* down a transition group (Figure 23.4C). This trend also runs counter to the main-group trend, where heavier members are so much larger that the outer electron is easier to remove.

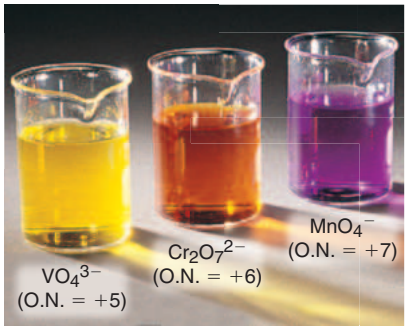
4. *Density.* Atomic size, and therefore volume, is inversely related to density. Across a period, densities increase, then level off, and finally dip a bit at the end of a series (Figure 23.4D). Down a transition group, densities increase dramatically because atomic volumes change little from Period 5 to 6, but atomic masses increase significantly. As a result, the Period 6 series contains some of the densest elements known: tungsten, rhenium, osmium, iridium, platinum, and gold have densities about 20 times that of water and twice that of lead.

Figure 23.4 Vertical trends in key properties within the transition elements. The trends are unlike those for the main-group elements.





A



B

Figure 23.5 Aqueous oxoanions of transition elements.

Chemical Properties of the Transition Elements

Like their atomic and physical properties, the chemical properties of transition elements are very different from those of main-group elements. Let's examine key properties in the Period 4 series and then see how behavior changes within a group.

Multiple Oxidation States One of the most characteristic chemical properties of the transition metals is the occurrence of *multiple oxidation states;* main-group metals display one or, at most, two states. For example, chromium and manganese (Figure 23.5A) have three common oxidation states and many others that are less common (Table 23.2). Since the *ns* and $(n - 1)d$ electrons are so close in energy, transition elements can use all or most of these electrons in bonding.

The highest oxidation state of elements in Groups 3B(3) through 7B(7) equals the group number. These states are seen when the elements combine with highly electronegative oxygen or fluorine. For instance, Figure 23.5B shows vanadium as vanadate ion (VO_4^{3-}; O.N. of V = +5), chromium as dichromate ($Cr_2O_7^{2-}$; O.N. of Cr = +6), and manganese as permanganate (MnO_4^-; O.N. of Mn = +7).

Elements in Groups 8B(8), 8B(9), and 8B(10) exhibit fewer oxidation states, and the highest state is less common and never equal to the group number. For example, we never encounter iron in the +8 state and only rarely in the +6 state. The +2 and +3 states are the most common ones for iron* and cobalt, and the +2 state is most common for nickel, copper, and zinc. *The +2 oxidation state is common because ns^2 electrons are readily lost.*

Table 23.2 Oxidation States and *d*-Orbital Occupancy of the Period 4 Transition Metals†

Oxidation State	3B (3) Sc	4B (4) Ti	5B (5) V	6B (6) Cr	7B (7) Mn	8B (8) Fe	8B (9) Co	8B (10) Ni	1B (11) Cu	2B (12) Zn
0	d^1	d^2	d^3	d^5	d^5	d^6	d^7	d^8	d^{10}	d^{10}
+1			d^3	d^5	d^5	d^6	d^7	d^8	d^{10}	
+2		d^2	d^3	d^4	d^5	d^6	d^7	d^8	d^9	d^{10}
+3	d^0	d^1	d^2	d^3	d^4	d^5	d^6	d^7	d^8	
+4		d^0	d^1	d^2	d^3	d^4	d^5	d^6		
+5			d^0	d^1	d^2		d^4			
+6				d^0	d^1	d^4				
+7					d^0					

†The most important orbital occupancies are in color.

Metallic Behavior, Oxide Acidity, and Valence-State Electronegativity Atomic size and oxidation state have a major effect on the nature of bonding in transition metal compounds. Like the metals in Groups 3A(13), 4A(14), and 5A(15), the transition elements in their *lower* oxidation states behave chemically more like metals. That is, *ionic bonding is more prevalent for the lower oxidation states, and covalent bonding is more prevalent for the higher states.* For example, at room temperature, $TiCl_2$ (O.N. = +2) is an ionic solid, whereas $TiCl_4$ (O.N. = +4) is a molecular liquid (see also Figure 14.11, p. 585). In the higher oxidation states, the atoms have

*Iron *seems* to have unusual oxidation states in magnetite (Fe_3O_4) and pyrite (FeS_2), but it doesn't. In magnetite, one-third of the metal ions are Fe^{2+} and two-thirds are Fe^{3+}, which gives a 1/1 ratio of FeO/Fe_2O_3 and a formula of Fe_3O_4. Pyrite contains Fe^{2+} combined with the disulfide ion, S_2^{2-}.

higher charge densities (higher ratio of charge to volume, p. 529), so they polarize the electron clouds of the nonmetal ions more strongly and the bonding becomes more covalent. For the same reason, the oxides become less basic (more acidic) as the oxidation state increases: TiO is weakly basic in water, whereas TiO_2 is amphoteric (reacts with both acid and base).

Why does oxide acidity increase with oxidation state? And, in addition to forming oxides, how can a metal like chromium or manganese form an oxoanion in which it uses covalent bonds? The answers involve a type of "effective" electronegativity called *valence-state electronegativity,* which also has numerical values. A metal atom in a positive oxidation state has a greater attraction for the bonded electrons, that is, a higher electronegativity, than in its zero oxidation state. Thus, for example, the electronegativity of elemental chromium is 1.6, close to that of aluminum (1.5), another active metal. For chromium(III), the value increases to 1.7, still characteristic of a metal. But, for chromium(VI), the value is 2.3, close to values of some nonmetals, such as phosphorus (2.1) and sulfur (2.5). Thus, like P in PO_4^{3-} and S in SO_4^{2-}, Cr in CrO_4^{2-} is covalently bonded at the center of an oxoanion of a relatively strong acid, H_2CrO_4, and manganese(VII) in MnO_4^- behaves similarly in the strong acid $HMnO_4$.

Reducing Strength Table 23.3 shows the standard electrode potentials of the Period 4 transition metals in their +2 oxidation state in acid solution. Note that, in general, reducing strength decreases across the series. All the Period 4 transition metals, except copper, are active enough to reduce H^+ from aqueous acid to form hydrogen gas. In contrast to the rapid reaction at room temperature of the Group 1A(1) and 2A(2) metals with water, however, most transition metals have an oxide coating that allows rapid reaction only with hot water or steam.

Table 23.3 Standard Electrode Potentials of Period 4 M^{2+} Ions

Half-Reaction			$E°$ (V)
$Ti^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Ti(s)$	−1.63
$V^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$V(s)$	−1.19
$Cr^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Cr(s)$	−0.91
$Mn^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Mn(s)$	−1.18
$Fe^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Fe(s)$	−0.44
$Co^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Co(s)$	−0.28
$Ni^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Ni(s)$	−0.25
$Cu^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Cu(s)$	0.34
$Zn^{2+}(aq) + 2e^-$	$\rightleftharpoons$	$Zn(s)$	−0.76

Color and Magnetism of Compounds *Most main-group ionic compounds are colorless* because the metal ion has a filled outer level (noble gas electron configuration, ns^2 or ns^2np^6). With only *much* higher energy orbitals available to receive an excited electron, the ion does not absorb visible light. In contrast, electrons in a partially filled *d* sublevel can absorb visible wavelengths and move to *slightly* higher energy orbitals. As a result, *many transition metal compounds have striking colors.* Exceptions are the compounds of scandium, titanium(IV), and zinc, which are colorless because their metal ions have either an empty *d* sublevel (Sc^{3+} or Ti^{4+}: [Ar] $3d^0$) or a filled one (Zn^{2+}: [Ar] $3d^{10}$) (Figure 23.6).

Magnetic properties are also related to sublevel occupancy (Section 8.4). *Most main-group metal ions are diamagnetic* for the same reason they are colorless: all their electrons are paired. In contrast, *many transition metal compounds are paramagnetic because of their unpaired d electrons.* Transition metal ions with a d^0 or d^{10} configuration are also colorless and diamagnetic.

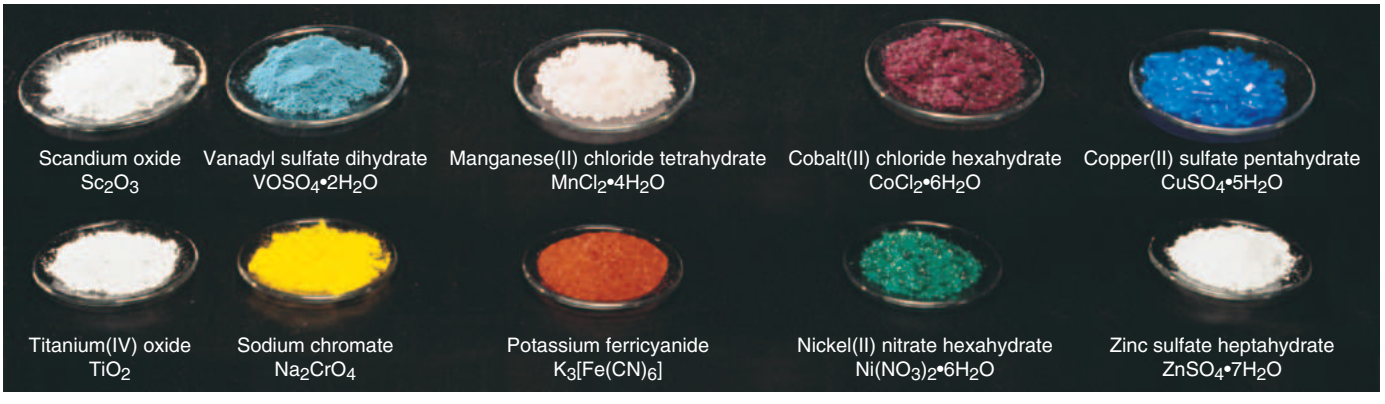


Figure 23.6 Colors of representative compounds of the Period 4 transition metals.

Table 23.4 Some Properties of Group 6B(6) Elements

Element	Atomic Radius (pm)	IE_1 (kJ/mol)	$E°$ (V) for $M^{3+}(aq) \mid M(s)$
Cr	128	653	−0.74
Mo	139	685	−0.20
W	139	770	−0.11

Chemical Behavior Within a Group The *increase* in reactivity going down a group of main-group metals due to the *decrease* in IE_1 does *not* occur going down a group of transition metals. The chromium (Cr) group [6B(6)] shows a typical pattern (Table 23.4). IE_1 *increases* down the group, which makes the two heavier members *less* reactive than the lightest one. Chromium is also a much stronger reducing agent than molybdenum (Mo) or tungsten (W), as shown by the standard electrode potentials.

The similarity in atomic size of members of Periods 5 and 6 leads to similar chemical behavior, which has some important consequences. Because Mo and W compounds behave similarly, their ores often occur together in nature, which makes these elements very difficult to separate. The same situation occurs with zirconium and hafnium in Group 4B(4) and with niobium and tantalum in Group 5B(5).

Summary of Section 23.1

- All transition elements are metals.
- Atoms of the *d*-block elements have $(n - 1)d$ orbitals being filled, and their ions have an empty *ns* orbital.
- Unlike the trends for the main-group elements, atomic size, electronegativity, and first ionization energy change relatively little across a transition series. Because of the lanthanide contraction, atomic size changes little from Period 5 to 6 in a transition metal group; thus, electronegativity, first ionization energy, and density *increase* down such a group.
- Transition metals typically have several oxidation states, with the +2 state most common. The elements exhibit less metallic behavior in their higher states, as they have higher valence-state electronegativity.
- Most Period 4 transition metals are active enough to reduce hydrogen ion from acid solution.
- Many transition metal compounds are colored and paramagnetic because the metal ion has unpaired *d* electrons.
- In contrast to main-group metals, reactivity decreases down a transition group.

23.2 THE INNER TRANSITION ELEMENTS

The 14 **lanthanides**—cerium (Ce; $Z = 58$) through lutetium (Lu; $Z = 71$)—and the 14 **actinides** below them—thorium (Th; $Z = 90$) through lawrencium (Lr; $Z = 103$)—are called **inner transition elements** because their seven inner 4*f* or 5*f* orbitals are being filled.

The Lanthanides

The lanthanides are also known as the *rare earth elements,* but many are not rare: cerium (Ce), for instance, ranks 26th in abundance (by mass %) and is five times more abundant than lead. All the lanthanides are silvery, high-melting metals.

As with other transition elements, atomic properties vary little across the period. As a result, chemical properties are so similar that the two ores of lanthanides, ceria and yttria, are mixtures of compounds of all 14 of them. This natural co-occurrence

arises because the elements exist as M^{3+} ions of very similar radii. Most lanthanides have the ground-state electron configuration [Xe] $6s^2 4f^x 5d^0$, where x varies across the series. The three exceptions (Ce, Gd, and Lu) have a single electron in one of their 5*d* orbitals: cerium ([Xe] $6s^2 4f^1 5d^1$) forms a stable 4+ ion with an empty (f^0) sublevel, and the Gd^{3+} and Lu^{3+} ions have a stable half-filled (f^7) or filled (f^{14}) sublevel.

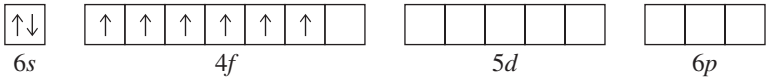
Lanthanide compounds are used in tinted glass, electronic devices (magnets, batteries, and lasers), and high-quality camera lenses, but two industrial applications account for over 60% of the total usage. In gasoline refining, catalysts used to "crack" hydrocarbons into smaller molecules are 5% by mass rare earth oxides. In steelmaking, a mixture of lanthanides, called *misch metal,* removes carbon impurities from molten iron and steel. Recently, shortages of some lanthanides has caused concern for many electronic applications.

SAMPLE PROBLEM 23.2 Finding the Number of Unpaired Electrons

Problem The alloy $SmCo_5$ forms a permanent magnet because both samarium and cobalt have unpaired electrons. How many unpaired electrons are in Sm ($Z = 62$)?

Plan We write the condensed electron configuration of Sm and then, using Hund's rule and the aufbau principle, place the electrons in a partial orbital diagram and count the unpaired electrons.

Solution Samarium is the eighth element after Xe. Two electrons go into the 6*s* sublevel. In general, the 4*f* sublevel fills before the 5*d* (among the lanthanides, only Ce, Gd, and Lu have 5*d* electrons), so the remaining electrons go into the 4*f*. Thus, the condensed configuration of Sm is [Xe] $6s^2 4f^6$. There are seven *f* orbitals, so each of the six *f* electrons enters a separate orbital:



Thus, Sm has six unpaired electrons.

Check Six 4*f* e^- plus two 6*s* e^- plus the 54 e^- in Xe gives 62, the atomic number of Sm.

FOLLOW-UP PROBLEMS

23.2A How many unpaired electrons are in the Er^{3+} ion?

23.2B How many unpaired electrons are in the Dy^{3+} ion?

SOME SIMILAR PROBLEMS 23.30, 23.31, and 23.34

The Actinides

All actinides are radioactive. Like the lanthanides, they have very similar physical and chemical properties. Thorium and uranium occur in nature, but the transuranium elements, those with *Z* greater than 92, have been synthesized in particle accelerators (as we discuss in Section 24.3). The actinides are silvery and chemically reactive and, like the lanthanides, form highly colored compounds. The actinides and lanthanides have similar outer-electron configurations. Although the +3 oxidation state is characteristic of the actinides, as it is for the lanthanides, other states also occur. For example, uranium exhibits +3 through +6 states, with the +6 state the most prevalent; thus, the most common oxide of uranium is UO_3.

Summary of Section 23.2

- There are two series of inner transition elements. The lanthanides (4*f* series) have a common +3 oxidation state and exhibit very similar properties.
- The actinides (5*f* series) are radioactive. All actinides have a +3 oxidation state; several, including uranium, have higher states as well.

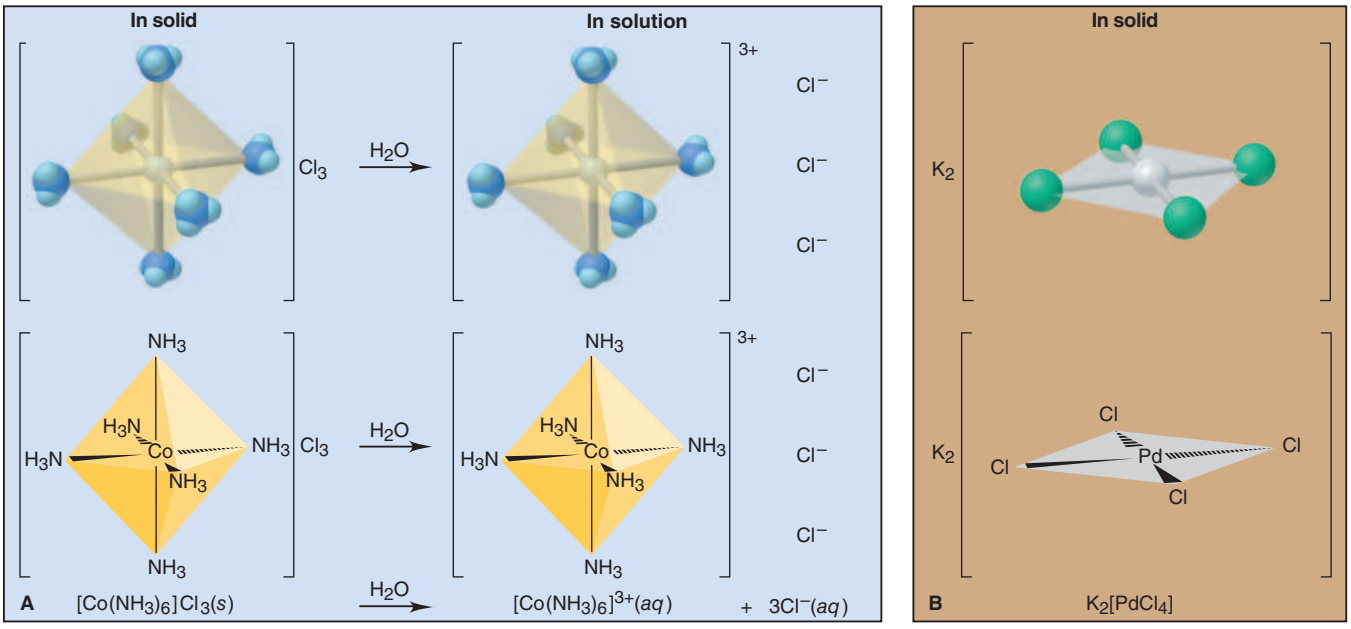


Figure 23.7 Components of a coordination compound. Coordination compounds are shown as models *(top)*, wedge-bond perspective drawings *(middle)*, and formulas *(bottom)*. **A,** When $[Co(NH_3)_6]Cl_3$ dissolves in water, the six ligands remain bound in the complex ion. **B,** $K_2[PdCl_4]$ has four Cl^- ligands and two K^+ counter ions.

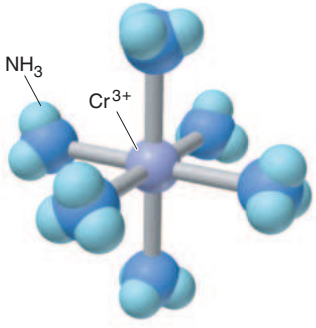


The complex ion $Cr(NH_3)_6^{3+}$ has a central Cr^{3+} ion bonded to six NH_3 ligands.

23.3 COORDINATION COMPOUNDS

The most distinctive feature of transition metal chemistry is the common occurrence of **coordination compounds** (or *complexes*). These species contain at least one **complex ion,** which consists of *a central metal cation bonded to molecules and/or anions called* ***ligands*** *(see margin).* To maintain charge neutrality, the complex ion is associated with **counter ions.** In the coordination compound $[Co(NH_3)_6]Cl_3$ (Figure 23.7A), the complex ion (in square brackets) is $[Co(NH_3)_6]^{3+}$, the six NH_3 molecules bonded to the Co^{3+} are ligands, and the three Cl^- ions are counter ions.

A coordination compound behaves like an electrolyte in water: the complex ion and counter ions separate, but the complex ion behaves like a polyatomic ion because *the ligands and central metal ion remain attached.* Thus, as Figure 23.7A shows, 1 mol of $[Co(NH_3)_6]Cl_3$ yields 1 mol of $[Co(NH_3)_6]^{3+}$ ions and 3 mol of Cl^- ions. This section covers the structure, naming, and properties of complex ions.

Complex Ions: Coordination Numbers, Geometries, and Ligands

A complex ion is described by the metal ion and the number and types of ligands attached to it. The ion's structure is related to coordination number and geometry.

Coordination Numbers The **coordination number** is the *number of ligand atoms* bonded directly to the central metal ion. It is *specific* for a given metal ion in a particular oxidation state and compound. The coordination number of the Co^{3+} ion in $[Co(NH_3)_6]^{3+}$ is 6 because six ligand atoms (N of NH_3) are bonded to it. The coordination number of the Pt^{2+} ion in many of its complexes is 4, whereas that of the Pt^{4+} ion in its complexes is 6. Copper(II) may have a coordination number of 2, 4, or 6 in different complex ions. In general, *the most common coordination number in complex ions is 6,* but 2 and 4 are often seen, and some higher ones are known.

Table 23.5 Coordination Numbers and Shapes of Some Complex Ions

Coordination Number	Shape		Examples
2	Linear		$[CuCl_2]^-$, $[Ag(NH_3)_2]^+$, $[AuCl_2]^-$
4	Square planar		$[Ni(CN)_4]^{2-}$, $[PdCl_4]^{2-}$, $[Pt(NH_3)_4]^{2+}$, $[Cu(NH_3)_4]^{2+}$
4	Tetrahedral		$[Cu(CN)_4]^{3-}$, $[Zn(NH_3)_4]^{2+}$, $[CdCl_4]^{2-}$, $[MnCl_4]^{2-}$
6	Octahedral		$[Ti(H_2O)_6]^{3+}$, $[V(CN)_6]^{4-}$, $[Cr(NH_3)_4Cl_2]^+$, $[Mn(H_2O)_6]^{2+}$, $[FeCl_6]^{3-}$, $[Co(en)_3]^{3+}$

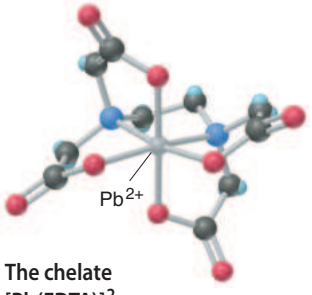
Geometries The geometry (shape) depends on *the coordination number and the metal ion.* Table 23.5 shows the geometries for coordination numbers 2, 4, and 6. A complex ion whose metal ion has a coordination number of 2, such as $[Ag(NH_3)_2]^+$, is *linear.* The coordination number 4 gives rise to either of two geometries. Most d^8 metal ions form *square planar* complex ions (Figure 23.7B). The d^{10} ions form *tetrahedral* complex ions. A coordination number of 6 results in an *octahedral* geometry, as shown by $[Co(NH_3)_6]^{3+}$ (Figure 23.7A). Note the similarity with some of the molecular shapes in VSEPR theory (Section 10.2).

Ligands The ligands of complex ions are *molecules or anions* with one or more **donor atoms.** Each *donates a lone pair of electrons* to the metal ion, thus forming a covalent bond. Because they must have at least one lone pair, donor atoms often come from Group 5A(15), 6A(16), or 7A(17). (As you learned in Section 18.9, ligands are Lewis bases.)

Ligands are classified in terms of their number of donor atoms, or "teeth":

- *Monodentate* (Latin, "one-toothed") ligands bond through a single donor atom.
- *Bidentate* ligands have two donor atoms, each of which bonds to the metal ion.
- *Polydentate* ligands have more than two donor atoms.

Bidentate and polydentate ligands give rise to *rings* in the complex ion. For instance, ethylenediamine (abbreviated *en*) has a chain of four atoms (**:**N—C—C—N**:**), so it forms a five-membered ring, with the two electron-donating N atoms bonding to the metal ion. Such ligands seem to grab the metal ion like claws, so a complex ion that contains them is also called a **chelate** (pronounced "KEY-late"; Greek *chela,* "crab's claw"). With its six donor atoms, the ethylenediaminetetraacetate ($EDTA^{4-}$) ion forms very stable complexes with metal ions. This property makes EDTA useful in treating *heavy-metal poisoning*. Ingested by the patient, the $EDTA^{4-}$ ion removes lead *(see margin)* and other heavy-metal ions from the blood and other body fluids.



The chelate $[Pb(EDTA)]^{2-}$.

Table 23.6 on the next page shows some common ligands in coordination compounds. Note that each ligand has one or more donor atoms (colored type), each with a lone pair of electrons to donate, thereby forming a covalent bond to the metal ion. Since the bidentate ligand ethylenediamine has two atoms that form bonds to the

Table 23.6 Some Common Ligands in Coordination Compounds

Ligand Type	Examples							
Monodentate	H_2O:	water	$:F:^-$	fluoride ion	$[:C\equiv N:]^-$	cyanide ion	$[:O-H]^-$	hydroxide ion
	$:NH_3$	ammonia	$:Cl:^-$	chloride ion	$[:S=C=N:]^-$ (or)	thiocyanate ion	$[:O-N=O:]^-$ (or)	nitrite ion
Bidentate	 ethylenediamine (en)		 oxalate ion					
Polydentate	 diethylenetriamine		 triphosphate ion				 ethylenediaminetetraacetate ion ($EDTA^{4-}$)	

metal ion, the complex ion $[Cr(en)_3]^{3+}$ has a coordination number of 6 (two covalent bonds per ligand); the complex ion $[Pb(EDTA)]^{2-}$ has one polydentate ligand with six donor atoms, so it also has a coordination number of 6.

Formulas and Names of Coordination Compounds

The combination of ions in a coordination compound is the key to writing its formula and name. A coordination compound can consist of a complex cation with simple anionic counter ions, a complex anion with simple cationic counter ions, or even a complex cation with complex anion as counter ion.

Determining the Charge of the Metal Ion To know the number of cations and anions, we must know the ion charges, and we use basic arithmetic to find them:

- For a compound with a *complex anion,* say, $K_2[Co(NH_3)_2Cl_4]$, we know that the K^+ counter ions balance the charge of the complex anion, which contains two NH_3 molecules and four Cl^- ions as ligands. The two NH_3 are neutral, the four Cl^- have a total charge of $4-$, and the entire complex ion must have a charge of $2-$ to balance the two K^+. The charge of the central metal ion is

$$\begin{aligned}\text{Charge of complex ion} &= \text{charge of metal ion} + \text{total charge of ligands}\\ 2- &= \text{charge of metal ion} + [(2\times 0) + (4\times 1-)]\end{aligned}$$

  So, Charge of metal ion $= (2-) - (4-) = 2+$; that is, Co^{2+}

- For a compound with a *complex cation,* say $[Co(NH_3)_4Cl_2]Cl$, the complex ion is $[Co(NH_3)_4Cl_2]^+$ and one Cl^- is the counter ion. The four NH_3 ligands are neutral, the two Cl^- ligands have a total charge of $2-$, and the complex cation has a charge of $1+$, so the central metal ion must be Co^{3+}:

$$\begin{aligned}\text{Charge of metal ion} &= \text{charge of complex ion} - \text{total charge of ligands}\\ &= \quad 1+ \quad - [(4\times 0) + (2\times 1-)] = 3+\end{aligned}$$

Rules for Writing Formulas There are three rules for writing formulas of coordination compounds (the first two are the same as those for the formula of any ionic compound):

1. *The cation is written before the anion.*
2. *The charge of the cation(s) is balanced by the charge of the anion(s).*
3. *For the complex ion, neutral ligands are written before anionic ligands, and the formula of the whole ion is placed in brackets.*

SAMPLE PROBLEM 23.3 Finding the Coordination Number and Charge of the Central Metal Ion in a Coordination Compound

Problem Give the coordination number and the charge of the central metal ion in each coordination compound:
(a) $Na_2[Zn(OH)_4]$
(b) $K[Co(H_2O)_2(C_2O_4)_2]$
(c) $[Ru(H_2O)_2(NH_3)_2Cl_2]Br$

Plan To find the coordination number, we use Table 23.6 to determine the number of ligand atoms bonded to the central metal ion in the complex ion (in square brackets). Counter ions (those ions outside the brackets) are not included when determining the coordination number. We know that the charge of the complex ion must balance the charge of the counter ions; the charge of the metal ion is equal to the charge of the complex ion minus the total charge of the ligands.

Solution **(a)** Each of the four monodentate OH^- ligands forms one bond to the metal ion for a coordination number of 4. Since the two Na^+ counter ions have a total charge of 2+, the charge of the complex ion is 2−; the four OH^- ligands have a total charge of 4−. The charge of the zinc ion is

$$\text{Charge of metal ion} = \text{charge of complex ion} - \text{total charge of ligands}$$
$$= (2-) - (4-) = 2+$$

(b) There are two monodentate H_2O ligands, each forming one bond to the metal ion; since the two $C_2O_4^{2-}$ ligands are bidentate, each of them forms two bonds to the metal ion, for a total of four bonds. Thus, the coordination number is 6. Since the K^+ counter ion has a charge of 1+, the charge of the complex ion is 1−. The H_2O ligands are neutral, and the two $C_2O_4^{2-}$ ligands have a total charge of 4−. The charge of the cobalt ion is

$$\text{Charge of metal ion} = (1-) - [0 + (4-)] = 3+$$

(c) The complex has two H_2O, two NH_3, and two Cl^- ligands, each of which forms one bond to the metal ion for a coordination number of 6. Since the Br^- counter ion has a 1− charge, the complex ion has a charge of 1+. The H_2O and NH_3 ligands are neutral, and the two Cl^- ligands have a total charge of 2−. The charge of the ruthenium ion is

$$\text{Charge of metal ion} = (1+) - [0 + 0 + (2-)] = 3+$$

Check Be sure that the coordination number equals the sum of the number of monodentate ligands and twice the number of bidentate ligands. Be sure that the charges of the metal ion, ligands, and counter ions sum to zero.

FOLLOW-UP PROBLEMS

23.3A Give the coordination number and the charge of the central metal ion in each coordination compound:
(a) $[Co(en)_2Br_2]NO_3$
(b) $Mg_3[CrCl_5Br]_2$

23.3B Write the formula of the coordination compound composed of the following:
(a) A Mn^{2+} central ion with a coordination number of 6, cyanide ligands, and potassium counter ions
(b) A Cu^{2+} central ion with a coordination number of 4, ethylenediamine ligands, and sulfate as the counter ion

SOME SIMILAR PROBLEMS 23.47, 23.48, 23.51, and 23.52

Rules for Naming Coordination Compounds Originally named after their discoverer or color, coordination compounds are named systematically according to a set of rules. Let's see how to name $[Co(NH_3)_4Cl_2]Cl$. As we go through the naming steps, refer to Tables 23.7 and 23.8 on the next page.

1. *The cation is named before the anion.* Thus, we name the $[Co(NH_3)_4Cl_2]^+$ ion before the Cl^- counter ion.
2. *Within the complex ion, the ligands are named in alphabetical order* ***before*** *the metal ion.* In the $[Co(NH_3)_4Cl_2]^+$ ion, four NH_3 and two Cl^- are named before Co^{3+}.

Table 23.7 Names of Some Neutral and Anionic Ligands

Neutral		Anionic	
Name	**Formula**	**Name**	**Formula**
Aqua	H_2O	Fluoro	F^-
Ammine	NH_3	Chloro	Cl^-
Carbonyl	CO	Bromo	Br^-
Nitrosyl	NO	Iodo	I^-
		Hydroxo	OH^-
		Cyano	CN^-

Table 23.8 Names of Some Metal Ions in Complex Anions

Metal	Name in Anion
Iron	Ferrate
Copper	Cuprate
Lead	Plumbate
Silver	Argentate
Gold	Aurate
Tin	Stannate

3. *Neutral ligands generally have the molecule name,* but there are a few exceptions (Table 23.7). *Anionic ligands drop the -ide and add -o after the root name;* thus, the anion name *fluoride* for an F^- ion becomes the ligand name *fluoro*. The two ligands in $[Co(NH_3)_4Cl_2]^+$ are *ammine* (NH_3) and *chloro* (Cl^-) with *ammine* coming before *chloro* alphabetically.
4. *A numerical prefix indicates the number of ligands of a particular type.* For example, *tetra*ammine denotes *four* NH_3, and *di*chloro denotes *two* Cl^-. Other prefixes are *tri-, penta-,* and *hexa-*. But prefixes do *not* affect the alphabetical order: *tetraammine* comes before *dichloro.* For ligand names that include a numerical prefix (such as ethylene*di*amine), we use *bis* (2), *tris* (3), or *tetrakis* (4) to indicate the number of such ligands, followed by the ligand name in parentheses. For example, a complex ion that has two ethylenediamine ligands has *bis(ethylenediamine)* in its name.
5. *The oxidation state of the metal ion has a Roman numeral (in parentheses) only if the metal ion can have more than one state.* Since cobalt can have +2 and +3 states, we add a III to name the complex ion. Thus, the compound is

   tetraamminedichlorocobalt(III) chloride

   The only typographical space in the name comes between cation and anion.
6. *If the complex ion is an anion, we drop the ending of the metal name and add -ate.* Thus, the name for $K[Pt(NH_3)Cl_5]$ is potassium amminepentachloroplatinate(IV). There is one K^+ counter ion, so the complex anion has a charge of 1−. The five Cl^- ligands have a total charge of 5−, so Pt must be in the +4 oxidation state. For some metals, we use the Latin root with the *-ate* ending (Table 23.8). For example, the name for $Na_4[FeBr_6]$ is sodium hexabromoferrate(II).

SAMPLE PROBLEM 23.4 Writing Names and Formulas of Coordination Compounds

Problem **(a)** What is the systematic name of $Na_3[AlF_6]$?
(b) What is the systematic name of $[Co(en)_2Cl_2]NO_3$?
(c) What is the formula of tetraamminebromochloroplatinum(IV) chloride?
(d) What is the formula of hexaamminecobalt(III) tetrachloroferrate(III)?

Plan We use the rules presented above and the information in Tables 23.7 and 23.8.

Solution **(a)** The complex ion is $[AlF_6]^{3-}$. There are six *(hexa-)* F^- ions *(fluoro)* as ligands, so we have *hexafluoro.* The complex ion is an anion, so the ending of the metal ion (aluminum) must be changed to *-ate:* hexafluoroaluminate. Aluminum has only the +3 oxidation state, so we do *not* use a Roman numeral. The positive counter ion is named first and separated from the anion by a space: sodium hexafluoroaluminate.
(b) Listed alphabetically, there are two Cl^- *(dichloro)* and two en [*bis(ethylenediamine)*] as ligands. The complex ion is a cation, so the metal name is unchanged, but we specify its oxidation state because cobalt can have several. One NO_3^- balances the 1+ cation charge. With 2− for two Cl^- and 0 for two en, the metal must be *cobalt(III).* The word *nitrate* follows a space: dichlorobis(ethylenediamine)cobalt(III) nitrate.
(c) The central metal ion is written first, followed by the neutral ligands and then (in alphabetical order) by the negative ligands. *Tetraammine* is four NH_3, *bromo* is one Br^-, *chloro* is one Cl^-, and *platinate(IV)* is Pt^{4+}, so the complex ion is $[Pt(NH_3)_4BrCl]^{2+}$.

Its 2+ charge is the sum of 4+ for Pt^{4+}, 0 for four NH_3, 1− for one Br^-, and 1− for one Cl^-. To balance the 2+ charge, we need two Cl^- counter ions: $[Pt(NH_3)_4BrCl]Cl_2$.
(d) This compound consists of two different complex ions. In the cation, *hexaammine* is six NH_3 and *cobalt(III)* is Co^{3+}, so the cation is $[Co(NH_3)_6]^{3+}$. The 3+ charge is the sum of 3+ for Co^{3+} and 0 for six NH_3. In the anion, *tetrachloro* is four Cl^-, and *ferrate(III)* is Fe^{3+}, so the anion is $[FeCl_4]^-$. The 1− charge is the sum of 3+ for Fe^{3+} and 4− for four Cl^-. In the neutral compound, one 3+ cation must be balanced by three 1− anions: $[Co(NH_3)_6][FeCl_4]_3$.

Check Reverse the process to be sure you obtain the name or formula in the problem.

FOLLOW-UP PROBLEMS

23.4B **(a)** What is the formula of diaquabis(ethylenediamine)cobalt(III) sulfate? **(b)** What is the name of $Mg[Cr(NH_3)_2Cl_4]_2$?

SOME SIMILAR PROBLEMS 23.45, 23.46, 23.49, 23.50, 23.53, 23.54, 23.57, and 23.58

Isomerism in Coordination Compounds

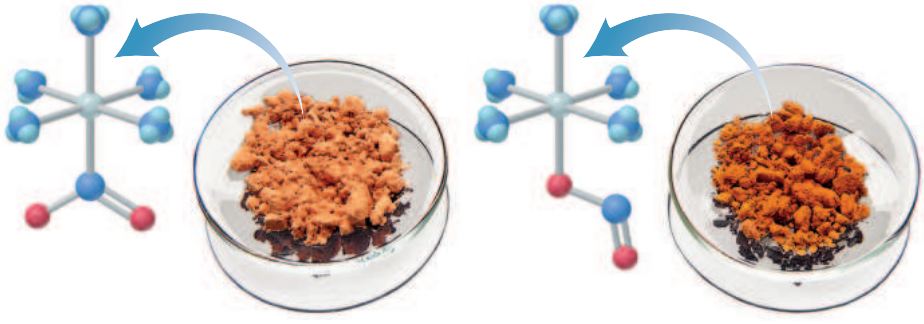
Isomers are compounds with the same chemical formula but different properties. Recall the discussion of isomerism in organic compounds (Section 15.2); coordination compounds exhibit the same two broad categories—constitutional isomers and stereoisomers.

Constitutional Isomers: Atoms Connected Differently Compounds with the same formula, but with the atoms connected differently, are **constitutional (structural) isomers.** Coordination compounds exhibit two types:

1. **Coordination isomers** occur when the composition of the complex ion, but not of the compound, is different. This type of isomerism occurs in two ways:

- *Exchange of ligand and counter ion*. For example, in $[Pt(NH_3)_4Cl_2](NO_2)_2$, the Cl^- ions are the ligands, and the NO_2^- ions are counter ions; in $[Pt(NH_3)_4(NO_2)_2]Cl_2$, the roles are reversed. A common test to see whether Cl^- is a ligand or a counter ion is to treat a solution of the compound with $AgNO_3$; the Cl^- counter ion will form a white precipitate of AgCl, but the Cl^- ligand won't. Thus, a solution of $[Pt(NH_3)_4Cl_2](NO_2)_2$ does not form AgCl because Cl^- is bound to the metal ion, but a $[Pt(NH_3)_4(NO_2)_2]Cl_2$ solution forms 2 mol of AgCl per mole of compound.
- *Exchange of ligands*. This type of isomerism occurs in compounds consisting of two complex ions. For example, in $[Cr(NH_3)_6][Co(CN)_6]$ and $[Co(NH_3)_6][Cr(CN)_6]$, NH_3 is a ligand of Cr^{3+} in one compound and of Co^{3+} in the other.

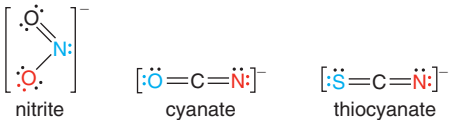
2. **Linkage isomers** occur when the composition of the complex ion is the same but the ligand donor atom is different. Some ligands can bind to the metal ion through *either of two donor atoms.* For example, the nitrite ion can bind through the N atom (*nitro,* O_2N:) or either of the O atoms (*nitrito,* ONO:) to give linkage isomers, such as pentaammine*nitro*cobalt(III) chloride $[Co(NH_3)_5(NO_2)]Cl_2$ and pentaammine*nitrito*cobalt(III) chloride $[Co(NH_3)_5(ONO)]Cl_2$ (Figure 23.8).



Nitro isomer, $[Co(NH_3)_5(NO_2)]Cl_2$ ***Nitrito*** isomer, $[Co(NH_3)_5(ONO)]Cl_2$

Figure 23.8 A pair of linkage (constitutional) isomers.

Other examples of ligands that have more than one donor atom are the cyanate ion, which can attach via the O atom (*cyanato,* NCO:) or the N atom (*isocyanato,* OCN:), and the thiocyanate ion, which can attach via the S atom or the N atom:



Stereoisomers: Atoms Arranged Differently in Space **Stereoisomers** are compounds that have the same atomic connections but different spatial arrangements of the atoms. *Geometric* and *optical* isomers, which we discussed for organic compounds, occur with coordination compounds as well:

1. **Geometric isomers** (also called ***cis-trans* isomers** and *diastereomers*) occur when atoms or groups of atoms are arranged differently in space relative to the central metal ion. For example, the square planar $[Pt(NH_3)_2Cl_2]$ has two arrangements, which give rise to two different compounds (Figure 23.9A). The isomer with identical ligands *next* to each other is *cis*-diamminedichloroplatinum(II), and the one with identical ligands *across* from each other is *trans*-diamminedichloroplatinum(II).

These isomers have remarkably different biological behaviors. In the mid-1960s, Barnett Rosenberg and his colleagues found that *cis*-$[Pt(NH_3)_2Cl_2]$ (cisplatin) was an antitumor agent. It and several closely related platinum(II) complexes are still used to treat certain types of cancer. In contrast, *trans*-$[Pt(NH_3)_2Cl_2]$ has no antitumor effect. Cisplatin may work by becoming oriented within a cancer cell such that a donor atom on each DNA strand can replace a Cl^- ligand, and it binds the platinum(II) strongly, preventing DNA replication (Section 15.6).

Octahedral complexes also exhibit *cis-trans* isomerism (Figure 23.9B). The *cis* isomer of the $[Co(NH_3)_4Cl_2]^+$ ion has the two Cl^- ligands at any two adjacent positions of the ion's octahedral shape, whereas the *trans* isomer has these ligands across from each other.

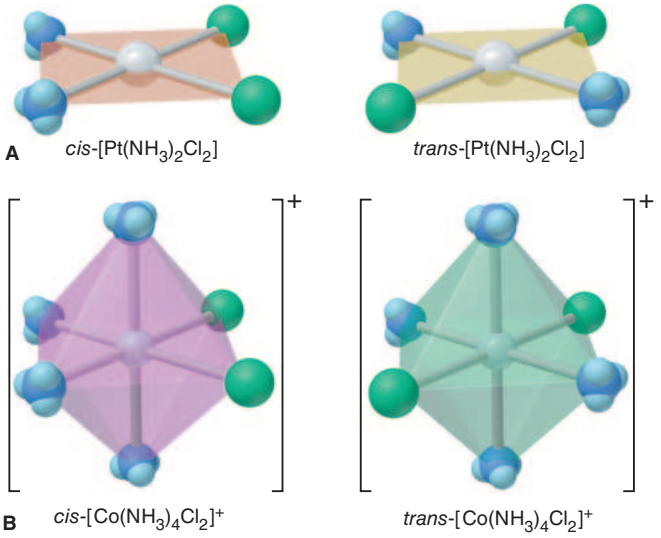


Figure 23.9 **Geometric *(cis-trans)* isomerism. A,** The *cis* and *trans* isomers of $[Pt(NH_3)_2Cl_2]$. **B,** The *cis* and *trans* isomers of $[Co(NH_3)_4Cl_2]^+$. The colored shapes indicate the actual colors of the species.

2. **Optical isomers** (also called *enantiomers*) occur when a molecule and its mirror image cannot be superimposed (see Figures 15.8 to 15.10, pp. 626–627). Unlike other types of isomers, which have distinct physical properties, optical isomers are physically identical except for *the direction in which they rotate the plane of polarized light.* Many octahedral complex ions show optical isomerism, which we can determine by rotating one isomer and seeing if it is superimposable on the

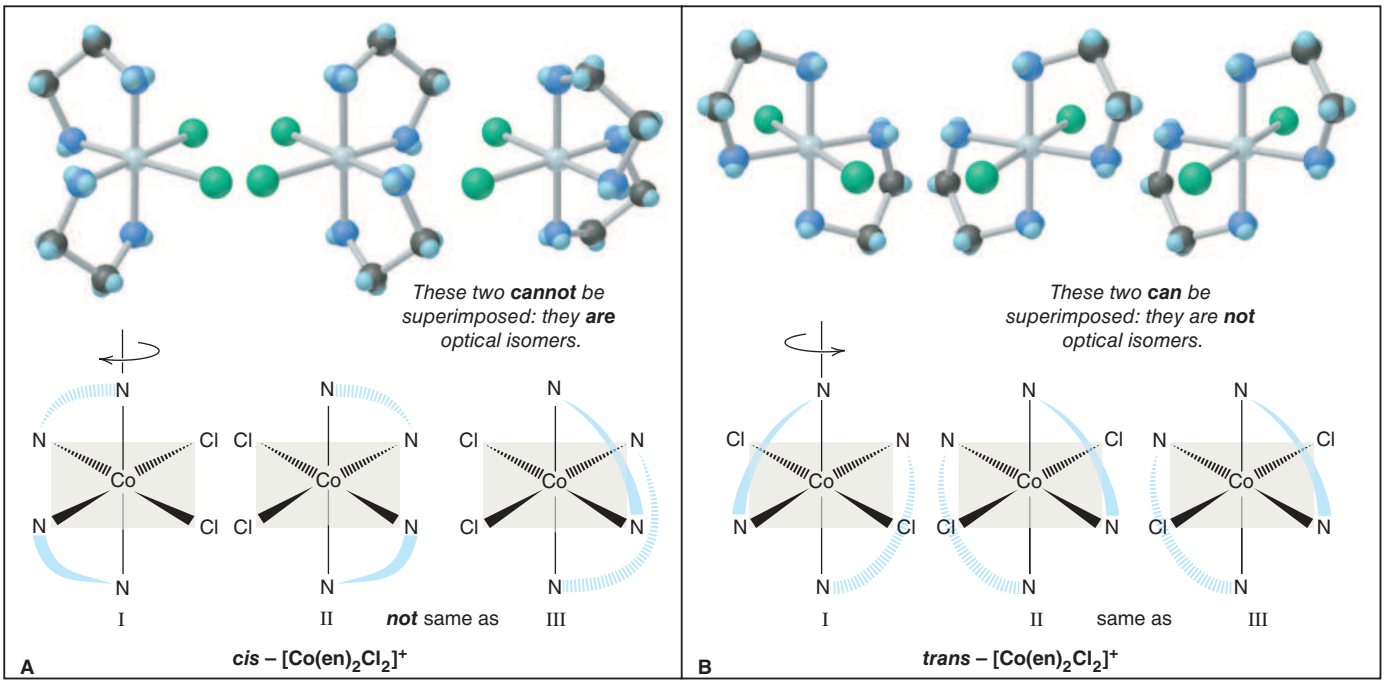

Figure 23.10 **Optical isomerism in an octahedral complex ion. A,** Structure I and its mirror image, structure II, are optical isomers of *cis*-$[Co(en)_2Cl_2]^+$. (The curved wedges represent the bidentate ligand ethylenediamine, $H_2N—CH_2—CH_2—NH_2$.) **B,** The *trans* isomer does *not* have optical isomers.

other isomer (its mirror image). For example, in Figure 23.10A, the two structures (I and II) of *cis*-$[Co(en)_2Cl_2]^+$, the *cis*-dichlorobis(ethylenediamine)cobalt(III) ion, are mirror images of each other. Rotate structure I clockwise 180° around a vertical axis, and you obtain III. The Cl^- ligands of III match those of II, but the en ligands do not: II and III (which is I rotated) are not superimposable: they are optical isomers. One isomer is designated *d*-$[Co(en)_2Cl_2]^+$ and the other is *l*-$[Co(en)_2Cl_2]^+$, depending on whether it rotates polarized light to the right (*d*- for "dextro-") or to the left (*l*- for "levo-"). (The *d*- or *l*- designation can only be determined by experiment.)

In contrast, as shown in Figure 23.10B, the two structures of the *trans*-dichlorobis(ethylenediamine)cobalt(III) ion are *not* optical isomers: rotate I 90° counterclockwise around a vertical axis and you obtain III, which *is* superimposable on II.

Figure 23.11 is an overview of the most common types of isomerism in coordination compounds.

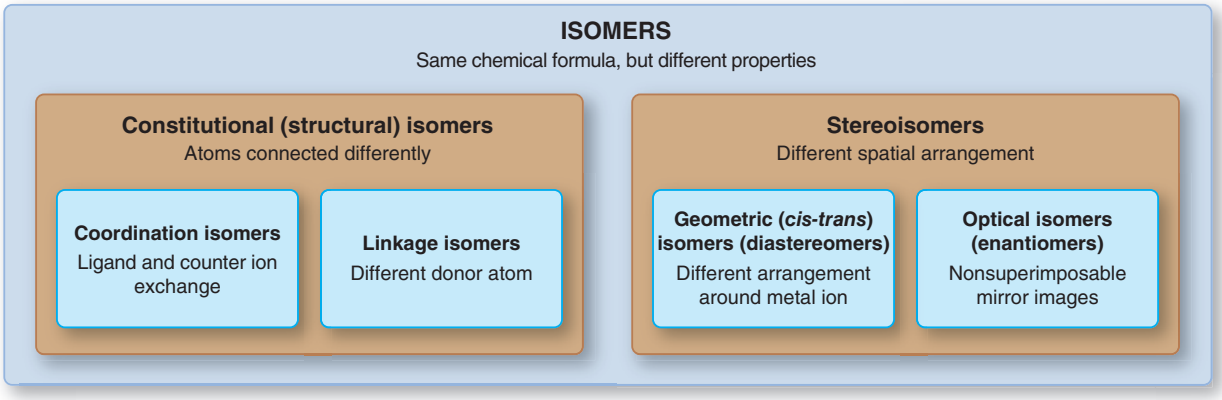

Figure 23.11 **Important types of isomerism in coordination compounds.**

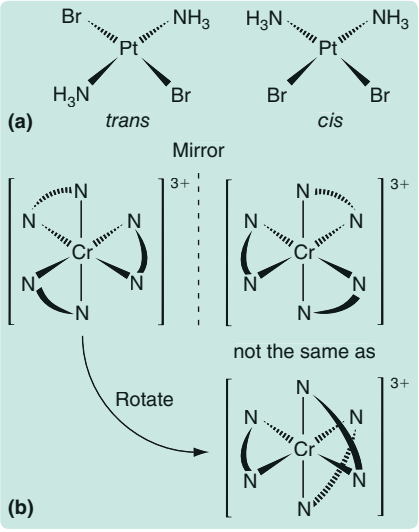


SAMPLE PROBLEM 23.5 **Determining the Type of Stereoisomerism**

Problem Draw stereoisomers for each of the following and state the type of isomerism:
(a) $[Pt(NH_3)_2Br_2]$ (square planar) **(b)** $[Cr(en)_3]^{3+}$ (en = $H_2\ddot{N}CH_2CH_2\ddot{N}H_2$)

Plan We determine the geometry around each metal ion and the nature of the ligands. If there are different ligands that can be placed in different positions relative to each other, geometric *(cis-trans)* isomerism occurs. Then, we see whether the mirror image of an isomer is superimposable on the original. If it is *not,* optical isomerism also occurs.

Solution **(a)** The square planar Pt(II) complex has two different monodentate ligands. Each pair of ligands can lie next to or across from each other *(see margin)*. Thus, geometric isomerism occurs. Each isomer *is* superimposable on a mirror image of itself, so there is no optical isomerism.
(b) Ethylenediamine (en) is a bidentate ligand. The Cr^{3+} has a coordination number of 6 and an octahedral geometry, like Co^{3+}. The three bidentate ligands are identical, so there is no geometric isomerism. However, the complex ion has a nonsuperimposable mirror image *(see margin)*. Thus, optical isomerism occurs.

FOLLOW-UP PROBLEMS
23.5A What stereoisomers, if any, are possible for the $[Co(NH_3)_2(en)Cl_2]^+$ ion?
23.5B Draw all of the stereoisomers of the $[Ru(H_2O)_2(NH_3)_2Cl_2]^+$ ion.
SOME SIMILAR PROBLEMS 23.63–23.66

Summary of Section 23.3

- Coordination compounds consist of a complex ion and charge-balancing counter ions. The complex ion has a central metal ion bonded to neutral and/or anionic ligands, which have one or more donor atoms that each have a lone pair of electrons.
- The most common complex-ion geometry is octahedral (six ligand atoms bonding).
- Formulas and names of coordination compounds follow systematic rules.
- Coordination compounds can exhibit constitutional isomerism (coordination and linkage) and stereoisomerism (geometric and optical).

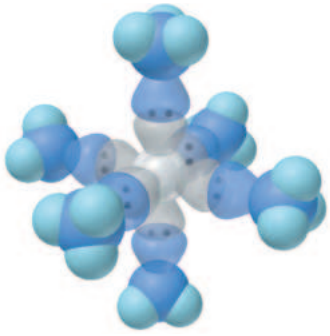
23.4 THEORETICAL BASIS FOR THE BONDING AND PROPERTIES OF COMPLEXES

In this section, we consider valence bond theory and crystal field theory, which address different features of complexes: how metal-ligand bonds form, why certain geometries are preferred, and why complexes are brightly colored and often paramagnetic.

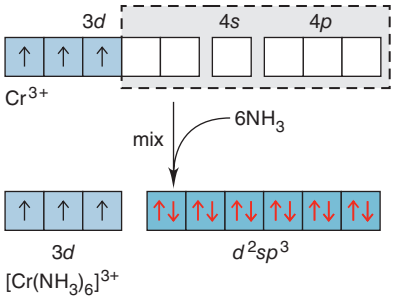
Applying Valence Bond Theory to Complex Ions

Valence bond (VB) theory, which helps explain bonding and structure in main-group compounds (Section 11.1), can also be used to describe bonding in complex ions. In the formation of a complex ion, the *filled* ligand orbital overlaps an *empty* metal-ion orbital: *the ligand (Lewis base) donates an electron pair, and the metal ion (Lewis acid) accepts it to form a covalent bond in the complex ion (Lewis adduct)* (Section 18.9). A bond in which one atom contributes both electrons is a **coordinate covalent bond;** once formed, it is identical to any covalent single bond.

Recall that the VB concept of hybridization proposes mixing particular combinations of *s*, *p*, and *d* orbitals to obtain sets of hybrid orbitals, which have specific geometries. For coordination compounds, the model proposes that *the type of metal-ion orbital hybridization determines the geometry of the complex ion.* Let's discuss orbital combinations that lead to octahedral, square planar, and tetrahedral geometries.



Orbital contour depiction of $[Cr(NH_3)_6]^{3+}$



Six d^2sp^3 hybrid orbitals form and are filled with six NH_3 lone pairs (red).

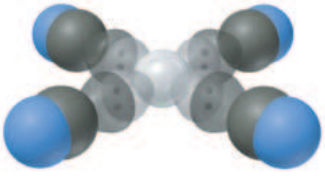
Figure 23.12 **Hybrid orbitals and bonding in the octahedral $[Cr(NH_3)_6]^{3+}$ ion.**

Octahedral Complexes The hexaamminechromium(III) ion, $[Cr(NH_3)_6]^{3+}$, is an *octahedral complex* (Figure 23.12). The six lowest-energy, *empty* orbitals of the Cr^{3+} ion—two 3*d*, one 4*s*, and three 4*p*—mix and become six equivalent d^2sp^3 hybrid orbitals that point toward the corners of an octahedron.* Six NH_3 molecules donate lone pairs from their N atoms to form six metal-ligand bonds. Three unpaired 3*d* electrons of the central Cr^{3+} ion ([Ar] $3d^3$) remain in unhybridized orbitals and make the complex ion paramagnetic.

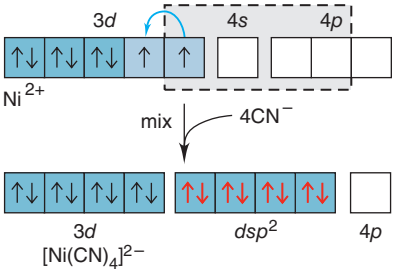
Square Planar Complexes Metal ions with a d^8 configuration usually form *square planar complexes* (Figure 23.13). In the $[Ni(CN)_4]^{2-}$ ion, for example, the model proposes that one 3*d*, one 4*s*, and two 4*p* orbitals of Ni^{2+} mix and form four dsp^2 hybrid orbitals, which point to the corners of a square and accept one electron pair from each of four CN^- ligands.

A look at the ground-state electron configuration of the Ni^{2+} ion, however, raises a key question: how can the Ni^{2+} ion ([Ar] $3d^8$) offer an empty 3*d* orbital for accepting a lone pair, if its eight 3*d* electrons lie in three filled and two half-filled orbitals? Apparently, in the d^8 configuration of Ni^{2+}, electrons in the half-filled orbitals *pair up* and leave one 3*d* orbital empty. This explanation is consistent with the fact that the complex is diamagnetic (no unpaired electrons). Moreover, it means that the energy *gained* by using a 3*d* orbital for bonding in the hybrid orbital is greater than the energy *required* to overcome repulsions from pairing the 3*d* electrons.

*Note the difference between hybrid-orbital designations here and in Chapter 11, even though both designations give the orbitals in energy order. In $[Cr(NH_3)_6]^{3+}$, the 3*d* orbitals have a *lower n* value than the 4*s* and 4*p* orbitals, so the hybrid orbitals are d^2sp^3. But, for SF_6, the 3*d* orbitals have the *same n* value as the 3*s* and 3*p* orbitals of S, so the designation is sp^3d^2.



Orbital contour depiction of $[Ni(CN)_4]^{2-}$



Two lone 3d electrons pair; four dsp^2 hybrid orbitals form and are filled with four CN^- lone pairs (red).

Figure 23.13 **Hybrid orbitals and bonding in the square planar $[Ni(CN)_4]^{2-}$ ion.**

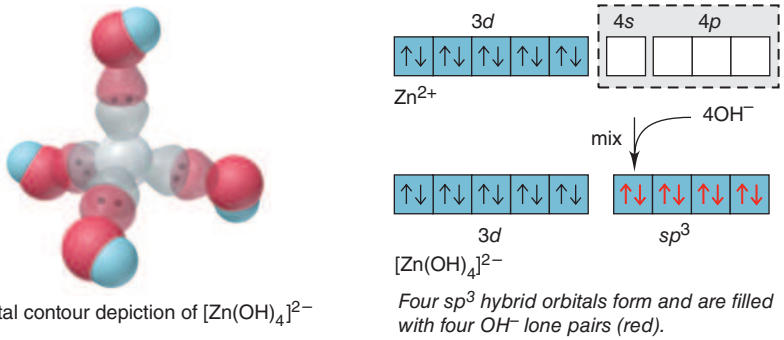


Figure 23.14 **Hybrid orbitals and bonding in the tetrahedral $[Zn(OH)_4]^{2-}$ ion.**

Tetrahedral Complexes Metal ions that have a filled *d* sublevel, such as Zn^{2+} ([Ar] $3d^{10}$), often form diamagnetic *tetrahedral complexes* (Figure 23.14). In the $[Zn(OH)_4]^{2-}$ ion, for example, VB theory proposes that the lowest *empty* Zn^{2+} orbitals—one 4*s* and three 4*p*—mix to become four sp^3 hybrid orbitals that point to the corners of a tetrahedron and are occupied by lone pairs, one from each of four OH^- ligands.

Crystal Field Theory

The VB model is easy to picture and rationalizes bonding and shape, but it treats the orbitals as little more than empty "slots" for accepting electron pairs. Moreover, it gives no insight into the colors of these compounds and sometimes predicts their magnetic properties incorrectly. For this reason, other models are applied more often. Although **crystal field theory** provides little insight about metal-ligand bonding, it explains color and magnetism by highlighting the *effect on d-orbital energies of the metal ion as the ligands approach.* Before we discuss the theory, let's consider why a substance is colored.

What Is Color? White light consists of all wavelengths (λ) in the visible range (Section 7.1) and can be dispersed into colors of a narrower wavelength range. Objects appear colored in white light because they absorb only certain wavelengths: an opaque object *reflects* the other wavelengths, and a clear one *transmits* them. If an object absorbs all visible wavelengths, it appears black; if it reflects all, it appears white.

Each color has a *complementary* color; for example, green and red are complementary colors. Figure 23.15 shows these relationships on an artist's color wheel in which complementary colors are wedges opposite each other. A mixture of complementary colors absorbs all visible wavelengths and appears black.

An object has a particular color for one of two reasons:

- It reflects (or transmits) light of *that* color. Thus, if an object absorbs all wavelengths *except* green, the reflected (or transmitted) light is seen as green.
- It absorbs light of the *complementary* color. Thus, if the object absorbs only red, the *complement* of green, the remaining mixture of reflected (or transmitted) wavelengths is also seen as green.

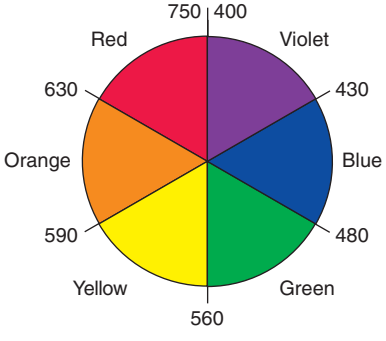

Figure 23.15 **An artist's wheel.** Colors, with approximate wavelength ranges (in nm), are shown as wedges.

Table 23.9 lists the color absorbed and the resulting color observed. The relation between absorbed and observed colors is demonstrated by the seasonal colors of deciduous trees. In the spring and summer, leaves contain high concentrations of the photosynthetic pigment *chlorophyll* and lower concentrations of other pigments called *xanthophylls.* Chlorophyll absorbs strongly in the blue and red regions, reflecting mostly green. In the fall, photosynthesis slows, so the leaf no longer makes chlorophyll. The green fades as the chlorophyll decomposes, revealing the xanthophylls

Table 23.9 Relation Between Absorbed and Observed Colors

Absorbed Color	λ (nm)	Observed Color	λ (nm)
Violet	400	Green-yellow	560
Blue	450	Orange	600
Blue-green	490	Red	620
Yellow-green	570	Violet	410
Yellow	580	Dark blue	430
Orange	600	Blue	450
Red	650	Green	520

Foliage changing color in autumn.

that were present but masked by the chlorophyll. Xanthophylls absorb green and blue strongly, reflecting bright yellows and reds *(see photo)*.

Splitting of *d* Orbitals in an Octahedral Field of Ligands The crystal field model explains that the properties of complexes result from the splitting of *d*-orbital energies, which arises from *electrostatic attractions between the metal cation and the negative charge of the ligands.* This negative charge is either partial, as in a polar covalent ligand like NH_3, or full, as in an anionic ligand like Cl^-. Picture six ligands approaching a metal ion along the mutually perpendicular *x*, *y*, and *z* axes, which forms an octahedral arrangement (Figure 23.16A). Let's follow the orientation of ligand and orbital and how the approach affects orbital energies.

1. *Orientation of ligand and metal-ion orbitals.* As ligands approach, their electron pairs repel electrons in the five *d* orbitals of the metal ion. In the isolated ion, the *d* orbitals have different orientations but *equal* energies. But, in the negative field of ligands, the *d* electrons are *repelled unequally because of their different orbital orientations.* The ligands moving *along* the *x*, *y*, and *z* axes approach

- *Directly toward* the lobes of the $d_{x^2-y^2}$ and d_{z^2} orbitals (Figure 23.16B and C).
- *Between* the lobes of the d_{xy}, d_{xz}, and d_{yz} orbitals (Figure 23.16D to F).

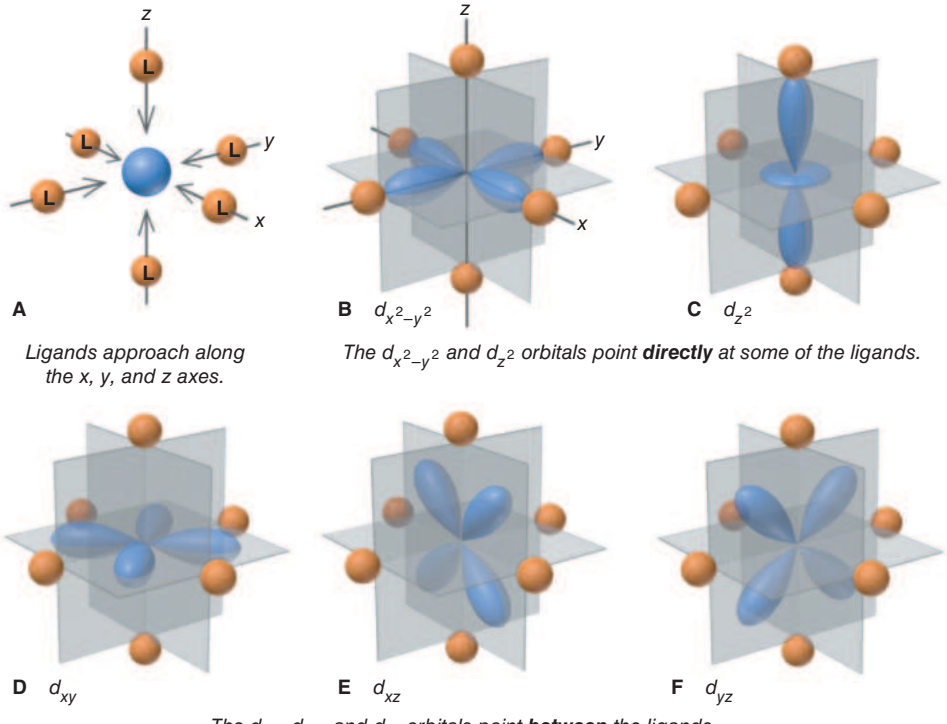

Figure 23.16 The five *d* orbitals in an octahedral field of ligands.

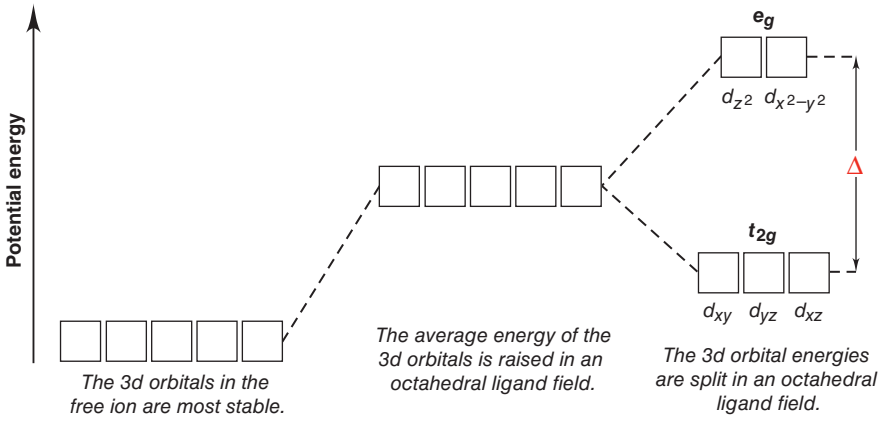

Figure 23.17 Splitting of *d*-orbital energies in an octahedral field of ligands.

2. *Effect on d-orbital energies*. As a result of these different orientations, electrons in the $d_{x^2-y^2}$ and d_{z^2} orbitals experience *stronger* repulsions than do electrons in the d_{xy}, d_{xz}, and d_{yz} orbitals. An energy diagram shows that the five *d* orbitals are most stable in the free ion and their *average* energy is higher in the ligand field. But *the orbital energies split, with two d orbitals higher in energy and three lower* (Figure 23.17):

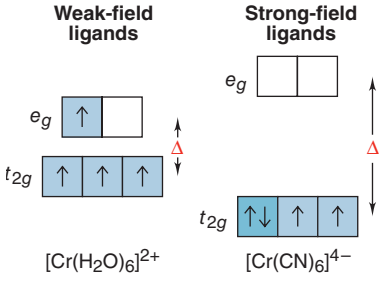
- The two higher energy orbitals are $\boldsymbol{e_g}$ **orbitals** and arise from the $d_{x^2-y^2}$ and d_{z^2}.
- The three lower energy orbitals are $\boldsymbol{t_{2g}}$ **orbitals** and arise from the d_{xy}, d_{xz}, and d_{yz}.

3. *The crystal field effect*. This splitting of orbital energies is called the *crystal field effect,* and the energy difference between e_g and t_{2g} orbitals is the **crystal field splitting energy (Δ).** Different ligands create crystal fields of different strength:

- **Strong-field ligands** lead to a *larger* splitting energy (larger Δ).
- **Weak-field ligands** lead to a *smaller* splitting energy (smaller Δ).

For instance, H_2O is a weak-field ligand, and CN^- is a strong-field ligand (Figure 23.18). Note the different orbital occupancies; we discuss the reason for these differences shortly.

Figure 23.18 The effect of ligands on splitting energy and orbital occupancy.



Explaining the Colors of Transition Metal Complexes The color of a coordination compound is determined by Δ of its complex ion. When the ion absorbs radiant energy, electrons can use that energy to move from the lower energy t_{2g} level to the higher energy e_g level. Recall from Chapter 7 that the *difference* between two atomic energy levels is equal to the energy (and inversely related to the wavelength) of the absorbed photon:

$$\Delta E_{\text{electron}} = E_{\text{photon}} = h\nu = hc/\lambda$$

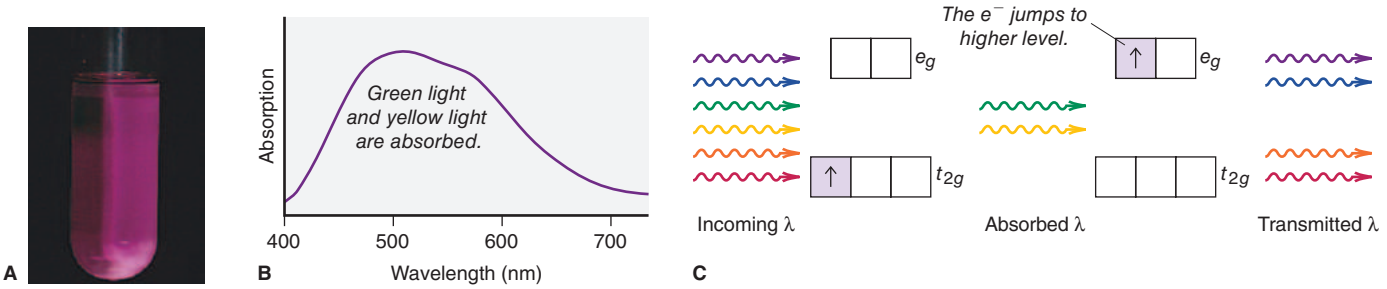


Figure 23.19 **The color of $[Ti(H_2O)_6]^{3+}$. A,** The hydrated Ti^{3+} ion is purple. **B,** An absorption spectrum shows that green light and yellow light are absorbed and other wavelengths are transmitted. **C,** An orbital diagram depicts the colors absorbed when the *d* electron jumps to the higher level.

Consider the $[Ti(H_2O)_6]^{3+}$ ion, which appears purple in aqueous solution (Figure 23.19). Hydrated Ti^{3+} has its one *d* electron in one of the three lower energy t_{2g} orbitals. The energy difference (Δ) between the t_{2g} and e_g orbitals in this ion corresponds to the energy of photons between the green and yellow range. When white light shines on the solution, these colors of light are absorbed, and the electron jumps to one of the e_g orbitals. Red, blue, and violet light are transmitted, so the solution appears purple.

Absorption spectra can show the wavelengths absorbed by (1) a metal ion with different ligands and (2) different metal ions with the same ligand. Such data allow us to relate the energy of the absorbed light to Δ and make two key observations:

- *For a given ligand,* color depends on the *oxidation state of the metal ion.* In Figure 23.20A, aqueous $[V(H_2O)_6]^{2+}$ *(left)* is violet and $[V(H_2O)_6]^{3+}$ *(right)* is yellow.
- *For a given metal ion,* color depends on the *ligand.* A single ligand substitution can affect the wavelengths absorbed and, thus, the color. For example, replacing one NH_3 ligand in the yellow $[Cr(NH_3)_6]^{3+}$ ion with a Cl^- ligand results in a purple $[Cr(NH_3)_5Cl]^{2+}$ ion (Figure 23.20B).

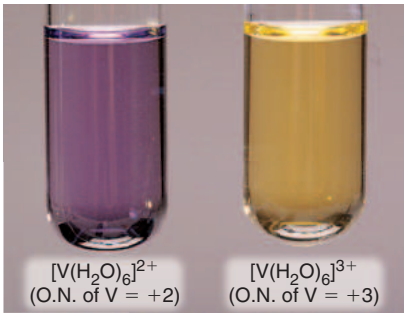

Figure 23.20 **Effects of oxidation state and ligand on color. A,** Solutions of two hydrated vanadium ions. **B,** A change in one ligand can influence the color.

The Spectrochemical Series The fact that color depends on the ligand allows us to create a **spectrochemical series,** which ranks the ability of a ligand to split *d*-orbital energies (Figure 23.21). Using this series, we can predict the *relative* magnitude of Δ for a series of octahedral complexes of a *given* metal ion. As Δ increases, higher energies (shorter wavelengths) of light must be absorbed to excite electrons. Although we cannot predict the actual color of a given complex, we can determine whether a complex will absorb longer or shorter wavelengths than other complexes in the series.

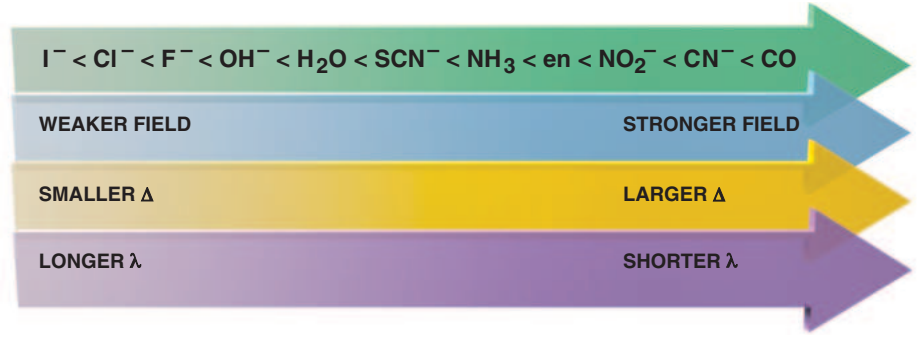

Figure 23.21 **The spectrochemical series.** For reference, water is a weak-field ligand.

SAMPLE PROBLEM 23.6 Ranking Crystal Field Splitting Energies (Δ) for Complex Ions of a Metal

Problem Rank $[Ti(H_2O)_6]^{3+}$, $[Ti(CN)_6]^{3-}$, and $[Ti(NH_3)_6]^{3+}$ in terms of Δ and of the energy of visible light absorbed.

Plan The formulas show that Ti has the same oxidation state (+3) in the three ions. Using Figure 23.21, we rank the ligands by crystal field strength: the stronger the ligand, the greater the splitting, and the higher the energy of light absorbed.

Solution The ligand field strength is in the order $CN^- > NH_3 > H_2O$, so the relative size of Δ and energy of light absorbed is

$$Ti(CN)_6^{3-} > Ti(NH_3)_6^{3+} > Ti(H_2O)_6^{3+}$$

FOLLOW-UP PROBLEMS

23.6A Which complex ion absorbs visible light of higher energy, $[V(H_2O)_6]^{3+}$ or $[V(NH_3)_6]^{3+}$?

23.6B Some of the complex ions that Co^{3+} forms are $[Co(en)_3]^{3+}$, $[Co(NH_3)_5Cl]^{2-}$, $[Co(NH_3)_4Cl_2]^+$, and $[Co(NH_3)_5(H_2O)]^{3+}$. The observed colors of these ions (listed in arbitrary order) are red, green, purple, and yellow. Match each complex ion with its color.

SOME SIMILAR PROBLEMS 23.92–23.95, 23.97, and 23.98

Explaining the Magnetic Properties of Transition Metal Complexes Splitting of energy levels gives rise to magnetic properties based on the number of *unpaired* electrons in the metal ion's *d* orbitals. Based on Hund's rule, electrons occupy orbitals of equal energy one at a time. When all lower energy orbitals are half-filled,

- The next electron can enter a half-filled orbital and pair up by overcoming a repulsive *pairing energy* ($E_{pairing}$).
- The next electron can enter an empty, higher energy orbital by overcoming Δ.

Thus, *the relative sizes of $E_{pairing}$ and Δ determine the occupancy of d orbitals,* which determines the number of unpaired electrons and, thus, the magnetic behavior of the ion.

As an example, the isolated Mn^{2+} ion ([Ar] $3d^5$) has five unpaired electrons of equal energy (Figure 23.22A). In an octahedral field of ligands, orbital occupancy is affected by the ligand in one of two ways:

- *Weak-field ligands and high-spin complexes.* Weak-field ligands, such as H_2O in $[Mn(H_2O)_6]^{2+}$, cause a *small* splitting energy, so it takes *less* energy for *d* electrons to jump to the e_g set and stay unpaired than to pair up in the t_{2g} set (Figure 23.22B). Thus, for weak-field ligands, $E_{pairing} > \Delta$. Therefore, *the number of unpaired electrons in the complex ion is the* ***same*** *as in the free ion:* weak-field ligands create **high-spin complexes,** those with the *maximum* number of unpaired electrons.
- *Strong-field ligands and low-spin complexes.* In contrast, strong-field ligands, such as CN^- in $[Mn(CN)_6]^{4-}$, cause a *large* splitting energy, so it takes *more* energy for electrons to jump to the e_g set than to pair up in the t_{2g} set (Figure 23.22C). Thus, for strong-field ligands, $E_{pairing} < \Delta$. Therefore, *the number of unpaired electrons in the complex ion is* ***less*** *than in the free ion.* Strong-field ligands create **low-spin complexes,** those with *fewer* unpaired electrons.

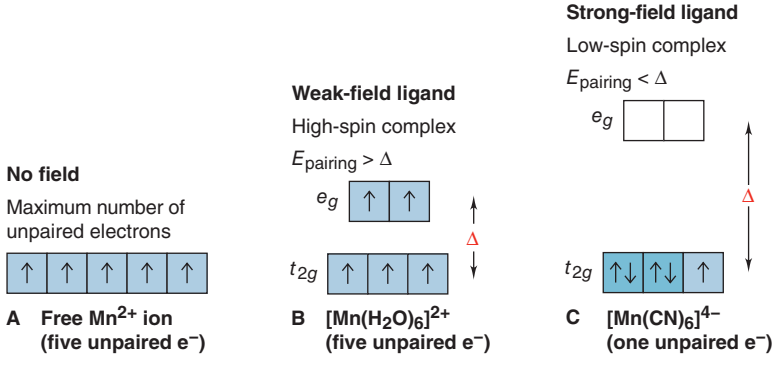

Figure 23.22 High-spin and low-spin octahedral complex ions of Mn^{2+}.

Orbital diagrams for d^1 through d^9 ions in octahedral complexes show that high-spin *and* low-spin options are possible only for d^4, d^5, d^6, and d^7 ions (Figure 23.23). With three t_{2g} orbitals available, d^1, d^2, and d^3 ions always form high-spin complexes because there is no need to pair up. Similarly, d^8 and d^9 ions always form high-spin complexes because the t_{2g} set is filled with six electrons, so the e_g orbitals *must* have either two (d^8) or one (d^9) unpaired electron(s).

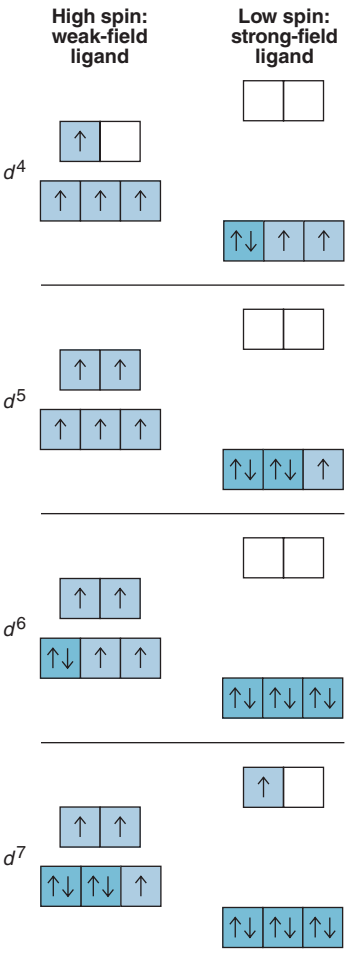

Figure 23.23 Orbital occupancy for high-spin and low-spin octahedral complexes of d^4 through d^7 metal ions.

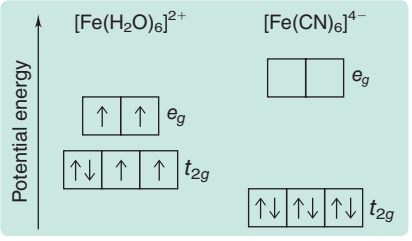
SAMPLE PROBLEM 23.7 Identifying High-Spin and Low-Spin Complex Ions

Problem Iron(II) forms a complex in hemoglobin. For each of the two octahedral complex ions $[Fe(H_2O)_6]^{2+}$ and $[Fe(CN)_6]^{4-}$, draw an energy diagram showing orbital splitting, predict the number of unpaired electrons, and identify the ion as low spin or high spin.

Plan The Fe^{2+} electron configuration shows the number of d electrons, and the spectrochemical series (Figure 23.21) shows the relative ligand strengths. We draw energy diagrams and separate the t_{2g} and e_g orbital sets more for the strong-field ligand. Then we add electrons, noting that a weak-field ligand gives the *maximum* number of unpaired electrons and a high-spin complex, whereas a strong-field ligand gives the *minimum* number of unpaired electrons and a low-spin complex.

Solution Fe^{2+} has the [Ar] $3d^6$ configuration. H_2O produces smaller splitting than CN^-. The energy diagrams are shown below. The $[Fe(H_2O)_6]^{2+}$ ion has four unpaired electrons (high spin), and the $[Fe(CN)_6]^{4-}$ ion has no unpaired electrons (low spin).



Comment **1.** H_2O is a weak-field ligand, so it forms high-spin complexes. **2.** We cannot confidently predict the spin of a complex without having actual values for Δ and $E_{pairing}$. **3.** Cyanide ions and carbon monoxide are toxic because they bind to the iron complexes in proteins involved in cellular energy (Chemical Connections, pp. 962 and 1043).

FOLLOW-UP PROBLEMS

23.7A How many unpaired electrons do you expect for $[Mn(CN)_6]^{3-}$? Is this a high-spin or low-spin complex ion?

23.7B How many unpaired electrons do you expect for $[CoF_6]^{3-}$? Is this a high-spin or low-spin complex ion?

SOME SIMILAR PROBLEMS 23.88–23.91

Crystal Field Splitting in Tetrahedral and Square Planar Complexes Four ligands around a metal ion also cause d-orbital splitting, but the magnitude and pattern of the splitting depend on whether the ligands approach from a tetrahedral or a square planar orientation.

1. *Tetrahedral complexes.* When the ligands approach from the corners of a tetrahedron, none of the five d orbitals is directly in their paths (Figure 23.24A, *next page*). Thus, the overall attraction of ligand and metal ion is weaker, so the splitting of d-orbital energies is *less* in a tetrahedral than an octahedral complex with the same ligands:

$$\Delta_{tetrahedral} < \Delta_{octahedral}$$

Repulsions are minimized when the ligands approach the d_{xy}, d_{xz}, and d_{yz} orbitals closer than they do the $d_{x^2-y^2}$ and d_{z^2} orbitals. This situation is the *opposite of the octahedral case,* so the relative d-orbital energies are reversed: the d_{xy}, d_{xz}, and d_{yz} orbitals become *higher* in energy than the $d_{x^2-y^2}$ and d_{z^2} orbitals. *Only high-spin tetrahedral complexes are known* because the magnitude of Δ is always smaller than $E_{pairing}$, regardless of the ligand.

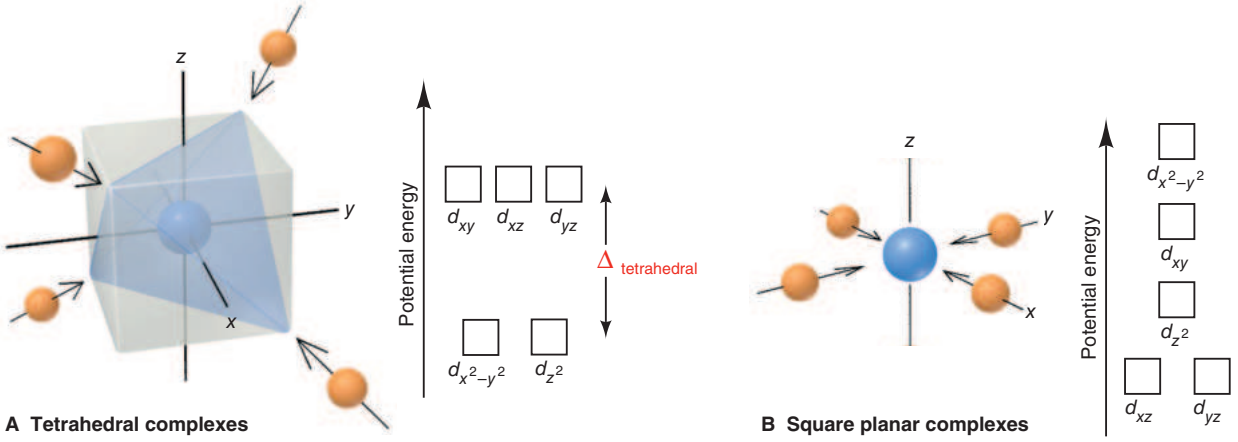


Figure 23.24 **Splitting of *d*-orbital energies. A,** The pattern of splitting by a tetrahedral field of ligands is the opposite of the octahedral pattern. **B,** Splitting by a square planar field of ligands decreases the energies of d_{xz}, d_{yz}, and especially d_{z^2} orbitals relative to the octahedral pattern.

2. *Square planar complexes.* The effects of the ligand field in the square planar case are easier to picture if we imagine starting with an octahedral geometry and then removing the two ligands along the *z*-axis (Figure 23.24B). With no *z*-axis interactions present, any *d* orbital with a *z*-axis component has lower energy, with the d_{z^2} orbital decreasing most, and the d_{xz} and d_{yz} also decreasing. In contrast, the two *d* orbitals in the *xy*-plane interact strongly with the ligands, and because the $d_{x^2-y^2}$ orbital has its lobes *on* the axes, its energy is highest. The d^8 metal ions form square planar complexes, such as $[PdCl_4]^{2-}$. They are *low spin* and usually *diamagnetic* because the four pairs of *d* electrons fill the four lowest-energy orbitals.

A Final Word About Bonding Theories As you have seen in several other cases, no one model is satisfactory in every respect. For complex ions, VB theory offers a simple picture of bond formation but does not even attempt to explain spectral and magnetic behavior of complexes. Crystal field theory predicts those two behaviors but offers no insight into the covalent nature of metal-ligand bonding. Thus, chemists now rely on the more comprehensive and quantitative *ligand field theory,* which combines aspects of the previous two models with MO theory (Section 11.3). While beyond the scope of this text, this powerful model predicts bond properties from the overlap of metal ion and ligand orbitals as well as the spectral and magnetic properties resulting from the splitting of the metal ion's *d* orbitals.

In addition to their important chemical applications, complexes of the transition elements play vital roles in living systems, as the following Chemical Connections essay describes.

Summary of Section 23.4

- According to valence bond theory, complex ions have coordinate covalent bonds between ligands (Lewis bases) and metal ions (Lewis acids).
- Ligand lone pairs occupy hybridized metal-ion orbitals, leading to the characteristic shapes of complex ions.
- According to crystal field theory, the surrounding field of ligands splits a metal ion's *d*-orbital energies. The crystal field splitting energy (Δ) depends on the charge of the metal ion and the crystal field strength of the ligands.
- Δ influences the color (energy of the photons absorbed) and paramagnetism (number of unpaired *d* electrons) of a complex ion. Strong-field ligands create a large Δ and produce low-spin complexes that absorb light of higher energy (shorter wavelength); the reverse is true of weak-field ligands.
- Several transition metals, including iron and zinc, are essential dietary components in trace amounts because they are crucial to the biochemical function of key proteins.

Transition Metals as Essential Dietary Trace Elements

Living things consist primarily of water and complex organic compounds made of four *building-block elements* C, O, H, and N. They also contain seven other elements, known as *macro*nutrients because they occur in fairly high concentrations (in order of atomic number): Na, Mg, P, S, Cl, K, and Ca. In addition, organisms contain a large number of elements in low concentrations, and most of these *micro*nutrients, or *trace elements,* are transition metals.

With the exception of scandium and titanium, all Period 4 transition elements are essential to organisms (Table B23.1, *next page*), and plants also require molybdenum (from Period 5). A transition metal ion typically lies next to a protein chain covalently bonded to surrounding amino acid R groups whose N and O atoms act as ligands. Despite the complexity of biomolecules, the principles of bonding and *d*-orbital splitting are the same as in simple inorganic systems. In this discussion, we focus on iron and zinc.

Iron and the Heme Group

Iron plays a crucial role in oxygen transport in all vertebrates. The oxygen-transporting protein hemoglobin (Figure B23.1A) consists of four folded protein chains called *globins,* each cradling the iron-containing complex *heme*. Each heme complex has an Fe^{2+} ion at the center of a tetradentate ring ligand *porphin* and bonded to the ligand's four N lone pairs to form a *square planar* complex. When heme is bound in hemoglobin, the complex becomes *square pyramidal,* with an N atom from a nearby amino acid (histidine) as the fifth ligand. Hemoglobin exists in two forms, depending on the presence of O_2, which acts as a sixth ligand:

- *In the lungs*, where $[O_2]$ is high, heme binds O_2 to form *oxyhemoglobin*, which is transported in the arteries to tissues. With O_2 bound, heme exists as part of an *octahedral* complex (Figure B23.1B). Since O_2 is a strong-field ligand, the d^6 Fe^{2+} ion is part of a low-spin complex. Because of the relatively large *d*-orbital splitting, oxyhemoglobin absorbs blue (high-energy) light, so arterial blood is bright red.
- *At the tissues*, where $[O_2]$ is low, the bound O_2 is released, and *deoxyhemoglobin* forms, which is transported in the veins back to the lungs. Without the O_2, the Fe^{2+} ion is part of a high-spin complex, which has relatively small *d*-orbital splitting. Thus, deoxyhemoglobin absorbs red (low-energy) light, and venous blood is dark, purplish red.

The relative position of Fe^{2+} in the plane of the porphin ring also depends on the presence of the sixth ligand. Bound to O_2, Fe^{2+} moves *into* the porphin plane; when O_2 is released, it moves slightly *out of* the plane. This tiny (60 pm) change due to the binding or release of O_2 alters the shape of the globin chain. And this change in shape alters the shape of the next globin chain, triggering the release or attachment of *its* O_2, and so on to the other two globin chains. This "cooperation" among the four globin chains allows hemoglobin to rapidly pick up O_2 from the lungs and unload it rapidly in the tissues.

Heme binding of O_2 is an equilibrium process. Carbon monoxide is toxic because it binds to Fe^{2+} about 200 times more tightly than O_2 does; each CO that binds eliminates one heme

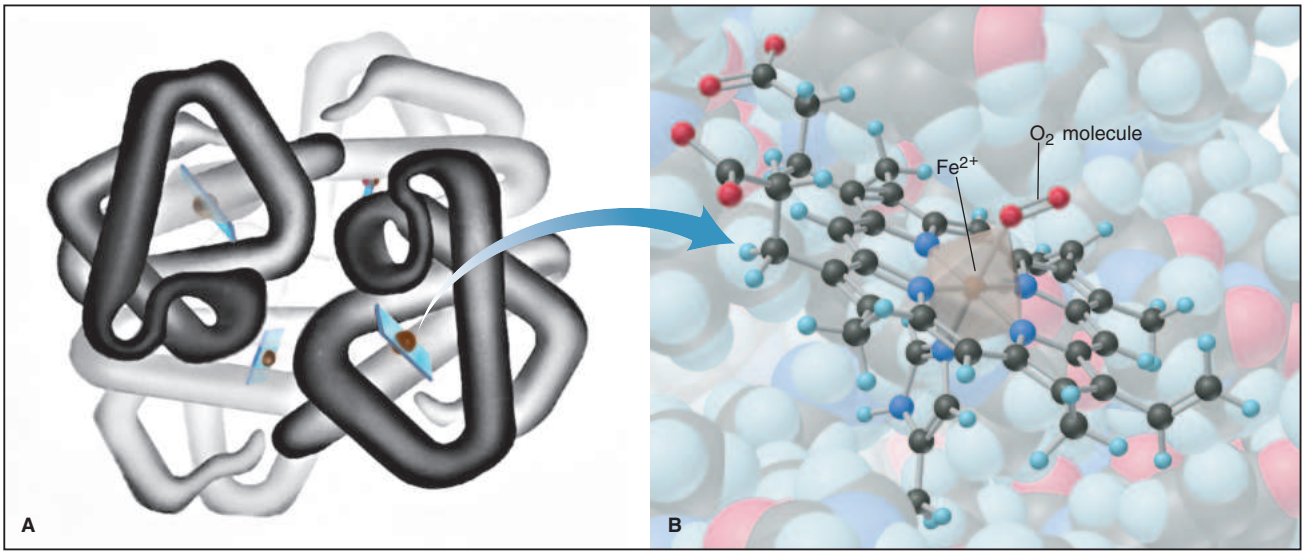

Figure B23.1 Hemoglobin and the octahedral complex in heme. **A,** Hemoglobin consists of four protein chains, each with a bound heme. (Illustration by Irving Geis. Rights owned by Howard Hughes Medical Institute. Not to be used without permission.) **B,** In oxyhemoglobin, the octahedral complex in heme has an O_2 molecule as the sixth ligand for iron(II).

Transition Metals as Essential Dietary Trace Elements (continued)

Table B23.1 Some Transition Metal Trace Elements in Humans

Element	Biomolecule Containing Element	Function of Biomolecule
Vanadium	Protein (?)	Redox couple in fat metabolism (?)
Chromium	Glucose tolerance factor	Glucose utilization
Manganese	Isocitrate dehydrogenase	Cell respiration
Iron	Hemoglobin and myoglobin	Oxygen transport
	Cytochrome *c*	Cell respiration; ATP formation
	Catalase	Decomposition of H_2O_2
Cobalt	Cobalamin (vitamin B_{12})	Development of red blood cells
Copper	Ceruloplasmin	Hemoglobin synthesis
	Cytochrome oxidase	Cell respiration; ATP formation
Zinc	Carbonic anhydrase	Elimination of CO_2
	Carboxypeptidase A	Protein digestion
	Alcohol dehydrogenase	Metabolism of ethanol

group from functioning. Like O_2, CO is a strong-field ligand and produces a bright red, "healthy" look in the poisoned individual. Because binding is reversible, breathing high concentrations of O_2 displaces CO from the heme:

$$\text{heme—CO} + O_2 \rightleftharpoons \text{heme—}O_2 + \text{CO}$$

Porphin is a very common biological ligand. Chlorophyll has Mg^{2+} and vitamin B_{12} has Co^{3+} at the center of a very similar ring system. Heme itself is found not only in hemoglobin, but also in proteins called *cytochromes* that are involved in energy metabolism (see Chemical Connections, pp. 962–963).

Zinc and the Enzyme Active Site

The zinc ion occurs at the active sites of several enzymes. With its d^{10} configuration, Zn^{2+} forms tetrahedral complexes with the N atoms of three amino acid groups at three positions, and the fourth position is free to interact with the molecule undergoing reaction (Figure B23.2). In its role as Lewis acid, Zn^{2+} accepts a lone pair from the reactant as a step in the catalytic process. Consider the enzyme carbonic anhydrase, which catalyzes the reaction between H_2O and CO_2 during respiration:

$$CO_2(g) + H_2O(l) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$

The Zn^{2+} at the active site binds three histidine N atoms, and the O of the reactant H_2O is the fourth donor atom. By withdrawing electron density from the O—H bonds, the Zn^{2+} makes the H_2O acidic enough to lose a proton. In the rate-determining step, the bound OH^- ion is attracted to the partially positive C of CO_2 much more strongly than the lone pair of a free water molecule would be; thus, the reaction rate is higher. One reason Cd^{2+} is toxic is that it competes with Zn^{2+} for the carbonic anhydrase active site.

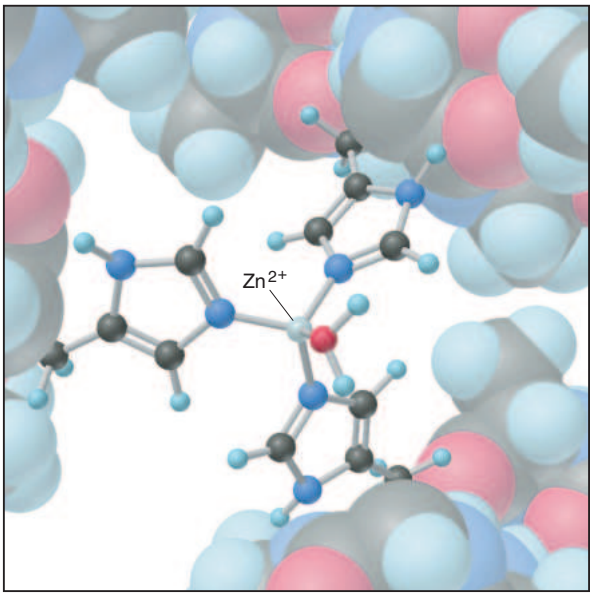

Figure B23.2 The tetrahedral Zn^{2+} complex in carbonic anhydrase.

Problems

B23.1 (a) Identify each compound's central metal ion and give its oxidation state: chlorophyll, heme, and vitamin B_{12}. (b) What similarity in structure do these compounds have?

B23.2 Suggest a structural reason why carbonic anhydrase synthesized with Ni^{2+}, Fe^{2+}, or Mn^{2+} in place of Zn^{2+} has less catalytic efficiency.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. The positions of the *d*- and *f*-block elements and the general forms of their atomic and ionic electron configurations (§23.1)
2. How atomic size, ionization energy, and electronegativity vary across a period and down a group of transition elements and how these trends differ from those of the main-group elements; why the densities of Period 6 transition elements are so high (§23.1)
3. Why the transition elements often have multiple oxidation states and why the +2 state is common (§23.1)
4. Why metallic behavior (prevalence of ionic bonding and basic oxides) of transition elements decreases as oxidation state increases; how valence-state electronegativity explains transition metal atoms in oxoanions (§23.1)
5. Why many transition metal compounds are colored and paramagnetic (§23.1)
6. The common +3 oxidation state of lanthanides and the similarity in their M^{3+} radii; the radioactivity of actinides (§23.2)
7. The coordination numbers, geometries, and ligand structures of complex ions (§23.3)
8. How coordination compounds are named and their formulas written (§23.3)
9. The types of constitutional isomerism (coordination and linkage) and stereoisomerism (geometric and optical) of coordination compounds (§23.3)
10. How valence bond theory uses hybridization to account for the shapes of octahedral, square planar, and tetrahedral complexes (§23.4)
11. How crystal field theory explains that approaching ligands cause *d*-orbital energies to split (§23.4)
12. How the relative crystal field strength of ligands (spectrochemical series) affects the *d*-orbital splitting energy (Δ) (§23.4)
13. How the magnitude of Δ accounts for the energy of light absorbed and, thus, the color of a complex (§23.4)
14. How the relative sizes of pairing energy and Δ determine the occupancy of *d* orbitals and, thus, the magnetic properties of complexes (§23.4)
15. How *d*-orbital splitting in tetrahedral and square planar complexes differs from that in octahedral complexes (§23.4)

Master These Skills

1. Writing electron configurations of transition metal atoms and ions (SP 23.1)
2. Using a partial orbital diagram to determine the number of unpaired electrons in a transition metal atom or ion (SP 23.2)
3. Recognizing the structural components of complex ions (§23.3)
4. Determining the coordination number and charge of the central metal ion in coordination compounds (SP 23.3)
5. Naming and writing formulas of coordination compounds (SP 23.4)
6. Determining the type of stereoisomerism in complexes (SP 23.5)
7. Correlating a complex ion's shape with the number and type of hybrid orbitals of the central metal ion (§23.4)
8. Using the spectrochemical series to rank complex ions in terms of Δ and the energy of light absorbed (SP 23.6)
9. Using the spectrochemical series to determine if a complex ion is high or low spin (SP 23.7)

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

23.1A (a) Ag^+: $4d^{10}$
(b) Cd^{2+}: $4d^{10}$
(c) Ir^{3+}: $5d^6$

23.1B (a) Ta^{3+}; (b) Mn^{4+}; (c) Os^{3+}

23.2A Three; Er^{3+} is [Xe] $4f^{11}$:

23.2B Five; Dy^{3+} is [Xe] $4f^9$:

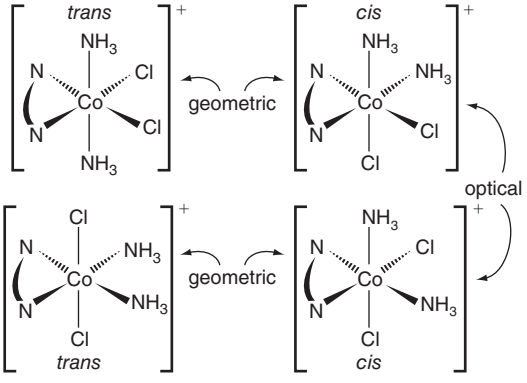
23.3A (a) Coordination number = 6; Co^{3+}
(b) Coordination number = 6; Cr^{3+}

23.3B (a) $K_4[Mn(CN)_6]$; (b) $[Cu(en)_2]SO_4$

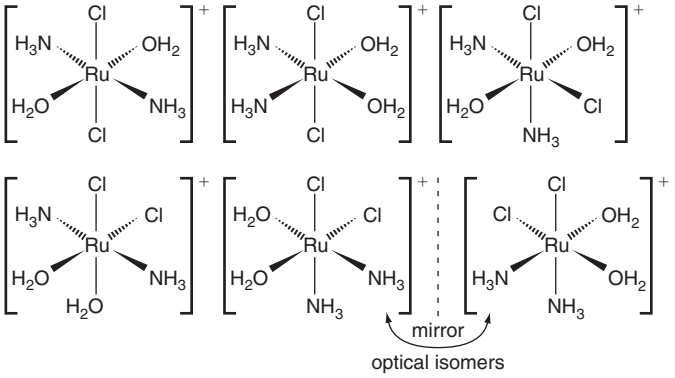
23.4A (a) Pentaaquabromochromium(III) chloride
(b) $Ba_3[Co(CN)_6]_2$

23.4B (a) $[Co(H_2O)_2(en)_2]_2(SO_4)_3$
(b) magnesium diamminetetrachlorochromate(III)

23.5A Two sets of *cis-trans* isomers, and the two *cis* isomers are optical isomers.



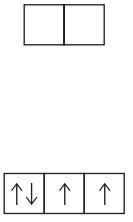
23.5B Five geometric isomers; the *cis* isomer has an optical isomer.



23.6A Both metal ions are V^{3+}; in terms of ligand field energy, $NH_3 > H_2O$, so $[V(NH_3)_6]^{3+}$ absorbs light of higher energy.

23.6B $[Co(en)_3]^{3+}$ is yellow, $[Co(NH_3)_5Cl]^{2+}$ is purple, $[Co(NH_3)_4Cl_2]^+$ is green, and $[Co(NH_3)_5(H_2O)]^{3+}$ is red.

23.7A The metal ion is Mn^{3+}: [Ar] $3d^4$.



Two unpaired *d* electrons; low-spin complex

23.7B The metal ion is Co^{3+}: [Ar] $3d^6$.

Four unpaired *d* electrons; high-spin complex

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Note: In these problems, the term *electron configuration* refers to the condensed, ground-state electron configuration.

Properties of the Transition Elements

(Sample Problem 23.1)

Concept Review Questions

23.1 How is the *n* value of the *d* sublevel of a transition element related to the period number of the element?

23.2 Write the general electron configuration of a transition element (a) in Period 5; (b) in Period 6.

23.3 What is the general rule concerning the order in which electrons are removed from a transition metal atom to form an ion? Give an example from Group 5B(5). Name two types of measurements used to study electron configurations of ions.

23.4 What is the maximum number of unpaired *d* electrons that an atom or ion can possess? Give an example of an atom and an ion that have this number.

23.5 How does the variation in atomic size across a transition series contrast with the change across the main-group elements of the same period? Why?

23.6 (a) What is the lanthanide contraction? (b) How does it affect atomic size down a group of transition elements? (c) How does it influence the densities of the Period 6 transition elements?

23.7 (a) What is the range in electronegativity across the first (3*d*) transition series? (b) What is the range across Period 4 of the main-group elements? (c) Explain the difference.

23.8 (a) Explain the major difference between the number of oxidation states of most transition elements and that of most main-group elements. (b) Why is the +2 oxidation state so common among transition elements? (c) What is valence-state electronegativity? Is the electronegativity of Cr different in CrO, Cr_2O_3, and CrO_3? Explain.

23.9 (a) What behavior distinguishes paramagnetic and diamagnetic substances? (b) Why are paramagnetic ions common among transition elements but not main-group elements? (c) Why are colored solutions of metal ions common among transition elements but not main-group elements?

Skill-Building Exercises (grouped in similar pairs)

23.10 Using the periodic table to locate each element, write the electron configuration of (a) V; (b) Y; (c) Hg.

23.11 Using the periodic table to locate each element, write the electron configuration of (a) Ru; (b) Cu; (c) Ni.

23.12 Using the periodic table to locate each element, write the electron configuration of (a) Os; (b) Co; (c) Ag.

23.13 Using the periodic table to locate each element, write the electron configuration of (a) Zn; (b) Mn; (c) Re.

23.14 Give the electron configuration and the number of unpaired electrons for (a) Sc^{3+}; (b) Cu^{2+}; (c) Fe^{3+}; (d) Nb^{3+}.

23.15 Give the electron configuration and the number of unpaired electrons for (a) Cr^{3+}; (b) Ti^{4+}; (c) Co^{3+}; (d) Ta^{2+}.

23.16 What is the highest oxidation state for (a) Ta; (b) Zr; (c) Mn?

23.17 What is the highest oxidation state for (a) Nb; (b) Y; (c) Tc?

23.18 Which transition metals have a maximum O.N. of +6?

23.19 Which transition metals have a maximum O.N. of +4?

23.20 In which compound does Cr exhibit greater metallic behavior, CrF_2 or CrF_6? Explain.

23.21 VF_5 is a liquid that boils at 48°C, whereas VF_3 is a solid that melts above 800°C. Explain this difference in properties.

23.22 Is it more difficult to oxidize Cr or Mo? Explain.

23.23 Is MnO_4^- or ReO_4^- a stronger oxidizing agent? Explain.

23.24 Which oxide, CrO_3 or CrO, is more acidic in water? Why?

23.25 Which oxide, Mn_2O_3 or Mn_2O_7, is more basic in water? Why?

Problems in Context

23.26 The green patina of Cu-alloy roofs results from corrosion in the presence of O_2, H_2O, CO_2, and sulfur compounds. The other members of Group 1B(11), Ag and Au, do not form a patina. Corrosion of Cu and Ag in the presence of sulfur compounds leads to a black tarnish, but Au does not tarnish. This pattern is different from that in Group 1A(1), where ease of oxidation *increases* down the group. Explain these different group patterns.

The Inner Transition Elements

(Sample Problem 23.2)

Concept Review Questions

23.27 What atomic property of the lanthanides leads to their remarkably similar chemical properties?

23.28 (a) What is the maximum number of unpaired electrons in a lanthanide ion? (b) How does this number relate to occupancy of the 4*f* subshell?

23.29 Which of the actinides are radioactive?

Skill-Building Exercises (grouped in similar pairs)

23.30 Give the electron configuration of (a) La; (b) Ce^{3+}; (c) Es; (d) U^{4+}.

23.31 Give the electron configuration of (a) Pm; (b) Lu^{3+}; (c) Th; (d) Fm^{3+}.

23.32 Only a few lanthanides show an oxidation state other than +3. Two of these, europium (Eu) and terbium (Tb), are found near the middle of the series, and their unusual oxidation states can be associated with a half-filled *f* subshell. (a) Write the electron configurations of Eu^{2+}, Eu^{3+}, and Eu^{4+}. Why is Eu^{2+} a common ion, whereas Eu^{4+} is unknown? (b) Write the electron configurations of Tb^{2+}, Tb^{3+}, and Tb^{4+}. Would you expect Tb to show a +2 or a +4 oxidation state? Explain.

23.33 Cerium (Ce) and ytterbium (Yb) exhibit some oxidation states in addition to +3. (a) Write the electron configurations of Ce^{2+}, Ce^{3+}, and Ce^{4+}. (b) Write the electron configurations of Yb^{2+}, Yb^{3+}, and Yb^{4+}. (c) In addition to the 3+ ions, the ions Ce^{4+} and Yb^{2+} are stable. Suggest a reason for this stability.

Problems in Context

23.34 Which lanthanide has the maximum number of unpaired electrons in both its atom and 3+ ion? Give the number of unpaired electrons in the atom and ion.

Coordination Compounds

(Sample Problems 23.3 to 23.5)

Concept Review Questions

23.35 Describe the makeup of a complex ion, including the nature of the ligands and their interaction with the central metal ion. Explain how a complex ion can be positive or negative and how it occurs as part of a neutral coordination compound.

23.36 What electronic feature must a donor atom of a ligand have?

23.37 What is the coordination number of a metal ion in a complex ion? How does it differ from oxidation number?

23.38 What structural feature is characteristic of a chelate?

23.39 What geometries are associated with the coordination numbers 2, 4, and 6?

23.40 What are the coordination numbers of cobalt(III), platinum(II), and platinum(IV) in complexes?

23.41 How is a complex ion a Lewis adduct?

23.42 What does the ending *-ate* in a complex ion name signify?

23.43 In what order are the metal ion and ligands given in the name of a complex ion?

23.44 Is a linkage isomer a type of constitutional isomer or stereoisomer? Explain.

Skill-Building Exercises (grouped in similar pairs)

23.45 Give systematic names for the following formulas:
(a) $[Ni(H_2O)_6]Cl_2$ (b) $[Cr(en)_3](ClO_4)_3$ (c) $K_4[Mn(CN)_6]$

23.46 Give systematic names for the following formulas:
(a) $[Co(NH_3)_4(NO_2)_2]Cl$ (b) $[Cr(NH_3)_6][Cr(CN)_6]$
(c) $K_2[CuCl_4]$

23.47 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.45?

23.48 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.46?

23.49 Give systematic names for the following formulas:
(a) $K[Ag(CN)_2]$ (b) $Na_2[CdCl_4]$ (c) $[Co(NH_3)_4(H_2O)Br]Br_2$

23.50 Give systematic names for the following formulas:
(a) $K[Pt(NH_3)Cl_5]$ (b) $[Cu(en)(NH_3)_2][Co(en)Cl_4]$
(c) $[Pt(en)_2Br_2](ClO_4)_2$

23.51 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.49?

23.52 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.50?

23.53 Give formulas corresponding to the following names:
(a) Tetraamminezinc sulfate
(b) Pentaamminechlorochromium(III) chloride
(c) Sodium bis(thiosulfato)argentate(I)

23.54 Give formulas corresponding to the following names:
(a) Dibromobis(ethylenediamine)cobalt(III) sulfate
(b) Hexaamminechromium(III) tetrachlorocuprate(II)
(c) Potassium hexacyanoferrate(II)

23.55 What is the coordination number of the metal ion and the number of individual ions per formula unit in each of the compounds in Problem 23.53?

23.56 What is the coordination number of the metal ion and the number of individual ions per formula unit in each of the compounds in Problem 23.54?

23.57 Give formulas corresponding to the following names:
(a) Hexaaquachromium(III) sulfate
(b) Barium tetrabromoferrate(III)
(c) Bis(ethylenediamine)platinum(II) carbonate

23.58 Give formulas corresponding to the following names:
(a) Potassium tris(oxalato)chromate(III)
(b) Tris(ethylenediamine)cobalt(III) pentacyanoiodomanganate(II)
(c) Diamminediaquabromochloroaluminum nitrate

23.59 Give the coordination number of the metal ion and the number of ions per formula unit in each compound in Problem 23.57.

23.60 Give the coordination number of the metal ion and the number of ions per formula unit in each compound in Problem 23.58.

23.61 Which of these ligands can participate in linkage isomerism: (a) NO_2^-; (b) SO_2; (c) NO_3^-? Explain with Lewis structures.

23.62 Which of these ligands can participate in linkage isomerism: (a) SCN^-; (b) $S_2O_3^{2-}$ (thiosulfate); (c) HS^-? Explain with Lewis structures.

23.63 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $[Pt(CH_3NH_2)_2Br_2]$ (b) $[Pt(NH_3)_2FCl]$ (c) $[Pt(H_2O)(NH_3)FCl]$

23.64 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $[Zn(en)F_2]$ (b) $[Zn(H_2O)(NH_3)FCl]$ (c) $[Pd(CN)_2(OH)_2]^{2-}$

23.65 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $[PtCl_2Br_2]^{2-}$ (b) $[Cr(NH_3)_5(NO_2)]^{2+}$ (c) $[Pt(NH_3)_4I_2]^{2+}$

23.66 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $[Co(NH_3)_5Cl]Br_2$ (b) $[Pt(CH_3NH_2)_3Cl]Br$
(c) $[Fe(H_2O)_4(NH_3)_2]^{2+}$

Problems in Context

23.67 Chromium(III), like cobalt(III), has a coordination number of 6 in many of its complex ions. Before Alfred Werner, in the 1890s, established the idea of a complex ion, coordination compounds had traditional formulas. Compounds are known that have the traditional formula $CrCl_3 \cdot nNH_3$, where $n = 3$ to 6. Which of the compounds has an electrical conductivity in aqueous solution similar to that of an equimolar NaCl solution?

23.68 When $MCl_4(NH_3)_2$ is dissolved in water and treated with $AgNO_3$, 2 mol of AgCl precipitates immediately for each mole of $MCl_4(NH_3)_2$. Give the coordination number of M in the complex.

23.69 Palladium, like its group neighbor platinum, forms four-coordinate Pd(II) and six-coordinate Pd(IV) complexes. Write formulas for the complexes with these compositions:
(a) $PdK(NH_3)Cl_3$ (b) $PdCl_2(NH_3)_2$ (c) PdK_2Cl_6 (d) $Pd(NH_3)_4Cl_4$

Theoretical Basis for the Bonding and Properties of Complexes

(Sample Problems 23.6 and 23.7)

Concept Review Questions

23.70 (a) What is a coordinate covalent bond?
(b) Is it involved when $FeCl_3$ dissolves in water? Explain.
(c) Is it involved when HCl gas dissolves in water? Explain.

23.71 According to valence bond theory, what set of orbitals is used by a Period 4 metal ion in forming (a) a square planar complex; (b) a tetrahedral complex?

23.72 A metal ion uses d^2sp^3 orbitals when forming a complex. What is its coordination number and the shape of the complex?

23.73 A complex in solution absorbs green light. What is the color of the solution?

23.74 In terms of the theory of color absorption, explain two ways that a solution can be blue.

23.75 (a) What is the crystal field splitting energy (Δ)?
(b) How does it arise for an octahedral field of ligands?
(c) How is it different for a tetrahedral field of ligands?

23.76 What is the distinction between a weak-field ligand and a strong-field ligand? Give an example of each.

23.77 Is a complex with the same number of unpaired electrons as the free gaseous metal ion termed high spin or low spin?

23.78 How do the relative magnitudes of $E_{pairing}$ and Δ affect the paramagnetism of a complex?

23.79 Why are there both high-spin and low-spin octahedral complexes but only high-spin tetrahedral complexes?

Skill-Building Exercises (grouped in similar pairs)

23.80 Give the number of *d* electrons (*n* of d^n) for the central metal ion in (a) $[TiCl_6]^{2-}$; (b) $K[AuCl_4]$; (c) $[RhCl_6]^{3-}$.

23.81 Give the number of *d* electrons (*n* of d^n) for the central metal ion in (a) $[Cr(H_2O)_6](ClO_3)_2$; (b) $[Mn(CN)_6]^{2-}$; (c) $[Ru(NO)(en)_2Cl]Br$.

23.82 How many *d* electrons (*n* of d^n) are in the central metal ion in (a) $Ca[IrF_6]$; (b) $[HgI_4]^{2-}$; (c) $[Co(EDTA)]^{2-}$?

23.83 How many *d* electrons (*n* of d^n) are in the central metal ion in (a) $[Ru(NH_3)_5Cl]SO_4$; (b) $Na_2[Os(CN)_6]$; (c) $[Co(NH_3)_4CO_3I]$?

23.84 Sketch the orientation of the orbitals relative to the ligands in an octahedral complex to explain the splitting and the relative energies of the d_{xy} and the $d_{x^2-y^2}$ orbitals.

23.85 The two e_g orbitals are identical in energy in an octahedral complex but have different energies in a square planar complex, with the d_{z^2} orbital being much lower in energy than the $d_{x^2-y^2}$. Explain with orbital sketches.

23.86 Which of these ions *cannot* form both high- and low-spin octahedral complexes: (a) Ti^{3+}; (b) Co^{2+}; (c) Fe^{2+}; (d) Cu^{2+}?

23.87 Which of these ions *cannot* form both high- and low-spin octahedral complexes: (a) Mn^{3+}; (b) Nb^{3+}; (c) Ru^{3+}; (d) Ni^{2+}?

23.88 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that H_2O is a weak-field ligand):
(a) $[Cr(H_2O)_6]^{3+}$ (b) $[Cu(H_2O)_4]^{2+}$ (c) $[FeF_6]^{3-}$

23.89 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that H_2O is a weak-field ligand):
(a) $[Cr(CN)_6]^{3-}$ (b) $[Rh(CO)_6]^{3+}$ (c) $[Co(OH)_6]^{4-}$

23.90 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that H_2O is a weak-field ligand):
(a) $[MoCl_6]^{3-}$ (b) $[Ni(H_2O)_6]^{2+}$ (c) $[Ni(CN)_4]^{2-}$

23.91 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that H_2O is a weak-field ligand):
(a) $[Fe(C_2O_4)_3]^{3-}$ ($C_2O_4^{2-}$ creates a weaker field than H_2O does.)
(b) $[Co(CN)_6]^{4-}$ (c) $[MnCl_6]^{4-}$

23.92 Rank the following in order of *increasing* Δ and energy of light absorbed: $[Cr(NH_3)_6]^{3+}$, $[Cr(H_2O)_6]^{3+}$, $[Cr(NO_2)_6]^{3-}$.

23.93 Rank the following in order of *decreasing* Δ and energy of light absorbed: $[Cr(en)_3]^{3+}$, $[Cr(CN)_6]^{3-}$, $[CrCl_6]^{3-}$.

23.94 A complex, ML_6^{2+}, is violet. The same metal forms a complex with another ligand, Q, that creates a weaker field. What color might MQ_6^{2+} be expected to show? Explain.

23.95 $[Cr(H_2O)_6]^{2+}$ is violet. Another CrL_6 complex is green. Can ligand L be CN^-? Can it be Cl^-? Explain.

Problems in Context

23.96 Octahedral $[Ni(NH_3)_6]^{2+}$ is paramagnetic, whereas planar $[Pt(NH_3)_4]^{2+}$ is diamagnetic, even though both metal ions are d^8 species. Explain.

23.97 The hexaaqua complex $[Ni(H_2O)_6]^{2+}$ is green, whereas the hexaammonia complex $[Ni(NH_3)_6]^{2+}$ is violet. Explain.

23.98 Three of the complex ions that are formed by Co^{3+} are $[Co(H_2O)_6]^{3+}$, $[Co(NH_3)_6]^{3+}$, and $[CoF_6]^{3-}$. These ions have the observed colors (listed in arbitrary order) yellow-orange, green, and blue. Match each complex with its color. Explain.

Comprehensive Problems

23.99 When neptunium (Np) and plutonium (Pu) were discovered, the periodic table did not include the actinides, so these elements were placed in Groups 7B(7) and 8B(8). When americium (Am) and curium (Cm) were synthesized, they were placed in Groups 8B(9) and 8B(10). However, during chemical isolation procedures, Glenn Seaborg and his colleagues, who had synthesized these elements, could not find their compounds among other compounds of members of the same groups, which led Seaborg to suggest they were part of a new inner transition series.
(a) How do the electron configurations of these elements support Seaborg's suggestion?
(b) The highest fluorides of Np and Pu are hexafluorides, as is the highest fluoride of uranium. How does this chemical evidence support the placement of Np and Pu as *inner* transition elements rather than transition elements?

23.100 How many different formulas are there for octahedral complexes with a metal M and four ligands A, B, C, and D? Give the number of isomers for each formula and describe the isomers.

23.101 At one time, it was common to write the formula for copper(I) chloride as Cu_2Cl_2, instead of CuCl, analogously to Hg_2Cl_2 for mercury(I) chloride. Use electron configurations to explain why Hg_2Cl_2 and CuCl are both correct.

23.102 For the compound $[Co(en)_2Cl_2]Cl$, give:
(a) The coordination number of the metal ion
(b) The oxidation number of the central metal ion
(c) The number of individual ions per formula unit
(d) The moles of AgCl that precipitate when 1 mol of compound is dissolved in water and treated with $AgNO_3$

23.103 Hexafluorocobaltate(III) ion is a high-spin complex. Draw the orbital-energy splitting diagram for its *d* orbitals.

23.104 A salt of each of the ions in Table 23.3 (p. 1023) is dissolved in water. A Pt electrode is immersed in each solution and connected to a 0.38-V battery. All of the electrolytic cells are run for the same amount of time with the same current.
(a) In which cell(s) will a metal plate out? Explain.
(b) Which cell will plate out the least mass of metal? Explain.

23.105 Criticize and correct the following statement: strong-field ligands always give rise to low-spin complexes.

23.106 Some octahedral complexes have distorted shapes. In some, two metal-ligand bonds that are 180° apart are shorter than the other four. In $[Cu(NH_3)_6]^{2+}$, for example, two Cu—N bonds are 207 pm long, and the other four are 262 pm long. (a) Calculate the longest distance between two N atoms in this complex. (b) Calculate the shortest distance between two N atoms.

23.107 In many species, a transition metal has an unusually high or low oxidation state. Write balanced equations for the following and find the oxidation state of the transition metal in the product:
(a) Iron(III) ion reacts with hypochlorite ion in basic solution to form ferrate ion (FeO_4^{2-}), Cl^-, and water.
(b) Potassium hexacyanomanganate(II) reacts with K metal to form $K_6[Mn(CN)_6]$.
(c) Heating sodium superoxide (NaO_2) with Co_3O_4 produces Na_4CoO_4 and O_2 gas.
(d) Vanadium(III) chloride reacts with Na metal under a CO atmosphere to produce $Na[V(CO)_6]$ and NaCl.
(e) Barium peroxide reacts with nickel(II) ions in basic solution to produce $BaNiO_3$.
(f) Bubbling CO through a basic solution of cobalt(II) ion produces $[Co(CO)_4]^-$, CO_3^{2-}, and water.
(g) Heating cesium tetrafluorocuprate(II) with F_2 gas under pressure gives Cs_2CuF_6.
(h) Heating tantalum(V) chloride with Na metal produces NaCl and Ta_6Cl_{15}, in which half of the Ta is in the +2 state.
(i) Potassium tetracyanonickelate(II) reacts with hydrazine (N_2H_4) in basic solution to form $K_4[Ni_2(CN)_6]$ and N_2 gas.

23.108 Draw a Lewis structure with lowest formal charges for MnO_4^-.

23.109 The coordination compound $[Pt(NH_3)_2(SCN)_2]$ displays two types of isomerism. Name the types and give names and structures for the six possible isomers.

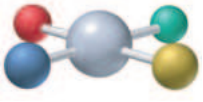
23.110 An octahedral complex with three different ligands (A, B, and C) can have formulas with three different ratios of the ligands:
$[MA_4BC]^{n+}$, such as $[Co(NH_3)_4(H_2O)Cl]^{2+}$
$[MA_3B_2C]^{n+}$, such as $[Cr(H_2O)_3Br_2Cl]$
$[MA_2B_2C_2]^{n+}$, such as $[Cr(NH_3)_2(H_2O)_2Br_2]^+$
For each example, give the name, state the type(s) of isomerism present, and draw all isomers.

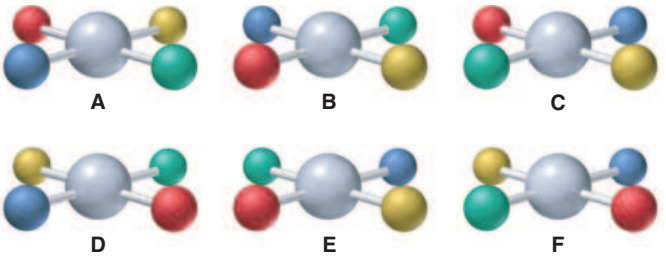
23.111 In $[Cr(NH_3)_6]Cl_3$, the $[Cr(NH_3)_6]^{3+}$ ion absorbs visible light in the blue-violet range, and the compound is yellow-orange. In $[Cr(H_2O)_6]Br_3$, the $[Cr(H_2O)_6]^{3+}$ ion absorbs visible light in the red range, and the compound is blue-gray. Explain these differences in light absorbed and color of the compound.

23.112 The actinides Pa, U, and Np form a series of complex ions, such as the anion in the compound $Na_3[UF_8]$, in which the central metal ion has an unusual geometry and oxidation state. In the crystal structure, the complex ion can be pictured as resulting from interpenetration of simple cubic arrays of uranium and fluoride ions. (a) What is the coordination number of the metal ion in the complex ion? (b) What is the oxidation state of uranium in the compound? (c) Sketch the complex ion.

23.113 Several coordination isomers, with both Co and Cr as 3+ ions, have the molecular formula $CoCrC_6H_{18}N_{12}$. (a) Give the name and formula of the isomer in which the Co complex ion has six NH_3 groups. (b) Give the name and formula of the isomer in which the Co complex ion has one CN and five NH_3 groups.

23.114 Consider the square planar complex shown at right. Which of the structures A–F are geometric isomers of it?

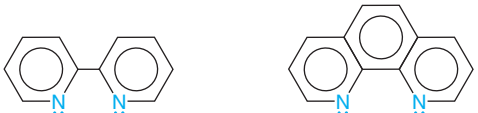




23.115 A shortcut to finding optical isomers is to see if the complex has a *plane of symmetry*—a plane passing through the metal atom such that every atom on one side of the plane is matched by an identical one at the same distance from the plane on the other side. Any planar complex has a plane of symmetry, since all atoms lie in one plane. Use this approach to determine whether these exist as optical isomers: (a) $[Zn(NH_3)_2Cl_2]$ (tetrahedral); (b) $[Pt(en)_2]^{2+}$; (c) *trans*-$[PtBr_4Cl_2]^{2-}$; (d) *trans*-$[Co(en)_2F_2]^+$; (e) *cis*-$[Co(en)_2F_2]^+$.

23.116 Alfred Werner (see Problem 23.67) prepared two compounds by heating a solution of $PtCl_2$ with triethyl phosphine, $P(C_2H_5)_3$, which is a ligand for Pt. Both compounds have, by mass, Pt, 38.8%; Cl, 14.1%; C, 28.7%; P, 12.4%; and H, 6.02%. Write formulas, structures, and systematic names for the two isomers.

23.117 Two bidentate ligands used extensively in analytical chemistry are bipyridyl (bipy) and *ortho*-phenanthroline (*o*-phen):



Draw structures and discuss the possibility of isomers for
(a) $[Pt(bipy)Cl_2]$ (b) $[Fe(o\text{-phen})_3]^{3+}$
(c) $[Co(bipy)_2F_2]^+$ (d) $[Co(o\text{-phen})(NH_3)_3Cl]^{2+}$

23.118 The effect of entropy on reactions appears in the stabilities of certain complexes. (a) In terms of number of product particles, predict which of the following will be favored in terms of ΔS°_{rxn}:

$$[Cu(NH_3)_4]^{2+}(aq) + 4H_2O(l) \longrightarrow [Cu(H_2O)_4]^{2+}(aq) + 4NH_3(aq)$$

$$[Cu(H_2NCH_2CH_2NH_2)_2]^{2+}(aq) + 4H_2O(l) \longrightarrow [Cu(H_2O)_4]^{2+}(aq) + 2en(aq)$$

(b) Given that the Cu—N bond strength is approximately the same in both complexes, which complex will be more stable with respect to ligand exchange in water? Explain.

23.119 You know the following about a coordination compound:
(1) The partial empirical formula is $KM(CrO_4)Cl_2(NH_3)_4$.
(2) It has A (red) and B (blue) crystal forms.
(3) When 1.0 mol of A or B reacts with 1.0 mol of $AgNO_3$, 0.50 mol of a red precipitate forms immediately.
(4) After the reaction in (3), 1.0 mol of A reacts very slowly with 1.0 mol of silver oxalate ($Ag_2C_2O_4$) to form 2.0 mol of a white precipitate. (Oxalate can displace other ligands.)
(5) After the reaction in (3), 1.0 mol of B does not react further with 1.0 mol of $AgNO_3$.

From this information, determine the following:
(a) The coordination number of M
(b) The group(s) bonded to M ionically and covalently
(c) The stereochemistry of the red and blue forms

23.120 The extent of crystal field splitting is often determined from spectra. (a) Given the wavelength (λ) of maximum absorption, find the crystal field splitting energy (Δ), in kJ/mol, for each of the following complex ions:

Ion	λ (nm)	Ion	λ (nm)
$[Cr(H_2O)_6]^{3+}$	562	$[Fe(H_2O)_6]^{2+}$	966
$[Cr(CN)_6]^{3-}$	381	$[Fe(H_2O)_6]^{3+}$	730
$[CrCl_6]^{3-}$	735	$[Co(NH_3)_6]^{3+}$	405
$[Cr(NH_3)_6]^{3+}$	462	$[Rh(NH_3)_6]^{3+}$	295
$[Ir(NH_3)_6]^{3+}$	244		

(b) Write a spectrochemical series for the ligands in the Cr complexes. (c) Use the Fe data to state how oxidation state affects Δ. (d) Use the Co, Rh, and Ir data to state how period number affects Δ.

23.121 Ionic liquids have many applications in engineering and materials science. The dissolution of the metavanadate ion in chloroaluminate ionic liquids has been studied:

$$VO_3^- + AlCl_4^- \longrightarrow VO_2Cl_2^- + AlOCl_2^-$$

(a) What is the oxidation number of V and Al in each ion?
(b) In reactions of V_2O_5 with HCl, acid concentration affects the product. At low acid concentration, $VO_2Cl_2^-$ and VO_3^- form:

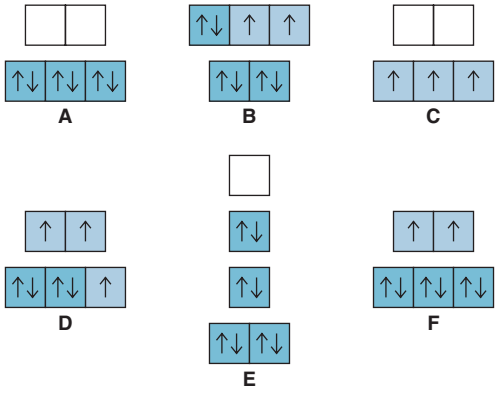
$$V_2O_5 + HCl \longrightarrow VO_2Cl_2^- + VO_3^- + H^+$$

At high acid concentration, $VOCl_3$ forms:

$$V_2O_5 + HCl \longrightarrow VOCl_3 + H_2O$$

Balance each equation, and state which, if either, is a redox process.
(c) What mass of $VO_2Cl_2^-$ or $VOCl_3$ can form from 12.5 g of V_2O_5 and the appropriate concentration of acid?

23.122 The orbital occupancies for the *d* orbitals of several complex ions are diagrammed below.



(a) Which diagram corresponds to the orbital occupancy of the cobalt ion in $[Co(CN)_6]^{3-}$?
(b) If diagram D depicts the orbital occupancy of the cobalt ion in $[CoF_6]^n$, what is the value of n?
(c) $[NiCl_4]^{2-}$ is paramagnetic and $[Ni(CN)_4]^{2-}$ is diamagnetic. Which diagrams correspond to the orbital occupancies of the nickel ions in these species?
(d) Diagram C shows the orbital occupancy of V^{2+} in the octahedral complex VL_6. Can you determine whether L is a strong- or weak-field ligand? Explain.

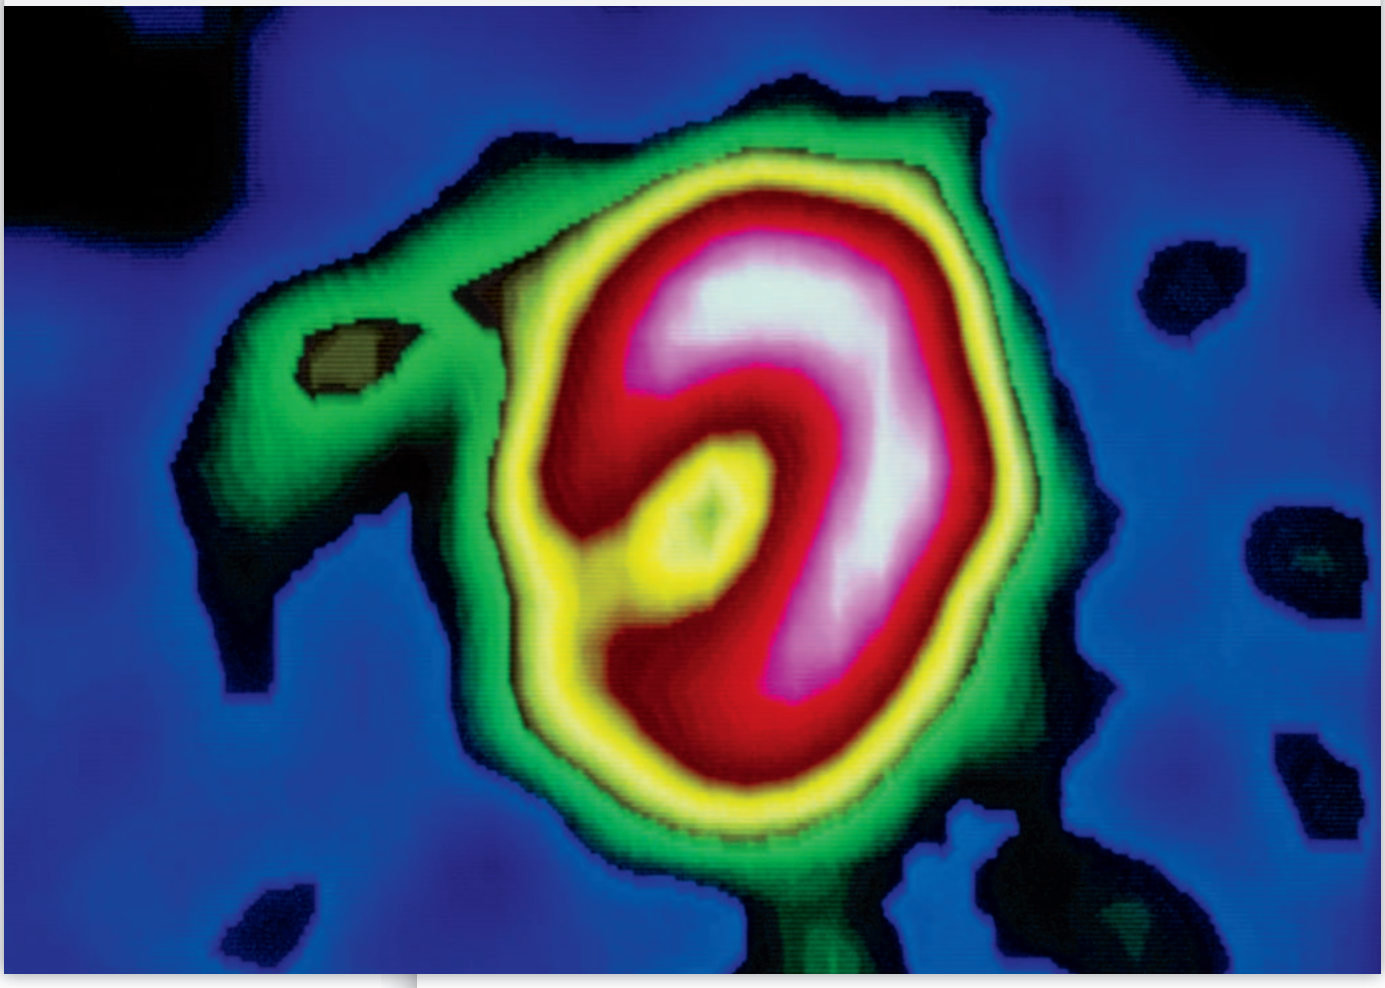
Nuclear Fusion



Concepts and Skills to Review Before You Study This Chapter

- discovery of the atomic nucleus (Section 2.4)
- protons, neutrons, mass number, and the ${}^{A}_{Z}X$ notation (Section 2.5)
- half-life and first-order reaction rate (Section 16.4)

Up to this point in the text, we have focused on the atom's electrons, treating the nucleus as their electrostatic anchor and examining the effect of its positive charge on atomic properties and, ultimately, chemical behavior. In this chapter, for the most part, we ignore the surrounding electrons and focus on the atom's tiny, dense core, which is held together by the strongest force in the universe. Scientists studying the structure and behavior of the nucleus see great mystery and wonder as well as a great number of applications. To cite just one example, modern medicine relies, to an ever-increasing extent, on diagnoses based on the emission of radiation from unstable nuclei. In fact, more than one in four hospital admissions now involve imaging tests that utilize *radioisotopes,* such as this false-color image *(facing page)* of heart muscle infused with trace amounts of an unstable isotope of thallium, ${}^{201}Tl$.

But society is ambivalent about some applications of nuclear research. The promise of abundant energy and treatments for disease is offset by the threat of nuclear waste contamination, reactor accidents, and unimaginable destruction from nuclear war or terrorism. Can the power of the nucleus be harnessed for our benefit, or are the risks too great? By studying this chapter, you'll learn the principles that can help you consider this vital question.

IN THIS CHAPTER . . . *We survey the field of nuclear chemistry, examining radioactive nuclei and their decay processes, especially the effects and applications of radioactivity and the interconversion of matter and energy.*

- We investigate nuclear stability to determine why some nuclei are stable and others undergo radioactive decay.
- We learn how radioactivity is detected and how the kinetics of decay is applied.
- We see how nuclei synthesized in particle accelerators have extended the periodic table.
- We consider the effects of radioactive emissions on matter, especially living tissue, and focus on some major uses of radioisotopes in science, technology, and medicine.
- We discuss the mass difference that arises when a nucleus forms from its subatomic particles and the energy that is equivalent to this difference.
- We explore current and future attempts to harness the energy released when heavy nuclei split and lighter ones fuse.
- We look at the nuclear processes in stars that continually create chemical elements.

24.1 RADIOACTIVE DECAY AND NUCLEAR STABILITY

A stable nucleus remains intact indefinitely, but *the great majority of nuclei are unstable.* An unstable nucleus exhibits **radioactivity,** the spontaneous disintegration of a nucleus by the emission of radiation. In Section 24.2, you'll see that each type of unstable nucleus has its own characteristic *rate* of radioactive decay. In this section, we cover important terms and notation for nuclei, discuss some key events in the discovery of radioactivity, define the types of emission, and describe various modes of radioactive decay and how to predict which occurs for a given nucleus. Let's begin, however, with a brief comparison of chemical change and nuclear change.

Table 24.1 Comparison of Chemical and Nuclear Reactions

Chemical Reactions	Nuclear Reactions
1. One substance is converted into another, but atoms never change identity.	1. Atoms of one element typically are converted into atoms of another element.
2. Electrons in orbitals are involved as bonds break and form; nuclear particles do not take part.	2. Protons, neutrons, and other nuclear particles are involved; electrons in orbitals take part much less often.
3. Reactions are accompanied by relatively small changes in energy and no measurable changes in mass.	3. Reactions are accompanied by relatively large changes in energy and measurable changes in mass.
4. Reaction rates are influenced by temperature, concentration, catalysts, and the compound in which an element occurs.	4. Reaction rates depend on number of nuclei, but are not affected by temperature, catalysts, or, except on rare occasions, the compound in which an element occurs.

Comparing Chemical and Nuclear Change

The changes that occur in atomic nuclei differ strikingly from chemical changes (Table 24.1). In chemical reactions, electrons are shared or transferred to form *compounds,* while nuclei remain unchanged. In nuclear reactions, the roles are reversed: electrons take part much less often, while nuclei undergo changes that, in nearly every case, form different *elements.* Nuclear reactions are often accompanied by energy changes a million times greater than those for chemical reactions, energy changes so large that the accompanying changes in mass *are* detectable. Moreover, nuclear reaction yields and rates are *not* subject to the effects of pressure, temperature, and catalysis that chemical reactions are.

The Components of the Nucleus: Terms and Notation

Big Atom with a Tiny, Massive Core

If you could strip the electrons from the atoms in an object and compress the nuclei together, the object would lose only a fraction of a percent of its mass, but it would shrink to 0.0000000000001% (10^{-13}%) of its volume!

Recall from Chapter 2 that the nucleus contains essentially all the atom's mass but is only about 10^{-5} times its radius and, therefore, 10^{-15} times its volume, making the nucleus incredibly dense: about 10^{14} g/mL. ◆ *Protons* and *neutrons,* the elementary particles that make up the nucleus, are called **nucleons.** A **nuclide** is a nucleus with a particular composition, that is, with specific numbers of the two types of nucleons. Most elements occur in nature as a mixture of **isotopes,** atoms with the characteristic number of protons of the element but different numbers of neutrons. For example, oxygen has three naturally occurring isotopes, carbon also has three, but tin has ten, the most of any element. *Thus, each isotope of an element has a different nuclide.*

The relative mass and charge of a particle—nucleon, elementary particle, or nuclide—are described by the notation ${}^{A}_{Z}\mathrm{X}$, where X is the *symbol* for the particle, A is the *mass number,* or the total number of nucleons, and Z is the *charge* of the particle; for nuclei, A is the *sum of protons and neutrons* and Z is the *number of protons* (atomic number). In this notation, the three subatomic elementary particles are

$${}^{0}_{-1}\mathrm{e}\ (\text{electron}),\ {}^{1}_{1}\mathrm{p}\ (\text{proton}),\ \text{and}\ {}^{1}_{0}\mathrm{n}\ (\text{neutron})$$

(A proton is also sometimes represented as ${}^{1}_{1}\mathrm{H}^{+}$.) The number of neutrons (N) in a nucleus is the mass number (A) minus the atomic number (Z): $N = A - Z$. The two naturally occurring stable isotopes of chlorine, for example, have 17 protons (Z = 17), but one has 18 neutrons (${}^{35}_{17}\mathrm{Cl}$, also written ${}^{35}\mathrm{Cl}$) and the other has 20 (${}^{37}_{17}\mathrm{Cl}$, or ${}^{37}\mathrm{Cl}$). Nuclides can also be designated with the element name followed by the mass number, for example, chlorine-35 and chlorine-37. In naturally occurring samples of an element or its compounds, *the isotopes of the element are present in specific proportions* that vary only very slightly (but see Chapter 2, p. 56). Thus, in a sample of sodium chloride (or any Cl-containing substance), 75.77% of the Cl atoms are chlorine-35 and the remaining 24.23% are chlorine-37.

To understand this chapter, it's very important that you are comfortable with nuclear notations, so please take a moment to review Sample Problem 2.4 (p. 54) and Problems 2.39 to 2.46 (p. 84).

The Discovery of Radioactivity and the Types of Emissions

In 1896, the French physicist Antoine-Henri Becquerel accidentally discovered that uranium minerals emit a penetrating radiation that can expose a photographic plate. Becquerel also found that the radiation creates an electric discharge in air, thus providing a means for measuring its intensity.

Curie and Rutherford: The Nature of Radioactivity and Element Identity Based on Becquerel's discovery, in 1898, a young doctoral student named Marie Sklodowska Curie began a search for other minerals that behaved like uranium minerals. She found that thorium minerals also emit radiation and, most importantly, that *the intensity of the radiation is directly proportional to the concentration of the element in the mineral, not to the formula of the mineral or compound*. Curie named the emissions *radioactivity* and showed that they are *unaffected by temperature, pressure, or other physical and chemical conditions.*

After months of painstaking chemical work, Curie and her husband, physicist Pierre Curie, showed clear evidence of two new elements in pitchblende, the principal ore of uranium: polonium (Po; $Z = 84$), the most metallic member of Group 6A(16), and radium (Ra; $Z = 88$), the heaviest alkaline earth metal.

Then, focusing on obtaining a measurable amount of radium, Curie started with several tons of pitchblende residues from which the uranium had been extracted and worked arduously for four years to isolate 0.1 g of radium chloride, which she melted and electrolyzed to obtain pure metallic radium. Curie is the only person to have received two Nobel Prizes in science, one in physics for her research into radioactivity, and the other in chemistry for her discoveries of polonium and radium.

During the next few years, Becquerel, the Curies, and Paul Villard in France and Ernest Rutherford and his coworkers in England studied the nature of radioactive emissions. A key finding was the observation of Rutherford and his colleague Frederick Soddy that elements other than radium were formed when radium decayed. In 1902, they proposed that radioactive emission results in the change of one element into another. This explanation seemed like a return to alchemy and was met with disbelief and ridicule. We now know it to be true: *when a nuclide of one element decays, it emits radiation and usually changes into a nuclide of a different element.*

Types of Radioactive Emissions There are three natural types of radioactive emissions:

- **Alpha particles** (symbolized α, ${}^{4}_{2}\alpha$, or ${}^{4}_{2}He^{2+}$) are identical to helium-4 nuclei.
- **Beta particles** (symbolized β, β^{-}, or sometimes ${}^{0}_{-1}\beta$) are high-speed electrons. (The emission of an electron from a nucleus may seem strange, but as you'll see shortly, it results from a nuclear reaction.)
- **Gamma rays** (symbolized γ, or sometimes ${}^{0}_{0}\gamma$) are very high-energy photons.

Figure 24.1 illustrates the behavior of these emissions in an electric field: the positively charged α particles curve to a small extent toward the negative plate, the negatively charged β particles curve to a greater extent toward the positive plate (because they have lower mass), and the uncharged γ rays are not affected by the electric field.

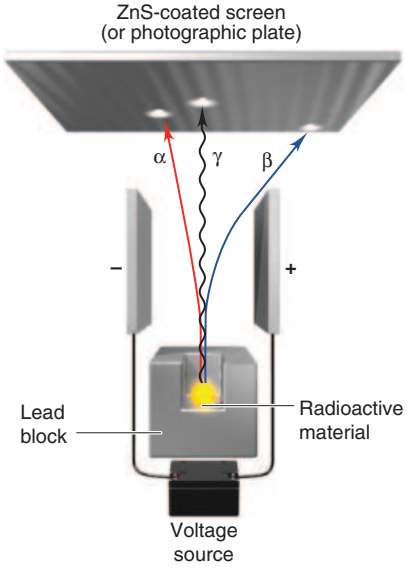


Figure 24.1 How the three types of radioactive emissions behave in an electric field.

Modes of Radioactive Decay; Balancing Nuclear Equations

When a nuclide decays, it forms a nuclide of lower energy, and the excess energy is carried off by the emitted radiation and the recoiling nucleus. The decaying, or reactant, nuclide is called the *parent;* the product nuclide is called the *daughter.* Nuclides can decay in several ways. As each of the major modes of decay is introduced (Table 24.2, *next page*), we'll show examples of that mode and apply the key principle used to balance nuclear reactions: *the total Z (charge, number of protons) and the total A (sum of protons and neutrons) of the reactants equal those of the products:*

$$\begin{matrix}\text{Total } A \\ \text{Total } Z\end{matrix}\ \text{Reactants} = \begin{matrix}\text{Total } A \\ \text{Total } Z\end{matrix}\ \text{Products} \qquad (24.1)$$

Table 24.2 Modes of Radioactive Decay*

Mode	Emission	Decay Process	Change in A	Change in Z	Change in N
α Decay	α ($^4_2He^{2+}$)		−4	−2	−2
β^- Decay†	β^- ($^0_{-1}\beta$)		0	+1	−1
	Net:	$^1_0n \rightarrow {}^1_1p + {}^0_{-1}\beta$ (in nucleus → in nucleus + β^- expelled)			
Positron (β^+) emission†	β^+ ($^0_1\beta$)		0	−1	+1
	Net:	$^1_1p \rightarrow {}^1_0n + {}^0_1\beta$ (in nucleus → in nucleus + β^+ expelled)			
Electron (e^-) capture (EC)†	x-ray		0	−1	+1
	Net:	$^0_{-1}e$ (absorbed from low-energy orbital) + ^1_1p (in nucleus) → ^1_0n (in nucleus)			
Gamma (γ) emission	γ		0	0	0

*Nuclear chemists consider β^- decay, positron emission, and electron capture to be three decay modes of the more general process known as beta decay (see text).

†Neutrinos (ν) or antineutrinos ($\bar{\nu}$) are also formed during the three modes of beta decay. Although we will not include them in other equations in the chapter, keep in mind that antineutrinos are always expelled during β^- decay, and neutrinos are expelled during β^+ emission and e^- capture. The mass of a neutrino or antineutrino is estimated to be less than 10^{-4} the mass of an electron.

1. **Alpha (α) decay** involves the loss of an α particle from a nucleus. For each α particle emitted by the parent, *A decreases by 4 and Z decreases by 2* in the daughter. Every element beyond bismuth (Bi; $Z = 83$) is radioactive and exhibits α decay, which is *the most common means for a heavy, unstable nucleus to become more stable*. For example, radium undergoes α decay to yield radon (Rn; $Z = 86$):

$$^{226}_{88}\text{Ra} \longrightarrow {}^{222}_{86}\text{Rn} + {}^{4}_{2}\alpha$$

Note that the *A* value for Ra equals the sum of the *A* values for Rn and α ($226 = 222 + 4$), and that the *Z* value for Ra equals the sum of the *Z* values for Rn and α ($88 = 86 + 2$).

2. **Beta (β) decay** is a more general class of radioactive decay that includes three modes: β^- decay, β^+ emission, and electron capture.

- **β^- decay** (or *negatron emission*) occurs through the ejection of a β^- particle from the nucleus. This change does not involve expulsion of a β^- particle that was in the nucleus; rather, *a neutron is converted into a proton, which remains in the nucleus, and a β^- particle, which is expelled immediately:*

$$^{1}_{0}\text{n} \longrightarrow {}^{1}_{1}\text{p} + {}^{0}_{-1}\beta$$

  As always, the totals of the *A* and the *Z* values for reactant and products are equal. Radioactive nickel-63 becomes stable copper-63 through β^- decay:

$$^{63}_{28}\text{Ni} \longrightarrow {}^{63}_{29}\text{Cu} + {}^{0}_{-1}\beta$$

  Another example is the β^- decay of carbon-14, used in radiocarbon dating:

$$^{14}_{6}\text{C} \longrightarrow {}^{14}_{7}\text{N} + {}^{0}_{-1}\beta$$

  Note that *β^- decay results in a product nuclide with the same A but with Z one greater (one more proton) than in the reactant nuclide.* In other words, an atom of the element with the next *higher* atomic number is formed. Although equations in this chapter do not include it, a neutral particle called an antineutrino ($\bar{\nu}$) is also emitted during β^- decay. The mass of the antineutrino is thought to be much less than 10^{-4} times that of an electron.
- **Positron (β^+) emission** is the emission of a β^+ particle from the nucleus. A key idea of modern physics is that most fundamental particles have corresponding *antiparticles* with the same mass but opposite charge. The **positron** is the antiparticle of the electron. Positron emission occurs through a process in which *a proton in the nucleus is converted into a neutron, and a positron is expelled:*

$$^{1}_{1}\text{p} \longrightarrow {}^{1}_{0}\text{n} + {}^{0}_{1}\beta$$

  Also emitted during this process is a *neutrino* (ν), the antiparticle of the antineutrino. In terms of the effect on *A* and *Z, positron emission has the opposite effect of β^- decay: the daughter has the same A but Z is one less (one fewer proton) than in the parent.* Thus, an atom of the element with the next *lower* atomic number forms. Carbon-11, a synthetic radioisotope, decays to a stable boron isotope through β^+ emission:

$$^{11}_{6}\text{C} \longrightarrow {}^{11}_{5}\text{B} + {}^{0}_{1}\beta$$

- **Electron (e^-) capture (EC)** occurs when the nucleus interacts with an electron in a low atomic energy level. The net effect is that *a proton is transformed into a neutron:*

$$^{1}_{1}\text{p} + {}^{0}_{-1}\text{e} \longrightarrow {}^{1}_{0}\text{n}$$

  (We use the symbol e^-, or $^{0}_{-1}\text{e}$, to distinguish an orbital electron from a beta particle, β^-, or $^{0}_{-1}\beta$.) The orbital vacancy is quickly filled by an electron that moves down from a higher energy level, and that process continues through still higher energy levels, with x-ray photons and neutrinos carrying off the energy difference in each step. Radioactive iron becomes stable manganese through electron capture:

$$^{55}_{26}\text{Fe} + {}^{0}_{-1}\text{e} \longrightarrow {}^{55}_{25}\text{Mn} + h\nu \text{ (x-rays and neutrinos)}$$

  Even though the processes are different, *electron capture has the same net effect as positron emission: Z* reduced by 1, *A* unchanged.

3. **Gamma (γ) emission** involves the radiation of high-energy γ photons (also called γ rays) from an excited nucleus. Just as an atom in an excited *electronic* state reduces its energy by emitting photons, usually in the UV and visible ranges (see Section 7.2), a nucleus in an excited state lowers its energy by emitting γ photons, which are of much higher energy (much shorter wavelength) than UV photons. Many nuclear processes leave the nucleus in an excited state, so γ *emission accompanies many other (mostly β) types of decay.* Several γ photons of different energies can be emitted from an excited nucleus as it returns to the ground state. Some of Marie Curie's experiments involved the release of γ rays, as in the decay of polonium-215:

$$^{215}_{84}\text{Po} \longrightarrow {}^{211}_{82}\text{Pb} + {}^{4}_{2}\alpha \text{ (several } \gamma \text{ emitted)}$$

Gamma emission often accompanies β^- decay:

$$^{99}_{43}\text{Tc} \longrightarrow {}^{99}_{44}\text{Ru} + {}^{0}_{-1}\beta \text{ (several } \gamma \text{ emitted)}$$

Because γ rays have no mass or charge, γ *emission does not change A or Z.* Two gamma rays are emitted when a particle and an antiparticle annihilate each other. In the medical technique known as *positron-emission tomography* (see Section 24.5), a positron and an electron annihilate each other (with all A and Z values shown):

$$^{0}_{1}\beta + {}^{0}_{-1}\text{e} \longrightarrow 2\,{}^{0}_{0}\gamma$$

SAMPLE PROBLEM 24.1 Writing Equations for Nuclear Reactions

Problem Write balanced equations for the following nuclear reactions:
(a) Naturally occurring thorium-232 undergoes α decay.
(b) Zirconium-86 undergoes electron capture.

Plan We first write a skeleton equation that includes the mass numbers, atomic numbers, and symbols of all the particles on the correct sides of the equation, showing the unknown product particle as $^{A}_{Z}\text{X}$. Then, because the total of mass numbers and the total of charges on the left side and the right side must be equal, we solve for A and Z, and use Z to determine X from the periodic table.

Solution **(a)** Writing the skeleton equation, with the α particle as a product:

$$^{232}_{90}\text{Th} \longrightarrow {}^{A}_{Z}\text{X} + {}^{4}_{2}\alpha$$

Solving for A and Z and balancing the equation: For A, $232 = A + 4$, so $A = 228$. For Z, $90 = Z + 2$, so $Z = 88$. From the periodic table, we see that the element with $Z = 88$ is radium (Ra). Thus, the balanced equation is

$$^{232}_{90}\text{Th} \longrightarrow {}^{228}_{88}\text{Ra} + {}^{4}_{2}\alpha$$

(b) Writing the skeleton equation, with the captured electron as a reactant:

$$^{86}_{40}\text{Zr} + {}^{0}_{-1}\text{e} \longrightarrow {}^{A}_{Z}\text{X}$$

Solving for A and Z and balancing the equation: For A, $86 + 0 = A$, so $A = 86$. For Z, $40 + (-1) = Z$, so $Z = 39$. The element with $Z = 39$ is yttrium (Y), so we have

$$^{86}_{40}\text{Zr} + {}^{0}_{-1}\text{e} \longrightarrow {}^{86}_{39}\text{Y}$$

Check Always read across superscripts and then across subscripts, with the yield arrow as an equal sign, to check your arithmetic. In part (a), for example, $232 = 228 + 4$, and $90 = 88 + 2$.

FOLLOW-UP PROBLEMS

Brief Solutions for ***all*** *Follow-up Problems appear at the end of the chapter.*

24.1A Write a balanced equation for the nuclear reaction in which fluorine-20 undergoes β^- decay.

24.1B Write a balanced equation for the reaction in which a nuclide undergoes β^- decay and changes to cesium-133.

SOME SIMILAR PROBLEMS 24.8–24.15

Nuclear Stability and the Mode of Decay

Can we predict how, and whether, an unstable nuclide will decay? Our knowledge of the nucleus is much less complete than that of the whole atom, but some patterns emerge by observing naturally occurring nuclides.

The Band of Stability Two key factors determine the stability of a nuclide:

1. The number of neutrons (N), the number of protons (Z), and their ratio (N/Z), which we calculate from $(A - Z)/Z$. This factor relates primarily to nuclides that undergo one of the three modes of β decay.
2. The total mass of the nuclide, which mostly relates to nuclides that undergo α decay.

A plot of numbers of neutrons vs. protons for all stable nuclides (Figure 24.2A) shows:

- The points form a narrow **band of stability** that gradually curves above the line for $N = Z$ $(N/Z = 1)$.
- The only stable nuclides with $N/Z < 1$ are $^{1}_{1}H$ and $^{3}_{2}He$.
- Many lighter nuclides with $N = Z$ are stable, such as $^{4}_{2}He$, $^{12}_{6}C$, $^{16}_{8}O$, and $^{20}_{10}Ne$; the heaviest of these is $^{40}_{20}Ca$. Thus, for lighter nuclides, one neutron for each proton $(N = Z)$ is enough to provide stability.
- The N/Z ratio of stable nuclides gradually increases as Z increases. For example, for $^{56}_{26}Fe$, $N/Z = 1.15$; for $^{107}_{47}Ag$, $N/Z = 1.28$; for $^{184}_{74}W$, $N/Z = 1.49$, and, finally, for $^{209}_{83}Bi$, $N/Z = 1.52$. Thus, for heavier stable nuclides, $N > Z$ $(N/Z > 1)$, and N increases faster than Z. As we discuss shortly, and show in Figure 24.2B, if N/Z of a nuclide is either too high (above the band) or not high enough (below the band), the nuclide is unstable and undergoes one of the three modes of beta decay.
- All nuclides with $Z > 83$ are unstable.* Thus, the largest members of Main Groups 1A(1) through 8A(18), actinium and the actinides (Z = 89–103), and the other elements of the fourth ($6d$) transition series (Z = 104–112), are radioactive and (as discussed shortly) undergo α decay.

*In 2003, French nuclear physicists discovered that $^{209}_{83}Bi$ actually undergoes α decay, but the half-life is 1.9×10^{19} yr, about a billion times longer than the estimated age of the universe. Bismuth ($Z = 83$) can thus be considered stable.

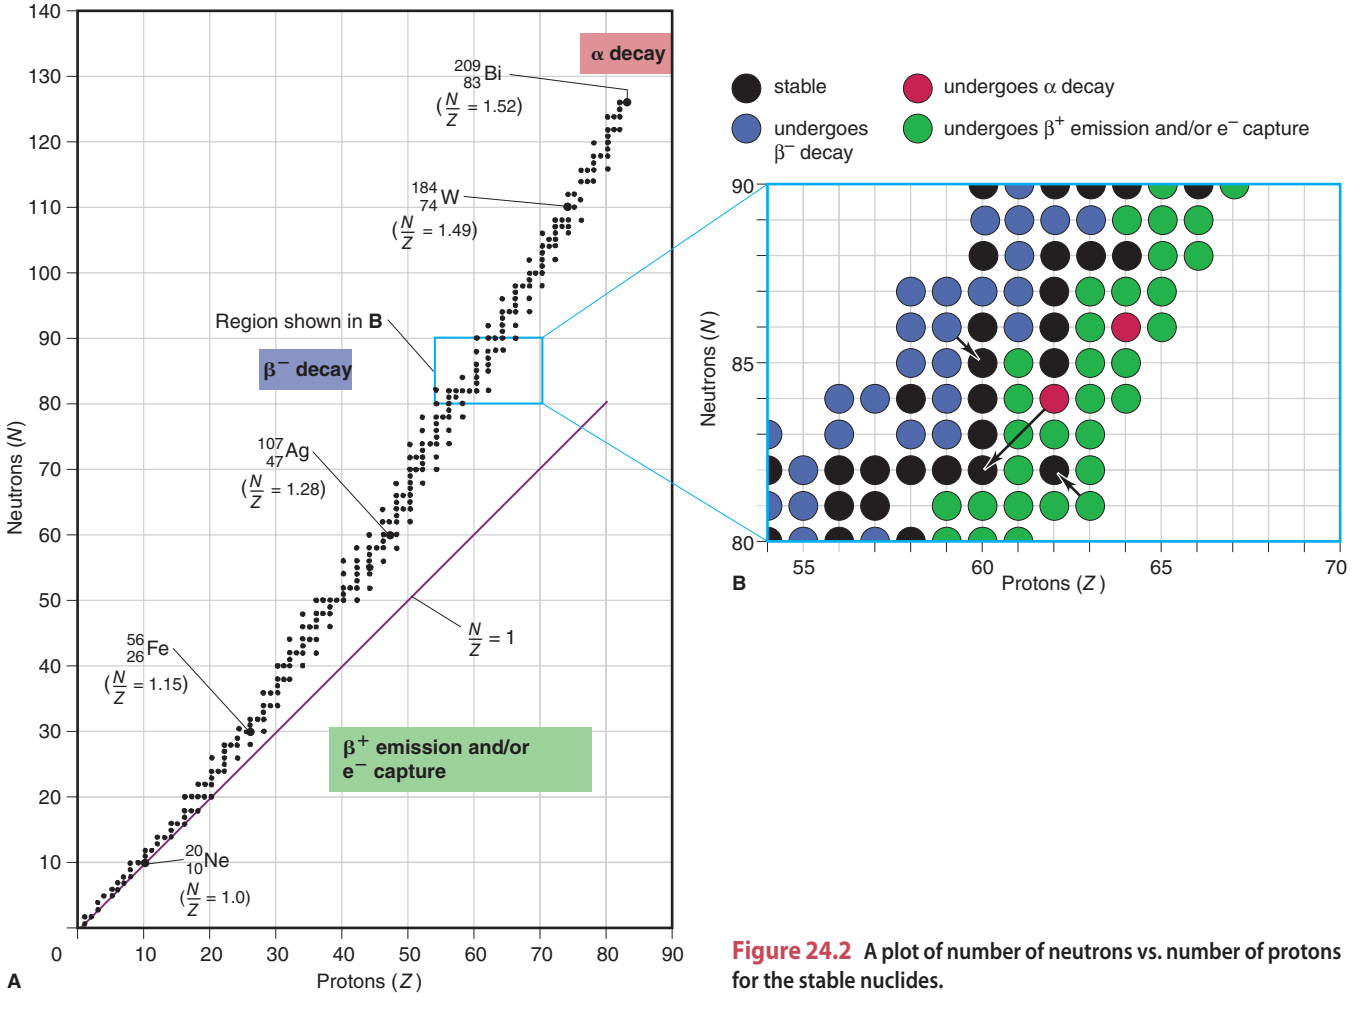

Figure 24.2 A plot of number of neutrons vs. number of protons for the stable nuclides.

Table 24.3 Number of Stable Nuclides for Elements 48 to 54*

Element	Atomic No. (*Z*)	No. of Nuclides

In	49	2
Sn	**50**	**10**
Sb	51	2
Te	**52**	**8**
I	53	1
Xe	**54**	**9**

*Even *Z* shown in boldface.

Table 24.4 An Even-Odd Breakdown of the Stable Nuclides

Z	*N*	No. of Nuclides
Even	Even	157
Even	Odd	53
Odd	Even	50
Odd	Odd	4
	TOTAL	264

Stability and Nuclear Structure Nuclear structure is related to nuclear stability in several ways:

1. *The effect of the strong force*. Given that protons are positively charged and neutrons are uncharged, the first question to ask is why does the nucleus stay together? Nuclear scientists answer this question and explain the importance of N and Z values in terms of two opposing forces: electrostatic repulsive forces between protons would break the nucleus apart if not for an attractive force called the **strong force,** which exists between all nucleons (protons and neutrons). This force is 137 times stronger than the repulsive force but *operates only over the short distances within the nucleus*. Thus, the *attractive* strong force overwhelms the much weaker *repulsive* electrostatic force and keeps the nucleus together.

2. *Odd and even numbers of nucleons*. The oddness or evenness of N and Z values is related to some important patterns of nuclear stability. Two interesting points become apparent when we classify the known stable nuclides:

- Elements with an even Z (number of protons) usually have a larger number of stable nuclides than elements with an odd Z. Table 24.3 demonstrates this point for cadmium ($Z = 48$) through xenon ($Z = 54$).
- Well over half the stable nuclides have *both* even N and even Z (Table 24.4). Only four nuclides with odd N and odd Z are stable: ${}^{2}_{1}\text{H}$, ${}^{6}_{3}\text{Li}$, ${}^{10}_{5}\text{B}$, and ${}^{14}_{7}\text{N}$.

3. *Nucleon energy levels*. One model of nuclear structure that attempts to explain the stability of even values of N and Z postulates that protons and neutrons lie in *nucleon energy levels,* and that greater stability results from the *pairing of spins* of like nucleons. (Note the analogy to electron energy levels and the stability from pairing of electron spins.)

Just as noble gases—with 2, 10, 18, 36, 54, and 86 electrons—are exceptionally stable because they have filled *electron* energy levels, nuclides with N or Z values of 2, 8, 20, 28, 50, 82 (and $N = 126$) are exceptionally stable. These so-called *magic numbers* are thought to correspond to the numbers of protons or neutrons in filled *nucleon* energy levels. A few examples are ${}^{50}_{22}\text{Ti}$ ($N = 28$), ${}^{88}_{38}\text{Sr}$ ($N = 50$), and the ten stable nuclides of tin ($Z = 50$). Some extremely stable nuclides have two magic numbers: ${}^{4}_{2}\text{He}$, ${}^{16}_{8}\text{O}$, ${}^{40}_{20}\text{Ca}$, and ${}^{208}_{82}\text{Pb}$ ($N = 126$).

SAMPLE PROBLEM 24.2 Predicting Nuclear Stability

Problem Which of the following nuclides would you predict to be stable and which radioactive: **(a)** ${}^{18}_{10}\text{Ne}$; **(b)** ${}^{32}_{16}\text{S}$; **(c)** ${}^{236}_{90}\text{Th}$; **(d)** ${}^{123}_{56}\text{Ba}$? Explain.

Plan In order to evaluate the stability of each nuclide, we determine the N and Z values, the N/Z ratio from $(A - Z)/Z$, the value of Z, stable N/Z ratios (from Figure 24.2A), and whether Z and N are even or odd.

Solution **(a)** Radioactive. This nuclide has $N = 8$ $(18 - 10)$ and $Z = 10$, so $N/Z = \dfrac{18 - 10}{10} = 0.8$. Except for hydrogen-1 and helium-3, no nuclides with $N < Z$ are stable; despite its even N and Z, this nuclide has too few neutrons to be stable.

(b) Stable. This nuclide has $N = Z = 16$, so $N/Z = 1.0$. With $Z < 20$ and even N and Z, this nuclide is most likely stable.

(c) Radioactive. This nuclide has $Z = 90$, and every nuclide with $Z > 83$ is radioactive.

(d) Radioactive. This nuclide has $N = 67$ and $Z = 56$, so $N/Z = 1.20$. For Z values of 55 to 60, Figure 24.2A shows $N/Z \geq 1.3$, so it has too few neutrons to be stable.

Check By consulting a table of isotopes, such as the one in the *CRC Handbook of Chemistry and Physics,* we find that our predictions are correct.

FOLLOW-UP PROBLEMS

24.2A Predict whether each of the following nuclides is stable or radioactive and explain your prediction: **(a)** ${}^{10}_{5}\text{B}$; **(b)** ${}^{58}_{23}\text{V}$.

24.2B Why is ${}^{31}_{15}\text{P}$ stable but ${}^{30}_{15}\text{P}$ unstable?

SOME SIMILAR PROBLEMS 24.16–24.19

Predicting the Mode of Decay An unstable nuclide generally decays in a mode that shifts its *N*/*Z* ratio toward the band of stability. This fact is illustrated in Figure 24.2B, which expands the small region of $Z = 54$ to 70 in Figure 24.2A to show the stable *and* many of the unstable nuclides in that region, as well as their modes of decay. Note the following points:

1. *Neutron-rich nuclides.* Nuclides with too many neutrons for stability (a high *N*/*Z*) lie above the band of stability. They undergo β^- *decay,* which converts a neutron into a proton, thus reducing the value of *N*/*Z*.
2. *Proton-rich nuclides.* Nuclides with too many protons for stability (a low *N*/*Z*) lie below the band. They undergo β^+ *emission* and/or e^- *capture,* both of which convert a proton into a neutron, thus increasing the value of *N*/*Z*. (The rate of e^- capture increases with *Z*, so β^+ emission is more common among lighter elements and e^- capture more common among heavier elements.)
3. *Heavy nuclides.* Nuclides with $Z > 83$ (shown in Figure 24.2A) are too heavy to be stable and undergo α *decay,* which reduces their *Z* and *N* values by two units per emission.

With the information in Figure 24.2, predicting the mode of decay of an unstable nuclide means just comparing its *N*/*Z* ratio with those in the nearby region of the band of stability. But, even without Figure 24.2, we can often make an educated guess about mode of decay. The atomic mass of an element is the weighted average of its naturally occurring isotopes. Therefore,

- The mass number *A* of a *stable* nuclide will be relatively close to the atomic mass.
- If an *unstable* nuclide of an element (given *Z*) has an *A* value much higher than the atomic mass, *it is neutron rich and will probably decay by* β^- *emission.*
- If, on the other hand, the unstable nuclide has an *A* value much lower than the atomic mass, *it is proton rich and will probably decay by* β^+ *emission and/or* e^- *capture.*

In the next sample problem, we predict the mode of decay of some unstable nuclides.

SAMPLE PROBLEM 24.3 Predicting the Mode of Nuclear Decay

Problem Use the atomic mass of the element to predict the mode(s) of decay of the following radioactive nuclides: **(a)** $^{12}_{5}B$; **(b)** $^{234}_{92}U$; **(c)** $^{81}_{33}As$; **(d)** $^{127}_{57}La$.

Plan If the nuclide is too heavy to be stable ($Z > 83$), it undergoes α decay. For other cases, we use the *Z* value to obtain the atomic mass from the periodic table. If the mass number of the nuclide is higher than the atomic mass, the nuclide has too many neutrons: *N* too high $\Rightarrow \beta^-$ decay. If the mass number is lower than the atomic mass, the nuclide has too many protons: *Z* too high $\Rightarrow \beta^+$ emission and/or e^- capture.

Solution **(a)** This nuclide has $Z = 5$, which is boron (B), and the atomic mass is 10.81. The nuclide's *A* value of 12 is significantly higher than its atomic mass, so this nuclide is neutron rich. It will probably undergo β^- decay.
(b) This nuclide has $Z = 92$, so it will undergo α decay and decrease its total mass.
(c) This nuclide has $Z = 33$, which is arsenic (As), and the atomic mass is 74.92. The *A* value of 81 is much higher, so this nuclide is neutron rich and will probably undergo β^- decay.
(d) This nuclide has $Z = 57$, which is lanthanum (La), and the atomic mass is 138.9. The *A* value of 127 is much lower, so this nuclide is proton rich and will probably undergo β^+ emission and/or e^- capture.

Check To confirm our predictions in (a), (c), and (d), let's compare each nuclide's *N*/*Z* ratio to those in the band of stability: **(a)** This nuclide has $N = 7$ and $Z = 5$, so $N/Z = 1.40$, which is too high for this region of the band, so it will undergo β^- decay. **(c)** This nuclide has $N = 48$ and $Z = 33$, so $N/Z = 1.45$, which is too high for this region of the band, so it undergoes β^- decay. **(d)** This nuclide has $N = 70$ and $Z = 57$, so $N/Z = 1.23$, which is too low for this region of the band, so it undergoes β^+ emission and/or e^- capture. Our predictions based on *N*/*Z values* were the same as those based on atomic mass.

Comment Both possible modes of decay are observed for the nuclide in part (d).

FOLLOW-UP PROBLEMS

24.3A Use the *A* value for the nuclide and the atomic mass from the periodic table to predict the mode of decay of **(a)** $^{61}_{26}$Fe; **(b)** $^{241}_{95}$Am.

24.3B Use the *A* value for the nuclide and the atomic mass from the periodic table to predict the mode of decay of **(a)** $^{40}_{22}$Ti; **(b)** $^{65}_{27}$Co.

SOME SIMILAR PROBLEMS 24.20–24.23

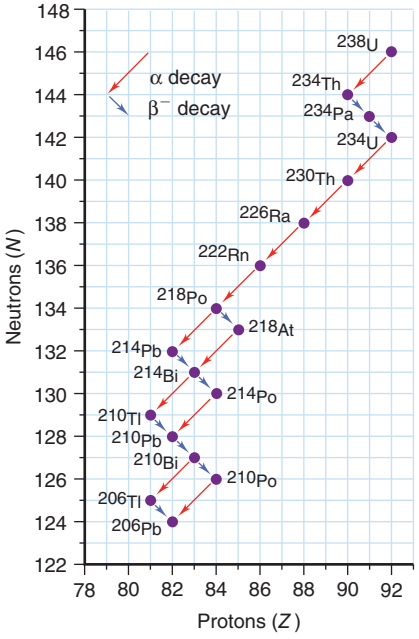

Figure 24.3 The ^{238}U decay series.

Decay Series A parent nuclide may undergo a series of decay steps before a stable daughter nuclide forms. The succession of steps is called a **decay series,** or **disintegration series,** and is typically depicted on a gridlike display. Figure 24.3 shows the decay series from uranium-238 to lead-206. Numbers of neutrons (*N*) are plotted against numbers of protons (*Z*) to form the grid, which displays a series of α and β^- decays. The typical zigzag pattern arises because $N > Z$, which means that α decay, which reduces both *N* and *Z* by two units, decreases *Z* slightly more than it does *N*. Therefore, α decays result in neutron-rich daughters, which undergo β^- decay to gain more stability. Note that a given nuclide can undergo both modes of decay. (Gamma emission accompanies many of these steps but does not affect the type of nuclide.)

The series in Figure 24.3 is one of three that occur in nature. All end with isotopes of lead whose nuclides all have one ($Z = 82$) or two ($N = 126$, $Z = 82$) magic numbers. A second series begins with uranium-235 and ends with lead-207, and a third begins with thorium-232 and ends with lead-208. (Neptunium-237 began a fourth series, but its half-life is so much less than the age of Earth that only traces of it remain today.)

Summary of Section 24.1

- In dramatic contrast to chemical reactions, nuclear reactions involve particles *within* the nucleus, usually result in atoms of different elements, are accompanied by measurable changes in mass, and are not affected by temperature, pressure, catalysis, or the nature of the compound.
- To become more stable, a radioactive nuclide may emit α particles ($^4_2He^{2+}$; helium-4 nuclei), β particles (β^- or $^0_{-1}\beta$; high-speed electrons), positrons (β^+ or $^0_1\beta$), or γ rays (high-energy photons) or may capture an orbital electron ($^0_{-1}e$).
- A narrow band of neutron-to-proton ratios *(N/Z)* includes those of all the stable nuclides.
- Even values of *N* and *Z* are associated with stable nuclides, as are certain "magic numbers" of neutrons and protons.
- By comparing a nuclide's mass number with the atomic mass and its *N/Z* ratio with those in the band of stability, we can predict that, in general, neutron-rich nuclides undergo β^- decay and proton-rich nuclides undergo β^+ emission and/or e^- capture. Heavy nuclides ($Z > 83$) undergo α decay.
- Three naturally occurring decay series all end in isotopes of lead.

24.2 THE KINETICS OF RADIOACTIVE DECAY

Both chemical and nuclear systems tend toward maximum stability. Just as the concentrations in a chemical system change in a predictable direction to give a stable equilibrium ratio, the type and number of nucleons in an unstable nucleus change in a predictable direction to give a stable *N/Z* ratio. As you know, however, the tendency of a chemical system to become more stable tells nothing about how long that process will take, and the same holds true for nuclear systems. In this section, we first see how radioactivity is detected and measured and then examine the kinetics of nuclear change; later, we'll examine the energetics of nuclear change.

Detection and Measurement of Radioactivity

Radioactive emissions interact with surrounding atoms. To determine the rate of nuclear decay, we measure radioactivity by observing the effects of these interactions over time. Because these effects can be electrically amplified billions of times, it is possible to detect the decay of a single nucleus. Ionization counters and scintillation counters are two devices used to measure radioactive emissions.

Ionization Counters An *ionization counter* detects radioactive emissions as they ionize a gas. Ionization produces free electrons and gaseous cations, which are attracted to electrodes that conduct a current to a recording device. The most common type of ionization counter is a **Geiger-Müller counter** (Figure 24.4). It consists of a tube filled with an argon-methane mixture; the tube housing acts as the cathode, and a thin wire in the center of the tube acts as the anode. Emissions from the sample enter the tube through a thin window and strike argon atoms, producing Ar^+ ions that migrate toward the cathode and free electrons that are accelerated toward the anode. These electrons collide with other argon atoms and free more electrons in an *avalanche effect.* The current created is amplified and appears as a meter reading and/or an audible click. An initial release of 1 electron can release 10^{10} electrons in a microsecond, giving the Geiger-Müller counter great sensitivity.

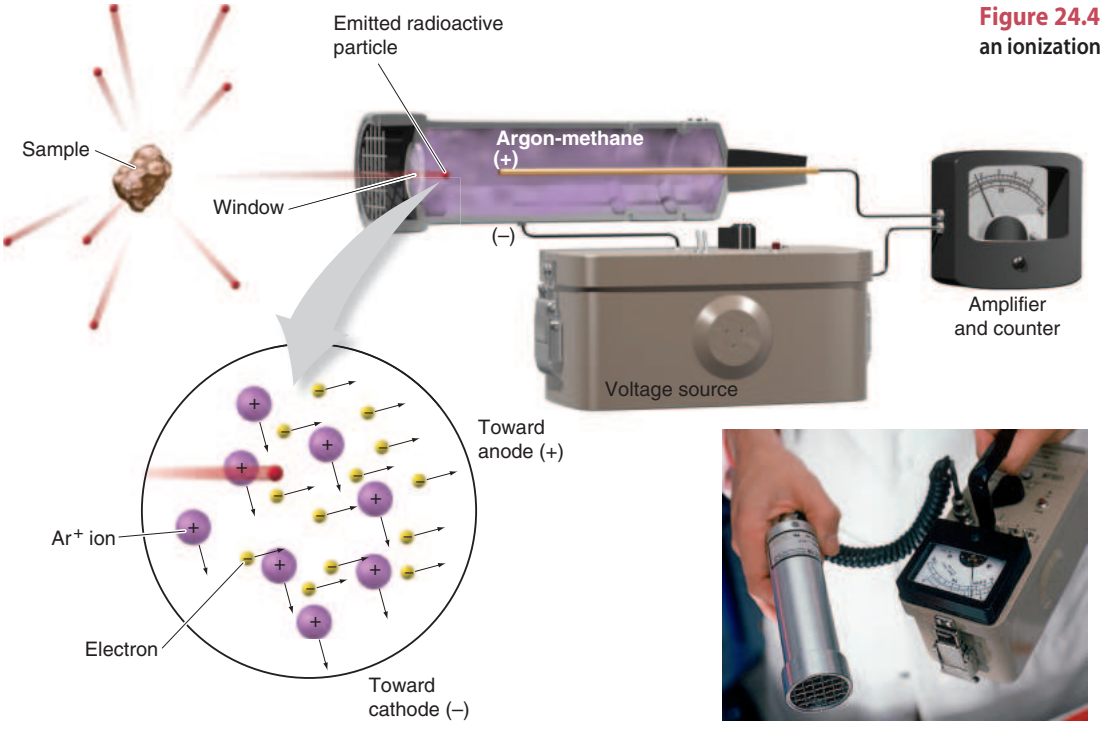

Figure 24.4 Detection of radioactivity by an ionization counter.

Scintillation Counters In a **scintillation counter,** radioactive emissions are detected by their ability to excite atoms and cause them to emit light. The light-emitting substance in the counter, called a *phosphor,* is coated onto part of a *photomultiplier tube,* a device that increases the original electrical signal. Incoming radioactive particles strike the phosphor, which emits photons. Each photon, in turn, strikes a cathode, releasing an electron through the photoelectric effect (Section 7.1). This electron hits other portions of the tube that release increasing numbers of electrons, and the resulting current is recorded. Liquid scintillation counters employ an organic mixture that contains a phosphor and a solvent (Figure 24.5). This "cocktail" dissolves the radioactive sample *and* emits pulses of light when excited by the emission. The number of pulses is proportional to the concentration of the radioactive substance. These counters are often used to measure β^- emissions from dissolved biological samples, particularly those containing compounds of ^3H and ^{14}C.

Figure 24.5 A scintillation "cocktail" in tubes to be placed in the counter.

The Rate of Radioactive Decay

Radioactive nuclei decay at a characteristic rate, regardless of the chemical substance in which they occur.

Activity and the Decay Constant The *decay rate,* or **activity ($\mathcal{A}$),** of a radioactive sample is the change in number of nuclei ($\mathcal{N}$) divided by the change in time (t). As with chemical reaction rates (Section 16.2), because the number of nuclei is *decreasing,* a minus sign precedes the expression to obtain a positive decay rate:

$$\text{Decay rate } (\mathcal{A}) = -\frac{\Delta \mathcal{N}}{\Delta t}$$

The SI unit of radioactivity is the **becquerel (Bq),** defined as one disintegration per second (d/s): 1 Bq = 1 d/s. A much larger and more common unit of radioactivity is the **curie (Ci),** which was originally defined as the number of disintegrations per second in 1 g of radium-226, but is now a fixed quantity:

$$1 \text{ Ci} = 3.70\times10^{10} \text{ d/s} \qquad \textbf{(24.2)}$$

Because the curie is so large, the millicurie (mCi) and microcurie (μCi) are commonly seen. The radioactivity of a sample is often given as a *specific activity,* the decay rate per gram.

An activity is meaningful only when we consider the large number of nuclei in a macroscopic sample. Suppose there are 1×10^{15} radioactive nuclei of a particular type in a sample and they decay at a rate of 10% per hour. Although any particular nucleus in the sample might decay in a microsecond or in a million hours, the *average* of all decays results in 10% of the entire collection of nuclei disintegrating each hour. During the first hour, 10% of the *original* number, or 1×10^{14} nuclei, will decay. During the next hour, 10% of the remaining 9×10^{14} nuclei, or 9×10^{13} nuclei, will decay. During the next hour, 10% of those remaining will decay, and so forth. Thus, for a large collection of radioactive nuclei, *the number decaying per unit time is proportional to the number present:*

$$\text{Decay rate } (\mathcal{A}) \propto \mathcal{N} \qquad \text{or} \qquad \mathcal{A} = k\mathcal{N}$$

where k is called the **decay constant** and is characteristic of each type of nuclide. The larger the value of k, the higher is the decay rate: larger $k \Rightarrow$ higher $\mathcal{A}$.

Combining the two expressions for decay rate just given, we obtain

$$\mathcal{A} = -\frac{\Delta \mathcal{N}}{\Delta t} = k\mathcal{N} \qquad \textbf{(24.3)}$$

Note that the activity depends only on $\mathcal{N}$ raised to the first power (and on the constant value of k). Therefore, *radioactive decay is a first-order process* (Section 16.4), but first order with respect to the *number* of nuclei rather than their concentration.

SAMPLE PROBLEM 24.4 Calculating the Specific Activity and the Decay Constant of a Radionuclide

Problem A sample of 2.6×10^{-12} mol of antimony-122 (^{122}Sb) emits 2.76×10^{8} β^- particles per minute.

(a) Calculate the specific activity of the sample (in Ci/g).

(b) Find the decay constant for ^{122}Sb.

Plan **(a)** The activity ($\mathcal{A}$) is the number of nuclei ($\mathcal{N}$) emitting a particle in a given time (t), and the specific activity is the activity per gram of sample. We are given $\mathcal{A}$, which is equal to the number of particles emitted per minute (2.76×10^{8} β^- particles), and we know the amount (mol) of sample. Because the sample is an isotope, we use the mass number in g/mol (122 g/mol) to find the mass (g). Converting $\mathcal{A}$ (in d/min) to curies (in d/s) and dividing by the mass gives the specific activity (in Ci/g). **(b)** The decay constant (k) relates the activity to the number of nuclei ($\mathcal{N}$). We know $\mathcal{A}$ (number of nuclei disintegrating/min) and the amount (in mol), so we use Avogadro's number to find $\mathcal{N}$ (number of nuclei) and apply Equation 24.3 to get k.

Solution **(a)** Finding the mass of the sample:

$$\text{Mass (g)} = (2.6\times10^{-12}\ \text{mol}\ ^{122}\text{Sb})\left(\frac{122\ \text{g}\ ^{122}\text{Sb}}{1\ \text{mol}\ ^{122}\text{Sb}}\right)$$
$$= 3.2\times10^{-10}\ \text{g}\ ^{122}\text{Sb}$$

Using the activity and the mass to find the specific activity:

$$\text{Specific activity (Ci/g)} = (2.76\times10^{8}\ \text{d/min})\left(\frac{1\ \text{min}}{60\ \text{s}}\right)\left(\frac{1\ \text{Ci}}{3.70\times10^{10}\ \text{d/s}}\right)\left(\frac{1}{3.2\times10^{-10}\ \text{g}}\right)$$
$$= \boxed{3.9\times10^{5}\ \text{Ci/g}}$$

(b) Using the activity and the amount to find the decay constant (Equation 24.3):

$$\text{Decay constant } (k) = \frac{\mathcal{A}\ \text{(nuclei/min)}}{\mathcal{N}\ \text{(nuclei)}} = \frac{2.76\times10^{8}\ \text{nuclei/min}}{(2.6\times10^{-12}\ \text{mol})(6.022\times10^{23}\ \text{nuclei/mol})}$$
$$= \boxed{1.8\times10^{-4}\ \text{min}^{-1}}$$

Check With so many exponents in the values, rounding is a good way to check the math. In (b), for example,

$$k = \frac{3\times10^{8}\ \text{nuclei/min}}{(3\times10^{-12}\ \text{mol})(6\times10^{23}\ \text{nuclei/mol})} = 2\times10^{-4}\ \text{min}^{-1}$$

FOLLOW-UP PROBLEMS

24.4A Arsenic-76 decays by β^- emission. If 3.4×10^{-8} mol of ^{76}As emits 1.53×10^{11} β^- particles per second, find the specific activity in **(a)** Ci/g; **(b)** Bq/g.

24.4B Chlorine-36 disintegrates by β^- decay. If 6.50×10^{-2} mol of ^{36}Cl emits 9.97×10^{12} β^- particles per hour, find the decay constant.

SOME SIMILAR PROBLEMS 24.33–24.40

Half-Life of Radioactive Decay Decay rates are also commonly expressed in terms of the fraction of nuclei that decay over a given time interval. The **half-life ($t_{1/2}$)** of a nuclide has the same meaning as for a chemical change (Section 16.4) and can be expressed in terms of number of nuclei, mass of radioactive substance, and activity:

- *Number of nuclei.* Half-life is the time it takes for half the nuclei in a sample to decay—*the number of nuclei remaining is halved after each half-life.* Figure 24.6 shows the decay of carbon-14, which has a half-life of 5730 years (yr), in terms of number of ^{14}C nuclei remaining:

$$^{14}_{6}\text{C} \longrightarrow {}^{14}_{7}\text{N} + {}^{0}_{-1}\beta$$

- *Mass.* As ^{14}C decays, the mass of ^{14}C decreases while the mass of ^{14}N increases. If we start with 1.0 g of ^{14}C, half that mass of ^{14}C (0.50 g) will be left after 5730 yr, half of that mass (0.25 g) after another 5730 yr, and so on.
- *Activity.* The activity depends on the number of nuclei, so the activity is halved after each succeeding half-life.

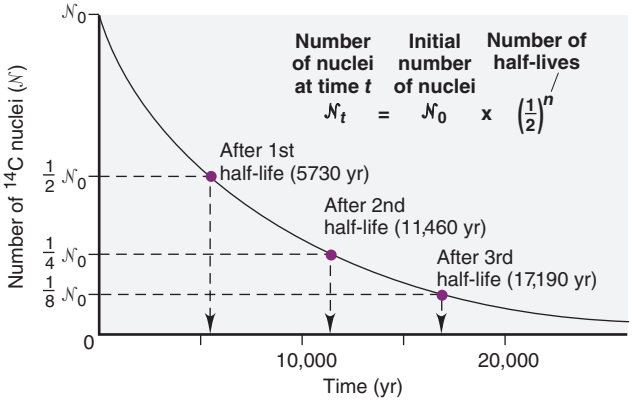

Figure 24.6 Decrease in number of ^{14}C nuclei over time.

We determine the half-life of a nuclear reaction from its rate constant. Rearranging Equation 24.3 and integrating over time gives an expression for finding the number of nuclei remaining, $\mathcal{N}_t$, after a given time t:

$$\ln\frac{\mathcal{N}_t}{\mathcal{N}_0} = -kt \quad \text{or} \quad \mathcal{N}_t = \mathcal{N}_0 e^{-kt} \quad \text{and} \quad \ln\frac{\mathcal{N}_0}{\mathcal{N}_t} = kt \tag{24.4}$$

where $\mathcal{N}_0$ is the number of nuclei at $t = 0$. (Note the similarity to Equation 16.4, p. 692.) To calculate the half-life ($t_{1/2}$), we set $\mathcal{N}_t$ equal to $\frac{1}{2}\mathcal{N}_0$ and solve for $t_{1/2}$:

$$\ln\frac{\mathcal{N}_0}{\frac{1}{2}\mathcal{N}_0} = kt_{1/2} \quad \text{so} \quad t_{1/2} = \frac{\ln 2}{k} \tag{24.5}$$

Exactly analogous to the half-life of a first-order chemical change, *this half-life is **not** dependent on the number of nuclei and is inversely related to the decay constant:*

large $k \Rightarrow$ short $t_{1/2}$ and small $k \Rightarrow$ long $t_{1/2}$

The decay constants and half-lives of many radioactive nuclides vary over a very wide range, even for the nuclides of a given element (Table 24.5).

Table 24.5 Decay Constants (k) and Half-Lives ($t_{1/2}$) of Beryllium Isotopes

Nuclide	k	$t_{1/2}$
$^{7}_{4}\text{Be}$	1.30×10^{-2}/day	53.3 days
$^{8}_{4}\text{Be}$	1.0×10^{16}/s	6.7×10^{-17} s
$^{9}_{4}\text{Be}$	Stable	
$^{10}_{4}\text{Be}$	4.3×10^{-7}/yr	1.6×10^{6} yr
$^{11}_{4}\text{Be}$	5.02×10^{-2}/s	13.8 s

SAMPLE PROBLEM 24.5 Finding the Number of Radioactive Nuclei

Problem Strontium-90 is a radioactive byproduct of nuclear reactors that behaves biologically like calcium, the element above it in Group 2A(2). When ^{90}Sr is ingested by mammals, it is found in their milk and eventually in the bones of those drinking the milk. If a sample of ^{90}Sr has an activity of 1.2×10^{12} d/s, what are the activity and the fraction of nuclei that have decayed after 59 yr ($t_{1/2}$ of ^{90}Sr = 29 yr)?

Plan The fraction of nuclei that have decayed is the change in number of nuclei, expressed as a fraction of the starting number. The activity of the sample ($\mathcal{A}$) is proportional to the number of nuclei ($\mathcal{N}$), so we know that

$$\text{Fraction decayed} = \frac{\mathcal{N}_0 - \mathcal{N}_t}{\mathcal{N}_0} = \frac{\mathcal{A}_0 - \mathcal{A}_t}{\mathcal{A}_0}$$

We are given $\mathcal{A}_0$ (1.2×10^{12} d/s), so we find $\mathcal{A}_t$ from the integrated form of the first-order rate equation (Equation 24.4), in which t is 59 yr. To solve that equation, we first need k, which we can calculate from the given $t_{1/2}$ (29 yr).

Solution Calculating the decay constant k:

$$t_{1/2} = \frac{\ln 2}{k} \quad \text{so} \quad k = \frac{\ln 2}{t_{1/2}} = \frac{0.693}{29\text{ yr}} = 0.024\text{ yr}^{-1}$$

Applying Equation 24.4 to calculate $\mathcal{A}_t$, the activity remaining at time t:

$$\ln\frac{\mathcal{N}_0}{\mathcal{N}_t} = \ln\frac{\mathcal{A}_0}{\mathcal{A}_t} = kt \quad \text{or} \quad \ln\mathcal{A}_0 - \ln\mathcal{A}_t = kt$$

So,
$$\ln\mathcal{A}_t = -kt + \ln\mathcal{A}_0 = -(0.024\text{ yr}^{-1}\times 59\text{ yr}) + \ln(1.2\times10^{12}\text{ d/s})$$
$$\ln\mathcal{A}_t = -1.4 + 27.81 = 26.4$$
$$\mathcal{A}_t = 2.9\times10^{11}\text{ d/s}$$

(All the data contain two significant figures, so we retained two in the answer.) Calculating the fraction decayed:

$$\text{Fraction decayed} = \frac{\mathcal{A}_0 - \mathcal{A}_t}{\mathcal{A}_0} = \frac{1.2\times10^{12}\text{ d/s} - 2.9\times10^{11}\text{ d/s}}{1.2\times10^{12}\text{ d/s}}$$
$$= 0.76$$

Check The answer is reasonable: t is about 2 half-lives, so $\mathcal{A}_t$ should be about $\frac{1}{4}\mathcal{A}_0$, or about 0.3×10^{12}; therefore, the activity should have decreased by about $\frac{3}{4}$.

Comment **1.** A useful substitution of Equation 24.4 for finding $\mathcal{A}_t$, the activity at time t, is $\mathcal{A}_t = \mathcal{A}_0 e^{-kt}$.

2. Another way to find the fraction of activity (or nuclei) remaining uses the number of half-lives ($t/t_{1/2}$). By combining Equations 24.4 and 24.5 and substituting $(\ln 2)/t_{1/2}$ for k, we obtain

$$\ln \frac{\mathcal{N}_0}{\mathcal{N}_t} = \left(\frac{\ln 2}{t_{1/2}}\right) t = \frac{t}{t_{1/2}} \ln 2 = \ln 2^{\frac{t}{t_{1/2}}}$$

Inverting the ratio gives

$$\ln \frac{\mathcal{N}_t}{\mathcal{N}_0} = \ln \left(\frac{1}{2}\right)^{\frac{t}{t_{1/2}}}$$

Taking the antilog gives

$$\text{Fraction remaining} = \frac{\mathcal{N}_t}{\mathcal{N}_0} = \left(\frac{1}{2}\right)^{\frac{t}{t_{1/2}}} = \left(\frac{1}{2}\right)^{\frac{59}{29}} = 0.24$$

So,

$$\text{Fraction decayed} = 1.00 - 0.24 = 0.76$$

FOLLOW-UP PROBLEMS

24.5A Sodium-24 ($t_{1/2}$ = 15 h) is used to study blood circulation. If a patient is injected with an aqueous solution of ^{24}NaCl whose activity is 2.5×10^9 d/s, how much of the activity is present in the patient's body and excreted fluids after 4.0 days?

24.5B Iron-59 ($t_{1/2}$ = 44.5 days) is a β^- emitter used to monitor spleen function during disease or after trauma. If an accident victim receives a 5.6-μCi dose, what fraction of the ^{59}Fe nuclei will have decayed after 17 days?

SOME SIMILAR PROBLEMS 24.41 and 24.42

Radioisotopic Dating

The historical record fades rapidly with time and is virtually nonexistent for events of more than a few thousand years ago. Much knowledge of prehistory comes from **radioisotopic dating,** which uses unstable isotopes, or **radioisotopes,** to determine the ages of objects. This technique supplies data in fields such as art history, archeology, geology, and paleontology.

The technique of *radiocarbon dating,* for which the American chemist Willard F. Libby won the Nobel Prize in chemistry in 1960, is based on measuring the amounts of ^{14}C and ^{12}C in materials of biological origin. The accuracy of the method falls off after about six half-lives of ^{14}C ($t_{1/2}$ = 5730 yr), so it is used to date objects up to about 36,000 years old.

Here is how radiocarbon dating works:

1. High-energy cosmic rays, consisting mainly of protons, enter the atmosphere from outer space and initiate a cascade of nuclear reactions, some of which produce neutrons that bombard ordinary ^{14}N atoms to form ^{14}C:

$$^{14}_{7}\text{N} + {}^{1}_{0}\text{n} \longrightarrow {}^{14}_{6}\text{C} + {}^{1}_{1}\text{p}$$

   Through the competing processes of formation and radioactive decay, the amount of ^{14}C in the atmosphere has remained nearly constant.*
2. The ^{14}C atoms combine with O_2, diffuse throughout the lower atmosphere, and enter the total carbon pool as gaseous $^{14}CO_2$ and aqueous $H^{14}CO_3^-$. They mix with ordinary $^{12}CO_2$ and $H^{12}CO_3^-$, reaching a constant $^{12}C/^{14}C$ ratio of about $10^{12}/1$.
3. The CO_2 is taken up by plants during photosynthesis, and then taken up and excreted by animals that eat the plants. Thus, the $^{12}C/^{14}C$ ratio of a living organism is the same as the ratio in the environment.
4. When an organism dies, it no longer absorbs or releases CO_2, so the $^{12}C/^{14}C$ ratio steadily increases because *the amount of ^{14}C decreases as it decays:*

$$^{14}_{6}\text{C} \longrightarrow {}^{14}_{7}\text{N} + {}^{0}_{-1}\beta$$

   The difference between the $^{12}C/^{14}C$ ratio in a dead organism and the ratio in living organisms reflects the time elapsed since the organism died.

*Cosmic ray intensity does vary slightly with time, which affects the amount of atmospheric ^{14}C. From ^{14}C activity in ancient trees, we know the amount fell slightly about 3000 years ago to current levels. Recently, nuclear testing and fossil-fuel combustion have also altered the fraction of ^{14}C slightly. Taking these factors into account improves the accuracy of the dating method.

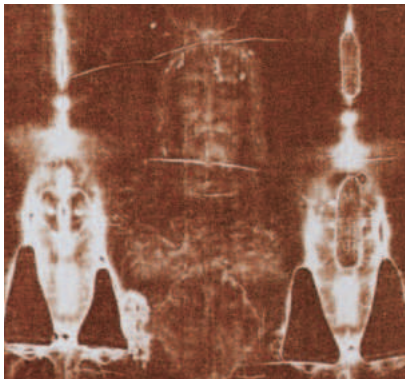
As you saw in Sample Problem 24.5, the first-order rate equation can be expressed in terms of a ratio of activities:

$$\ln \frac{\mathcal{N}_0}{\mathcal{N}_t} = \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} = kt$$

We use this expression in radiocarbon dating, where $\mathcal{A}_0$ is the activity in a living organism and $\mathcal{A}_t$ is the activity in the object whose age is unknown. Solving for t gives the age of the object:

$$t = \frac{1}{k} \ln \frac{\mathcal{A}_0}{\mathcal{A}_t} \qquad \textbf{(24.6)}$$

A useful graphical method in radioisotopic dating shows a plot of the natural logarithm of the specific activity vs. time, which gives a straight line with a slope of $-k$, the negative of the decay constant. Using such a plot and measuring the ^{14}C specific activity of an object, we can determine its age; examples appear in Figure 24.7.

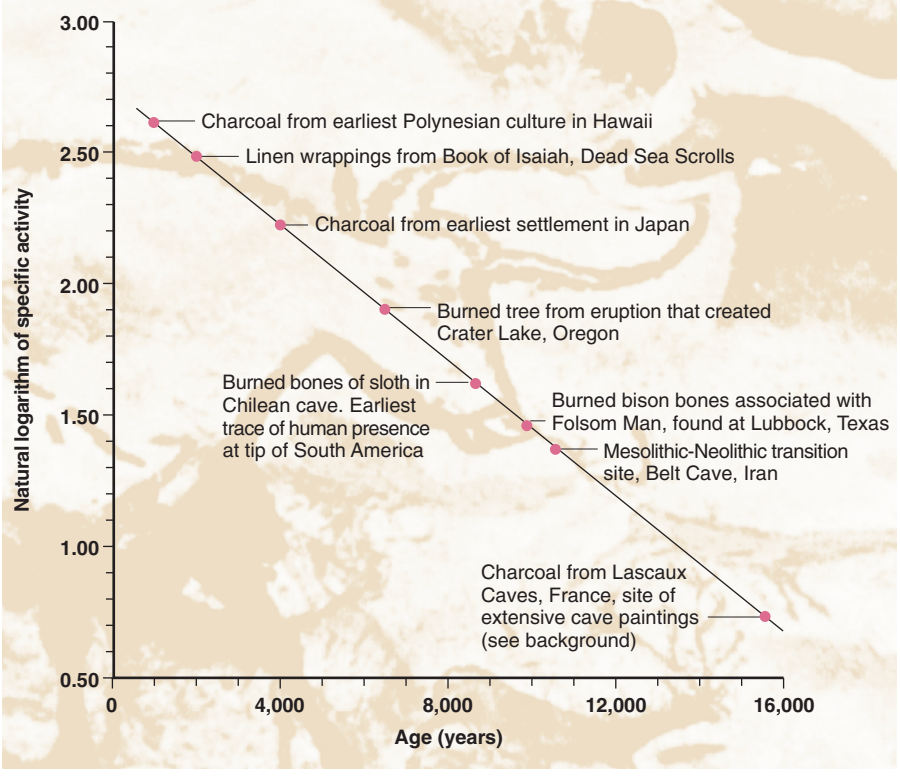


The Shroud of Turin.

One well-known example of the use of radiocarbon dating was in the determination of the age of the Shroud of Turin *(see photo)*. One of the holiest Christian relics, the shroud is a piece of linen that bears a faint image of a man's body and was thought to be the burial cloth used to wrap the body of Jesus Christ. However, three labs in Europe and the United States independently measured the $^{12}C/^{14}C$ ratio of a 50-mg piece of the linen and determined that the flax from which the cloth was made was grown between 1260 A.D. and 1390 A.D.

To determine the ages of more ancient objects or of objects that do not contain carbon, different radioisotopes are measured. For example, comparing the ratio of ^{238}U ($t_{1/2} = 4.5\times10^9$ yr) to its final decay product, ^{206}Pb, in meteorites gives 4.7 billion years for the age of the Solar System, and therefore Earth. From this and other isotope ratios, such as $^{40}K/^{40}Ar$ ($t_{1/2}$ of $^{40}K = 1.3\times10^9$ yr) and $^{87}Rb/^{87}Sr$ ($t_{1/2}$ of $^{87}Rb = 4.9\times10^{10}$ yr), Moon rocks collected by Apollo astronauts have been dated at 4.2 billion years old.

Figure 24.7 Ages of several objects determined by radiocarbon dating.



SAMPLE PROBLEM 24.6 Applying Radiocarbon Dating

Problem The charred bones of a sloth in a cave in Chile represent the earliest evidence of human presence at the southern tip of South America. A sample of the bone has a specific activity of 5.22 disintegrations per minute per gram of carbon (d/min·g). If the $^{12}C/^{14}C$ ratio for living organisms results in a specific activity of 15.3 d/min·g, how old are the bones ($t_{1/2}$ of ^{14}C = 5730 yr)?

Plan We calculate k from the given $t_{1/2}$ (5730 yr). Then we apply Equation 24.6 to find the age (t) of the bones, using the given activities of the bones ($\mathcal{A}_t$ = 5.22 d/min·g) and of a living organism ($\mathcal{A}_0$ = 15.3 d/min·g).

Solution Calculating k for ^{14}C decay:

$$k = \frac{\ln 2}{t_{1/2}} = \frac{0.693}{5730\ \text{yr}} = 1.21\times10^{-4}\ \text{yr}^{-1}$$

Calculating the age (t) of the bones:

$$t = \frac{1}{k}\ln\frac{\mathcal{A}_0}{\mathcal{A}_t} = \frac{1}{1.21\times10^{-4}\ \text{yr}^{-1}}\ln\left(\frac{15.3\ \text{d/min·g}}{5.22\ \text{d/min·g}}\right) = 8.89\times10^{3}\ \text{yr}$$

The bones are about 8890 years old.

Check The activity of the bones is between $\frac{1}{2}$ and $\frac{1}{4}$ the activity of a living organism, so the age should be between one and two half-lives (5730 to 11,460 yr).

FOLLOW-UP PROBLEMS

24.6A A sample of wood from an Egyptian mummy case has a specific activity of 9.41 d/min·g. How old is the case ($t_{1/2}$ of ^{14}C = 5730 yr)?

24.6B A fragment of a woolen tunic found in an ancient cemetery in Africa has a specific activity of 12.87 d/min·g. How old is the tunic ($t_{1/2}$ of ^{14}C = 5730 yr)?

SOME SIMILAR PROBLEMS 24.43 and 24.44

Summary of Section 24.2

- Ionization and scintillation counters measure the number of emissions from a radioactive sample.
- The decay rate (activity) of a sample is proportional to the number of radioactive nuclei. Nuclear decay is a first-order process, so half-life is constant.
- Radioisotopic methods, such as ^{14}C dating, determine the age of an object by measuring the ratio of specific isotopes in it.

24.3 NUCLEAR TRANSMUTATION: INDUCED CHANGES IN NUCLEI

The alchemists' dream of changing base metals into gold was never realized, but in the early 20th century, nuclear physicists *did* change one element into another. Research into **nuclear transmutation,** the *induced* conversion of the nucleus of one element into the nucleus of another, was closely linked to research into atomic structure and led to the discovery of the neutron and the production of artificial radioisotopes. Later, high-energy bombardment of nuclei in particle accelerators began the ongoing effort to create new nuclides and new elements, and, most recently, to understand fundamental questions of matter and energy.

Early Transmutation Experiments; Nuclear Shorthand Notation

The first recognized transmutation occurred in 1919, when Ernest Rutherford showed that α particles emitted from radium bombarded atmospheric nitrogen to form a proton and oxygen-17:

$$^{14}_{7}\text{N} + ^{4}_{2}\alpha \longrightarrow ^{1}_{1}\text{p} + ^{17}_{8}\text{O}$$

By 1926, experimenters had found that α bombardment transmuted most elements with low atomic numbers to the next higher element, with ejection of a proton.

Notation for Transmutation Reactions A shorthand notation used specifically for nuclear transmutation reactions shows the reactant (target) nucleus to the left and the product nucleus to the right of a set of parentheses, within which a comma separates the projectile particle from the ejected particle(s):

reactant nucleus (particle in, particle(s) out) product nucleus **(24.7)**

Using this notation, we write the previous reaction as ^{14}N (α,p) ^{17}O.

The Joliot-Curies in their laboratory.

The Neutron and the First Artificial Radioisotope An unexpected finding in a transmutation experiment led to *the discovery of the neutron*. When lithium, beryllium, and boron were bombarded with α particles, they emitted highly penetrating radiation that could not be deflected by a magnetic or electric field. Unlike γ radiation, these emissions were massive enough to eject protons from the substances they penetrated. In 1932, James Chadwick, a student of Rutherford, proposed that the emissions consisted of neutral particles with a mass similar to that of a proton, which he named *neutrons.* He received the Nobel Prize in physics in 1935 for his discovery.

In 1933, Irene and Frederic Joliot-Curie *(see photo),* daughter and son-in-law of Marie and Pierre Curie, created the first artificial radioisotope, phosphorus-30. When they bombarded aluminum foil with α particles, phosphorus-30 and neutrons were formed:

$$^{27}_{13}\text{Al} + ^{4}_{2}\alpha \longrightarrow ^{1}_{0}\text{n} + ^{30}_{15}\text{P} \quad \text{or} \quad ^{27}\text{Al}\ (\alpha,\text{n})\ ^{30}\text{P}$$

Since then, other techniques for producing artificial radioisotopes have been developed. In fact, the majority of the nearly 1000 known radionuclides have been produced artificially.

Particle Accelerators and the Transuranium Elements

During the 1930s and 1940s, researchers probing the nucleus bombarded elements with neutrons, α particles, protons, and **deuterons** (nuclei of the stable hydrogen isotope deuterium, ^{2}H). Neutrons are especially useful as projectiles because they have no charge and thus are not repelled as they approach a target nucleus. The other particles are all positive, so early researchers found it difficult to give them enough energy to overcome their repulsion by the target nuclei. Beginning in the 1930s, however, **particle accelerators** were invented to impart high kinetic energies to particles by placing them in an electric field, usually in combination with a magnetic field. In the simplest and earliest design, protons are introduced at one end of a tube and attracted to the other end by a potential difference.

Linear Accelerator A major advance was the *linear accelerator,* a series of separated tubes of increasing length that, through a source of alternating voltage, change their charge from positive to negative in synchrony with the movement of the particle through them (Figure 24.8).

A proton, for example, exits the first tube just when that tube becomes positive and the next tube negative. Repelled by the first tube and attracted by the second, the proton accelerates across the gap between them. The process is performed in stages to achieve high particle energies without having to apply a single high voltage. A 40-ft linear accelerator with 46 tubes, built in California after World War II, accelerated protons to speeds several million times faster than earlier accelerators.

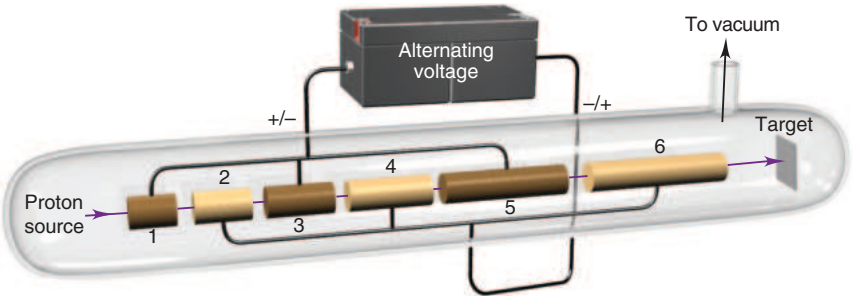


Figure 24.8 Schematic diagram of a linear accelerator.

Other Early Particle Accelerators Two early accelerators represent important design advances:

- The *cyclotron* (Figure 24.9) was invented by E. O. Lawrence in 1930. Typically 1–2 m in diameter, it applies the principle of the linear accelerator but uses electromagnets to give the particle a spiral path to save space. The magnets lie within an evacuated chamber above and below two "dees," open, D-shaped electrodes that act like the tubes in the linear design. The particle is accelerated as it passes from one dee, which is momentarily positive, to the other, which is momentarily negative. Its speed and path radius increase until it is deflected toward the target nucleus.
- The *synchrotron* uses a synchronously increasing magnetic field to make the particle's path circular rather than spiral.

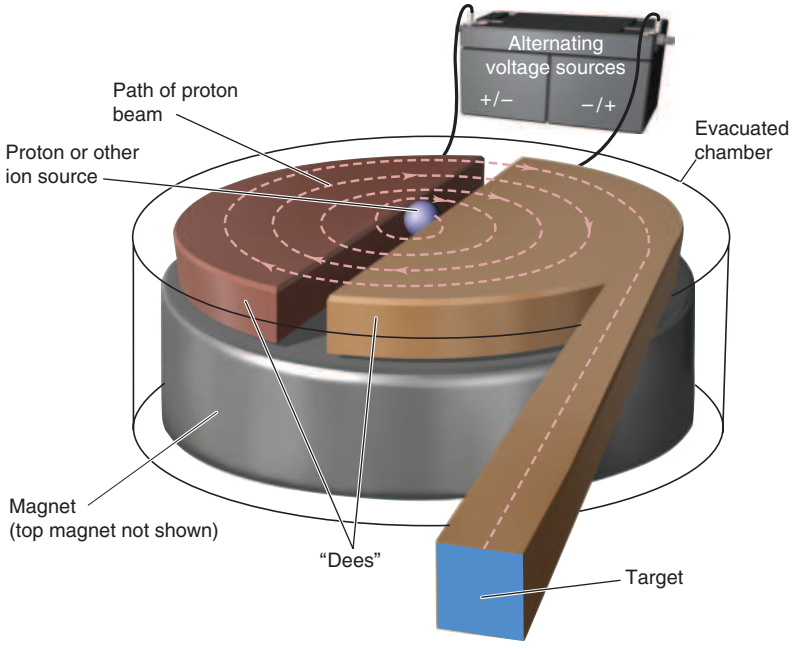

Figure 24.9 Schematic diagram of a cyclotron.

Powerful Modern Accelerators Some very powerful accelerators used to study the physics of high-energy particle collisions include both a linear section and a synchrotron section. The *tevatron* at the Fermi Lab near Chicago has a circumference of 3.9 miles and can accelerate particles to an energy slightly less than 1×10^{12} electron volts (1 TeV) before colliding them.

The world's most powerful accelerator is the Large Hadron Collider (LHC) near Geneva, Switzerland *(see photo)*. The first successful collision of protons in the LHC was achieved in early 2010. When operating at peak capacity, the LHC accelerates protons to an energy of 7 TeV as they travel around the main ring at a speed of 11,000 revolutions per second, attaining a final speed about 99.99% of the speed of light before colliding with other protons. Physicists are now studying the results of these high-energy subatomic collisions for information on the fundamental nature of matter and the early universe.

A small section of the Large Hadron Collider.

Synthesis of Transuranium Elements Scientists use accelerators for many applications, from producing radioisotopes used in medical applications to studying the fundamental nature of matter. Perhaps the most specific application for chemists is the synthesis of **transuranium elements,** those with atomic numbers higher than uranium, the heaviest naturally occurring element. Some reactions that were used to form several of these elements appear in Table 24.6. The transuranium elements include the remaining actinides (Z = 93 to 103), in which the 5*f* sublevel is filled, and the elements in the fourth transition series (Z = 104 to 112), in which the 6*d* sublevel is filled, and the remaining elements in the 7*p* sublevel (Z = 113 to 118).

Table 24.6 Formation of Some Transuranium Nuclides*

Reaction	Half-life of Product
$^{239}_{94}\text{Pu} + 2\,^{1}_{0}\text{n} \longrightarrow {}^{241}_{95}\text{Am} + {}^{0}_{-1}\beta$	432 yr
$^{239}_{94}\text{Pu} + {}^{4}_{2}\alpha \longrightarrow {}^{242}_{96}\text{Cm} + {}^{1}_{0}\text{n}$	163 days
$^{241}_{95}\text{Am} + {}^{4}_{2}\alpha \longrightarrow {}^{243}_{97}\text{Bk} + 2\,^{1}_{0}\text{n}$	4.5 h
$^{242}_{96}\text{Cm} + {}^{4}_{2}\alpha \longrightarrow {}^{245}_{98}\text{Cf} + {}^{1}_{0}\text{n}$	45 min
$^{253}_{99}\text{Es} + {}^{4}_{2}\alpha \longrightarrow {}^{256}_{101}\text{Md} + {}^{1}_{0}\text{n}$	76 min
$^{243}_{95}\text{Am} + {}^{18}_{8}\text{O} \longrightarrow {}^{256}_{103}\text{Lr} + 5\,^{1}_{0}\text{n}$	28 s

*Like chemical reactions, nuclear reactions may occur in several steps. For example, the first reaction here is actually an overall process that occurs in three steps:
(1) $^{239}_{94}\text{Pu} + {}^{1}_{0}\text{n} \longrightarrow {}^{240}_{94}\text{Pu}$ (2) $^{240}_{94}\text{Pu} + {}^{1}_{0}\text{n} \longrightarrow {}^{241}_{94}\text{Pu}$ (3) $^{241}_{94}\text{Pu} \longrightarrow {}^{241}_{95}\text{Am} + {}^{0}_{-1}\beta$

Z	Name (symbol)
104	rutherfordium (Rf)
105	dubnium (Db)
106	seaborgium (Sg)
107	bohrium (Bh)
108	hassium (Hs)
109	meitnerium (Mt)
110	darmstadtium (Ds)
111	roentgenium (Rg)
112	copernicium (Cn)
114	flerovium (Fl)
116	livermorium (Lv)

Conflicting claims of discovery by scientists in the United States and the former Soviet Union led to controversies about names for some of the more recently synthesized elements. To provide interim names until the disputes could be settled, the International Union of Pure and Applied Chemistry (IUPAC) adopted a system that uses the atomic number as the basis for a Latin name. Thus, for example, element 104 was named unnilquadium (un = 1, nil = 0, quad = 4, ium = metal suffix), with the symbol Unq. After much compromise, IUPAC has finalized these names *(see margin).* As of late 2013, elements 113, 115, 117, and 118 have not yet been named.

Summary of Section 24.3

- One nucleus can be transmuted to another through bombardment with high-energy particles.
- Accelerators increase the kinetic energy of particles in nuclear bombardment experiments and are used to produce transuranium elements and radioisotopes for medical use.

24.4 IONIZATION: EFFECTS OF NUCLEAR RADIATION ON MATTER

In 1986, an accident at the Chernobyl nuclear facility in the former Soviet Union released radioactivity that, according to the World Health Organization, will eventually cause thousands of cancer deaths. In the same year, isotopes used in medical treatment emitted radioactivity that prevented thousands of cancer deaths. In this section and Section 24.5, we examine radioactivity's harmful and beneficial effects.

The key to both of these effects is that *nuclear changes cause chemical changes in surrounding matter.* In other words, even though the nucleus of an atom may undergo a reaction with little or no involvement of the atom's electrons, the emissions from that reaction *do* affect the electrons of nearby atoms.

Virtually all radioactivity causes **ionization** in surrounding matter, as the emissions collide with atoms and dislodge electrons:

$$\text{Atom} \xrightarrow{\text{ionizing radiation}} \text{ion}^{+} + \text{e}^{-}$$

From each ionization event, a cation and a free electron result, and the number of such *cation-electron pairs* produced is directly related to the energy of the incoming **ionizing radiation.**

Many applications of ionizing radiation depend not only on the ionizing event itself, but also on secondary processes. For example, in a Geiger-Müller counter, the free electron of the cation-electron pair often collides with another atom, which ejects a second electron, and in a scintillation counter, the initial ionization eventually results in the emission of light. In nuclear power plants (Section 24.7), the initial process as well as several secondary processes cause the release of heat that makes steam to create electricity.

Effects of Ionizing Radiation on Living Tissue

Ionizing radiation has a destructive effect on living tissue, and if the ionized atom is part of a key biological macromolecule or cell membrane, the results can be devastating to the cell and perhaps the organism.

The danger from a radionuclide depends on three factors: the type of radiation, its half-life, and, most importantly, its biological behavior. For example, both ^{235}U and ^{239}Pu emit α particles and have long half-lives, but uranium is rapidly excreted by the body, whereas plutonium behaves like calcium and, thus, is incorporated into bones and teeth. One of the most dangerous radionuclides, even worse than plutonium, is $^{90}Sr^{2+}$ (formed during a nuclear explosion) because it behaves very similarly to Ca^{2+} and is absorbed rapidly by bones. Let's first see how to measure radiation dose and then look in more detail at the damaging power of ionizing radiation.

Units of Radiation Dose and Its Effects To measure the effects of ionizing radiation, we need a unit for radiation dose. Units of radioactive decay, such as the becquerel and curie, measure the number of decay events in a given time but not their energy or absorption by matter. However, the number of cation-electron pairs produced in a given amount of living tissue *is* a measure of the energy absorbed by the tissue. Two pairs of related units are used to study this absorbed energy:

1. *The gray (Gy) and the rad.* The SI unit for energy absorption by living tissue is the **gray (Gy);** it is equal to 1 joule of energy absorbed per kilogram of body tissue: 1 Gy = 1 J/kg. A more widely used unit is the **rad (*r*adiation-*a*bsorbed *d*ose),** which is one-hundredth as much:

$$1 \text{ rad} = 0.01 \text{ J/kg} = 0.01 \text{ Gy}$$

2. *The rem and the sievert (Sv).* To measure actual tissue damage, we must account for differences in the strength of the radiation, the exposure time, and the type of tissue. To do this, we multiply the number of rads by a *r*elative *b*iological *e*ffectiveness (RBE) factor, which depends on the effect a given type of radiation has on a given tissue or body part. The product is the **rem (*r*oentgen *e*quivalent for *m*an),** the unit of radiation dosage equivalent to a given amount of tissue damage in a human:

$$\text{no. of rems} = \text{no. of rads} \times \text{RBE}$$

Doses are often expressed in millirems (10^{-3} rem). The SI unit for dosage equivalent is the **sievert (Sv).** It is defined in the same way as the rem but with absorbed dose in grays; thus, 1 rem = 0.01 Sv.

Penetrating Power of Emissions The effect on living tissue of a radiation dose depends on the penetrating power *and* ionizing ability of the radiation. Since water is the main component of living tissue, penetrating power is often measured in terms of the depth of water that stops 50% of incoming radiation. In Figure 24.10, the average values of the penetrating distances are shown in actual size for the three common types of emissions. Note, in general, that *penetrating power is inversely related to the mass, charge, and energy of the emission.* In other words, if a particle interacts strongly with matter, it penetrates only slightly, and vice versa.

Figure 24.10 Penetrating power of radioactive emissions.

1. *Alpha particles.* Alpha particles are massive and highly charged, which means that they interact with matter most strongly of the three common emissions. As a result, they penetrate so little that a piece of paper, light clothing, or the outer layer of skin can stop α radiation from an external source. However, if ingested, an α emitter can cause grave localized internal damage through extensive ionization. For example, in the early 20th century, wristwatch and clock dials were painted by hand with paint containing radium so they would glow in the dark. To write numbers clearly, the women who applied the paint "tipped" fine brushes repeatedly between their lips. Small amounts of ingested $^{226}Ra^{2+}$ were incorporated into their bones along with normal Ca^{2+}, which led to numerous cases of bone fracture and jaw cancer.

2. *Beta particles and positrons.* Beta particles (β^-) and positrons (β^+) have less charge and much less mass than α particles, so they interact less strongly with matter. Even though a given particle has less chance of causing ionization, a β^- (or β^+) emitter is a more destructive external source because the particles penetrate deeper. Specialized heavy clothing or a thick (0.5 cm) piece of metal is required to stop these particles. The relative danger from α and β^- emissions is shown by two international incidents involving poisoning. In 1957, an agent was poisoned by thallium-204, a β^- emitter, but he survived because β^- particles do relatively little radiation damage. In contrast, in 2006, another agent was poisoned with polonium-210, an α emitter, and died in three weeks because of the much greater radiation damage.

3. *Gamma rays.* Neutral, massless γ rays interact least with matter and, thus, penetrate most. A block of lead several inches thick is needed to stop them. Therefore, an external γ ray source is the most dangerous because the energy can ionize many layers of living tissue.

The extent of interaction with matter is variable for emitted *neutrons,* which are neutral and massive. Outside a nucleus, neutrons decay with a half-life of 10.6 min into a proton and an electron (and an antineutrino). With energies ranging from very low to very high, they may be scattered or captured by interaction with nuclei.

Molecular Interactions How does the damage take place on the molecular level? When ionizing radiation interacts with molecules, it causes the *loss of an electron from a bond or a lone pair.* The resulting charged species go on to form **free radicals,** molecular or atomic species with one or more unpaired electrons, which, as you know, are very reactive (Section 10.1, p. 403). They form electron pairs by attacking bonds in other molecules, often forming more free radicals. Two types of materials are especially vulnerable:

1. *Water.* When γ radiation strikes living tissue, for instance, the most likely molecule to absorb it is water, yielding an electron and a water ion-radical:

$$H_2O + \gamma \longrightarrow H_2O\bullet^+ + e^-$$

The products collide with other water molecules to form more free radicals:

$$H_2O\bullet^+ + H_2O \longrightarrow H_3O^+ + \bullet OH \qquad \text{and} \qquad e^- + H_2O \longrightarrow H\bullet + OH^-$$

These free radicals attack more H_2O and surrounding biomolecules, whose bonding and structure are intimately connected with their function (Section 15.6).

2. *Membranes and macromolecules.* The double bonds in membrane lipids are highly susceptible to free-radical attack:

$$H\bullet + RCH{=}CHR' \longrightarrow RCH_2{-}\dot{C}HR'$$

In this reaction, one electron of the π bond forms a C—H bond between one of the double-bonded carbons and the H•, and the other electron resides on the other carbon to form a free radical. Changes to lipid structure cause damage that results in leakage through cell membranes and destruction of the protective fatty tissue around organs. Changes to critical bonds in enzymes lead to their malfunction as catalysts of metabolic reactions. Changes in the nucleic acids and proteins that govern the rate of cell division can cause cancer. Genetic damage and mutations may occur when bonds in the DNA of sperm and egg cells are altered by free radicals.

Background Sources of Ionizing Radiation

We are continuously exposed to ionizing radiation from natural and artificial sources (Table 24.7). Indeed, life evolved in the presence of natural ionizing radiation, called **background radiation.** Ionizing radiation can alter bonds in DNA and cause harmful mutations but also causes the beneficial ones that allow species to evolve.

Background radiation has several natural sources:

1. *Cosmic radiation* increases with altitude because of decreased absorption by the atmosphere. Thus, people in Denver absorb twice as much cosmic radiation as people in Los Angeles; even a single jet flight involves measurable absorption.

2. Thorium and uranium minerals are present in rocks and soil. Radon, the heaviest noble gas [Group 8A(18)], is a radioactive product of uranium and thorium decay. Its concentration in the air we breathe is related to the presence of trace minerals in building materials and to the uranium content of local soil and rocks (Figure 24.11). Once it enters the body, radon poses a serious potential hazard as it decays to radioactive nuclides of Po, Pb, and Bi, through α, β^-, and γ emissions. The emissions damage lung tissue, and the heavy-metal atoms formed aggravate the problem. Recent EPA estimates indicate that radon contributes to 15% of annual lung cancer deaths.

3. About 150 g of K^+ ions is dissolved in the water in the tissues of an average adult, and 0.0118% of these ions are radioactive ^{40}K. The presence of these substances and of atmospheric $^{14}CO_2$ makes *all* food, water, clothing, and building materials slightly radioactive.

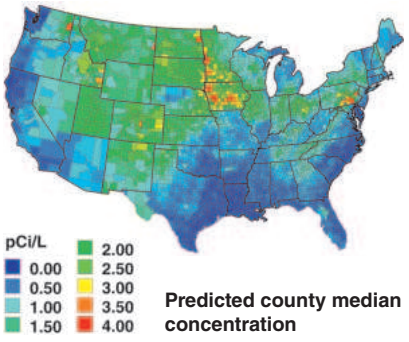

Figure 24.11 U.S. radon distribution.

Table 24.7 Typical Radiation Doses from Natural and Artificial Sources

Source of Radiation	Average Adult Exposure
Natural	
Cosmic radiation	30–50 mrem/yr
Radiation from the ground	
From clay soil and rocks	~25–170 mrem/yr
In wooden houses	10–20 mrem/yr
In brick houses	60–70 mrem/yr
In concrete (cinder block) houses	60–160 mrem/yr
Radiation from the air (mainly radon)	
Outdoors, average value	20 mrem/yr
In wooden houses	70 mrem/yr
In brick houses	130 mrem/yr
In concrete (cinder block) houses	260 mrem/yr
Internal radiation from minerals in tap water and daily intake of food (^{40}K, ^{14}C, Ra)	~40 mrem/yr
Artificial	
Diagnostic x-ray methods	
Lung (local)	0.04–0.2 rad/film
Kidney (local)	1.5–3 rad/film
Dental (dose to the skin)	≤1 rad/film
Therapeutic radiation treatment	Locally ≤ 10,000 rad
Other sources	
Jet flight (4 h)	~1 mrem
Nuclear testing	<4 mrem/yr
Nuclear power industry	<1 mrem/yr
Total average value	100–200 mrem/yr

The largest artificial source of radiation, and the one that is easiest to control, is from medical diagnostic techniques, especially x-rays. The radiation dosage from nuclear testing and radioactive waste disposal is miniscule for most people, but exposures for those living near test sites or disposal areas may be much higher.

Assessing the Risk from Ionizing Radiation

How much radiation is too much? To answer this question, we must ask several others: How strong is the exposure? How long is the exposure? Which tissue is exposed? Are children affected? One reason we lack clear data to answer these questions is that scientific ethical standards forbid the intentional exposure of humans in an experimental setting. However, accidentally exposed radiation workers and Japanese atomic bomb survivors have been studied extensively.

1. *Human studies*. Table 24.8 summarizes the immediate effects on humans of an acute single dose of ionizing radiation to the whole body. The severity of the effects increases with dose; a dose of 500 rem will kill about 50% of the exposed population within a month.

2. *Animal studies*. Most data on radiation risk come from laboratory animals, whose biological systems may differ greatly from ours. Nevertheless, studies with mice and dogs show that lesions and cancers appear after massive whole-body exposure, with rapidly dividing cells affected first. In an adult animal, these are cells of the bone marrow, organ linings, and reproductive organs, but many other tissues are affected in an immature animal or fetus.

3. *Models of risk assessment*. Studies in both animals and humans show an increase in the incidence of cancer from either a high, single exposure or a low, chronic exposure. Two current models of radiation risk are shown in Figure 24.12:

- The *linear response model* proposes that radiation effects, such as cancer risks, accumulate over time regardless of dose and that populations should not be exposed to any radiation above background levels.
- The *S-shaped response model* implies there is a threshold above which the effects are more significant: very low risk at low dose and high risk at high dose.

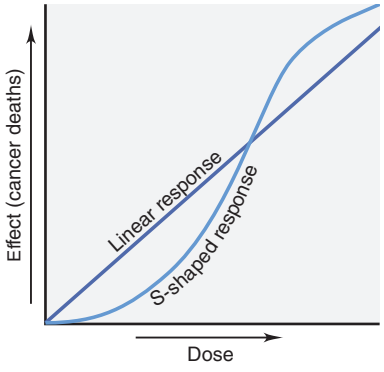

Figure 24.12 Two models of radiation risk.

Table 24.8 Acute Effects of a Single Dose of Whole-Body Irradiation

Dose (rem)	Effect	Lethal Dose	
		Population (%)	No. of Days
5–20	Possible late effect; possible chromosomal aberrations	—	—
20–100	Temporary reduction in white blood cells	—	—
50+	Temporary sterility in men (100+ rem = 1-yr duration)	—	—
100–200	"Mild radiation sickness": vomiting, diarrhea, tiredness in a few hours Reduction in infection resistance Possible bone growth retardation in children	—	—
300+	Permanent sterility in women	—	—
500	"Serious radiation sickness": marrow/intestine destruction	50–70	30
400–1000	Acute illness, early deaths	60–95	30
3000+	Acute illness, death in hours to days	100	2

4. *Hereditary effects*. Reliable data on hereditary (genetic) effects of radiation are few. Studies on fruit flies show a linear increase in genetic defects with both dose and exposure time. However, in the mouse, whose genetic system is obviously much more similar to ours than is the fruit fly's, a total dose given over a long period created one-third as many genetic defects as the same dose given over a short period. Therefore, rate of exposure is a key factor. The children of atomic bomb survivors show higher-than-normal childhood cancer rates, implying that their parents' reproductive systems were affected.

Summary of Section 24.4

- All radioactive emissions cause ionization.
- The effect of ionizing radiation on living matter depends on the quantity of energy absorbed and the extent of ionization in a given type of tissue. Radiation dose for the human body is measured in rem.
- Ionization forms free radicals, some of which proliferate and destroy biomolecular function.
- All organisms are exposed to varying quantities of natural ionizing radiation.
- Studies show that either a large acute dose or a chronic small dose is harmful.

24.5 APPLICATIONS OF RADIOISOTOPES

Radioisotopes are powerful tools for studying processes in biochemistry, medicine, materials science, environmental studies, and many other scientific and industrial fields. Such uses depend on the fact that *isotopes of an element exhibit* ***very*** *similar chemical and physical behavior.* In other words, except for having a less stable nucleus, a radioisotope has nearly the same properties as a nonradioactive isotope of the same element.* For example, the fact that $^{14}CO_2$ is utilized by a plant in the same way as $^{12}CO_2$ forms the basis of radiocarbon dating.

Radioactive Tracers

Just think how useful it could be to follow a substance through a complex process or from one region of a system to another. A tiny amount of a radioisotope mixed with a large amount of a stable isotope of the same element can act as a **tracer,** a chemical "beacon" emitting radiation that signals the presence of the substance.

Reaction Pathways Tracers are used to identify simple and complex reaction pathways.

1. *Inorganic systems*: *the periodate-iodide reaction.* One well-studied example is the reaction between periodate and iodide ions:

$$IO_4^-(aq) + 2I^-(aq) + H_2O(l) \longrightarrow I_2(s) + IO_3^-(aq) + 2OH^-(aq)$$

Is IO_3^- the result of IO_4^- reduction or I^- oxidation? When "cold" (nonradioactive) IO_4^- is added to a solution of I^- that contains some "hot" (radioactive, indicated in red) $^{131}I^-$, the I_2 is radioactive, not the IO_3^-:

$$IO_4^-(aq) + 2{}^{131}I^-(aq) + H_2O(l) \longrightarrow {}^{131}I_2(s) + IO_3^-(aq) + 2OH^-(aq)$$

These results show that IO_3^- forms through the reduction of IO_4^-, and that I_2 forms through the oxidation of I^-. To confirm this pathway, IO_4^- containing some $^{131}IO_4^-$ is added to a solution of I^-. As expected, the IO_3^- is radioactive, not the I_2:

$$^{131}IO_4^-(aq) + 2I^-(aq) + H_2O(l) \longrightarrow I_2(s) + {}^{131}IO_3^-(aq) + 2OH^-(aq)$$

Thus, tracers act like "handles" we can "hold" to follow the changing reactants.

*Although this statement is generally correct, differences in isotopic mass *can* influence bond strengths and therefore reaction rates. Such behavior is called a *kinetic isotope effect* and is particularly important for isotopes of hydrogen—^1H, ^2H, and ^3H—because their masses differ by such large proportions. Section 22.4 discussed how the kinetic isotope effect is employed in the industrial production of heavy water, D_2O.

2. *Biochemical pathways: photosynthesis.* Far more complex pathways can be followed with tracers as well. The photosynthetic pathway, in which energy from sunlight is used to form the chemical bonds of glucose, is the most essential and widespread metabolic process on Earth. It has an overall reaction that looks quite simple:

$$6CO_2(g) + 6H_2O(l) \xrightarrow[\text{chlorophyll}]{\text{light}} C_6H_{12}O_6(s) + 6O_2(g)$$

However, the actual process is extremely complex: 13 enzyme-catalyzed steps are required to incorporate each C atom from CO_2, so the six CO_2 molecules incorporated to form a molecule of $C_6H_{12}O_6$ require six repetitions of the pathway. Melvin Calvin and his coworkers took seven years to determine the pathway, using ^{14}C in CO_2 as the tracer and chromatography as the means of separating the products formed after different times of light exposure. Calvin won the Nobel Prize in chemistry in 1961 for this remarkable achievement.

Physiological Studies Tracers are used in many studies of physiological function. Some recent studies examine challenges of living in outer space. In an animal study of red blood cell loss during extended space flight, blood plasma volume was measured with ^{125}I-labeled albumin (a blood protein), and red blood cells labeled with ^{51}Cr as a trace substitute for Fe were used to assess survival of blood cells. In another study, blood flow in skin under long periods of microgravity was monitored using injected ^{133}Xe.

Material Flow Tracers are used in studies of solid surfaces and the flow of materials. Metal atoms hundreds of layers deep within a solid have been shown to exchange with metal ions from the surrounding solution within a matter of minutes. Chemists and engineers use tracers to study material movement in semiconductor chips, paint, and metal plating, in detergent action, and in the process of corrosion, to mention just a few of many applications.

Hydrologic engineers use tracers to study the volume and flow of large bodies of water. By following radionuclides that formed during atmospheric nuclear bomb tests (^3H in H_2O, $^{90}Sr^{2+}$, and $^{137}Cs^+$), scientists have mapped the flow of water from land to lakes and streams to oceans. They also use tracers to study the surface and deep ocean currents that circulate around the globe, the mechanisms of hurricane formation, and the mixing of the troposphere and stratosphere.

Various industries employ tracers to study material flow during manufacturing processes, such as the flow of ore pellets in smelting kilns, the paths of wood chips and bleach in paper mills, the diffusion of fungicide into lumber, and in a particularly important application, the porosity and leakage of oil and gas wells in geological formations.

Activation Analysis Another use of tracers is in *neutron activation analysis* (NAA). In this method, neutrons bombard a nonradioactive sample, converting a small fraction of its atoms to radioisotopes, which exhibit characteristic decay patterns, such as γ-ray spectra, that reveal the elements present. Unlike chemical analysis, NAA leaves the sample virtually intact, so the method can be used to determine the composition of a valuable object or a very small sample. For example, a painting thought to be a 16^{th}-century Dutch masterpiece was shown through NAA to be a 20^{th}-century forgery, because a microgram-sized sample of its pigment contained much less silver and antimony than the pigments used by the Dutch masters. Forensic chemists use NAA to detect traces of ammunition on a suspect's hand or traces of arsenic in the hair of a victim of poisoning.

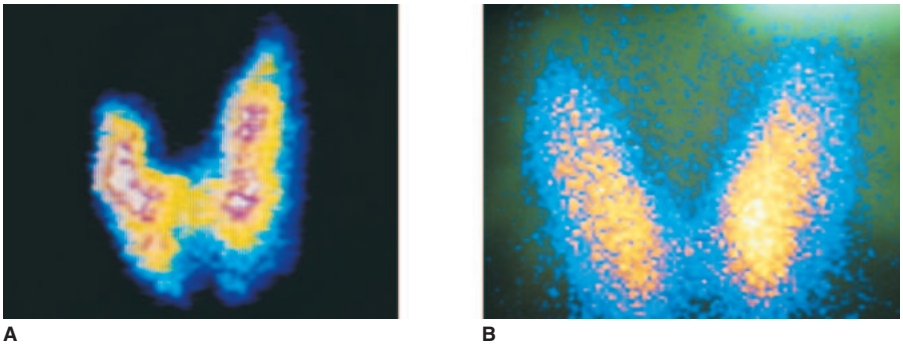
Automotive engineers employ NAA and γ-ray detectors to measure friction and wear of moving parts without having to take the engine apart. For example,

when a steel surface that has been neutron-activated to form some radioactive ^{59}Fe moves against a second steel surface, the amount of radioactivity on the second surface indicates the amount of material rubbing off. The radioactivity appearing in a lubricant placed between the surfaces can demonstrate the lubricant's ability to reduce wear.

Medical Diagnosis The largest use of radioisotopes is in medical science, as noted at the beginning of this chapter. Tracers with half-lives of a few minutes to a few days are employed to observe specific organs and body parts.

For example, a healthy thyroid gland incorporates dietary I^- into iodine-containing hormones at a known rate. To assess thyroid function, the patient drinks a solution containing a trace amount of $Na^{131}I$; the thyroid gland absorbs $^{131}I2$ ions, which undergo β^- decay, and the emissions produce an image of the gland (Figure 24.13A). Technetium-99 ($Z = 43$) is also used for imaging the thyroid (Figure 24.13B), as well as the heart, lungs, and liver. Technetium does not occur naturally, so the radioisotope (actually a metastable form, ^{99m}Tc) is prepared from radioactive molybdenum just before use:

$$^{99}_{42}Mo \longrightarrow {}^{99m}_{43}Tc + {}^{0}_{-1}\beta$$



A B

Figure 24.13 **The use of radioisotopes to image the thyroid gland. A,** This ^{131}I scan shows an asymmetric image that is indicative of disease. **B,** A ^{99}Tc scan of a healthy thyroid.

Tracers are also used to measure physiological processes, such as blood flow. The rate at which the heart pumps blood, for example, can be observed by injecting ^{59}Fe, which becomes incorporated into the hemoglobin of blood cells. Several radioisotopes used in medical diagnosis are listed in Table 24.9.

Positron-emission tomography (PET) is a powerful imaging method for observing brain structure and function. A biological substance is synthesized with one of its atoms replaced by an isotope that emits positrons. The substance is injected into a patient's bloodstream, from which it is taken up into the brain. The isotope emits positrons, each of which annihilates a nearby electron. In this process, two γ photons are emitted simultaneously 180° from each other:

$$^{0}_{1}\beta + {}^{0}_{-1}e \longrightarrow 2\,{}^{0}_{0}\gamma$$

An array of detectors around the patient's head pinpoints the sites of γ emission, and the image is analyzed by computer. Two of the isotopes used are ^{15}O, injected as $H_2{}^{15}O$ to measure blood flow, and ^{18}F bonded to a glucose analog to measure glucose uptake, which is an indicator of energy metabolism.

Among many fascinating findings revealed by PET are those that show how changes in blood flow and glucose uptake accompany normal or abnormal brain activity (Figure 24.14, *next page*). Also, substances incorporating ^{11}C and ^{15}O are being investigated using PET to learn how molecules interact with and move along the surface of a catalyst.

Table 24.9 Some Radioisotopes Used as Medical Tracers

Isotope	Body Part or Process
^{11}C, ^{18}F, ^{13}N, ^{15}O	PET studies of brain, heart
^{60}Co, ^{192}Ir	Cancer therapy
^{64}Cu	Metabolism of copper
^{59}Fe	Blood flow, spleen
^{67}Ga	Tumor imaging
^{123}I, ^{131}I	Thyroid
^{111}In	Brain, colon
^{42}K	Blood flow
^{81m}Kr	Lung
^{99m}Tc	Heart, thyroid, liver, lung, bone
^{201}Tl	Heart muscle
^{90}Y	Cancer, arthritis

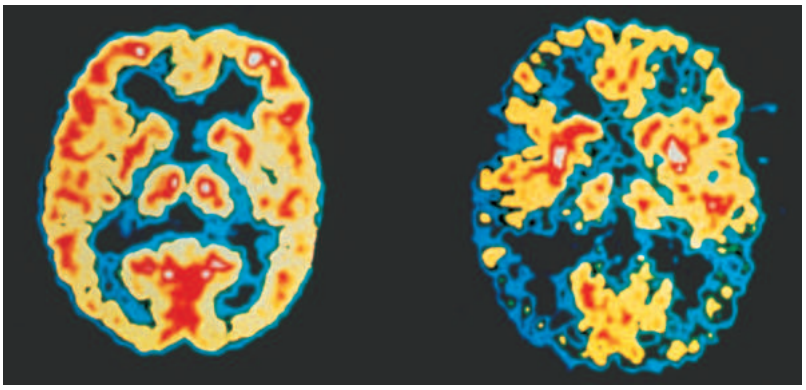


Figure 24.14 PET and brain activity. These PET scans show brain activity in a normal person *(left)* and in a patient with Alzheimer's disease *(right)*. Red and yellow indicate relatively high activity within a region.

Additional Applications of Ionizing Radiation

Many other uses of radioisotopes involve higher-energy ionizing radiation.

1. *Radiation therapy.* Cancer cells divide more rapidly than normal cells, so radioisotopes that interfere with cell division kill more cancer cells than normal ones. Implants of ^{198}Au or of ^{90}Sr, which decays to the γ-emitting ^{90}Y, have been used to destroy pituitary and breast tumor cells, and γ rays from ^{60}Co have been used to destroy tumors of the brain and other body parts.

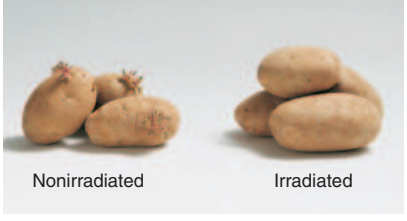

Figure 24.15 The increased shelf life of irradiated food.

2. *Destruction of microbes.* Irradiation of food increases shelf life by killing microorganisms that cause rotting or spoilage (Figure 24.15), but the practice is controversial. Advocates point to the benefits of preserving fresh foods, grains, and seeds for long periods, whereas opponents suggest that irradiation might lower the food's nutritional content or produce harmful byproducts. Irradiation also provides a way to destroy newer, more resistant bacterial strains that survive the increasing use of the more common antibiotics in animal feed. The United Nations has approved irradiation for potatoes, wheat, chicken, and strawberries, and, in 2003, the U.S. Food and Drug Administration approved it as well.

3. *Insect control.* Ionizing radiation has been used to control harmful insects. Captured males are sterilized by radiation and released to mate, thereby reducing the number of offspring. This method has been used to control the Mediterranean fruit fly in California and disease-causing insects, such as the tsetse fly and malarial mosquito, in other parts of the world.

4. *Power for spacecraft instruments.* A nonharmful use of ionizing radiation relies on its secondary processes. Most spacecraft use solar energy to provide power for instruments. In deep-space missions, when solar energy is too weak, however, a radioisotope heater unit (RHU) has been used. It consists of a $^{238}PuO_2$ fuel pellet the size of a pencil eraser that is clad within a multilayered graphite and metal shell a little smaller than a flashlight battery. The whole RHU weighs only 40 g.

Summary of Section 24.5

- Radioisotopic tracers have been used to study reaction mechanisms, material flow, elemental composition, and medical conditions.
- Ionizing radiation has been used in devices that destroy cancer tissue, kill organisms that spoil food, control insect populations, and power spacecraft instruments.

24.6 THE INTERCONVERSION OF MASS AND ENERGY

Most of the nuclear processes we've considered so far have involved radioactive decay, in which a nucleus emits one or a few small particles or photons to become a more stable and, usually, slightly lighter nucleus. Two other nuclear processes cause much greater mass changes. In nuclear **fission,** *a heavy nucleus splits into two much lighter nuclei*. In nuclear **fusion,** the opposite process occurs: *two lighter nuclei combine to form a heavier one*. Both fission and fusion release enormous quantities of energy. Let's look at the origins of this energy by examining the change in mass that accompanies the breakup of a nucleus into its nucleons and then determine the energy that is equivalent to this mass change.

The Mass Difference Between a Nucleus and Its Nucleons

For most of the 20th century, we knew that mass and energy are interconvertible. The separate mass and energy conservation laws are combined to state that *the total quantity of mass-energy in the universe is constant.* Therefore, when *any* reacting system releases or absorbs energy, it also loses or gains mass.

Mass Difference in Chemical Reactions The interconversion of mass and energy is not important for chemical reactions because the energy changes involved in breaking or forming chemical bonds are so small that the mass changes are negligible. For example, when 1 mol of water breaks up into its atoms, heat is absorbed and we have:

$$H_2O(g) \longrightarrow 2H(g) + O(g) \qquad \Delta H^\circ_{rxn} = 2 \times \text{BE of O—H} = 934 \text{ kJ}$$

We find the mass that is equivalent to this energy from *Einstein's equation:*

$$E = mc^2 \quad \text{or} \quad \Delta E = \Delta m c^2 \quad \text{so} \quad \Delta m = \frac{\Delta E}{c^2} \tag{24.8}$$

where Δm is the mass difference between reactants and products:

$$\Delta m = m_{\text{products}} - m_{\text{reactants}}$$

Substituting the enthalpy of reaction (in J/mol) for ΔE and the numerical value for c (2.9979×10^8 m/s), we obtain

$$\Delta m = \frac{9.34\times10^5 \text{ J/mol}}{(2.9979\times10^8 \text{ m/s})^2} = 1.04\times10^{-11} \text{ kg/mol} = 1.04\times10^{-8} \text{ g/mol}$$

(Units of kg/mol are obtained because the joule includes the kilogram: 1 J = 1 kg·m^2/s^2.) The mass of 1 mol of H_2O molecules (reactant) is about 10 ng *less* than the combined masses of 2 mol of H atoms and 1 mol of O atoms (products), a change difficult to measure with even the most advanced balance. Such minute mass changes when bonds break or form allow us to assume that, for all practical purposes, mass is conserved in *chemical* reactions.

Mass Difference in Nuclear Reactions The much larger mass change that accompanies a *nuclear* process is related to the enormous energy required to bind the nucleons together in a nucleus. In an analogy with the calculation above involving the water molecule, consider the change in mass that occurs when one ^{12}C nucleus breaks apart into its nucleons—six protons and six neutrons:

$$^{12}C \longrightarrow 6\,{}^1_1p + 6\,{}^1_0n$$

We calculate this mass difference in a special way. By combining the mass of six H *atoms* and six neutrons and then subtracting the mass of one ^{12}C *atom,* the masses of the electrons cancel: six e^- (in six ^1H atoms) cancel six e^- (in one ^{12}C

atom). The mass of one ^{1}H atom is 1.007825 amu, and the mass of one neutron is 1.008665 amu, so

$$\begin{aligned}\text{Mass of six } ^{1}\text{H atoms} &= 6 \times 1.007825 \text{ amu} = 6.046950 \text{ amu}\\ \text{Mass of six neutrons} &= 6 \times 1.008665 \text{ amu} = 6.051990 \text{ amu}\\ \text{Total mass} &= 12.098940 \text{ amu}\end{aligned}$$

The mass of the reactant, one ^{12}C atom, is 12 amu (exactly). The mass difference (Δm) we obtain is the total mass of the nucleons minus the mass of the nucleus:

$$\begin{aligned}\Delta m &= 12.098940 \text{ amu} - 12.000000 \text{ amu}\\ &= 0.098940 \text{ amu}/^{12}\text{C} = 0.098940 \text{ g/mol } ^{12}\text{C}\end{aligned}$$

Two key points emerge from these calculations:

- *The mass of the nucleus is* ***less*** *than the combined masses of its nucleons:* there is *always* a mass decrease when nucleons form a nucleus.
- The mass change of this nuclear process (9.89×10^{-2} g/mol $\approx$ $10.\times10^{-2}$, or 0.10 g/mol) is nearly 10 million times what we found earlier for the chemical process of breaking the bonds in water (10.4×10^{-9} g/mol) and can be measured easily on any laboratory balance.

Nuclear Binding Energy and Binding Energy per Nucleon

Einstein's equation for the relation between mass and energy allows us to find the energy equivalent of any mass change. For 1 mol of ^{12}C, after converting grams to kilograms, we have

$$\begin{aligned}\Delta E = \Delta mc^2 &= (9.8940\times10^{-5} \text{ kg/mol})(2.9979\times10^{8} \text{ m/s})^2\\ &= 8.8921\times10^{12} \text{ J/mol} = 8.8921\times10^{9} \text{ kJ/mol}\end{aligned}$$

This quantity of energy is called the **nuclear binding energy** for carbon-12, and the positive value means *energy is absorbed. The nuclear binding energy is the energy required to break 1 mol of nuclei into individual nucleons:*

$$\text{Nucleus} + \text{nuclear binding energy} \longrightarrow \text{nucleons}$$

Thus, the nuclear binding energy is *qualitatively* analogous to the sum of bond energies of a covalent compound or the lattice energy of an ionic compound. But, *quantitatively*, nuclear binding energies are typically several million times greater.

The Electron Volt as the Unit of Binding Energy We use joules to express the binding energy per mole of nuclei, but the joule is much too large a unit to express the binding energy of a single nucleus. Instead, nuclear scientists use the **electron volt (eV),** the energy an electron acquires when it moves through a potential difference of 1 volt:

$$1 \text{ eV} = 1.602\times10^{-19} \text{ J}$$

Binding energies are commonly expressed in millions of electron volts, that is, in *mega–electron volts* (MeV):

$$1 \text{ MeV} = 10^{6} \text{ eV} = 1.602\times10^{-13} \text{ J}$$

A particularly useful factor converts the atomic mass unit to its energy equivalent in electron volts:

$$1 \text{ amu} = 931.5\times10^{6} \text{ eV} = 931.5 \text{ MeV} \qquad \textbf{(24.9)}$$

Nuclear Stability and Binding Energy per Nucleon Earlier we found the mass change when ^{12}C breaks apart into its nucleons to be 0.098940 amu. The binding energy per ^{12}C nucleus, expressed in MeV, is

$$\frac{\text{Binding energy}}{^{12}\text{C nucleus}} = 0.098940 \text{ amu} \times \frac{931.5 \text{ MeV}}{1 \text{ amu}} = 92.16 \text{ MeV}$$

We can compare the stability of nuclides of different elements by determining the *binding energy per nucleon.* For ^{12}C, we have

$$\text{Binding energy per nucleon} = \frac{\text{binding energy}}{\text{no. of nucleons}} = \frac{92.16 \text{ MeV}}{12 \text{ nucleons}} = 7.680 \text{ MeV/nucleon}$$

SAMPLE PROBLEM 24.7 Calculating the Binding Energy per Nucleon

Problem Iron-56 is an extremely stable nuclide. Compute the binding energy per nucleon for ^{56}Fe and compare it with that for ^{12}C (mass of ^{56}Fe atom = 55.934939 amu; mass of ^{1}H atom = 1.007825 amu; mass of neutron = 1.008665 amu).

Plan Iron-56 has 26 protons and 30 neutrons. We calculate the mass difference, Δm, when the nucleus forms by subtracting the given mass of one ^{56}Fe atom from the sum of the masses of 26 ^{1}H atoms and 30 neutrons. To find the binding energy per nucleon, we multiply Δm by the equivalent in MeV (931.5 MeV/amu) and divide by the number of nucleons (56).

Solution Calculating the mass difference, Δm:

$$\begin{aligned}\text{Mass difference} &= [(26 \times \text{mass } ^{1}\text{H atom}) + (30 \times \text{mass neutron})] - \text{mass } ^{56}\text{Fe atom} \\ &= [(26)(1.007825 \text{ amu}) + (30)(1.008665 \text{ amu})] - 55.934939 \text{ amu} \\ &= 0.52846 \text{ amu}\end{aligned}$$

Calculating the binding energy per nucleon:

$$\text{Binding energy per nucleon} = \frac{0.52846 \text{ amu} \times 931.5 \text{ MeV/amu}}{56 \text{ nucleons}} = 8.790 \text{ MeV/nucleon}$$

An ^{56}Fe nucleus would require more energy per nucleon to break up into its nucleons than would ^{12}C (7.680 MeV/nucleon), so ^{56}Fe is more stable than ^{12}C.

Check The answer is consistent with the great stability of ^{56}Fe. Given the number of decimal places in the values, rounding to check the math is useful only to find a *major* error. The number of nucleons (56) is exact, so we retain four significant figures.

FOLLOW-UP PROBLEMS

24.7A Enormous amounts of nickel and iron make up Earth's core, and nickel-58 is a very stable nuclide. Find the binding energy per nucleon of ^{58}Ni and compare it with the value for ^{56}Fe from the sample problem (mass of ^{58}Ni atom = 57.935346 amu).

24.7B Uranium-235 is an essential component of the fuel in nuclear power plants. Calculate the binding energy per nucleon for ^{235}U (mass of ^{235}U atom = 235.043924 amu). Is this nuclide more or less stable than ^{12}C (see value in sample problem)?

SOME SIMILAR PROBLEMS 24.79–24.82

Fission or Fusion: Increasing the Binding Energy per Nucleon Calculations similar to those in Sample Problem 24.7 for other nuclides show that the binding energy per nucleon varies considerably. The essential point is that *the greater the binding energy per nucleon, the more stable the nuclide is.*

Figure 24.16 shows a plot of the binding energy per nucleon vs. mass number. It provides information about nuclide stability and the two possible processes—fission and fusion—nuclides undergo to form more stable nuclides. Most nuclides with fewer

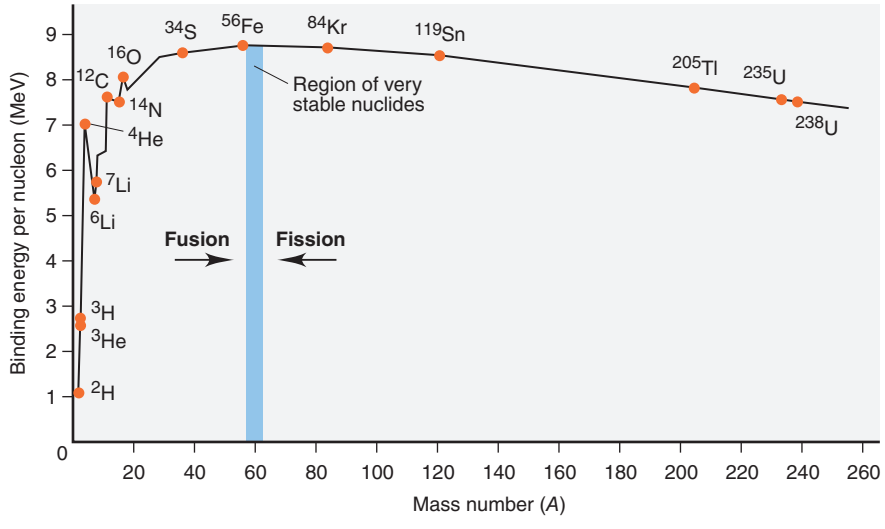

Figure 24.16 The variation in binding energy per nucleon.

than 10 nucleons have a relatively small binding energy per nucleon. The ^{4}He nucleus is an exception—it is stable enough to be emitted intact as an α particle. Above $A = 12$, the binding energy per nucleon varies from about 7.6 to 8.8 MeV.

The most important observation is that *the binding energy per nucleon peaks at elements with $A \approx 60$.* In other words, nuclides become more stable with increasing mass number up to around 60 nucleons and then become less stable with higher numbers of nucleons. The existence of a peak of stability suggests that there are two ways nuclides can increase their binding energy per nucleon:

- *Fission.* A heavier nucleus can *split into lighter nuclei (closer to $A \approx 60$)* by undergoing fission. The product nuclei have greater binding energy per nucleon (are more stable) than the reactant nucleus, and the difference in *energy is released.* Nuclear power plants generate energy through fission, as do atomic bombs (Section 24.7).
- *Fusion.* Lighter nuclei, on the other hand, can *combine to form a heavier nucleus (closer to $A \approx 60$)* by undergoing fusion. Once again, the product is more stable than the reactants, and *energy is released.* The Sun and other stars generate energy through fusion, as do thermonuclear (hydrogen) bombs. In these examples and in all current research efforts for developing fusion as a useful energy source, hydrogen nuclei fuse to form the very stable helium-4 nucleus.

In Section 24.7, we examine fission and fusion and their applications.

Summary of Section 24.6

- The mass of a nucleus is less than the sum of the masses of its nucleons. The energy equivalent to this mass difference is the nuclear binding energy, often expressed in units of MeV.
- The binding energy per nucleon is a measure of nuclide stability and varies with the number of nucleons. Nuclides with $A \approx 60$ are most stable.
- Lighter nuclides join (fusion) or heavier nuclides split (fission) to create more stable products.

24.7 APPLICATIONS OF FISSION AND FUSION

Of the many beneficial applications of nuclear reactions, the greatest is the potential for abundant quantities of energy, which is based on the multimillion-fold increase in energy yield of nuclear reactions over chemical reactions. Our experience with nuclear energy from power plants in the last quarter of the 20th century, however, has shown that we must improve ways to tap this energy source safely and economically and deal with the waste generated. In this section, we discuss how fission and fusion occur and how we are applying them.

The Process of Nuclear Fission

During the mid-1930s, Enrico Fermi and coworkers bombarded uranium ($Z = 92$) with neutrons in an attempt to synthesize transuranium elements. Many of the unstable nuclides produced were tentatively identified as having $Z > 92$, but other scientists were skeptical. Four years later, the German chemist Otto Hahn and his associate F. Strassmann showed that one of these unstable nuclides was an isotope of barium ($Z = 56$). The Austrian physicist Lise Meitner, a coworker of Hahn, and her nephew Otto Frisch proposed that barium resulted from the *splitting* of the uranium nucleus into *smaller* nuclei, a process that they called *fission* as an analogy to cell division in biology. Element 109 was named *meitnerium* in honor of this extraordinary physicist who proposed the correct explanation of nuclear fission and discovered the element protactinium (Pa; $Z = 91$) as well as numerous radioisotopes.

The ^{235}U nucleus can split in many different ways, giving rise to various daughter nuclei, but all routes have the same general features. Figure 24.17 depicts one of these fission patterns. Neutron bombardment results in a highly excited ^{236}U nucleus, which splits apart in 10^{-14} s. The products are two nuclei of unequal mass, two to

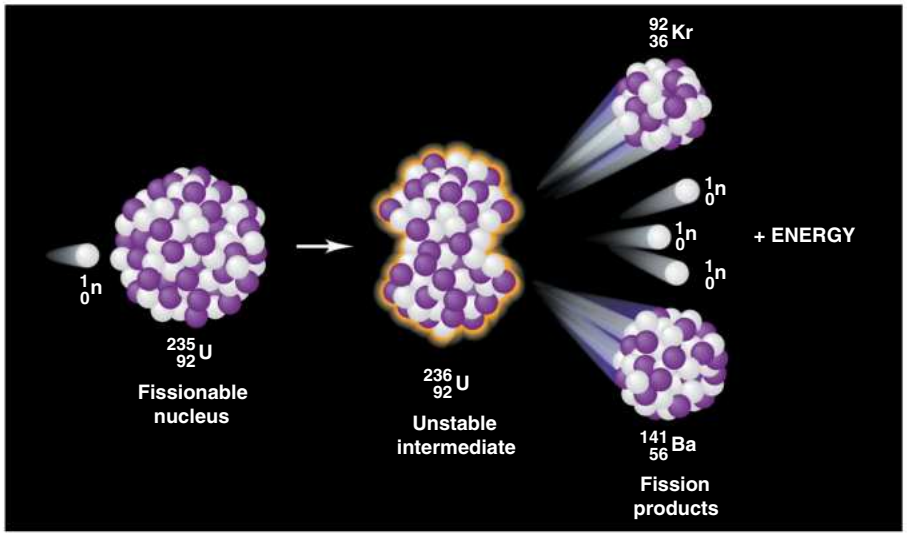

Figure 24.17 Fission of ^{235}U caused by neutron bombardment.

four neutrons (average of 2.4), and a large quantity of energy. A single ^{235}U nucleus releases 3.5×10^{-11} J when it splits; 1 mol of ^{235}U (about $\frac{1}{2}$ lb) releases 2.1×10^{13} J—a billion times as much energy as burning $\frac{1}{2}$ lb of coal (about 2×10^{4} J)!

Chain Reaction and Critical Mass We harness the energy of nuclear fission, much of which eventually appears as heat, by means of a **chain reaction** (Figure 24.18): the few neutrons that are released by the fission of one nucleus collide with other fissionable nuclei and cause them to split, releasing more neutrons, and so on, in a self-sustaining process (in Figure 24.18, vertical dashed lines separate the steps). In this manner, the energy released increases rapidly because each fission event in a chain reaction releases about two-and-a-half times as much energy as the preceding one.

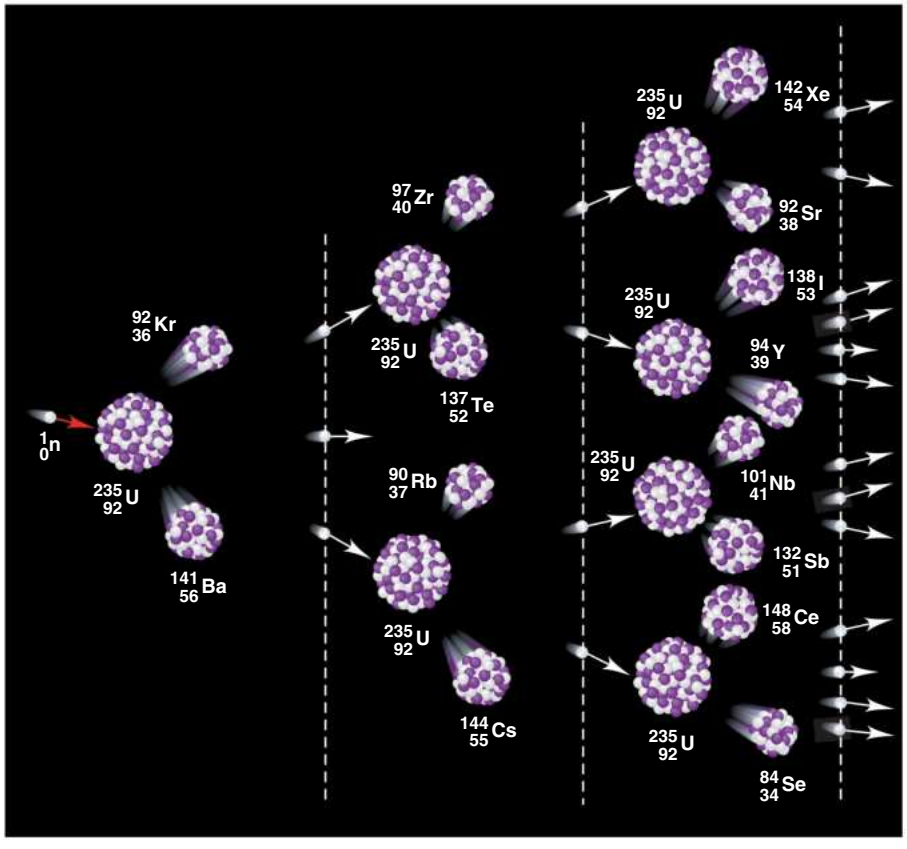

Figure 24.18 A chain reaction involving fission of ^{235}U.

Whether a chain reaction occurs depends on the mass (and thus the volume) of the fissionable sample. If the piece of uranium is large enough, the product neutrons strike another fissionable nucleus *before* flying out of the sample, and a chain reaction takes place. The mass required to achieve a chain reaction is called the **critical mass.** If the sample has less than the critical mass (a *subcritical mass*), too many product neutrons leave the sample before they collide with, and cause the fission of, another ^{235}U nucleus, and thus a chain reaction does not occur.

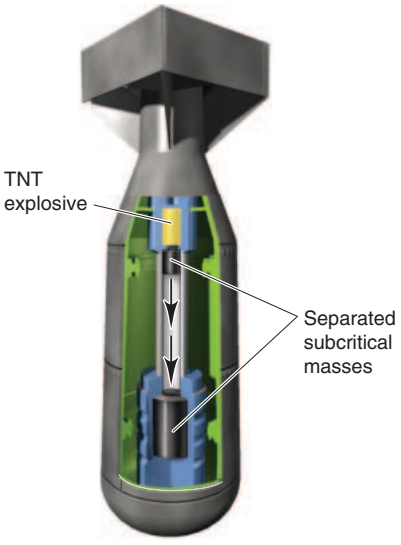

Figure 24.19 An atomic bomb based on ^{235}U.

Uncontrolled Fission: The Atomic Bomb An uncontrolled chain reaction can be adapted to make an extremely powerful explosive, as several of the world's leading atomic physicists hypothesized just prior to World War II. In August 1939, Albert Einstein wrote the president of the United States, Franklin Delano Roosevelt, to this effect, warning of the danger of allowing the Nazi government to develop this power first. It was this concern that led to the Manhattan Project, an enormous scientific effort to develop a bomb based on nuclear fission, which was initiated in 1941.* In August 1945, the United States detonated two atomic bombs over Japan, and the horrible destructive power of these bombs was a major factor in the surrender of the Japanese a few days later.

In an atomic bomb, small explosions of trinitrotoluene (TNT) bring subcritical masses of fissionable material together to exceed the critical mass, and the ensuing chain reaction brings about the explosion (Figure 24.19). The proliferation of nuclear power plants, which use fissionable materials to generate energy for electricity, has increased concern that more countries (and unscrupulous individuals) may have access to such material for making bombs. Since the devastating terrorist attacks of September 11, 2001 in the United States, this concern has been heightened.

Controlled Fission: Nuclear Energy Reactors Like a coal-fired power plant, *a nuclear power plant generates heat to produce steam, which turns a turbine attached to an electric generator*. But a nuclear plant has the potential to produce electric power much more cleanly than by the combustion of coal.

1. *Operation of a nuclear power plant.* Heat generation takes place in the **reactor core** of a nuclear plant (Figure 24.20). The core contains the *fuel rods,* which consist of fuel enclosed in tubes of a corrosion-resistant zirconium alloy. The fuel is uranium(IV) oxide (UO_2) that has been *enriched* from 0.7% ^{235}U, the natural abundance of this fissionable isotope, to the 3% to 4% ^{235}U required to sustain a chain reaction in a practical volume. (Enrichment of nuclear fuel is the most important application of Graham's law; see p. 230.) Sandwiched between the fuel rods are movable *control rods* made of cadmium or boron (or, in nuclear submarines, hafnium), substances that absorb neutrons very efficiently. When the control rods are lowered between the fuel rods, the chain reaction slows because fewer neutrons are available to bombard uranium atoms; when they are raised, the chain reaction speeds up. Neutrons that leave the fuel-rod assembly collide with a *reflector,* usually made of a beryllium alloy, which absorbs very few neutrons. Reflecting the neutrons back to the fuel rods speeds the chain reaction.

Flowing around the fuel and control rods in the reactor core is the *moderator,* a substance that slows the neutrons, making them much better at causing fission than the fast ones emerging directly from the fission event. In most modern reactors, the moderator also acts as the *coolant,* the fluid that transfers the released heat to the steam-producing region. *Light-water reactors* use H_2O as the moderator because ^{1}H absorbs neutrons to some extent; in heavy-water reactors, D_2O is used. The advantage of D_2O is that it absorbs very few neutrons, leaving more available for fission, so heavy-water reactors can use uranium that has been *less enriched*. As the coolant flows around the encased fuel, pumps circulate it through coils that transfer its heat

*For an excellent scientific and historical account of the development of the atomic bomb, see R. Rhodes, *The Making of the Atomic Bomb,* New York, Simon and Schuster, 1986.

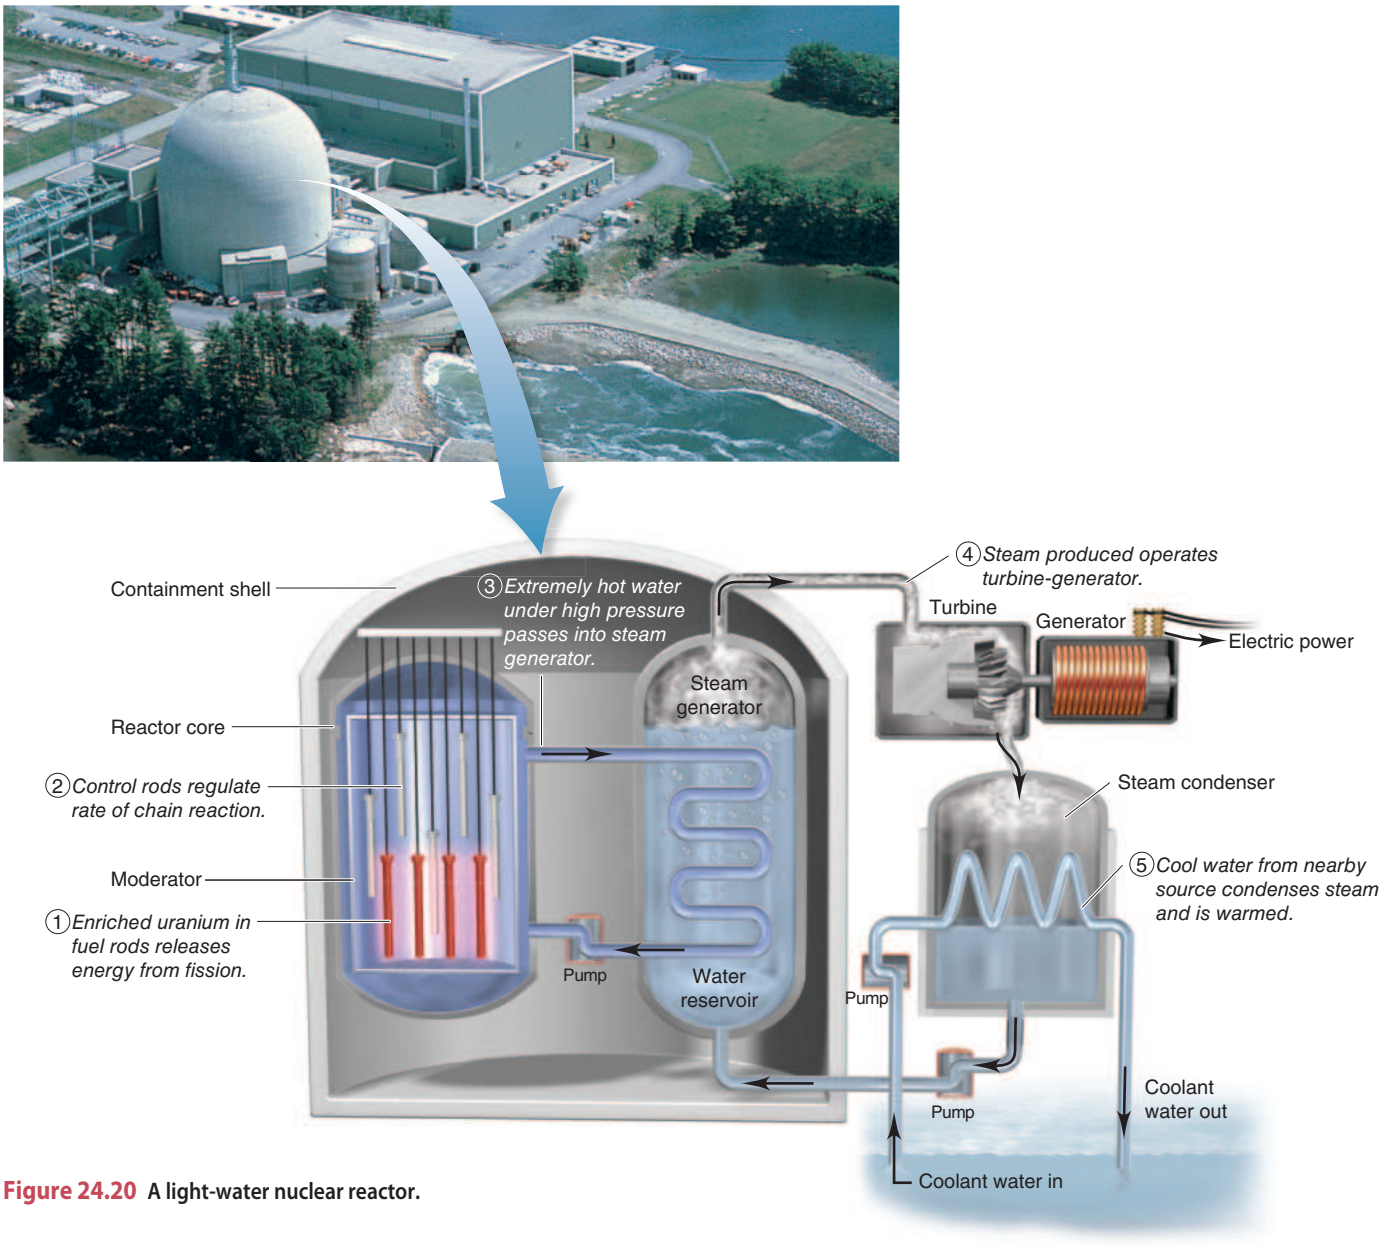

Figure 24.20 **A light-water nuclear reactor.**

to the water reservoir. Steam formed in the reservoir turns the turbine that runs the generator. The steam then enters a condenser, where water from a lake or river is used to cool it back to liquid that is returned to the water reservoir. Often (although not shown here), large cooling towers aid in this step (see Figure 13.20, p. 535).

2. *Breeder reactors.* Because ^{235}U is not an abundant isotope, the *breeder reactor* was designed to consume one type of nuclear fuel as it produces another. Outside the moderator, fuel rods are surrounded by natural U_3O_8, which contains 99.3% *nonfissionable* ^{238}U atoms. As neutrons formed during ^{235}U fission escape the fuel rod, they collide with ^{238}U, transmuting it into ^{239}Pu, another fissionable nucleus:

$$^{238}_{92}U + {}^{1}_{0}n \longrightarrow {}^{239}_{92}U \qquad (t_{1/2} \text{ of } {}^{239}_{92}U = 23.5 \text{ min})$$

$$^{239}_{92}U \longrightarrow {}^{239}_{93}Np + {}^{0}_{-1}\beta \qquad (t_{1/2} \text{ of } {}^{239}_{93}Np = 2.35 \text{ days})$$

$$^{239}_{93}Np \longrightarrow {}^{239}_{94}Pu + {}^{0}_{-1}\beta \qquad (t_{1/2} \text{ of } {}^{239}_{94}Pu = 2.4\times10^{4} \text{ yr})$$

Although breeder reactors can make fuel as they operate, they are difficult and expensive to build, and ^{239}Pu is extremely toxic and long lived. Breeder reactors are not used in the United States, although several are operating in Europe and Japan.

3. *Power plant accidents and other concerns.* Some major accidents at nuclear plants have caused decidedly negative public reactions. In 1979, malfunctions of coolant pumps and valves at the Three-Mile Island facility in Pennsylvania led to melting of some of the fuel and damage to the reactor core, but the release of only a very small amount (about 1 Ci) of radioactive gases into the atmosphere. In 1986, a million times as much radioactivity (1 MCi) was released when a cooling system failure at the Chernobyl plant in Ukraine caused a much greater melting of fuel and an uncontrolled reaction. High-pressure steam and ignited graphite moderator rods caused the reactor building to explode and expel radioactive debris. Carried by prevailing winds, the radioactive particles contaminated vegetables and milk in much of Europe. Severe health problems have resulted.* And, in 2011, an earthquake and subsequent tsunami caused vast destruction in northern Japan, affecting the Fukushima Dai-ichi nuclear facility and causing the breakdown of cooling-water pumps and the melting of three reactor cores. Large amounts of radioactive steam were released into the air, and radioactive water is still entering the sea, with serious, long-term health effects expected.

4. *Current use of nuclear power.* Despite potential safety problems, nuclear power remains an important source of electricity. In the late 1990s, nearly every European country employed nuclear power, and it is the major power source in some countries—Sweden creates 50% of its electricity this way and France almost 80%. Currently, the United States obtains about 20% of its electricity from nuclear power, and Canada slightly less. As our need for energy grows and climate change from fossil-fuel consumption worsens, safer reactors will be designed and built. However, as a result of the disaster in Japan, many countries are reevaluating their use of nuclear energy. For example, Germany has commited to closing all its nuclear power plants by 2022.

5. *Thermal pollution and waste disposal.* Even a smoothly operating nuclear power plant has certain inherent problems. The problem of *thermal pollution* is common to all power plants. Water used to condense the steam is several degrees warmer when returned to its source, which can harm aquatic organisms (Section 13.4). A more serious problem is *nuclear waste disposal.* Many of the fission products formed in nuclear reactors have long half-lives, and no satisfactory plan for their permanent disposal has yet been devised. Proposals to place the waste in containers and bury them in deep bedrock cannot possibly be field-tested for the thousands of years the material will remain harmful. Leakage of radioactive material into groundwater is a danger, and earthquakes can occur even in geologically stable regions. It remains to be seen whether we can operate fission reactors *and* dispose of the waste safely and economically.

The Promise of Nuclear Fusion

Nuclear fusion in the Sun is the ultimate source of nearly all the energy—and chemical elements—on Earth. In fact, *all the elements heavier than hydrogen were formed in fusion and decay processes within stars,* as the next Chemical Connections essay describes.

Much research is being devoted to making nuclear fusion a practical, direct source of energy on Earth. To understand the advantages of fusion, let's consider one of the most discussed fusion reactions, in which deuterium and tritium react:

$$^{2}_{1}\mathrm{H} + {}^{3}_{1}\mathrm{H} \longrightarrow {}^{4}_{2}\mathrm{He} + {}^{1}_{0}\mathrm{n}$$

*An even greater release of radioactivity (1.1 MCi), involving several radionuclides including the extremely dangerous ^{90}Sr, occurred in 1957 in Kyshtym, a town in the South Ural Mountains of Russia. As a result, radioactivity spread globally, but the accident was kept secret by the former Soviet government until 1980.

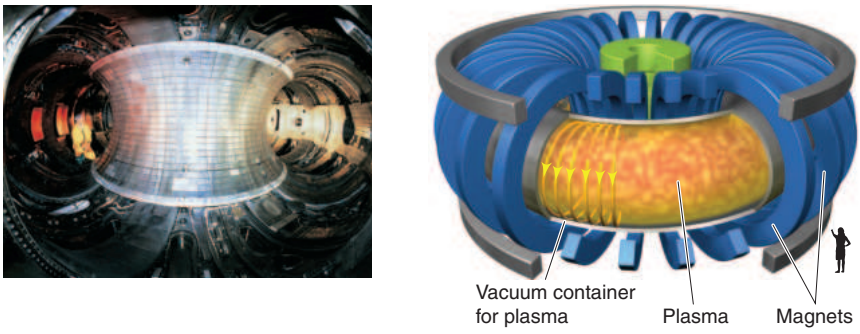

Figure 24.21 The tokamak design for magnetic containment of a fusion plasma.

This reaction produces 1.7×10^9 kJ/mol, an enormous quantity of energy with no radioactive byproducts. Moreover, the reactant nuclei are relatively easy to come by. We obtain deuterium from the electrolysis of water (Section 22.4). In nature, tritium forms through the cosmic (neutron) irradiation of ^{14}N:

$$^{14}_{7}N + {}^{1}_{0}n \longrightarrow {}^{3}_{1}H + {}^{12}_{6}C$$

However, this process results in a natural abundance of only $10^{-7}\%$ ^3H. More practically, tritium is produced in nuclear accelerators by bombarding lithium-6 or by surrounding the fusion reactor itself with material containing lithium-6:

$$^{6}_{3}Li + {}^{1}_{0}n \longrightarrow {}^{3}_{1}H + {}^{4}_{2}He$$

Thus, in principle, fusion *seems* promising and may represent an ideal source of power. However, some extremely difficult technical problems remain. Fusion requires enormous energy in the form of heat to give the positively charged nuclei enough kinetic energy to force themselves together. The fusion of deuterium and tritium, for example, occurs at practical rates at about 10^8 K, a temperature hotter than the Sun's core! How can such conditions be achieved?

Two current research approaches have promise. In one, atoms are stripped of their electrons at high temperatures, which results in a gaseous *plasma,* a neutral mixture of positive nuclei and electrons. Because of the extreme temperatures needed for fusion, no *material* can contain the plasma. The most successful approach to date has been to enclose the plasma within a magnetic field. The *tokamak* design has a donut-shaped container in which a helical magnetic field confines the plasma and prevents it from contacting the walls (Figure 24.21). Scientists at the Princeton University Plasma Physics facility have achieved some success in generating energy from fusion this way. In another approach, the high temperature is reached by using many focused lasers to compress and heat the fusion reactants. In any event, one or more major breakthroughs are needed before fusion will be a practical, everyday source of energy.

Summary of Section 24.7

- In nuclear fission, neutron bombardment causes a nucleus to split into two smaller nuclei and release neutrons that split other nuclei, giving rise to a chain reaction.
- A nuclear power plant controls the rate of the chain reaction to produce heat that creates steam, which is used to generate electricity.
- Potential hazards, such as radiation leaks, thermal pollution, and disposal of nuclear waste, remain current concerns.
- Nuclear fusion holds great promise as a source of clean abundant energy, but it requires extremely high temperatures and is not yet practical.
- The elements were formed through a complex series of nuclear reactions in evolving stars.

Origin of the Elements in the Stars

How did the universe begin? Where did matter come from? How were the elements formed? The most accepted model proposes that a sphere of unimaginable properties—diameter of 10^{-28} cm, density of 10^{96} g/mL (density of a nucleus $\approx 10^{14}$ g/mL), and temperature of 10^{32} K—exploded in a "Big Bang," for reasons not yet known, and distributed its contents through the void of space. Cosmologists consider this moment the beginning of time.

One second later, the universe was an expanding mixture of neutrons, protons, and electrons, denser than rock and hotter than an exploding hydrogen bomb (about 10^{10} K). In the next few minutes, it became a gigantic fusion reactor creating the first atomic nuclei other than ^{1}H: ^{2}H, ^{3}He, and ^{4}He. After 10 min, more than 25% of the mass of the universe existed as ^{4}He, and only about 0.025% as ^{2}H. About 100 million years later, or about 15 billion years ago, gravitational forces pulled this cosmic mixture into primitive, contracting stars.

This account of the origin of the universe is based on the observation of spectra from the Sun, other stars, nearby galaxies, and cosmic (interstellar) dust. Spectral analysis of planets and chemical analysis of Earth and Moon rocks, meteorites, and cosmic-ray particles furnish data about isotope abundance. From these, a model has been developed for **stellar nucleosynthesis,** the creation of the elements in stars. The overall process occurs in several stages during a star's evolution, and the entire sequence of steps occurs only in very massive stars, having 10 to 100 times the mass of the Sun. Each step involves a contraction of the volume of the star that results in higher temperature and yields heavier nuclei. Such events are forming elements in stars today. The key stages in the process are shown in Figure B24.1 and described below:

1. *Hydrogen burning produces He.* The initial contraction of a star heats its core to about 10^{7} K, at which point a fusion process called *hydrogen burning* begins. Through three possible reactions (one is shown below), helium nuclei are produced from the abundant protons:

$$4\,{}^{1}_{1}\mathrm{H} \longrightarrow {}^{4}_{2}\mathrm{He} + 2\,{}^{0}_{1}\beta + 2\nu + \text{energy}$$

2. *Helium burning produces C, O, Ne, and Mg.* After several billion years of hydrogen burning, about 10% of the ^{1}H is consumed, and the star contracts further. The ^{4}He forms a dense core, hot enough (2×10^{8} K) to fuse ^{4}He nuclei. The energy released during *helium burning* expands the remaining ^{1}H into

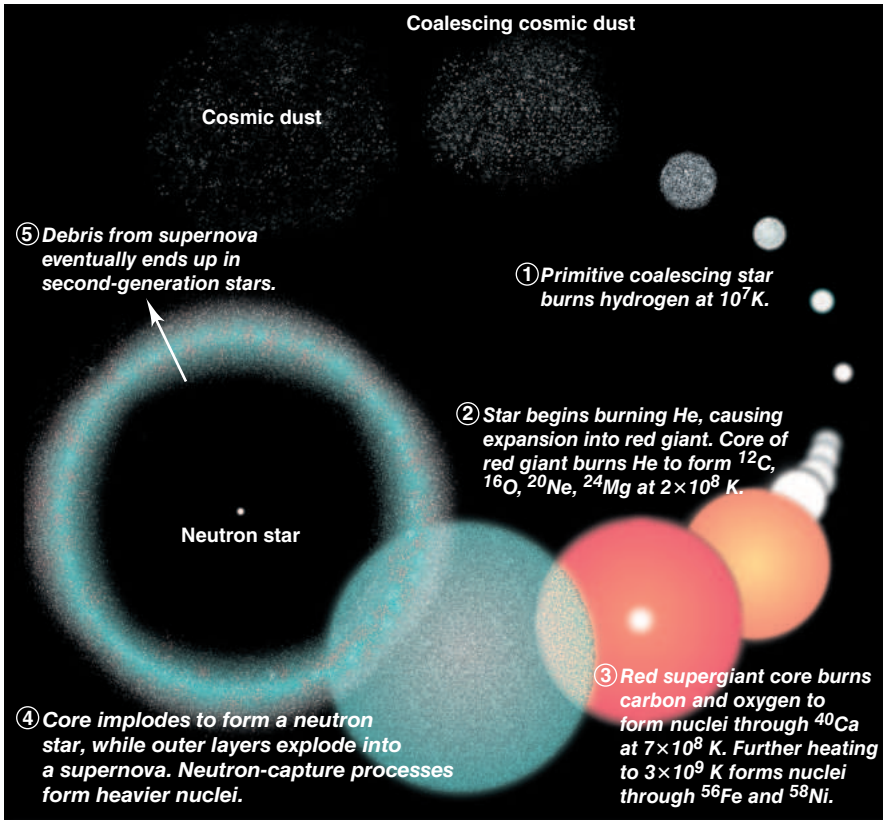

Figure B24.1 Element synthesis in the life cycle of a star.

a vast envelope: the star becomes a *red giant,* more than 100 times its original diameter. Within its core, pairs of ^{4}He nuclei (α particles) fuse into unstable ^{8}Be nuclei ($t_{1/2} = 7\times10^{-17}$ s), which play the role of an activated complex in chemical reactions. A ^{8}Be nucleus collides with another ^{4}He to form ^{12}C. Then, further fusion with ^{4}He creates nuclei up to ^{24}Mg:

$$^{12}\text{C} \xrightarrow{\alpha} {}^{16}\text{O} \xrightarrow{\alpha} {}^{20}\text{Ne} \xrightarrow{\alpha} {}^{24}\text{Mg}$$

3. *Elements through Fe and Ni form.* For another 10 million years, ^{4}He is consumed, and the heavier nuclei created form a core. This core contracts and heats, expanding the star into a *supergiant.* Within the hot core (7×10^8 K), *carbon and oxygen burning* occur:

$$^{12}\text{C} + {}^{12}\text{C} \longrightarrow {}^{23}\text{Na} + {}^{1}\text{H}$$
$$^{12}\text{C} + {}^{16}\text{O} \longrightarrow {}^{28}\text{Si} + \gamma$$

Absorption of α particles forms nuclei up to ^{40}Ca:

$$^{12}\text{C} \xrightarrow{\alpha} {}^{16}\text{O} \xrightarrow{\alpha} {}^{20}\text{Ne} \xrightarrow{\alpha} {}^{24}\text{Mg} \xrightarrow{\alpha} {}^{28}\text{Si} \xrightarrow{\alpha} {}^{32}\text{S} \xrightarrow{\alpha} {}^{36}\text{Ar} \xrightarrow{\alpha} {}^{40}\text{Ca}$$

Further contraction and heating to a temperature of 3×10^9 K allow reactions in which nuclei release neutrons, protons, and α particles and then recapture them. As a result, nuclei with lower binding energies supply nucleons to create those with higher binding energies. In stars of moderate mass, less than 10 times the mass of the Sun, this process stops at iron-56 and nickel-58, the nuclei with the highest binding energies.

4. *Heavier elements form.* In very massive stars, the next stage is the most spectacular. With all the fuel consumed, the core collapses within a second. Many Fe and Ni nuclei break down into neutrons and protons. Protons capture electrons to form neutrons, and the entire core forms an incredibly dense *neutron star.* (An Earth-sized star that became a neutron star would fit in the Houston Astrodome!) As the core implodes, the outer layers explode in a *supernova,* which expels material throughout space. A supernova occurs an average of every few hundred years in each galaxy or once every second somewhere in the universe. The heavier elements are formed during supernova events and are found in *second-generation stars,* those that coalesce from interstellar ^{1}H and ^{4}He and the debris of exploded first-generation stars.

Heavier elements form through *neutron-capture* processes. In the *s-process* (*slow* neutron-capture process), a nucleus captures a neutron, sometime over a period of 10 to 1000 years. If the resulting nucleus is unstable, it undergoes β^- decay to form the next element, as in this conversion of ^{68}Zn to ^{70}Ge:

$$^{68}\text{Zn} \xrightarrow{\text{n}} {}^{69}\text{Zn} \xrightarrow{\beta^-} {}^{69}\text{Ga} \xrightarrow{\text{n}} {}^{70}\text{Ga} \xrightarrow{\beta^-} {}^{70}\text{Ge}$$

The stable isotopes of most heavy elements up to ^{209}Bi form by the s-process.

Less stable isotopes and those with A greater than 230 cannot form by the s-process because their half-lives are too short. These form by the *r-process* (*rapid* neutron-capture process) during the fury of the supernova. Many neutron captures, followed by many β^- decays, occur in a second, as when ^{56}Fe is converted to ^{79}Br:

$$^{56}_{26}\text{Fe} + 23\,^{1}_{0}\text{n} \longrightarrow {}^{79}_{26}\text{Fe} \longrightarrow {}^{79}_{35}\text{Br} + 9\,{}^{0}_{-1}\beta$$

We know from the heavy elements present in the Sun that it is at least a second-generation star presently undergoing hydrogen burning. Together with its planets, it was formed from the dust of exploded stars about 4.6×10^9 years ago. This means that many of the atoms on Earth, including some within you, came from exploded stars and are older than the Solar System itself!

Any theory of element formation must be consistent with the element abundances we observe (Section 22.1). Although local compositions, such as those of Earth and the Sun, differ, and mineral grains in meteorites may have abnormal isotopic compositions, large regions of the universe have, on average, similar compositions. Scientists believe element forming reaches a dynamic equilibrium, resulting in *relatively constant amounts of the isotopes.*

Problems

B24.1 Compare the s- and r-processes in stellar nucleosynthesis in terms of rate, number of neutrons absorbed, and types of isotopes formed.

B24.2 The overall reaction taking place during hydrogen burning in a young star is

$$4\,^{1}_{1}\text{H} \longrightarrow {}^{4}_{2}\text{He} + 2\,^{0}_{1}\beta + 2\nu + \text{energy}$$

How much energy (in MeV) is released per He nucleus formed? Per mole of He formed? (Masses of atoms: $^1_1$H atom = 1.007825 amu; $^4_2$He atom = 4.00260 amu; mass of positron = 5.48580×10^{-4} amu.)

B24.3 Cosmologists modeling the origin of the elements postulate nuclides with very short half-lives. One of these short-lived nuclides, ^{8}Be ($t_{1/2} = 7\times10^{-17}$ s), is thought to play a key role in stellar nucleosynthesis by fusing with ^{4}He to form ^{12}C. Another model proposes the simultaneous fusion of three ^{4}He nuclei to form ^{12}C. Comment on the validity of this alternative mechanism.

B24.4 The s-process produces isotopes of elements up to ^{209}Bi. This process is terminated when ^{209}Bi captures a neutron to produce ^{210}Bi, which subsequently undergoes β^- decay to produce nuclide A, which then decays by emitting an α particle to form nuclide B. This nuclide captures three neutrons to produce nuclide C, which undergoes β^- decay to produce nuclide D, starting the cycle again. Write balanced nuclear equations for the formation of nuclides A through D.

CHAPTER REVIEW GUIDE

Learning Objectives

Relevant section (§) and/or sample problem (SP) numbers appear in parentheses.

Understand These Concepts

1. How nuclear changes differ, in general, from chemical changes (§24.1)
2. The meanings of *radioactivity, nucleon, nuclide,* and *isotope* (§24.1)
3. Characteristics of three types of radioactive emissions: α, β, and γ (§24.1)
4. The various modes of radioactive decay and how each changes the values of *A* and *Z* (§24.1)
5. How the *N*/*Z* ratio, the even-odd nature of *N* and *Z,* and magic numbers correlate with nuclear stability (§24.1)
6. How an unstable nuclide's mass number or *N*/*Z* ratio correlates with its mode of decay (§24.1)
7. How a decay series combines numerous decay steps and ends with a stable nuclide (§24.1)
8. How ionization and scintillation counters detect and measure radioactivity (§24.2)
9. Why radioactive decay is a first-order process; the meanings of *decay rate* and *specific activity* (§24.2)
10. The meaning of *half-life* in the context of radioactive decay (§24.2)
11. How the specific activity of an isotope in an object is used to determine the object's age (§24.2)
12. How particle accelerators and reactors are used to synthesize new nuclides (§24.3)
13. The units of radiation dose; the effects on living tissue of various dosage levels; the inverse relationship between the mass and charge of an emission and its penetrating power (§24.4)
14. How ionizing radiation creates free radicals that damage tissue; sources and risks of ionizing radiation (§24.4)
15. How radioisotopes are used in research, analysis, and medical diagnosis (§24.5)
16. Why the mass of a nucleus is less than the total mass of its nucleons and how this mass difference is related to the nuclear binding energy (§24.6)
17. How nuclear stability is related to binding energy per nucleon (§24.6)
18. How heavy nuclides undergo fission and lighter ones undergo fusion to increase the binding energy per nucleon (§24.6)
19. The current application of fission and potential application of fusion to produce energy (§24.7)

Master These Skills

1. Expressing the mass and charge of a particle with the ${}^{A}_{Z}\mathrm{X}$ notation (§24.1; see also §2.5)
2. Using changes in the values of *A* and *Z* to write and balance nuclear equations (SP 24.1)
3. Using the *N*/*Z* ratio, the even-odd nature of *N* and *Z*, and the presence of magic numbers to predict nuclear stability (SP 24.2)
4. Using the atomic mass of the element or the *N*/*Z* ratio to predict the mode of decay of an unstable nuclide (SP 24.3)
5. Converting units of radioactivity (§24.2)
6. Calculating specific activity, decay constant, half-life, and number of nuclei (§24.2 and SPs 24.4 and 24.5)
7. Estimating the age of an object from the specific activity and half-life of carbon-14 (SP 24.6)
8. Writing notations for nuclear transmutations (§24.3)
9. Calculating radiation dose and converting units (§24.4)
10. Calculating the mass difference between a nucleus and its nucleons and the energy equivalent (§24.6)
11. Calculating the binding energy per nucleon and using it to compare stabilities of nuclides (SP 24.7)

Key Equations and Relationships

Page numbers appear in parentheses.

24.1 Balancing a nuclear equation (1055):

$$\text{Total } {}^{A}_{Z}\text{Reactants} = \text{Total } {}^{A}_{Z}\text{Products}$$

24.2 Defining the unit of radioactivity (curie, Ci) (1064):

$$1\text{ Ci} = 3.70\times10^{10}\text{ disintegrations per second (d/s)}$$

24.3 Expressing the decay rate (activity) for radioactive nuclei (1064):

$$\text{Decay rate } (\mathcal{A}) = -\frac{\Delta\mathcal{N}}{\Delta t} = k\mathcal{N}$$

24.4 Finding the number of nuclei remaining after a given time, $\mathcal{N}_t$ (1066):

$$\ln\frac{\mathcal{N}_t}{\mathcal{N}_0} = -kt \quad \text{or} \quad \mathcal{N}_t = \mathcal{N}_0 e^{-kt}$$

24.5 Finding the half-life of a radioactive nuclide (1066):

$$t_{1/2} = \frac{\ln 2}{k}$$

24.6 Calculating the time to reach a given specific activity (age of an object in radioisotopic dating) (1068):

$$t = \frac{1}{k}\ln\frac{\mathcal{A}_0}{\mathcal{A}_t}$$

24.7 Writing a transmutation in shorthand notation (1070):

reactant nucleus (particle in, particle(s) out) product nucleus

24.8 Adapting Einstein's equation to calculate mass difference and/or nuclear binding energy (1081):

$$\Delta m = \frac{\Delta E}{c^2} \quad \text{or} \quad \Delta E = \Delta m c^2$$

24.9 Relating the atomic mass unit to its energy equivalent in MeV (1082):

$$1\text{ amu} = 931.5\times10^{6}\text{ eV} = 931.5\text{ MeV}$$

BRIEF SOLUTIONS TO FOLLOW-UP PROBLEMS

24.1A ${}^{20}_{9}\text{F} \longrightarrow {}^{20}_{10}\text{Ne} + {}^{0}_{-1}\beta$

24.1B ${}^{133}_{54}\text{Xe} \longrightarrow {}^{133}_{55}\text{Cs} + {}^{0}_{-1}\beta$

24.2A (a) Stable. Like many light nuclides (those with $Z < 20$) for which $N = Z$, this one ($Z = 5$) is stable. (b) Radioactive. This nuclide has both odd N (35) and odd Z (23) and $N/Z = 1.52$, which is too high for this region of the band of stability.

24.2B ${}^{31}\text{P}$ has an even N (16), but ${}^{30}\text{P}$ has both N and Z odd. ${}^{31}\text{P}$ also has a slightly higher N/Z ratio that is closer to the band of stability.

24.3A (a) Iron (Fe) has an atomic mass of 55.85 amu. The A value of 61 is higher: β^- decay. (b) $Z > 83$, which is too high for stability: α decay.

24.3B (a) Titanium's atomic mass is 47.87 amu, which is much higher than the A value of 40; this nuclide most likely decays by electron capture or β^+ emission. (b) Cobalt's atomic mass is 58.93 amu, which is much lower than the A value of 65; it will probably undergo β^- decay.

24.4A (a) $\text{Mass (g)} = 3.4\times10^{-8}\text{ mol } {}^{76}\text{As} \times 76\text{ g/mol}$

$$= 2.6\times10^{-8}\text{ g } {}^{76}\text{As}$$

$$\text{Specific activity (Ci/g)} = 1.53\times10^{11}\text{ d/s} \times \frac{1\text{ Ci}}{3.70\times10^{10}\text{ d/s}} \times \frac{1}{2.6\times10^{-6}\text{ g}}$$

$$= 1.6\times10^{6}\text{ Ci/g}$$

(b) $$\text{Specific activity (Bq/g)} = 1.53\times10^{11}\text{ d/s} \times \frac{1\text{ Bq}}{1\text{ d/s}} \times \frac{1}{2.6\times10^{-6}\text{ g}}$$

$$= 5.9\times10^{16}\text{ Bq/g}$$

24.4B $$k = \frac{\mathcal{A}\text{ (nuclei/h)}}{\mathcal{N}\text{ (nuclei)}} = \frac{9.97\times10^{12}\text{ nuclei/h}}{(6.50\times10^{-2}\text{ mol})(6.022\times10^{23}\text{ nuclei/mol})}$$

$$= 2.55\times10^{-10}\text{ h}^{-1}$$

24.5A $$\ln\mathcal{A}_t = -kt + \ln\mathcal{A}_0$$

$$= -\left(\frac{\ln 2}{15\text{ h}} \times 4.0\text{ days} \times \frac{24\text{ h}}{1\text{ day}}\right) + \ln(2.5\times10^{9})$$

$$= 17.20$$

$$\mathcal{A}_t = 3.0\times10^{7}\text{ d/s}$$

24.5B $$\mathcal{A}_0 = 5.6\times10^{-6}\text{ Ci} \times \frac{3.70\times10^{10}\text{ d/s}}{1\text{ Ci}} = 2.1\times10^{5}\text{ d/s}$$

$$\ln\mathcal{A}_t = -kt + \ln\mathcal{A}_0$$

$$= -\left(\frac{\ln 2}{44.5\text{ days}} \times 17\text{ days}\right) + \ln(2.1\times10^{5}\text{ d/s})$$

$$= -0.265 + 12.25\text{ d/s} = 11.99\text{ d/s}$$

$$\mathcal{A}_t = 1.6\times10^{5}\text{ d/s}$$

$$\text{Fraction decayed} = \frac{2.1\times10^{5}\text{ d/s} - 1.6\times10^{5}\text{ d/s}}{2.1\times10^{5}\text{ d/s}} = 0.23$$

24.6A $$t = \frac{1}{k}\ln\frac{\mathcal{A}_0}{\mathcal{A}_t} = \frac{5730\text{ yr}}{\ln 2}\ln\left(\frac{15.3\text{ d/min·g}}{9.41\text{ d/min·g}}\right)$$

$$= 4.02\times10^{3}\text{ yr}$$

The mummy case is about 4000 years old.

24.6B $$t = \frac{1}{k}\ln\frac{\mathcal{A}_0}{\mathcal{A}_t} = \frac{5730\text{ yr}}{\ln 2}\ln\left(\frac{15.3\text{ d/min·g}}{12.87\text{ d/min·g}}\right) = 1430\text{ yr}$$

24.7A ${}^{58}\text{Ni}$ has 28 ${}^{1}_{1}\text{p}$ and 30 ${}^{1}_{0}\text{n}$.

$$\Delta m = [(28 \times 1.007825\text{ amu}) + (30 \times 1.008665\text{ amu})] - 57.935346\text{ amu}$$

$$= 0.543704\text{ amu}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{0.543704\text{ amu} \times \frac{931.5\text{ MeV}}{1\text{ amu}}}{58\text{ nucleons}}$$

$$= 8.732\text{ MeV/nucleon}$$

Therefore, ${}^{56}\text{Fe}$ (8.790 MeV/nucleon) is slightly more stable than ${}^{58}\text{Ni}$.

24.7B ${}^{235}\text{U}$ has 92 ${}^{1}_{1}\text{p}$ and 143 ${}^{1}_{0}\text{n}$.

$$\Delta m = [(92 \times 1.007825\text{ amu}) + (143 \times 1.008665\text{ amu})] - 235.043924\text{ amu}$$

$$= 1.9151\text{ amu}$$

$$\frac{\text{Binding energy}}{\text{nucleon}} = \frac{1.9151\text{ amu} \times \frac{931.5\text{ MeV}}{1\text{ amu}}}{235\text{ nucleons}}$$

$$= 7.591\text{ MeV/nucleon}$$

Therefore, ${}^{235}\text{U}$ is less stable than ${}^{12}\text{C}$ (7.680 MeV/nucleon).

PROBLEMS

Problems with **colored** numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and give the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Radioactive Decay and Nuclear Stability

(Sample Problems 24.1 to 24.3)

Concept Review Questions

24.1 How do chemical and nuclear reactions differ in
(a) Magnitude of the energy change?
(b) Effect on rate of increasing temperature?
(c) Effect on rate of higher reactant concentration?
(d) Effect on yield of higher reactant concentration?

24.2 Sulfur has four naturally occurring stable isotopes. The one with the lowest mass number is sulfur-32, which is also the most abundant (95.02%).
(a) What percentage of the S atoms in a matchhead are ^{32}S?
(b) The isotopic mass of ^{32}S is 31.972070 amu. Is the atomic mass of S larger, smaller, or equal to this mass? Explain.

24.3 What led Marie Curie to draw the following conclusions? (a) Radioactivity is a property of the element and not the compound in which it is found. (b) A highly radioactive element, aside from uranium, occurs in pitchblende.

24.4 Which of the following processes produce an atom of a *different* element: (a) α decay; (b) β^- decay; (c) γ emission; (d) β^+ emission; (e) e^- capture? Show how Z and N change, if at all, with each process.

24.5 Why is ^3_2He stable, but ^2_2He has never been detected?

24.6 How do the modes of decay differ for a neutron-rich nuclide and a proton-rich nuclide?

24.7 Why might it be difficult to use only a nuclide's N/Z ratio to predict whether it will decay by β^+ emission or by e^- capture? What other factor is important?

Skill-Building Exercises (grouped in similar pairs)

24.8 Write balanced nuclear equations for the following:
(a) Alpha decay of $^{234}_{92}U$
(b) Electron capture by neptunium-232
(c) Positron emission by $^{12}_{7}N$

24.9 Write balanced nuclear equations for the following:
(a) β^- decay of sodium-26
(b) β^- decay of francium-223
(c) Alpha decay of $^{212}_{83}Bi$

24.10 Write balanced nuclear equations for the following:
(a) β^- emission by magnesium-27
(b) β^+ emission by $^{23}_{12}Mg$
(c) Electron capture by $^{103}_{46}Pd$

24.11 Write balanced nuclear equations for the following:
(a) β^- decay of silicon-32
(b) Alpha decay of polonium-218
(c) Electron capture by $^{110}_{49}In$

24.12 Write balanced nuclear equations for the following:
(a) Formation of $^{48}_{22}Ti$ through positron emission
(b) Formation of silver-107 through electron capture
(c) Formation of polonium-206 through α decay

24.13 Write balanced nuclear equations for the following:
(a) Formation of $^{241}_{95}Am$ through β^- decay
(b) Formation of $^{228}_{89}Ac$ through β^- decay
(c) Formation of $^{203}_{83}Bi$ through α decay

24.14 Write balanced nuclear equations for the following:
(a) Formation of ^{186}Ir through electron capture
(b) Formation of francium-221 through α decay
(c) Formation of iodine-129 through β^- decay

24.15 Write balanced nuclear equations for the following:
(a) Formation of ^{52}Mn through positron emission
(b) Formation of polonium-215 through α decay
(c) Formation of ^{81}Kr through electron capture

24.16 Which nuclide(s) would you predict to be stable? Why?
(a) $^{20}_{8}O$ (b) $^{59}_{27}Co$ (c) $^{9}_{3}Li$

24.17 Which nuclide(s) would you predict to be stable? Why?
(a) $^{146}_{60}Nd$ (b) $^{114}_{48}Cd$ (c) $^{88}_{42}Mo$

24.18 Which nuclide(s) would you predict to be stable? Why?
(a) ^{127}I (b) tin-106 (c) ^{68}As

24.19 Which nuclide(s) would you predict to be stable? Why?
(a) ^{48}K (b) ^{79}Br (c) argon-32

24.20 What is the most likely mode of decay for each?
(a) $^{238}_{92}U$ (b) $^{48}_{24}Cr$ (c) $^{50}_{25}Mn$

24.21 What is the most likely mode of decay for each?
(a) $^{111}_{47}Ag$ (b) $^{41}_{17}Cl$ (c) $^{110}_{44}Ru$

24.22 What is the most likely mode of decay for each?
(a) ^{15}C (b) ^{120}Xe (c) ^{224}Th

24.23 What is the most likely mode of decay for each?
(a) ^{106}In (b) ^{141}Eu (c) ^{241}Am

24.24 Why is $^{52}_{24}Cr$ the most stable isotope of chromium?

24.25 Why is $^{40}_{20}Ca$ the most stable isotope of calcium?

Problems in Context

24.26 ^{237}Np is the parent nuclide of a decay series that starts with α emission, followed by β^- emission, and then two more α emissions. Write a balanced nuclear equation for each step.

24.27 Why is helium found in deposits of uranium and thorium ores? What kind of radioactive emission produces it?

24.28 In a natural decay series, how many α and β^- emissions per atom of uranium-235 result in an atom of lead-207?

The Kinetics of Radioactive Decay

(Sample Problems 24.4 to 24.6)

Concept Review Questions

24.29 What electronic process is the basis for detecting radioactivity in (a) a scintillation counter; (b) a Geiger-Müller counter?

24.30 What is the reaction order of radioactive decay? Explain.

24.31 After 1 min, three radioactive nuclei remain from an original sample of six. Is it valid to conclude that $t_{1/2}$ equals 1 min? Is this conclusion valid if the original sample contained 6×10^{12} nuclei and 3×10^{12} remain after 1 min? Explain.

24.32 Radioisotopic dating depends on the constant rate of decay and formation of various nuclides in a sample. How is the proportion of ^{14}C kept relatively constant in living organisms?

Skill-Building Exercises (grouped in similar pairs)

24.33 What is the specific activity (in Ci/g) if 1.65 mg of an isotope emits 1.56×10^{6} α particles per second?

24.34 What is the specific activity (in Ci/g) if 2.6 g of an isotope emits 4.13×10^{8} β^- particles per hour?

24.35 What is the specific activity (in Bq/g) if 8.58 μg of an isotope emits 7.4×10^{4} α particles per minute?

24.36 What is the specific activity (in Bq/g) if 1.07 kg of an isotope emits 3.77×10^{7} β^- particles per minute?

24.37 If one-trillionth of the atoms of a radioactive isotope disintegrate each day, what is the decay constant of the process?

24.38 If 2.8×10^{-10}% of the atoms of a radioactive isotope disintegrate in 1.0 yr, what is the decay constant of the process?

24.39 If 1.00×10^{-12} mol of ^{135}Cs emits 1.39×10^{5} β^- particles in 1.00 yr, what is the decay constant?

24.40 If 6.40×10^{-9} mol of ^{176}W emits 1.07×10^{15} β^+ particles in 1.00 h, what is the decay constant?

24.41 The isotope $^{212}_{83}Bi$ has a half-life of 1.01 yr. What mass (in mg) of a 2.00-mg sample will remain after 3.75×10^{3} h?

24.42 The half-life of radium-226 is 1.60×10^{3} yr. How many hours will it take for a 2.50-g sample to decay to the point where 0.185 g of the isotope remains?

24.43 A rock contains 270 μmol of ^{238}U ($t_{1/2} = 4.5\times10^{9}$ yr) and 110 μmol of ^{206}Pb. Assuming that all the ^{206}Pb comes from decay of the ^{238}U, estimate the rock's age.

24.44 A fabric remnant from a burial site has a $^{14}C/^{12}C$ ratio of 0.735 of the original value. How old is the fabric?

Problems in Context

24.45 Due to decay of ^{40}K, cow's milk has a specific activity of about 6×10^{-11} mCi per milliliter. How many disintegrations of ^{40}K nuclei are there per minute in an 8.0-oz glass of milk?

24.46 Plutonium-239 ($t_{1/2} = 2.41\times10^{4}$ yr) represents a serious nuclear waste hazard. If seven half-lives are required to reach a tolerable level of radioactivity, how long must ^{239}Pu be stored?

24.47 A rock that contains 3.1×10^{-15} mol of ^{232}Th ($t_{1/2} = 1.4\times10^{10}$ yr) has 9.5×10^{4} fission tracks, each track representing the fission of one atom of ^{232}Th. How old is the rock?

24.48 A volcanic eruption melts a large chunk of rock, and all gases are expelled. After cooling, $^{40}_{18}Ar$ accumulates from the ongoing decay of $^{40}_{19}K$ in the rock ($t_{1/2} = 1.25\times10^{9}$ yr). When a piece of rock is analyzed, it is found to contain 1.38 mmol of ^{40}K and 1.14 mmol of ^{40}Ar. How long ago did the rock cool?

Nuclear Transmutation: Induced Changes in Nuclei

Concept Review Questions

24.49 Irene and Frederic Joliot-Curie converted $^{27}_{13}Al$ to $^{30}_{15}P$ in 1933. Why was this transmutation significant?

24.50 Early workers mistakenly thought neutron beams were γ radiation. Why? What evidence led to the correct conclusion?

24.51 Why must the electrical polarity of the tubes in a linear accelerator be reversed at very short time intervals?

24.52 Why does bombardment with protons usually require higher energies than bombardment with neutrons?

Skill-Building Exercises (grouped in similar pairs)

24.53 Determine the missing species in these transmutations, and write a full nuclear equation from the shorthand notation:

(a) ^{10}B (α,n) __

(b) ^{28}Si (d,__) ^{29}P (where d is a deuteron, ^{2}H)

(c) __ (α,2n) ^{244}Cf

24.54 Name the unidentified species, and write each transmutation process in shorthand notation: (a) gamma irradiation of a nuclide yields a proton, a neutron, and ^{29}Si; (b) bombardment of ^{252}Cf with ^{10}B yields five neutrons and a nuclide; (c) bombardment of ^{238}U with a particle yields three neutrons and ^{239}Pu.

Problems in Context

24.55 Elements 104, 105, and 106 have been named rutherfordium (Rf), dubnium (Db), and seaborgium (Sg), respectively. These elements are synthesized from californium-249 by bombarding with carbon-12, nitrogen-15, and oxygen-18 nuclei, respectively. Four neutrons are formed in each reaction as well. (a) Write balanced nuclear equations for the formation of these elements. (b) Write the equations in shorthand notation.

Ionization: Effects of Nuclear Radiation on Matter

Concept Review Questions

24.56 The effects on matter of γ rays and α particles differ. Explain.

24.57 What is a cation-electron pair, and how does it form?

24.58 Why is ionizing radiation more harmful to children than adults?

24.59 Why is ·OH more dangerous than OH^- in an organism?

Skill-Building Exercises (grouped in similar pairs)

24.60 A 135-lb person absorbs 3.3×10^{-7} J of energy from radioactive emissions. (a) How many rads does she receive? (b) How many grays (Gy) does she receive?

24.61 A 3.6-kg laboratory animal receives a single dose of 8.92×10^{-4} Gy. (a) How many rads did the animal receive? (b) How many joules did the animal absorb?

24.62 A 70.-kg person exposed to ^{90}Sr absorbs 6.0×10^{5} β^- particles, each with an energy of 8.74×10^{-14} J. (a) How many grays does the person receive? (b) If the RBE is 1.0, how many millirems is this? (c) What is the equivalent dose in sieverts (Sv)?

24.63 A laboratory rat weighs 265 g and absorbs 1.77×10^{10} β^- particles, each with an energy of 2.20×10^{-13} J. (a) How many rads does the animal receive? (b) What is this dose in Gy? (c) If the RBE is 0.75, what is the equivalent dose in Sv?

Problems in Context

24.64 If 2.50 pCi [1 pCi (picocurie) = 1×10^{-12} Ci] of radioactivity from ^{239}Pu is emitted in a 95-kg human for 65 h, and each disintegration has an energy of 8.25×10^{-13} J, how many grays does the person receive?

24.65 A small region of a cancer patient's brain is exposed for 24.0 min to 475 Bq of radioactivity from ^{60}Co for treatment of a tumor. If the brain mass exposed is 1.858 g and each β^- particle emitted has an energy of 5.05×10^{-14} J, what is the dose in rads?

Applications of Radioisotopes

Concept Review Questions

24.66 What two ways are radioactive tracers used in organisms?

24.67 Why is neutron activation analysis (NAA) useful to art historians and criminologists?

24.68 Positrons cannot penetrate matter more than a few atomic diameters, but positron emission of radiotracers can be monitored in medical diagnosis. Explain.

24.69 A steel part is treated to form some iron-59. Oil used to lubricate the part emits 298 β^- particles (with the energy characteristic of ^{59}Fe) per minute per milliliter of oil. What other information would you need to calculate the rate of removal of the steel from the part during use?

Problems in Context

24.70 The oxidation of methanol to formaldehyde can be accomplished by reaction with chromic acid:

$$6H^+(aq) + 3CH_3OH(aq) + 2H_2CrO_4(aq) \longrightarrow 3CH_2O(aq) + 2Cr^{3+}(aq) + 8H_2O(l)$$

The reaction can be studied with the stable isotope tracer ^{18}O and mass spectrometry. When a small amount of $CH_3{}^{18}OH$ is present in the alcohol reactant, $CH_2{}^{18}O$ forms. When a small amount of $H_2Cr^{18}O_4$ is present, $H_2{}^{18}O$ forms. Does chromic acid or methanol supply the O atom to the aldehyde? Explain.

The Interconversion of Mass and Energy

(Sample Problem 24.7)

Note: Data for problems in this section: mass of ^{1}H atom = 1.007825 amu; mass of neutron = 1.008665 amu.

Concept Review Questions

24.71 Many scientists at first reacted skeptically to Einstein's equation, $E = mc^2$. Why?

24.72 How does a change in mass arise when a nuclide forms from nucleons?

24.73 When a nucleus forms from nucleons, is energy absorbed or released? Why?

24.74 What is the binding energy per nucleon? Why is the binding energy per nucleon, rather than per nuclide, used to compare nuclide stability?

Skill-Building Exercises (grouped in similar pairs)

24.75 A ^{3}H nucleus decays with an energy of 0.01861 MeV. Convert this energy into (a) electron volts; (b) joules.

24.76 Arsenic-84 decays with an energy of 1.57×10^{-15} kJ per nucleus. Convert this energy into (a) eV; (b) MeV.

24.77 How many joules are released when 1.5 mol of ^{239}Pu decays, if each nucleus releases 5.243 MeV?

24.78 How many MeV are released per nucleus when 3.2×10^{-3} mol of chromium-49 releases 8.11×10^5 kJ?

24.79 Oxygen-16 is one of the most stable nuclides. The mass of a ^{16}O atom is 15.994915 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

24.80 Lead-206 is the end product of ^{238}U decay. One ^{206}Pb atom has a mass of 205.974440 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

24.81 Cobalt-59 is the only stable isotope of this transition metal. One ^{59}Co atom has a mass of 58.933198 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

24.82 Iodine-131 is one of the most important isotopes used in the diagnosis of thyroid cancer. One atom has a mass of 130.906114 amu. Calculate the binding energy (a) per nucleon in MeV; (b) per atom in MeV; (c) per mole in kJ.

Problems in Context

24.83 The ^{80}Br nuclide decays either by β^- decay or by electron capture. (a) What is the product of each process? (b) Which process releases more energy? (Masses of atoms: ^{80}Br = 79.918528 amu; ^{80}Kr = 79.916380 amu; ^{80}Se = 79.916520 amu; neglect the mass of electrons involved because these are atomic, not nuclear, masses.)

Applications of Fission and Fusion

Concept Review Questions

24.84 What is the minimum number of neutrons from each fission event that must be absorbed by other nuclei for a chain reaction to be sustained?

24.85 In what main way is fission different from radioactive decay? Are all fission events in a chain reaction identical? Explain.

24.86 What is the purpose of enrichment in the preparation of fuel rods? How is it accomplished?

24.87 Describe the nature and purpose of these components of a nuclear reactor: (a) control rods; (b) moderator; (c) reflector.

24.88 State an advantage and a disadvantage of heavy-water reactors compared to light-water reactors.

24.89 What are the expected advantages of fusion reactors over fission reactors?

24.90 Why is iron the most abundant element in Earth's core?

Problems in Context

24.91 The reaction that will probably power the first commercial fusion reactor is

$$^3_1H + {}^2_1H \longrightarrow {}^4_2He + {}^1_0n$$

How much energy would be produced per mole of reaction? (Masses of atoms: $^3_1$H = 3.01605 amu; $^2_1$H = 2.0140 amu; $^4_2$He = 4.00260 amu; mass of $^1_0$n = 1.008665 amu.)

Comprehensive Problems

24.92 Some $^{243}_{95}$Am was present when Earth formed, but it all decayed in the next billion years. The first three steps in this decay series are emissions of an α particle, a β^- particle, and another α particle. What other isotopes were present on the young Earth in a rock that contained some $^{243}_{95}$Am?

24.93 Curium-243 undergoes α decay to plutonium-239:

$$^{243}Cm \longrightarrow {}^{239}Pu + \alpha$$

(a) Find the change in mass, Δm (in kg). (Masses: ^{243}Cm = 243.0614 amu; ^{239}Pu = 239.0522 amu; ^{4}He = 4.0026 amu; 1 amu = 1.661×10^{-24} g.)
(b) Find the energy released in joules.

(c) Find the energy released in kJ/mol of reaction, and comment on the difference between this value and a typical heat of reaction for a chemical change, which is a few hundred kJ/mol.

24.94 Plutonium "triggers" for nuclear weapons were manufactured at the Rocky Flats plant in Colorado. An 85-kg worker inhaled a dust particle containing 1.00 μg of $^{239}_{94}Pu$, which resided in his body for 16 h ($t_{1/2}$ of $^{239}Pu = 2.41\times10^4$ yr; each disintegration released 5.15 MeV). (a) How many rads did he receive? (b) How many grays?

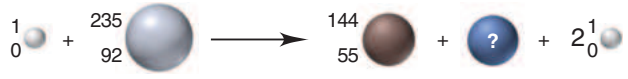
24.95 Archeologists removed some charcoal from a Native American campfire, burned it in O_2, and bubbled the CO_2 formed into $Ca(OH)_2$ solution (limewater). The $CaCO_3$ that precipitated was filtered and dried. If 4.58 g of the $CaCO_3$ had a radioactivity of 3.2 d/min, how long ago was the campfire?

24.96 A 5.4-μg sample of $^{226}RaCl_2$ has a radioactivity of 1.5×10^5 Bq. Calculate $t_{1/2}$ of ^{226}Ra.

24.97 How many rads does a 65-kg human receive each year from the approximately 10^{-8} g of $^{14}_{6}C$ naturally present in her body ($t_{1/2} = 5730$ yr; each disintegration releases 0.156 MeV)?

24.98 A sample of AgCl emits 175 nCi/g. A saturated solution prepared from the solid emits 1.25×10^{-2} Bq/mL due to radioactive Ag^+ ions. What is the molar solubility of AgCl?

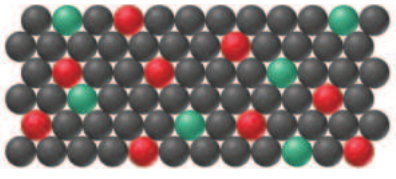
24.99 The scene below depicts a neutron bombarding ^{235}U:



(a) Is this an example of fission or of fusion? (b) Identify the other nuclide formed. (c) What is the most likely mode of decay of the nuclide with $Z = 55$?

24.100 What fraction of the ^{235}U ($t_{1/2} = 7.0\times10^8$ yr) created when Earth was formed would remain after 2.8×10^9 yr?

24.101 ^{238}U ($t_{1/2} = 4.5\times10^9$ yr) begins a decay series that ultimately forms ^{206}Pb. The scene below depicts the relative number of ^{238}U atoms *(red)* and ^{206}Pb atoms *(green)* in a mineral. If all the Pb comes from ^{238}U, calculate the age of the sample.



24.102 Technetium-99m is a metastable nuclide used in numerous cancer diagnostic and treatment programs. It is prepared just before use because it decays rapidly through γ emission:

$$^{99m}Tc \longrightarrow {}^{99}Tc + \gamma$$

Use the data below to determine (a) the half-life of ^{99m}Tc; (b) the percentage of the isotope that is lost if it takes 2.0 h to prepare and administer the dose.

Time (h)	γ Emission (photons/s)
0	5000.
4	3150.
8	2000.
12	1250.
16	788
20	495

24.103 How many curies are produced by 1.0 mol of ^{40}K ($t_{1/2} = 1.25\times10^9$ yr)? How many becquerels?

24.104 The fraction of a radioactive isotope remaining at time t is $(\frac{1}{2})^{t/t_{1/2}}$, where $t_{1/2}$ is the half-life. If the half-life of carbon-14 is 5730 yr, what fraction of carbon-14 in a piece of charcoal remains after (a) 10.0 yr; (b) 10.0×10^3 yr; (c) 10.0×10^4 yr? (d) Why is radiocarbon dating more reliable for the fraction remaining in part (b) than that in part (a) or in part (c)?

24.105 The isotopic mass of $^{210}_{86}Rn$ is 209.989669 amu. When this nuclide decays by electron capture, it emits 2.368 MeV. What is the isotopic mass of the resulting nuclide?

24.106 Exactly 0.1 of the radioactive nuclei in a sample decay per hour. Thus, after n hours, the fraction of nuclei remaining is $(0.900)^n$. Find the value of n equal to one half-life.

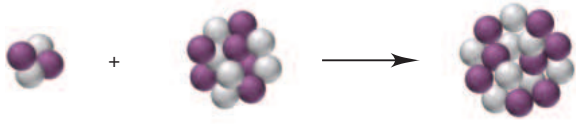
24.107 In neutron activation analysis (NAA), stable isotopes are bombarded with neutrons. Depending on the isotope and the energy of the neutron, various emissions are observed. What are the products when the following neutron-activated species decay? Write an overall equation in shorthand notation for the reaction starting with the stable isotope before neutron activation.

(a) $^{52}_{23}V^* \longrightarrow [\beta^-$ emission] (b) $^{64}_{29}Cu^* \longrightarrow [\beta^+$ emission]

(c) $^{28}_{13}Al^* \longrightarrow [\beta^-$ emission]

24.108 In the 1950s, radioactive material was spread over the land from aboveground nuclear tests. A woman drinks some contaminated milk and ingests 0.0500 g of ^{90}Sr, which is taken up by bones and teeth and not eliminated. (a) How much ^{90}Sr ($t_{1/2} = 29$ yr) is present in her body after 10 yr? (b) How long will it take for 99.9% of the ^{90}Sr that she ingested to decay?

24.109 The scene below represents a reaction (with neutrons gray and protons purple) that occurs during the lifetime of a star. (a) Write a balanced nuclear equation for the reaction. (b) If the mass difference is 7.7×10^{-2} amu, find the energy (kJ) released.



24.110 What volume of radon will be produced per hour at STP from 1.000 g of ^{226}Ra ($t_{1/2} = 1599$ yr; 1 yr = 8766 h; mass of one ^{226}Ra atom = 226.025402 amu)?

24.111 ^{90}Kr ($t_{1/2} = 32$ s) is used to study respiration. How soon after being made must a sample be administered to the patient if the activity must be at least 90% of the original activity?

24.112 Which isotope in each pair is more stable? Why?

(a) $^{140}_{55}Cs$ or $^{133}_{55}Cs$ (b) $^{79}_{35}Br$ or $^{78}_{35}Br$

(c) $^{28}_{12}Mg$ or $^{24}_{12}Mg$ (d) $^{14}_{7}N$ or $^{18}_{7}N$

24.113 A bone sample containing strontium-90 ($t_{1/2} = 29$ yr) emits 7.0×10^4 β^- particles per month. How long will it take for the emission to decrease to 1.0×10^4 particles per month?

24.114 The 23rd-century starship *Enterprise* uses a substance called "dilithium crystals" as its fuel.

(a) Assuming that this material is the result of fusion, what is the product of the fusion of two ^6Li nuclei?

(b) How much energy is released per kilogram of dilithium formed? (Mass of one ^6Li atom is 6.015121 amu.)

(c) When four ^1H atoms fuse to form ^4He, how many positrons are released?

(d) To determine the energy potential of the fusion processes in parts (b) and (c), compare the changes in mass per kilogram of dilithium and of ^{4}He.
(e) Compare the change in mass per kilogram in part (b) to that for the formation of ^{4}He by the method used in current fusion reactors (see p. 1088). (For masses, see Problem 24.91.)
(f) Using early 21st-century fusion technology, how much tritium can be produced per kilogram of ^{6}Li in the following reaction: $^6_3\text{Li} + {}^1_0\text{n} \longrightarrow {}^4_2\text{He} + {}^3_1\text{H}$? When this amount of tritium is fused with deuterium, what is the change in mass? How does this quantity compare with the use of dilithium in part (b)?

24.115 Uranium and radium are found in many rocky soils throughout the world. Both undergo radioactive decay, and one of the products is radon-222, the heaviest noble gas ($t_{1/2}$ = 3.82 days). Inhalation of this gas contributes to many lung cancers. According to Environmental Protection Agency recommendations, the level of radioactivity from radon in homes should not exceed 4.0 pCi/L of air.
(a) What is the safe level of radon in Bq/L of air?
(b) A home has a radon measurement of 41.5 pCi/L. The owner vents the basement in such a way that no more radon enters the living area. What is the activity of the radon remaining in the room air (in Bq/L) after 9.5 days?
(c) How many more days does it take to reach the EPA recommended level?

24.116 Nuclear disarmament could be accomplished if weapons were not "replenished." The tritium in warheads decays to helium with a half-life of 12.26 yr and must be replaced or the weapon is useless. What fraction of the tritium is lost in 5.50 yr?

24.117 A decay series starts with the synthetic isotope $^{239}_{92}$U. The first four steps are emissions of a β^- particle, another β^-, an α particle, and another α. Write a balanced nuclear equation for each step. Which natural series could start by this sequence?

24.118 How long can a 54-lb child be exposed to 1.0 mCi of radiation from ^{222}Rn before accumulating 1.0 mrad if the energy of each disintegration is 5.59 MeV?

24.119 An earthquake in the area of present-day San Francisco is to be dated by measuring the ^{14}C activity ($t_{1/2}$ = 5730 yr) of parts of a tree uprooted during the event. The tree parts have an activity of 12.9 d/min·g C, and a living tree has an activity of 15.3 d/min·g C. How long ago did the earthquake occur?

24.120 Were organisms a billion years ago exposed to more or less ionizing radiation than similar organisms today? Explain.

24.121 Tritium (^{3}H; $t_{1/2}$ = 12.26 yr) is continually formed in the upper troposphere by interaction of solar particles with nitrogen. As a result, natural waters contain a small amount of tritium. Two samples of wine are analyzed, one known to be made in 1941 and another made earlier. The water in the 1941 wine has 2.23 times as much tritium as the water in the other. When was the other wine produced?

24.122 Even though plutonium-239 ($t_{1/2} = 2.41\times10^4$ yr) is one of the main fission fuels, it is still a radiation hazard present in spent uranium fuel from nuclear power plants. How many years does it take for 99% of the plutonium-239 in spent fuel to decay?

24.123 Carbon from the remains of an extinct Australian marsupial, called *Diprotodon,* has a specific activity of 0.61 pCi/g. Modern carbon has a specific activity of 6.89 pCi/g. How long ago did the *Diprotodon* apparently become extinct?

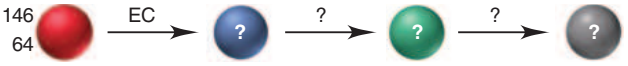
24.124 The reaction that allows for radiocarbon dating is the continual formation of carbon-14 in the upper atmosphere:

$$^{14}_7\text{N} + {}^1_0\text{n} \longrightarrow {}^{14}_6\text{C} + {}^1_1\text{H}$$

What is the energy change that is associated with this process in eV/reaction and in kJ/mol reaction? (Masses of atoms: $^{14}_7$N = 14.003074 amu; $^{14}_6$C = 14.003241 amu; $^1_1$H = 1.007825 amu; mass of $^1_0$n = 1.008665 amu.)

24.125 What is the nuclear binding energy of a lithium-7 nucleus in units of kJ/mol and eV/nucleus? (Mass of a lithium-7 atom = 7.016003 amu.)

24.126 Gadolinium-146 undergoes electron capture. Identify the product, and use Figure 24.2 to find the modes of decay and the two intermediate nuclides in the series:



24.127 Using 21st-century technology, hydrogen fusion requires temperatures around 10^8 K. But, lower initial temperatures are used if the hydrogen is compressed. In the late 24th century, the starship *Leinad* uses such methods to fuse hydrogen at 10^6 K.
(a) What is the kinetic energy of an H atom at 1.00×10^6 K?
(b) How many H atoms are heated to 1.00×10^6 K from the energy of one H and one anti-H atom annihilating each other?
(c) If the heated H atoms of part (b) fuse into ^{4}He atoms (with the loss of two positrons per ^{4}He formed), how much energy (in J) is generated?
(d) How much more energy is generated by the fusion in (c) than by the hydrogen-antihydrogen collision in (b)?
(e) Should the captain of the *Leinad* change the technology and produce ^{3}He (mass = 3.01603 amu) instead of ^{4}He?

24.128 A metastable (excited) form of ^{50}Sc changes to its stable form by emitting γ radiation with a wavelength of 8.73 pm. What is the change in mass of 1 mol of the isotope when it undergoes this change?

24.129 A sample of cobalt-60 ($t_{1/2}$ = 5.27 yr), a powerful γ emitter used to treat cancer, was purchased by a hospital on March 1, 2012. The sample must be replaced when its activity reaches 70.% of the original value. On what date must it be replaced?

24.130 Uranium-233 decays to thorium-229 by α decay, but the emissions have different energies and products: 83% emit an α particle with an energy of 4.816 MeV and give ^{229}Th in its ground state; 15% emit an α particle of 4.773 MeV and give ^{229}Th in excited state I; and 2% emit a lower energy α particle and give ^{229}Th in the higher excited state II. Excited state II emits a γ ray of 0.060 MeV to reach excited state I. (a) Find the γ-ray energy and wavelength that would convert excited state I to the ground state. (b) Find the energy of the α particle that would raise ^{233}U to excited state II.

24.131 Uranium-238 undergoes a slow decay step ($t_{1/2} = 4.5\times10^9$ yr) followed by a series of fast steps to form the stable isotope ^{206}Pb. Thus, on a time scale of billions of years, ^{238}U effectively decays "directly" to ^{206}Pb, and the relative amounts of these isotopes are used to find the age of some rocks. Two students derive equations relating number of half-lives (n) since the rock formed to the amounts of the isotopes:

Student 1: $$\left(\tfrac{1}{2}\right)^n = \frac{^{238}_{92}\text{U}}{^{206}_{82}\text{Pb}}$$

Student 2: $(\frac{1}{2})^n = \dfrac{^{238}_{92}\text{U}}{^{238}_{92}\text{U} + {}^{206}_{82}\text{Pb}}$

(a) Which equation is correct, and why?
(b) If a rock contains exactly twice as much ^{238}U as ^{206}Pb, what is its age in years?

24.132 In the naturally occurring thorium-232 decay series, the steps emit this sequence of particles: α, β^-, β^-, α, α, α, α, β^-, β^-, and α. Write a balanced equation for each step.

24.133 At death, a nobleman in ancient Egypt was mummified and his body contained 1.4×10^{-3} g of ^{40}K ($t_{1/2} = 1.25\times10^9$ yr), 1.2×10^{-8} g of ^{14}C ($t_{1/2} = 5730$ yr), and 4.8×10^{-14} g of ^{3}H ($t_{1/2} = 12.26$ yr). Which nuclide would give the most accurate estimate of the mummy's age? Explain.

24.134 Assuming that many radioactive nuclides can be considered safe after 20 half-lives, how long will it take for each of the following nuclides to be safe: (a) ^{242}Cm ($t_{1/2} = 163$ days); (b) ^{214}Po ($t_{1/2} = 1.6\times10^{-4}$ s); (c) ^{232}Th ($t_{1/2} = 1.39\times10^{10}$ yr)?

24.135 An ancient sword has a blade from the early Roman Empire, around 100 AD, but the wooden handle, inlaid wooden decorations, leather ribbon, and leather sheath have different styles. Given the following activities, estimate the age of each part. Which part was made near the time of the blade ($t_{1/2}$ of ^{14}C = 5730 yr; $\mathcal{A}_0 = 15.3$ d/min·g)?

Part	$\mathcal{A}_t$ (d/min·g)
Handle	10.1
Inlaid wood	13.8
Ribbon	12.1
Sheath	15.0

24.136 The starship *Voyager,* like many other vessels of the newly designed 24th-century fleet, uses antimatter as fuel.
(a) How much energy is released when 1.00 kg each of antimatter and matter annihilate each other?
(b) When the antimatter is atomic antihydrogen, a small amount of it is mixed with excess atomic hydrogen (gathered from interstellar space during flight). The annihilation releases so much heat that the remaining hydrogen nuclei fuse to form ^{4}He. If each hydrogen-antihydrogen collision releases enough heat to fuse 1.00×10^5 hydrogen atoms, how much energy (in kJ) is released per kilogram of antihydrogen?
(c) Which produces more energy per kilogram of antihydrogen, the procedure in part (a) or that in part (b)?

24.137 Use Einstein's equation, the mass in grams of 1 amu, and the relation between electron volts and joules to find the energy equivalent (in MeV) of a mass difference of 1 amu.

24.138 Determine the age of a rock containing 0.065 g of uranium-238 ($t_{1/2} = 4.5\times10^9$ yr) and 0.023 g of lead-206. (Assume that all the lead-206 came from ^{238}U decay.)

24.139 Plutonium-242 decays to uranium-238 by emission of an α particle with an energy of 4.853 MeV. The ^{238}U that forms is unstable and emits a γ ray (λ = 0.02757 nm). (a) Write balanced equations for these reactions. (b) What would be the energy of the α particle if ^{242}Pu decayed directly to the more stable ^{238}U?

24.140 Seaborgium-263 (Sg), the first isotope of element 106 synthesized, was produced, along with four neutrons, by bombarding californium-249 with oxygen-18. The ^{263}Sg then underwent a series of decays starting with three α emissions. Write balanced equations for the synthesis and the three α emissions of ^{263}Sg.

24.141 Some nuclear power plants use plutonium-239, which is produced in breeder reactors. The rate-determining step is the second β^- emission. How long does it take to make 1.00 kg of ^{239}Pu if the reaction is complete when the product is 90.% ^{239}Pu?

24.142 A random-number generator can be used to simulate the probability of a given atom decaying over a given time. For example, the formula "=RAND()" in an Excel spreadsheet returns a random number between 0 and 1; thus, for one radioactive atom and a time of one half-life, a number less than 0.5 means the atom decays and a number greater than 0.5 means it doesn't.
(a) Place the "=RAND()" formula in cells A1 to A10 of an Excel spreadsheet. In cell B1, place "=IF(A1<0.5, 0, 1)." This formula returns 0 if A1 is <0.5 (the atom decays) and 1 if A1 is >0.5 (the atom does not decay). Place analogous formulas in cells B2 to B10 (using the "Fill Down" procedure in Excel). To determine the number of atoms remaining after one half-life, sum cells B1 to B10 by placing "=SUM(B1:B10)" in cell B12. To create a new set of random numbers, click on an empty cell (e.g., B13) and hit "Delete." Perform 10 simulations, each time recording the total number of atoms remaining. Do half of the atoms remain after each half-life? If not, why not?
(b) Increase the number of atoms to 100 by placing suitable formulas in cells A1 to A100, B1 to B100, and B102. Perform 10 simulations, and record the number of atoms remaining each time. Are these results more realistic for radioactive decay? Explain.

24.143 In the following Excel-based simulation, the fate of 256 atoms is followed over five half-lives. Set up formulas in columns A and B, as in Problem 24.142, and simulate the fate of the sample of 256 atoms over one half-life. Cells B1 to B256 should contain 1 or 0. In cell C1, enter "=IF(B1=0, 0, RAND())." This returns 0 if the original atom decayed in the previous half-life or a random number between 0 and 1 if it did not. Fill the formula in C1 down to cell C256. Column D should have formulas similar to those in B, but with modified references, as should columns F, H, and J. Columns E, G, and I should have formulas similar to those in C, but with modified references. In cell B258, enter "=SUM(B1:B256)." This records the number of atoms remaining after the first half-life. Put formulas in cells D258, F258, H258, and J258 to record atoms remaining after subsequent half-lives.
(a) Ideally, how many atoms should remain after each half-life?
(b) Make a table of the atoms remaining after each half-life in four separate simulations. Compare these outcomes to the ideal outcome. How would you make the results more realistic?

24.144 Representations of three nuclei (with neutrons *gray* and protons *purple*) are shown below. Nucleus 1 is stable, but 2 and 3 are not. (a) Write the symbol for each isotope. (b) What is (are) the most likely mode(s) of decay for 2 and 3?

Common Mathematical Operations in Chemistry

In addition to basic arithmetic and algebra, four mathematical operations are used frequently in general chemistry: manipulating logarithms, using exponential notation, solving quadratic equations, and graphing data. Each is discussed briefly below.

MANIPULATING LOGARITHMS

Meaning and Properties of Logarithms

A *logarithm* is an exponent. Specifically, if $x^n = A$, we can say that the logarithm to the base x of the number A is n, and we can denote it as

$$\log_x A = n$$

Because logarithms are exponents, they have the following properties:

$$\log_x 1 = 0$$

$$\log_x (A \times B) = \log_x A + \log_x B$$

$$\log_x \frac{A}{B} = \log_x A - \log_x B$$

$$\log_x A^y = y \log_x A$$

Types of Logarithms

Common and natural logarithms are used in chemistry and the other sciences.

1. For *common* logarithms, the base (x in the examples above) is 10, but they are written without specifying the base; that is, $\log_{10} A$ is written more simply as $\log A$; thus, the notation *log* means base 10. The common logarithm of 1000 is 3; in other words, you must raise 10 to the 3rd power to obtain 1000:

$$\log 1000 = 3 \quad \text{or} \quad 10^3 = 1000$$

Similarly, we have

$$\log 10 = 1 \quad \text{or} \quad 10^1 = 10$$
$$\log 1{,}000{,}000 = 6 \quad \text{or} \quad 10^6 = 1{,}000{,}000$$
$$\log 0.001 = -3 \quad \text{or} \quad 10^{-3} = 0.001$$
$$\log 853 = 2.931 \quad \text{or} \quad 10^{2.931} = 853$$

The last example illustrates an important point about significant figures with all logarithms: *the number of significant figures in the number equals the number of digits to the right of the decimal point in the logarithm*. That is, the number 853 has three significant figures, and the logarithm 2.931 has three digits to the right of the decimal point.

To find a common logarithm with an electronic calculator, enter the number and press the LOG button.

2. For *natural* logarithms, the base is the number e, which is 2.71828 . . . , and $\log_e A$ is written ln A; thus, the notation *ln* means base e. The relationship between the common and natural logarithms is easily obtained:

$$\log 10 = 1 \quad \text{and} \quad \ln 10 = 2.303$$

Therefore, we have

$$\ln A = 2.303 \log A$$

To find a natural logarithm with an electronic calculator, enter the number and press the LN button. If your calculator does not have an LN button, enter the number, press the LOG button, and multiply by 2.303.

Antilogarithms

The *antilogarithm* is the base raised to the logarithm:

$$\text{antilogarithm (antilog) of } n \text{ is } 10^n$$

Using two of the earlier examples, the antilog of 3 is 1000, and the antilog of 2.931 is 853. To obtain the antilog with a calculator, enter the number and press the 10^x button. Similarly, to obtain the natural antilogarithm, enter the number and press the e^x button. [On some calculators, enter the number and first press INV and then the LOG (or LN) button.]

USING EXPONENTIAL (SCIENTIFIC) NOTATION

Many quantities in chemistry are very large or very small. For example, in the conventional way of writing numbers, the number of gold atoms in 1 gram of gold is

59,060,000,000,000,000,000,000 atoms (to four significant figures)

As another example, the mass in grams of one gold atom is

0.000000000000000000000003272 g (to four significant figures)

Exponential (scientific) notation provides a much more practical way of writing such numbers. In exponential notation, we express numbers in the form

$$A \times 10^n$$

where A (the coefficient) is greater than or equal to 1 and less than 10 (that is, $1 \leq A < 10$), and n (the exponent) is an integer.

If the number we want to express in exponential notation is larger than 1, the exponent is positive ($n > 0$); if the number is smaller than 1, the exponent is negative ($n < 0$). The size of n tells the number of places the decimal point (in conventional notation) must be moved to obtain a coefficient A greater than or equal to 1 and less than 10 (in exponential notation). In exponential notation, 1 gram of gold contains 5.906×10^{22} atoms, and each gold atom has a mass of 3.272×10^{-22} g.

Changing Between Conventional and Exponential Notation

In order to use exponential notation, you must be able to convert to it from conventional notation, and vice versa.

1. To change a number from conventional to exponential notation, move the decimal point to the left for numbers equal to or greater than 10 and to the right for numbers between 0 and 1:

   75,000,000 changes to 7.5×10^7 (decimal point 7 places to the left)

   0.006042 changes to 6.042×10^{-3} (decimal point 3 places to the right)

2. To change a number from exponential to conventional notation, move the decimal point the number of places indicated by the exponent to the right for numbers with positive exponents and to the left for numbers with negative exponents:

   1.38×10^5 changes to 138,000 (decimal point 5 places to the right)

   8.41×10^{-6} changes to 0.00000841 (decimal point 6 places to the left)

3. An exponential number with a coefficient greater than 10 or less than 1 can be changed to the standard exponential form by converting the coefficient to the standard form and adding the exponents:

$$582.3\times10^{6} \text{ changes to } 5.823 \times 10^{2} \times 10^{6} = 5.823\times10^{(2+6)} = 5.823\times10^{8}$$
$$0.0043\times10^{-4} \text{ changes to } 4.3 \times 10^{-3} \times 10^{-4} = 4.3\times10^{[(-3)+(-4)]} = 4.3\times10^{-7}$$

Using Exponential Notation in Calculations

In calculations, you can treat the coefficient and exponents separately and apply the properties of exponents (see earlier section on logarithms).

1. To multiply exponential numbers, multiply the coefficients, add the exponents, and reconstruct the number in standard exponential notation:

$$(5.5\times10^{3})(3.1\times10^{5}) = (5.5 \times 3.1)\times10^{(3+5)} = 17\times10^{8} = 1.7\times10^{9}$$
$$(9.7\times10^{14})(4.3\times10^{-20}) = (9.7 \times 4.3)\times10^{[14+(-20)]} = 42\times10^{-6} = 4.2\times10^{-5}$$

2. To divide exponential numbers, divide the coefficients, subtract the exponents, and reconstruct the number in standard exponential notation:

$$\frac{2.6\times10^{6}}{5.8\times10^{2}} = \frac{2.6}{5.8} \times 10^{(6-2)} = 0.45\times10^{4} = 4.5\times10^{3}$$
$$\frac{1.7\times10^{-5}}{8.2\times10^{-8}} = \frac{1.7}{8.2} \times 10^{[(-5)-(-8)]} = 0.21\times10^{3} = 2.1\times10^{2}$$

3. To add or subtract exponential numbers, change all numbers so that they have the same exponent, then add or subtract the coefficients:

$$(1.45\times10^{4}) + (3.2\times10^{3}) = (1.45\times10^{4}) + (0.32\times10^{4}) = 1.77\times10^{4}$$
$$(3.22\times10^{5}) - (9.02\times10^{4}) = (3.22\times10^{5}) - (0.902\times10^{5}) = 2.32\times10^{5}$$

SOLVING QUADRATIC EQUATIONS

A *quadratic equation* is one in which the highest power of x is 2. The general form of a quadratic equation is

$$ax^2 + bx + c = 0$$

where a, b, and c are numbers. For given values of a, b, and c, the values of x that satisfy the equation are called *solutions* of the equation. We calculate x with the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

We commonly require the quadratic formula when solving for some concentration in an equilibrium problem. For example, we might have an expression that is rearranged into the quadratic equation

$$\underset{a}{4.3}x^2 + \underset{b}{0.65}x - \underset{c}{8.7} = 0$$

Applying the quadratic formula, with $a = 4.3$, $b = 0.65$, and $c = -8.7$, gives

$$x = \frac{-0.65 \pm \sqrt{(0.65)^2 - 4(4.3)(-8.7)}}{2(4.3)}$$

The "plus or minus" sign ($\pm$) indicates that there are always two possible values for x. In this case, they are

$$x = 1.3 \quad \text{and} \quad x = -1.5$$

In any real physical system, however, only one of the values will have any meaning. For example, if x were $[H_3O^+]$, the negative value would give a negative concentration, which has no physical meaning.

GRAPHING DATA IN THE FORM OF A STRAIGHT LINE

Visualizing changes in variables by means of a graph is used throughout science. In many cases, it is most useful if the data can be graphed in the form of a straight line. Any equation will appear as a straight line if it has, or can be rearranged to have, the following general form:

$$y = mx + b$$

where y is the dependent variable (typically plotted along the vertical axis), x is the independent variable (typically plotted along the horizontal axis), m is the slope of the line, and b is the intercept of the line on the y axis. The intercept is the value of y when $x = 0$:

$$y = m(0) + b = b$$

The slope of the line is the change in y for a given change in x:

$$\text{Slope } (m) = \frac{y_2 - y_1}{x_2 - x_1} = \frac{\Delta y}{\Delta x}$$

The *sign* of the slope tells the *direction* of the line. If y increases as x increases, m is positive, and the line slopes upward with higher values of x; if y decreases as x increases, m is negative, and the line slopes downward with higher values of x. The *magnitude* of the slope indicates the *steepness* of the line. A line with $m = 3$ is three times as steep (y changes three times as much for a given change in x) as a line with $m = 1$.

Consider the linear equation $y = 2x + 1$. A graph of this equation is shown in Figure A.1. In practice, you can find the slope by drawing a right triangle to the line, using the line as the hypotenuse. Then, one leg gives Δy, and the other gives Δx. In the figure, $\Delta y = 8$ and $\Delta x = 4$.

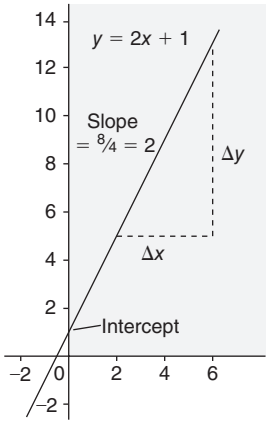

Figure A.1

At several places in the text, an equation is rearranged into the form of a straight line in order to determine information from the slope and/or the intercept. For example, in Chapter 16, we obtained the following expression:

$$\ln \frac{[A]_0}{[A]_t} = kt$$

Based on the properties of logarithms, we have

$$\ln [A]_0 - \ln [A]_t = kt$$

Rearranging into the form of an equation for a straight line gives

$$\ln [A]_t = -kt + \ln [A]_0$$
$$y = mx + b$$

Thus, a plot of $\ln [A]_t$ vs. t is a straight line, from which you can see that the slope is $-k$ (the negative of the rate constant) and the intercept is $\ln [A]_0$ (the natural logarithm of the initial concentration of A).

At many other places in the text, linear relationships occur that were not shown in graphical terms. For example, the conversion of temperature scales in Chapter 1 can also be expressed in the form of a straight line:

$$^\circ\text{F} = \tfrac{9}{5}{}^\circ\text{C} + 32$$
$$y = mx + b$$

APPENDIX C

Equilibrium Constants for Selected Substances*

Dissociation (Ionization) Constants (K_a) of Selected Acids

Name and Formula	Lewis Structure†	K_{a1}	K_{a2}	K_{a3}
Acetic acid CH_3COOH		1.8×10^{-5}		
Acetylsalicylic acid $CH_3COOC_6H_4COOH$		3.6×10^{-4}		
Adipic acid $HOOC(CH_2)_4COOH$		3.8×10^{-5}	3.8×10^{-6}	
Arsenic acid H_3AsO_4		6×10^{-3}	1.1×10^{-7}	3×10^{-12}
Ascorbic acid $H_2C_6H_6O_6$		1.0×10^{-5}	5×10^{-12}	
Benzoic acid C_6H_5COOH		6.3×10^{-5}		
Carbonic acid H_2CO_3		4.5×10^{-7}	4.7×10^{-11}	
Chloroacetic acid $ClCH_2COOH$		1.4×10^{-3}		
Chlorous acid $HClO_2$		1.1×10^{-2}		

*All values at 298 K, except for acetylsalicylic acid, which is at 37°C (310 K) in 0.15 *M* NaCl.

†Acidic (ionizable) proton(s) shown in red. Structures have lowest formal charges. Benzene rings show one resonance form.

(*continued*)

Dissociation (Ionization) Constants (K_a) of Selected Acids

Name and Formula	Lewis Structure†	K_{a1}	K_{a2}	K_{a3}
Citric acid $HOOCCH_2C(OH)(COOH)CH_2COOH$		7.4×10^{-4}	1.7×10^{-5}	4.0×10^{-7}
Formic acid $HCOOH$		1.8×10^{-4}		
Glyceric acid $HOCH_2CH(OH)COOH$		2.9×10^{-4}		
Glycolic acid $HOCH_2COOH$		1.5×10^{-4}		
Glyoxylic acid $HC(O)COOH$		3.5×10^{-4}		
Hydrocyanic acid HCN		6.2×10^{-10}		
Hydrofluoric acid HF		6.8×10^{-4}		
Hydrosulfuric acid H_2S		9×10^{-8}	1×10^{-17}	
Hypobromous acid $HBrO$		2.3×10^{-9}		
Hypochlorous acid $HClO$		2.9×10^{-8}		
Hypoiodous acid HIO		2.3×10^{-11}		
Iodic acid HIO_3		1.6×10^{-1}		
Lactic acid $CH_3CH(OH)COOH$		1.4×10^{-4}		
Maleic acid $HOOCCH{=}CHCOOH$		1.2×10^{-2}	4.7×10^{-7}	

(*continued*)

Dissociation (Ionization) Constants (K_a) of Selected Acids (*continued*)

Name and Formula	Lewis Structure†	K_{a1}	K_{a2}	K_{a3}
Malonic acid $HOOCCH_2COOH$		1.4×10^{-3}	2.0×10^{-6}	
Nitrous acid HNO_2		7.1×10^{-4}		
Oxalic acid $HOOCCOOH$		5.6×10^{-2}	5.4×10^{-5}	
Phenol C_6H_5OH		1.0×10^{-10}		
Phenylacetic acid $C_6H_5CH_2COOH$		4.9×10^{-5}		
Phosphoric acid H_3PO_4		7.2×10^{-3}	6.3×10^{-8}	4.2×10^{-13}
Phosphorous acid $HPO(OH)_2$		3×10^{-2}	1.7×10^{-7}	
Propanoic acid CH_3CH_2COOH		1.3×10^{-5}		
Pyruvic acid $CH_3C(O)COOH$		2.8×10^{-3}		
Succinic acid $HOOCCH_2CH_2COOH$		6.2×10^{-5}	2.3×10^{-6}	
Sulfuric acid H_2SO_4		Very large	1.0×10^{-2}	
Sulfurous acid H_2SO_3		1.4×10^{-2}	6.5×10^{-8}	

(*continued*)

Dissociation (Ionization) Constants (K_b) of Selected Amine Bases

Name and Formula	Lewis Structure†	K_{b1}	K_{b2}
Ammonia NH_3		1.76×10^{-5}	
Aniline $C_6H_5NH_2$		4.0×10^{-10}	
Diethylamine $(CH_3CH_2)_2NH$		8.6×10^{-4}	
Dimethylamine $(CH_3)_2NH$		5.9×10^{-4}	
Ethanolamine $HOCH_2CH_2NH_2$		3.2×10^{-5}	
Ethylamine $CH_3CH_2NH_2$		4.3×10^{-4}	
Ethylenediamine $H_2NCH_2CH_2NH_2$		8.5×10^{-5}	7.1×10^{-8}
Methylamine CH_3NH_2		4.4×10^{-4}	
tert-Butylamine $(CH_3)_3CNH_2$		4.8×10^{-4}	
Piperidine $C_5H_{10}NH$		1.3×10^{-3}	
n-Propylamine $CH_3CH_2CH_2NH_2$		3.5×10^{-4}	

†Blue type indicates the basic nitrogen and its lone pair.

(*continued*)

Dissociation (Ionization) Constants (K_b) of Selected Amine Bases (*continued*)

Name and Formula	Lewis Structure†	K_{b1}	K_{b2}
Isopropylamine $(CH_3)_2CHNH_2$		4.7×10^{-4}	
1,3-Propylenediamine $H_2NCH_2CH_2CH_2NH_2$		3.1×10^{-4}	3.0×10^{-6}
Pyridine C_5H_5N		1.7×10^{-9}	
Triethylamine $(CH_3CH_2)_3N$		5.2×10^{-4}	
Trimethylamine $(CH_3)_3N$		6.3×10^{-5}	

Dissociation (Ionization) Constants (K_a) of Some Hydrated Metal Ions

Free Ion	Hydrated Ion	K_a
Fe^{3+}	$Fe(H_2O)_6^{3+}(aq)$	6×10^{-3}
Sn^{2+}	$Sn(H_2O)_6^{2+}(aq)$	4×10^{-4}
Cr^{3+}	$Cr(H_2O)_6^{3+}(aq)$	1×10^{-4}
Al^{3+}	$Al(H_2O)_6^{3+}(aq)$	1×10^{-5}
Cu^{2+}	$Cu(H_2O)_6^{2+}(aq)$	3×10^{-8}
Pb^{2+}	$Pb(H_2O)_6^{2+}(aq)$	3×10^{-8}
Zn^{2+}	$Zn(H_2O)_6^{2+}(aq)$	1×10^{-9}
Co^{2+}	$Co(H_2O)_6^{2+}(aq)$	2×10^{-10}
Ni^{2+}	$Ni(H_2O)_6^{2+}(aq)$	1×10^{-10}

Formation Constants (K_f) of Some Complex Ions

Complex Ion	K_f
$Ag(CN)_2^-$	3.0×10^{20}
$Ag(NH_3)_2^+$	1.7×10^{7}
$Ag(S_2O_3)_2^{3-}$	4.7×10^{13}
AlF_6^{3-}	4×10^{19}
$Al(OH)_4^-$	3×10^{33}
$Be(OH)_4^{2-}$	4×10^{18}
CdI_4^{2-}	1×10^{6}
$Co(OH)_4^{2-}$	5×10^{9}
$Cr(OH)_4^-$	8.0×10^{29}
$Cu(NH_3)_4^{2+}$	5.6×10^{11}
$Fe(CN)_6^{4-}$	3×10^{35}
$Fe(CN)_6^{3-}$	4.0×10^{43}
$Hg(CN)_4^{2-}$	9.3×10^{38}
$Ni(NH_3)_6^{2+}$	2.0×10^{8}
$Pb(OH)_3^-$	8×10^{13}
$Sn(OH)_3^-$	3×10^{25}
$Zn(CN)_4^{2-}$	4.2×10^{19}
$Zn(NH_3)_4^{2+}$	7.8×10^{8}
$Zn(OH)_4^{2-}$	3×10^{15}

Solubility-Product Constants (K_{sp}) of Slightly Soluble Ionic Compounds

Name, Formula	K_{sp}
Carbonates	
Barium carbonate, $BaCO_3$	2.0×10^{-9}
Cadmium carbonate, $CdCO_3$	1.8×10^{-14}
Calcium carbonate, $CaCO_3$	3.3×10^{-9}
Cobalt(II) carbonate, $CoCO_3$	1.0×10^{-10}
Copper(II) carbonate, $CuCO_3$	3×10^{-12}
Lead(II) carbonate, $PbCO_3$	7.4×10^{-14}
Magnesium carbonate, $MgCO_3$	3.5×10^{-8}
Mercury(I) carbonate, Hg_2CO_3	8.9×10^{-17}
Nickel(II) carbonate, $NiCO_3$	1.3×10^{-7}
Strontium carbonate, $SrCO_3$	5.4×10^{-10}
Zinc carbonate, $ZnCO_3$	1.0×10^{-10}
Chromates	
Barium chromate, $BaCrO_4$	2.1×10^{-10}
Calcium chromate, $CaCrO_4$	1×10^{-8}
Lead(II) chromate, $PbCrO_4$	2.3×10^{-13}
Silver chromate, Ag_2CrO_4	2.6×10^{-12}
Cyanides	
Mercury(I) cyanide, $Hg_2(CN)_2$	5×10^{-40}
Silver cyanide, AgCN	2.2×10^{-16}
Halides	
Fluorides	
Barium fluoride, BaF_2	1.5×10^{-6}
Calcium fluoride, CaF_2	3.2×10^{-11}
Lead(II) fluoride, PbF_2	3.6×10^{-8}
Magnesium fluoride, MgF_2	7.4×10^{-9}
Strontium fluoride, SrF_2	2.6×10^{-9}
Chlorides	
Copper(I) chloride, CuCl	1.9×10^{-7}
Lead(II) chloride, $PbCl_2$	1.7×10^{-5}
Silver chloride, AgCl	1.8×10^{-10}
Bromides	
Copper(I) bromide, CuBr	5×10^{-9}
Silver bromide, AgBr	5.0×10^{-13}
Iodides	
Copper(I) iodide, CuI	1×10^{-12}
Lead(II) iodide, PbI_2	7.9×10^{-9}
Mercury(I) iodide, Hg_2I_2	4.7×10^{-29}
Silver iodide, AgI	8.3×10^{-17}
Hydroxides	
Aluminum hydroxide, $Al(OH)_3$	3×10^{-34}
Cadmium hydroxide, $Cd(OH)_2$	7.2×10^{-15}
Calcium hydroxide, $Ca(OH)_2$	6.5×10^{-6}
Cobalt(II) hydroxide, $Co(OH)_2$	1.3×10^{-15}
Copper(II) hydroxide, $Cu(OH)_2$	2.2×10^{-20}
Iron(II) hydroxide, $Fe(OH)_2$	4.1×10^{-15}
Iron(III) hydroxide, $Fe(OH)_3$	1.6×10^{-39}
Magnesium hydroxide, $Mg(OH)_2$	6.3×10^{-10}
Manganese(II) hydroxide, $Mn(OH)_2$	1.6×10^{-13}
Nickel(II) hydroxide, $Ni(OH)_2$	6×10^{-16}
Zinc hydroxide, $Zn(OH)_2$	3×10^{-16}
Iodates	
Barium iodate, $Ba(IO_3)_2$	1.5×10^{-9}
Calcium iodate, $Ca(IO_3)_2$	7.1×10^{-7}
Lead(II) iodate, $Pb(IO_3)_2$	2.5×10^{-13}
Silver iodate, $AgIO_3$	3.1×10^{-8}
Strontium iodate, $Sr(IO_3)_2$	3.3×10^{-7}
Zinc iodate, $Zn(IO_3)_2$	3.9×10^{-6}
Oxalates	
Barium oxalate dihydrate, $BaC_2O_4\cdot2H_2O$	1.1×10^{-7}
Calcium oxalate monohydrate, $CaC_2O_4\cdot H_2O$	2.3×10^{-9}
Strontium oxalate monohydrate, $SrC_2O_4\cdot H_2O$	5.6×10^{-8}
Phosphates	
Calcium phosphate, $Ca_3(PO_4)_2$	1.2×10^{-29}
Magnesium phosphate, $Mg_3(PO_4)_2$	5.2×10^{-24}
Silver phosphate, Ag_3PO_4	2.6×10^{-18}
Sulfates	
Barium sulfate, $BaSO_4$	1.1×10^{-10}
Calcium sulfate, $CaSO_4$	2.4×10^{-5}
Lead(II) sulfate, $PbSO_4$	1.6×10^{-8}
Radium sulfate, $RaSO_4$	2×10^{-11}
Silver sulfate, Ag_2SO_4	1.5×10^{-5}
Strontium sulfate, $SrSO_4$	3.2×10^{-7}
Sulfides	
Cadmium sulfide, CdS	1.0×10^{-24}
Copper(II) sulfide, CuS	8×10^{-34}
Iron(II) sulfide, FeS	8×10^{-16}
Lead(II) sulfide, PbS	3×10^{-25}
Manganese(II) sulfide, MnS	3×10^{-11}
Mercury(II) sulfide, HgS	2×10^{-50}
Nickel(II) sulfide, NiS	3×10^{-16}
Silver sulfide, Ag_2S	8×10^{-48}
Tin(II) sulfide, SnS	1.3×10^{-23}
Zinc sulfide, ZnS	2.0×10^{-22}

APPENDIX D

Standard Electrode (Half-Cell) Potentials*

Half-Reaction	$E°$ (V)
$F_2(g) + 2e^- \rightleftharpoons 2F^-(aq)$	+2.87
$O_3(g) + 2H^+(aq) + 2e^- \rightleftharpoons O_2(g) + H_2O(l)$	+2.07
$Co^{3+}(aq) + e^- \rightleftharpoons Co^{2+}(aq)$	+1.82
$H_2O_2(aq) + 2H^+(aq) + 2e^- \rightleftharpoons 2H_2O(l)$	+1.77
$PbO_2(s) + 3H^+(aq) + HSO_4^-(aq) + 2e^- \rightleftharpoons PbSO_4(s) + 2H_2O(l)$	+1.70
$Ce^{4+}(aq) + e^- \rightleftharpoons Ce^{3+}(aq)$	+1.61
$MnO_4^-(aq) + 8H^+(aq) + 5e^- \rightleftharpoons Mn^{2+}(aq) + 4H_2O(l)$	+1.51
$Au^{3+}(aq) + 3e^- \rightleftharpoons Au(s)$	+1.50
$Cl_2(g) + 2e^- \rightleftharpoons 2Cl^-(aq)$	+1.36
$Cr_2O_7^{2-}(aq) + 14H^+(aq) + 6e^- \rightleftharpoons 2Cr^{3+}(aq) + 7H_2O(l)$	+1.33
$MnO_2(s) + 4H^+(aq) + 2e^- \rightleftharpoons Mn^{2+}(aq) + 2H_2O(l)$	+1.23
$O_2(g) + 4H^+(aq) + 4e^- \rightleftharpoons 2H_2O(l)$	+1.23
$Br_2(l) + 2e^- \rightleftharpoons 2Br^-(aq)$	+1.07
$NO_3^-(aq) + 4H^+(aq) + 3e^- \rightleftharpoons NO(g) + 2H_2O(l)$	+0.96
$2Hg^{2+}(aq) + 2e^- \rightleftharpoons Hg_2^{2+}(aq)$	+0.92
$Hg_2^{2+}(aq) + 2e^- \rightleftharpoons 2Hg(l)$	+0.85
$Ag^+(aq) + e^- \rightleftharpoons Ag(s)$	+0.80
$Fe^{3+}(aq) + e^- \rightleftharpoons Fe^{2+}(aq)$	+0.77
$O_2(g) + 2H^+(aq) + 2e^- \rightleftharpoons H_2O_2(aq)$	+0.68
$MnO_4^-(aq) + 2H_2O(l) + 3e^- \rightleftharpoons MnO_2(s) + 4OH^-(aq)$	+0.59
$I_2(s) + 2e^- \rightleftharpoons 2I^-(aq)$	+0.53
$O_2(g) + 2H_2O(l) + 4e^- \rightleftharpoons 4OH^-(aq)$	+0.40
$Cu^{2+}(aq) + 2e^- \rightleftharpoons Cu(s)$	+0.34
$AgCl(s) + e^- \rightleftharpoons Ag(s) + Cl^-(aq)$	+0.22
$SO_4^{2-}(aq) + 4H^+(aq) + 2e^- \rightleftharpoons SO_2(g) + 2H_2O(l)$	+0.20
$Cu^{2+}(aq) + e^- \rightleftharpoons Cu^+(aq)$	+0.15
$Sn^{4+}(aq) + 2e^- \rightleftharpoons Sn^{2+}(aq)$	+0.13
$2H^+(aq) + 2e^- \rightleftharpoons H_2(g)$	**0.00**
$Pb^{2+}(aq) + 2e^- \rightleftharpoons Pb(s)$	−0.13
$Sn^{2+}(aq) + 2e^- \rightleftharpoons Sn(s)$	−0.14
$N_2(g) + 5H^+(aq) + 4e^- \rightleftharpoons N_2H_5^+(aq)$	−0.23
$Ni^{2+}(aq) + 2e^- \rightleftharpoons Ni(s)$	−0.25
$Co^{2+}(aq) + 2e^- \rightleftharpoons Co(s)$	−0.28
$PbSO_4(s) + H^+(aq) + 2e^- \rightleftharpoons Pb(s) + HSO_4^-(aq)$	−0.31
$Cd^{2+}(aq) + 2e^- \rightleftharpoons Cd(s)$	−0.40
$Fe^{2+}(aq) + 2e^- \rightleftharpoons Fe(s)$	−0.44
$Cr^{3+}(aq) + 3e^- \rightleftharpoons Cr(s)$	−0.74
$Zn^{2+}(aq) + 2e^- \rightleftharpoons Zn(s)$	−0.76
$2H_2O(l) + 2e^- \rightleftharpoons H_2(g) + 2OH^-(aq)$	−0.83
$Cr^{2+}(aq) + 2e^- \rightleftharpoons Cr(s)$	−0.91
$Mn^{2+}(aq) + 2e^- \rightleftharpoons Mn(s)$	−1.18
$Al^{3+}(aq) + 3e^- \rightleftharpoons Al(s)$	−1.66
$Mg^{2+}(aq) + 2e^- \rightleftharpoons Mg(s)$	−2.37
$Na^+(aq) + e^- \rightleftharpoons Na(s)$	−2.71
$Ca^{2+}(aq) + 2e^- \rightleftharpoons Ca(s)$	−2.87
$Sr^{2+}(aq) + 2e^- \rightleftharpoons Sr(s)$	−2.89
$Ba^{2+}(aq) + 2e^- \rightleftharpoons Ba(s)$	−2.90
$K^+(aq) + e^- \rightleftharpoons K(s)$	−2.93
$Li^+(aq) + e^- \rightleftharpoons Li(s)$	−3.05

*All values at 298 K. Written as reductions; $E°$ value refers to all components in their standard states: 1 *M* for dissolved species; 1 atm pressure for the gas behaving ideally; the pure substance for solids and liquids.

Answers to Selected Problems

Chapter 1

1.2 Gas molecules fill the entire container; the volume of a gas is the volume of the container. Solids and liquids have a definite volume. The volume of the container does not affect the volume of a solid or liquid. (a) gas (b) liquid (c) liquid **1.4** Physical property: a characteristic shown by a substance itself, without any interaction with or change into other substances. Chemical property: a characteristic of a substance that appears as it interacts with, or transforms into, other substances. (a) Color (yellow-green and silver to white) and physical state (gas and metal to crystals) are physical properties. The interaction between chlorine gas and sodium metal is a chemical property. (b) Color and magnetism are physical properties. No chemical changes. **1.6**(a) Physical change; there is only a temperature change. (b) Chemical change; the change in appearance indicates an irreversible chemical change. (c) Physical change; there is only a change in size, not composition. (d) Chemical change; the wood (and air) become different substances with different compositions. **1.8**(a) fuel (b) wood **1.13** Lavoisier measured the total mass of the reactants and products, not just the mass of the solids, and this total mass remained constant. His measurements showed that a gas was involved in the reaction. He called this gas *oxygen* (one of his key discoveries). **1.16** A well-designed experiment must have the following: (1) At least two variables that are related; (2) a way to control all the variables, so that only one at a time may be changed; (3) reproducible results. **1.20**(a) increases (b) remains the same (c) decreases (d) increases (e) remains the same **1.23** An extensive property depends on the amount of material present. An intensive property is the same regardless of how much material is present. (a) extensive property (b) intensive property (c) extensive property (d) intensive property **1.24**(a) $(2.54\ cm)^2/(1\ in)^2$ and $(1\ m)^2/(100\ cm)^2$ (b) $(1000\ m)^2/(1\ km)^2$ and $(100\ cm)^2/(1\ m)^2$ (c) $(1.609\times10^3\ m/mi)$ and $(1\ h/3600\ s)$ (d) $(1000\ g/2.205\ lb)$ and $(3.531\times10^{-5}\ ft^3/cm^3)$ **1.26** 1.43 nm **1.28** 3.94×10^3 in **1.30**(a) $2.07\times10^{-9}\ km^2$ (b) \$10.43 **1.32** Answers will vary, depending on the person's mass. **1.34**(a) $5.52\times10^3\ kg/m^3$ (b) $345\ lb/ft^3$ **1.36**(a) $2.56\times10^{-9}\ mm^3$ (b) 10^{-10} L **1.38**(a) $9.626\ cm^3$ (b) 64.92 g **1.40** $2.70\ g/cm^3$ **1.42**(a) 20.°C; 293 K (b) 109 K; −263°F (c) −273°C; −460.°F **1.45**(a) 2.47×10^{-7} m (b) 67.6 Å **1.52**(a) none (b) none (c) 0.0410 (d) 4.0100×10^4 **1.54**(a) 0.00036 (b) 35.83 (c) 22.5 **1.56** 6×10^2 **1.58**(a) 1.34 m (b) 21,621 mm^3 (c) 443 cm **1.60**(a) 1.310000×10^5 (b) 4.7×10^{-4} (c) 2.10006×10^5 (d) 2.1605×10^3 **1.62**(a) 5550 (b) 10,070. Chapter 2

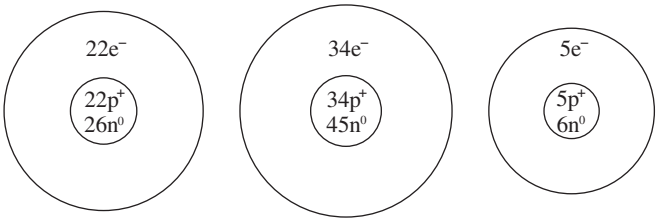
Answers to Boxed Reading Problems: B2.1 (a) 5 peaks (b) *m*/*e* ratio of heaviest particle = 74; *m*/*e* ratio of lightest particle = 35 **B2.3** (a) Since salt dissolves in water and pepper does not, add water to mixture and filter to remove solid pepper. Evaporate water to recover solid salt. (b) Distillation purifies the water and leaves the soot behind. (c) Warm the mixture; filter to remove glass; freeze the filtrate to obtain ice. (d) Heat the mixture; the ethanol will boil off (distill), while the sugar will remain behind. (e) Use column chromatography to separate the pigments.

• **2.1** Compounds contain different types of atoms; there is only one type of atom in an element. **2.4**(a) The presence of more than one element makes pure calcium chloride a compound. (b) There is only one kind of atom, so sulfur is an element. (c) The presence of more than one compound makes baking powder a mixture. (d) The presence of more than one type of atom means cytosine cannot be an element. The specific, not variable, arrangement means it is a compound. **2.12**(a) elements, compounds, and mixtures (b) compounds (c) compounds **2.14**(a) Law of definite composition: the composition is the same regardless of its source. (b) Law of mass conservation: the total quantity of matter does not change. (c) Law of multiple proportions: two elements can combine to form two different compounds that have different proportions of those elements. **2.16**(a) No, the percent by mass of each element in a compound is fixed. (b) Yes, the *mass* of each element in a compound depends on the amount of compound. **2.18** The two experiments demonstrate the law of definite composition. The unknown compound decomposes the same way both times. The experiments also demonstrate the law of conservation of mass since the total mass before reaction equals the total mass after reaction. **2.20**(a) 1.34 g F (b) 0.514 Ca; 0.486 F (c) 51.4 mass % Ca; 48.6 mass % F **2.22**(a) 0.603 (b) 322 g Mg **2.24** 3.498×10^{6} g Cu; 1.766×10^{6} g S **2.26** compound 1: 0.905 S/Cl; compound 2: 0.451 S/Cl; ratio: 2.00/1.00 **2.29** Coal A **2.31** Dalton postulated that atoms of an element are identical and that compounds result from the chemical combination of specific ratios of different elements. **2.32** If you know the ratio of any two quantities and the value of one of them, the other can always be calculated; in this case, the charge and the mass/charge ratio were known. **2.36** The atomic number is the number of protons in an atom's nucleus. When the atomic number changes, the identity of the element changes. The mass number is the total number of protons and neutrons in the nucleus. The identity of an element is based on the number of protons, not the number of neutrons. The mass number can vary (by a change in number of neutrons) without changing the identity of the element. **2.39** All three isotopes have 18 protons and 18 electrons. Their respective mass numbers are 36, 38, and 40, with the respective numbers of neutrons being 18, 20, and 22. **2.41**(a) These have the same number of protons and electrons, but different numbers of neutrons; same *Z*. (b) These have the same number of neutrons, but different numbers of protons and electrons; same *N*. (c) These have different numbers of protons, neutrons, and electrons; same *A*. **2.43**(a) $^{38}_{18}$Ar (b) $^{55}_{25}$Mn (c) $^{109}_{47}$Ag

2.45(a) $^{48}_{22}$Ti (b) $^{79}_{34}$Se (c) $^{11}_{5}$B



2.47 69.72 amu **2.49** ^{35}Cl = 75.774%, ^{37}Cl = 24.226% **2.52**(a) In the modern periodic table, the elements are arranged in order of increasing atomic number. (b) Elements in a group (or family) have similar chemical properties. (c) Elements can be classified as metals, metalloids, or nonmetals. **2.55** The alkali metals [Group 1A(1)] are metals and readily lose one electron to form cations; the halogens [Group 7A(17)] are nonmetals and readily gain one electron to form anions. **2.56**(a) germanium; Ge; 4A(14); metalloid (b) phosphorus; P; 5A(15); nonmetal (c) helium; He; 8A(18); nonmetal (d) lithium; Li; 1A(1); metal (e) molybdenum; Mo; 6B(6); metal **2.58**(a) Ra; 88 (b) Si; 14 (c) Cu; 63.55 amu (d) Br; 79.90 amu **2.60** Atoms of these two kinds of substances will form ionic bonds, in which one or more electrons are transferred from the metal atom to the nonmetal atom to form a cation and an anion, respectively. **2.63** Coulomb's law states the energy of attraction in an ionic bond is directly proportional to the product of charges and inversely proportional to the distance between charges. The product of charges in MgO [(2+) (2−)] is greater than that in LiF [(1+) (1−)]. Thus, MgO has stronger ionic bonding. **2.66** The Group 1A(1) elements form cations, and the Group 7A(17) elements form anions. **2.68** Each potassium atom loses one electron to form an ion with a 1+ charge. Each sulfur atom gains two electrons to form an ion with a 2− charge. Two potassium atoms, losing one electron each, are required for each sulfur atom, which gains two electrons. The oppositely charged ions attract each other to form an ionic solid, K_2S. **2.70** K^+; Br^- **2.72**(a) oxygen; 17; 6A(16); 2 (b) fluorine; 19; 7A(17); 2 (c) calcium; 40; 2A(2); 4 **2.74** Lithium forms the Li^+ ion; oxygen forms the O^{2-} ion. Number of O^{2-} ions = 4.2×10^{21} O^{2-} ions. **2.76** NaCl **2.78** The subscripts in a formula give the numbers of ions in a formula unit of the compound. The subscripts indicate that there are two F^- ions for each Mg^{2+} ion. Using this information and the mass of each element, we can calculate percent mass of each element in the compound. **2.80** The two samples are similar in that both contain 20 billion oxygen atoms and 20 billion hydrogen atoms. They differ in that they contain different types of molecules: H_2O_2 molecules in the hydrogen peroxide sample, and H_2 and O_2 molecules in the mixture. In addition, the mixture contains 20 billion molecules (10 billion H_2 and 10 billion O_2), while the hydrogen peroxide sample contains 10 billion molecules. **2.84**(a) Na_3N, sodium nitride (b) SrO, strontium oxide (c) $AlCl_3$, aluminum chloride **2.86**(a) MgF_2, magnesium fluoride (b) ZnS, zinc sulfide (c) $SrCl_2$, strontium chloride **2.88**(a) $SnCl_4$ (b) iron(III) bromide (c) CuBr (d) manganese(III) oxide **2.90**(a) cobalt(II) oxide (b) Hg_2Cl_2 (c) lead(II) acetate trihydrate (d) Cr_2O_3

4.24(a) 4.65 g K_2SO_4 (b) 0.0653 *M* $CaCl_2$ (c) 1.11×10^{20} Mg^{2+} ions **4.26**(a) 0.058 mol Al^{3+}; 3.5×10^{22} Al^{3+} ions; 0.18 mol Cl^-; 1.1×10^{23} Cl^- ions (b) 4.62×10^{-4} mol Li^+; 2.78×10^{20} Li^+ ions; 2.31×10^{-4} mol SO_4^{2-}; 1.39×10^{20} SO_4^{2-} ions (c) 1.50×10^{-2} mol K^+; 9.02×10^{21} K^+ ions; 1.50×10^{-2} mol Br^-; 9.02×10^{21} Br^- ions **4.28**(a) 0.0617 *M* KCl (b) 0.00363 *M* $(NH_4)_2SO_4$ (c) 0.138 *M* Na^+ **4.30**(a) 9.87 g HNO_3/L (b) 15.7 *M* HNO_3 **4.33**(a) Instructions: Be sure to wear goggles to protect your eyes! Pour approximately 2.0 gal of water into the container. Add to the water, slowly, and with mixing, 0.90 gal of concentrated HCl. Dilute to 3.0 gal with more water.

(b) 22.6 mL **4.36** Spectator ions do not appear in a net ionic equation because they are not involved in the reaction and serve only to balance charges. **4.40** Assuming that the left beaker contains $AgNO_3$ (because it has gray Ag^+ ions), the right must contain NaCl. Then, NO_3^- is blue, Na^+ is brown, and Cl^- is green.

Molecular equation: $AgNO_3(aq) + NaCl(aq) \longrightarrow AgCl(s) + NaNO_3(aq)$

Total ionic equation: $Ag^+(aq) + NO_3^-(aq) + Na^+(aq) + Cl^-(aq) \longrightarrow AgCl(s) + Na^+(aq) + NO_3^-(aq)$

Net ionic equation: $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$

4.41(a) Molecular: $Hg_2(NO_3)_2(aq) + 2KI(aq) \longrightarrow Hg_2I_2(s) + 2KNO_3(aq)$

Total ionic:

$Hg_2^{2+}(aq) + 2NO_3^-(aq) + 2K^+(aq) + 2I^-(aq) \longrightarrow Hg_2I_2(s) + 2K^+(aq) + 2NO_3^-(aq)$

Net ionic: $Hg_2^{2+}(aq) + 2I^-(aq) \longrightarrow Hg_2I_2(s)$

Spectator ions are K^+ and NO_3^-.

(b) Molecular: $FeSO_4(aq) + Sr(OH)_2(aq) \longrightarrow Fe(OH)_2(s) + SrSO_4(s)$

Total ionic: $Fe^{2+}(aq) + SO_4^{2-}(aq) + Sr^{2+}(aq) + 2OH^-(aq) \longrightarrow Fe(OH)_2(s) + SrSO_4(s)$

Net ionic: This is the same as the total ionic equation, because there are no spectator ions.

4.43(a) No precipitate will form. (b) A precipitate will form because silver ions, Ag^+, and bromide ions, Br^-, will combine to form a solid salt, silver bromide, AgBr. The ammonium and nitrate ions do not form a precipitate.
Molecular: $NH_4Br(aq) + AgNO_3(aq) \longrightarrow AgBr(s) + NH_4NO_3(aq)$
Total ionic: $NH_4^+(aq) + Br^-(aq) + Ag^+(aq) + NO_3^-(aq) \longrightarrow AgBr(s) + NH_4^+(aq) + NO_3^-(aq)$
Net ionic: $Ag^+(aq) + Br^-(aq) \longrightarrow AgBr(s)$
4.45(a) No precipitate will form.
(b) $BaSO_4$ will precipitate.
Molecular: $(NH_4)_2SO_4(aq) + BaCl_2(aq) \longrightarrow BaSO_4(s) + 2NH_4Cl(aq)$
Total ionic: $2NH_4^+(aq) + SO_4^{2-}(aq) + Ba^{2+}(aq) + 2Cl^-(aq) \longrightarrow BaSO_4(s) + 2NH_4^+(aq) + 2Cl^-(aq)$
Net ionic: $SO_4^{2-}(aq) + Ba^{2+}(aq) \longrightarrow BaSO_4(s)$
4.47 0.0354 *M* Pb^{2+} **4.49** 0.88 g $BaSO_4$ **4.51**(a) $PbSO_4$
(b) $Pb^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow PbSO_4(s)$ (c) 1.5 g $PbSO_4$
4.53 Potassium carbonate, K_2CO_3 **4.55** 2.206 mass % Cl^-
4.61(a) Formation of a gas, $SO_2(g)$, and of a nonelectrolyte (water) will cause the reaction to go to completion.
(b) Formation of a precipitate $Ba_3(PO_4)_2(s)$, and of a nonelectrolyte (water) will cause the reaction to go to completion.
4.63(a) 0.035 mol H^+ (b) 6.3×10^{-3} mol H^+ (c) 0.22 mol H^+
4.65(a) Molecular equation: $KOH(aq) + HBr(aq) \longrightarrow KBr(aq) + H_2O(l)$
Total ionic equation: $K^+(aq) + OH^-(aq) + H^+(aq) + Br^-(aq) \longrightarrow K^+(aq) + Br^-(aq) + H_2O(l)$
Net ionic equation: $OH^-(aq) + H^+(aq) \longrightarrow H_2O(l)$
The spectator ions are $K^+(aq)$ and $Br^-(aq)$.
(b) Molecular equation: $NH_3(aq) + HCl(aq) \longrightarrow NH_4Cl(aq)$
Total ionic equation: $NH_3(aq) + H^+(aq) + Cl^-(aq) \longrightarrow NH_4^+(aq) + Cl^-(aq)$
NH_3, a weak base, is written in the molecular (undissociated) form. HCl, a strong acid, is written as dissociated ions. NH_4Cl is a soluble compound because all ammonium compounds are soluble.
Net ionic equation: $NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$
Cl^- is the only spectator ion.
4.67 Total ionic equation: $CaCO_3(s) + 2H^+(aq) + 2Cl^-(aq) \longrightarrow Ca^{2+}(aq) + 2Cl^-(aq) + H_2O(l) + CO_2(g)$
Net ionic equation: $CaCO_3(s) + 2H^+(aq) \longrightarrow Ca^{2+}(aq) + H_2O(l) + CO_2(g)$
4.69 845 mL **4.71** 0.05839 *M* CH_3COOH **4.82**(a) S has O.N. = +6 in SO_4^{2-} (i.e., H_2SO_4) and O.N. = +4 in SO_2, so S has been reduced (and I^- oxidized); H_2SO_4 acts as an oxidizing agent.

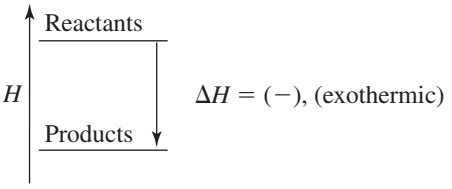
Chapter 6

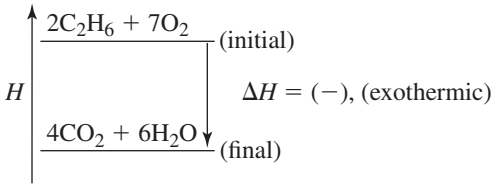
Answers to Boxed Reading Problem: B6.2 (a) $2C(coal) + 2H_2O(g) \longrightarrow CH_4(g) + CO_2(g)$ (b) 12 kJ (c) -3.30×10^4 kJ

• **6.4** Increase: eating food, lying in the sun, taking a hot bath. Decrease: exercising, taking a cold bath, going outside on a cold day. **6.6** The amount of the change in internal energy is the same for heater and air conditioner. Since both devices consume the same amount of electrical energy, the change in energy of the heater equals that of the air conditioner. **6.8** 0 J **6.10** 1.54×10^3 J **6.12**(a) 6.6×10^7 kJ (b) 1.6×10^7 kcal (c) 6.3×10^7 Btu **6.15** 8.8 h **6.17** Measuring the heat transfer at constant pressure is more convenient than measuring at constant volume. **6.19**(a) exothermic (b) endothermic (c) exothermic (d) exothermic (e) endothermic (f) endothermic (g) exothermic **6.22** −52 J

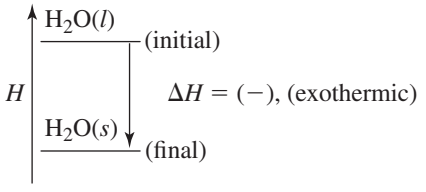
6.24



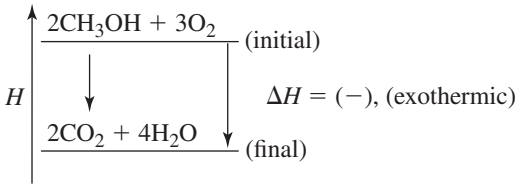
6.26(a) Combustion of ethane: $2C_2H_6(g) + 7O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(g) + \text{heat}$



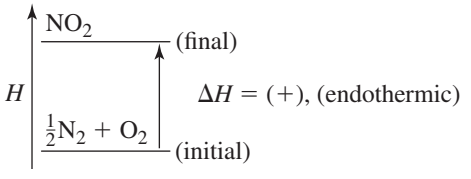
(b) Freezing of water: $H_2O(l) \longrightarrow H_2O(s) + \text{heat}$



6.28(a) $2CH_3OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(g) + \text{heat}$



(b) $\frac{1}{2}N_2(g) + O_2(g) + \text{heat} \longrightarrow NO_2(g)$



6.30(a) This is a phase change from the solid phase to the gas phase. Heat is absorbed by the system so q_{sys} is positive (+).

(b) The volume of the system is expanding as more moles of gas are present after the phase change than before. So the system has done work of expansion, and w is negative. Since $\Delta E_{sys} = q + w$, q is positive, and w is negative, the sign of ΔE_{sys} cannot be predicted. It will be positive if $q > w$ and negative if $q < w$. (c) $\Delta E_{univ} = 0$. If the system loses energy, the surroundings gain an equal quantity of energy. The sum of the energy of the system and the energy of the surroundings remains constant. **6.33** To determine the specific heat capacity of a substance, you need its mass, the heat added (or lost), and the change in temperature. **6.35** Heat capacity is the quantity of heat required to raise the temperature of an object 1 K. Specific heat capacity is the quantity of heat required to raise 1 g of a material by 1 K. Molar heat capacity is the quantity of heat required to raise the temperature of 1 mol of a substance by 1 K.
6.37 6.9×10^3 J **6.39** 295°C **6.41** 77.5°C **6.43** 45°C **6.45** 36.6°C
6.52 The reaction has a positive ΔH, because it requires the input of energy to break the oxygen-oxygen bond. **6.53** ΔH is negative; it is opposite in sign and half of the value for the vaporization of 2 mol of H_2O. **6.54**(a) exothermic (b) 20.2 kJ (c) -4.2×10^2 kJ (d) −15.7 kJ

7.13 1.3483×10^7 nm; 1.3483×10^8 Å **7.16**(a) 1.24×10^{15} s^{-1}; 8.21×10^{-19} J (b) 1.4×10^{15} s^{-1}; 9.0×10^{-19} J **7.18** Bohr's key assumption was that the electron in an atom does not radiate energy while in a stationary state, and it can move to a different orbit only by absorbing or emitting a photon whose energy is equal to the difference in energy between two states. These differences in energy correspond to the wavelengths in the known line spectra for the hydrogen atom. A solar system model does not allow for the movement of electrons between levels.
7.20(a) absorption (b) emission (c) emission (d) absorption
7.22 Yes, the predicted line spectra are accurate. The energies could be predicted from $E_n = \dfrac{-(Z^2)(2.18\times10^{-18}\text{ J})}{n^2}$, where Z is the atomic number for the atom or ion. The energy levels for Be^{3+} will be greater by a factor of 16 ($Z = 4$) than those for the hydrogen atom. This means that the pattern of lines will be similar, but the lines will be at different wavelengths. **7.23** 434.17 nm

Chapter 8

8.1 Elements are listed in the periodic table in a systematic way that correlates with a periodicity of their chemical and physical properties. The theoretical basis for the table in terms of sequential atomic number and electron configuration does not allow for a "new element" between Sn and Sb. **8.3**(a) predicted atomic mass = 54.23 amu (b) predicted melting point = 6.3°C **8.6** The quantum number m_s relates to just the electron; all the others describe the orbital. **8.9** Shielding occurs when electrons protect, or shield, other electrons from the full nuclear attraction. The effective nuclear charge is the nuclear charge an electron actually experiences. As the number of electrons, especially inner electrons, increases, the effective nuclear charge decreases. **8.11**(a) 6 (b) 10 (c) 2 **8.13**(a) 6 (b) 2 (c) 14 **8.16** Hund's rule states that electrons will occupy empty orbitals in a given sublevel (with parallel spins) before filling half-filled orbitals. The lowest energy arrangement has the maximum number of unpaired electrons with parallel spins.

N: $1s^2 2s^2 2p^3$ 
8.18 Main-group elements from the same group have similar outer electron configurations, and the A-group number equals the number of outer electrons. Outer electron configurations vary in a periodic manner within a period, with each succeeding element having an additional electron. **8.20** The maximum number of electrons in any energy level n is $2n^2$, so the $n = 4$ energy level holds a maximum of $2(4^2) = 32$ electrons. **8.21**(a) $n = 5$, $l = 0$, $m_l = 0$, and $m_s = +\frac{1}{2}$ (b) $n = 3$, $l = 1$, $m_l = +1$, and $m_s = -\frac{1}{2}$ (c) $n = 5$, $l = 0$, $m_l = 0$, and $m_s = +\frac{1}{2}$ (d) $n = 2$, $l = 1$, $m_l = +1$, and $m_s = -\frac{1}{2}$

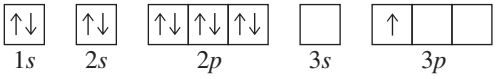
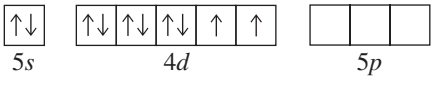
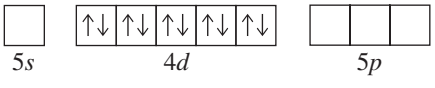
8.43 Na (first excited state): $1s^2 2s^2 2p^6 3p^1$



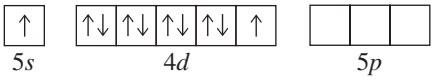
8.50 A high IE_1 and a very negative EA_1 suggest that the elements are halogens, in Group 7A(17), which form 1− ions. **8.53**(a) K < Rb < Cs (b) O < C < Be (c) Cl < S < K (d) Mg < Ca < K **8.55**(a) Ba < Sr < Ca (b) B < N < Ne (c) Rb < Se < Br (d) Sn < Sb < As **8.57** $1s^2 2s^2 2p^1$ (boron, B) **8.59**(a) Na (b) Na (c) Be **8.61**(1) Metals conduct electricity; nonmetals do not. (2) Metal ions have a positive charge; nonmetal ions have a negative charge. (3) Metal oxides are mostly ionic and act as bases; nonmetal oxides are mostly covalent and act as acids. **8.62** Metallic character increases down a group and decreases to the right across a period. These trends are the same as those for atomic size and opposite those for ionization energy. **8.65** Possible ions are 2+ and 4+. The 2+ ions form by loss of the outermost two *p* electrons; the 4+ ions form by loss of these and the outermost two *s* electrons. **8.69**(a) Rb (b) Ra (c) I **8.71**(a) As (b) P (c) Be **8.73** acidic solution; $SO_2(g) + H_2O(l) \longrightarrow H_2SO_3(aq)$ **8.75**(a) Cl^-: $1s^2 2s^2 2p^6 3s^2 3p^6$ (b) Na^+: $1s^2 2s^2 2p^6$ (c) Ca^{2+}: $1s^2 2s^2 2p^6 3s^2 3p^6$ **8.77**(a) Al^{3+}: $1s^2 2s^2 2p^6$ (b) S^{2-}: $1s^2 2s^2 2p^6 3s^2 3p^6$ (c) Sr^{2+}: $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6$ **8.79**(a) 0 (b) 3 (c) 0 (d) 1 **8.81** a, b, and d **8.83**(a) V^{3+}: [Ar] $3d^2$, paramagnetic (b) Cd^{2+}: [Kr] $4d^{10}$, diamagnetic (c) Co^{3+}: [Ar] $3d^6$, paramagnetic (d) Ag^+: [Kr] $4d^{10}$, diamagnetic **8.85** For palladium to be diamagnetic, all of its electrons must be paired. (a) You might first write the condensed electron configuration for Pd as [Kr] $5s^2 4d^8$. However, the partial orbital diagram is not consistent with diamagnetism.



(b) This is the only configuration that supports diamagnetism, [Kr] $4d^{10}$.



(c) Promoting an *s* electron into the *d* sublevel still leaves two electrons unpaired.



8.87(a) $Li^+ < Na^+ < K^+$ (b) $Rb^+ < Br^- < Se^{2-}$ (c) $F^- < O^{2-} < N^{3-}$ **8.90** Ce: [Xe] $6s^2 4f^1 5d^1$; Ce^{4+}: [Xe]; Eu: [Xe] $6s^2 4f^7$; Eu^{2+}: [Xe] $4f^7$. Ce^{4+} has a noble-gas configuration; Eu^{2+} has a half-filled *f* subshell. **8.91**(a) Cl_2O, dichlorine monoxide (b) Cl_2O_3, dichlorine trioxide (c) Cl_2O_5, dichlorine pentoxide (d) Cl_2O_7, dichlorine heptoxide (e) SO_3, sulfur trioxide (f) SO_2, sulfur dioxide (g) N_2O_5, dinitrogen pentoxide (h) N_2O_3, dinitrogen trioxide (i) CO_2, carbon dioxide (j) P_4O_{10}, tetraphosphorus decoxide **8.94**(a) $SrBr_2$, strontium bromide (b) CaS, calcium sulfide (c) ZnF_2, zinc fluoride (d) LiF, lithium fluoride **8.95**(a) 2009 kJ/mol (b) −549 kJ/mol **8.97** All ions except Fe^{8+} and Fe^{14+} are paramagnetic; Fe^+ and Fe^{3+} would be most attracted.

Chapter 9

Answers to Boxed Reading Problems: B9.1 The C═C bond shows absorption of IR at shorter wavelength (higher energy) because it is a stronger bond than C—C. The C≡C bond would show absorption at a shorter wavelength (higher energy) than the C═C bond since the triple bond has a higher bond energy than the double bond. **B9.2** (a) 7460 nm (symmetric stretch), 1.50×10^4 nm (bending), 4260 nm (asymmetrical stretch) (b) 2.66×10^{-20} J (symmetric stretch), 1.33×10^{-20} J (bending), 4.67×10^{-20} J (asymmetrical stretch); bending requires the least amount of energy.

• **9.1**(a) Greater ionization energy decreases metallic character. (b) Larger atomic radius increases metallic character. (c) Higher number of outer electrons decreases metallic character. (d) Larger effective nuclear charge decreases metallic character. **9.4**(a) Cs (b) Rb (c) As **9.6**(a) ionic (b) covalent (c) metallic **9.8**(a) covalent (b) ionic (c) covalent **9.10**(a) Rb· (b) ·Si· (c) :I· **9.12**(a) ·Sr· (b) :P· (c) :S· **9.14**(a) 6A(16); [noble gas] $ns^2 np^4$ (b) 3(A)13; [noble gas] $ns^2 np^1$ **9.17**(a) Because the lattice energy is the result of electrostatic attractions among the oppositely charged ions, its magnitude depends on several factors, including ionic size, ionic charge, and the arrangement of ions in the solid. For a particular arrangement of ions, the lattice energy increases as the charges on the ions increase and as their radii decrease. (b) A < B < C **9.20**(a) Ba^{2+}, [Xe]; Cl^-, [Ne] $3s^2 3p^6$, :Cl:$^-$; $BaCl_2$ (b) Sr^{2+}, [Kr]; O^{2-}, [He] $2s^2 2p^6$, :O:$^{2-}$; SrO (c) Al^{3+}, [Ne]; F^-, [He] $2s^2 2p^6$, :F:$^-$; AlF_3 (d) Rb^+, [Kr]; O^{2-}, [He] $2s^2 2p^6$, :O:$^{2-}$; Rb_2O **9.22**(a) 2A(2) (b) 6A(16) (c) 1A(1) **9.24**(a) 3A(13) (b) 2A(2) (c) 6A(16) **9.26**(a) BaS; the charge on each ion is twice the charge on the ions in CsCl. (b) LiCl; Li^+ is smaller than Cs^+. **9.28**(a) BaS; Ba^{2+} is larger than Ca^{2+}. (b) NaF; the charge on each ion is less than the charge on Mg and O. **9.30** 788 kJ; the lattice energy for NaCl is less than that for LiF, because the Na^+ and Cl^- ions are larger than Li^+ and F^- ions. **9.33** −336 kJ **9.34** When two chlorine atoms are far apart, there is no interaction between them. As the atoms move closer together, the nucleus of each atom attracts the electrons of the other atom. The closer the atoms, the greater this attraction; however, the repulsions of the two nuclei and the electrons also increase at the same time. The final internuclear distance is the distance at which maximum attraction is achieved

in spite of the repulsion. **9.35** The bond energy is the energy required to break the bond between H atoms and Cl atoms in one mole of HCl molecules in the gaseous state. Energy is needed to break bonds, so bond breaking is always endothermic and $\Delta H^\circ_{\text{bond breaking}}$ is positive. The quantity of energy needed to break the bond is released upon its formation, so $\Delta H^\circ_{\text{bond forming}}$ has the same magnitude as $\Delta H^\circ_{\text{bond breaking}}$ but is opposite in sign (always exothermic and negative). **9.39**(a) I—I < Br—Br < Cl—Cl (b) S—Br < S—Cl < S—H (c) C—N < C=N < C≡N **9.41**(a) C—O < C=O; the C=O bond (bond order = 2) is stronger than the C—O bond (bond order = 1). (b) C—H < O—H; O is smaller than C so the O—H bond is shorter and stronger than the C—H bond. **9.43** Less energy is required to break weak bonds. **9.45** Both are one-carbon molecules. Since methane contains no carbon-oxygen bonds, it will have the greater heat of reaction per mole for combustion. **9.47** −168 kJ **9.49** −22 kJ **9.50** −59 kJ **9.51** Electronegativity increases from left to right and increases from bottom to top within a group. Fluorine and oxygen are the two most electronegative elements. Cesium and francium are the two least electronegative elements. **9.53** The H—O bond in water is polar covalent. A nonpolar covalent bond occurs between two atoms with identical EN values. A polar covalent bond occurs when the atoms have different EN values. Ionic bonds result when the atoms have very different EN values.

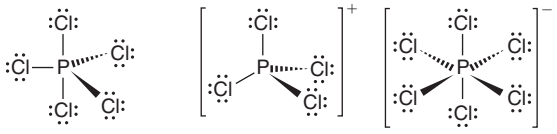
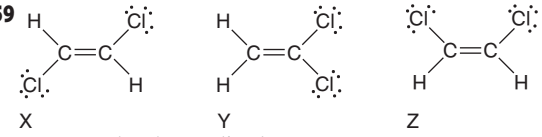
The N and O have lone pairs, so the bond angles are less than ideal. (b) All central atoms have four pairs, so the ideal bond angles are 109.5°. The lone pairs on the O reduce this value. (c) The B has three groups and an ideal bond angle of 120°. All the O's have four groups (ideal bond angles of 109.5°), two of which are lone pairs that reduce the bond angle.

10.51



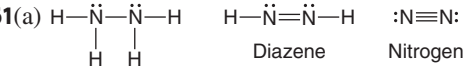
In the gas phase, PCl_5 is AX_5, so the shape is trigonal bipyramidal, and the bond angles are 120° and 90°. The PCl_4^+ ion is AX_4, so the shape is tetrahedral, and the bond angles are 109.5°. The PCl_6^- ion is AX_6, so the shape is octahedral, and the bond angles are 90°. **10.52** Molecules are polar if they have polar bonds that are not arranged to cancel each other. A polar bond is present any time there is a bond between elements with differing electronegativities. **10.55**(a) CF_4 (b) BrCl and SCl_2 **10.57**(a) SO_2, because it is polar and SO_3 is not. (b) IF has a greater electronegativity difference between its atoms. (c) SF_4, because it is polar and SiF_4 is not. (d) H_2O has a greater electronegativity difference between its atoms.

10.59



Yes, compound Y has a dipole moment.

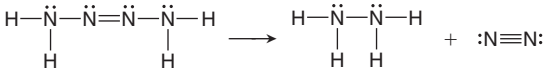
10.61(a)



Hydrazine Diazene Nitrogen

The single N—N bond (bond order = 1) is weaker and longer than the others. The triple bond (bond order = 3) is stronger and shorter than the others. The double bond (bond order = 2) has an intermediate strength and length.

(b) $\Delta H^\circ_{rxn} = -367$ kJ

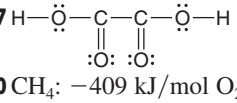


10.65(a) formal charges: Al = −1, end Cl = 0, bridging Cl = +1; I = −1, end Cl = 0, bridging Cl = +1 (b) The iodine atoms are each AX_4E_2, and the shape around each is square planar. These square planar portions are adjacent, giving a planar molecule.

10.70

(a) In propylene oxide, the shape around each C is tetrahedral, with ideal angles of 109.5°. (b) The C that is not part of the three-membered ring should have close to the ideal angle. The atoms in the ring form an equilateral triangle, so the angles around the two C's in the ring are reduced from the ideal 109.5° to nearly 60°. **10.75**(a) −1267 kJ/mol (b) −1226 kJ/mol (c) −1234.8 kJ/mol. The two answers differ by less than 10 kJ/mol. This is very good agreement since average bond energies were used to calculate answers a and b. (d) −37 kJ

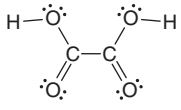
10.77



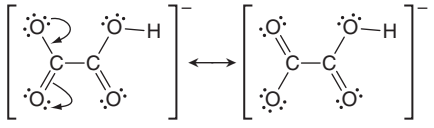
10.80 CH_4: −409 kJ/mol O_2; H_2S: −398 kJ/mol O_2

10.82(a) The O in the OH species has only 7 valence electrons, which is less than an octet, and 1 electron is unparied. (b) 426 kJ (c) 508 kJ **10.84**(a) The F atoms will substitute at the axial positions first. (b) PF_5 and PCl_3F_2

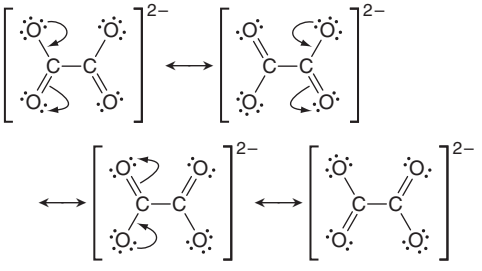
10.86 $H_2C_2O_4$:



$HC_2O_4^-$:



$C_2O_4^{2-}$:



In $H_2C_2O_4$, there are two shorter and stronger C═O bonds and two longer and weaker C—O bonds. In $HC_2O_4^-$, the carbon-oxygen bonds on the side retaining the H remain as one long, weak C—O and one short, strong C═O. The carbon-oxygen bonds on the other side of the molecule have resonance forms with a bond order of 1.5, so they are intermediate in length and strength. In $C_2O_4^{2-}$, all the carbon-oxygen bonds have a bond order of 1.5. **10.90** 22 kJ **10.91** Trigonal planar molecules are nonpolar, so AY_3 cannot be that shape. Trigonal pyramidal molecules and T-shaped molecules are polar, so AY_3 could have either of these shapes. **10.95**(a) 339 pm (b) 316 pm and 223 pm (c) 270 pm

(c)

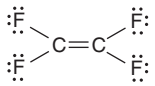
11.20(a) False. A double bond is one σ and one π bond. (b) False. A triple bond consists of one σ and two π bonds. (c) True (d) True (e) False. A π bond consists of a second pair of electrons after a σ bond has been previously formed. (f) False. End-to-end overlap results in a bond with electron density along the bond axis. **11.21**(a) Nitrogen uses sp^2 to form three σ bonds and one π bond. (b) Carbon uses *sp* to form two σ bonds and two π bonds. (c) Carbon uses sp^2 to form three σ bonds and one π bond.

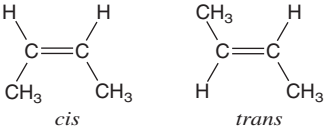
11.23(a) N: sp^2, forming two σ bonds and one π bond

(b) C: sp^2, forming three σ bonds and one π bond

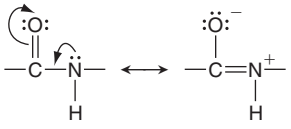


(c) C: *sp*, forming two σ bonds and two π bonds

11.25



The single bonds are all σ bonds. The double bond is one σ bond and one π bond. **11.26** Four MOs form from the four *p* atomic orbitals. The total number of MOs must equal the number of atomic orbitals. **11.28**(a) Bonding MOs have lower energy than antibonding MOs. Lower energy means more stable. (b) Bonding MOs do not have a nodal plane perpendicular to the bond. (c) Bonding MOs have higher electron density between nuclei than antibonding MOs. **11.30**(a) two (b) two (c) four **11.32**(a) A is π^*_{2p}, B is σ_{2p}, C is π_{2p}, and D is σ^*_{2p}. (b) π^*_{2p} (A), σ_{2p} (B), and π_{2p} (C) have at least one electron. (c) π^*_{2p} (A) has only one electron. **11.34**(a) stable (b) paramagnetic (c) $(\sigma_{2s})^2(\sigma^*_{2s})^1$ **11.36**(a) $C_2^+ < C_2 < C_2^-$ (b) $C_2^- < C_2 < C_2^+$ **11.40**(a) C (ring): sp^2; C (all others): sp^3; O (all): sp^3; N: sp^3 (b) 26 (c) 6 **11.42**(a) 17 (b) All carbons are sp^2; the ring N is sp^2, the other N's are sp^3. **11.44**(a) B changes from sp^2 to sp^3. (b) P changes from sp^3 to sp^3d. (c) C changes from *sp* to sp^2. Two electron groups surround C in C_2H_2, and three electron groups surround C in C_2H_4. (d) Si changes from sp^3 to sp^3d^2. (e) no change for S **11.46** P: tetrahedral, sp^3; N: trigonal pyramid, sp^3; C_1 and C_2: tetrahedral, sp^3; C_3: trigonal planar, sp^2 **11.51**(a) B and D are present. (b) Yes, *sp* hybrid orbitals. (c) Two sets of *sp* orbitals, four sets of sp^2 orbitals, and three sets of sp^3 orbitals. **11.52** Through resonance, the C—N bond gains some double-bond character, which hinders rotation about that bond.



11.56(a) C in $—CH_3$: sp^3; all other C atoms: sp^2; O in two C—O bonds: sp^3; O in two C═O bonds: sp^2 (b) two (c) eight; one **11.57**(a) four (b) eight

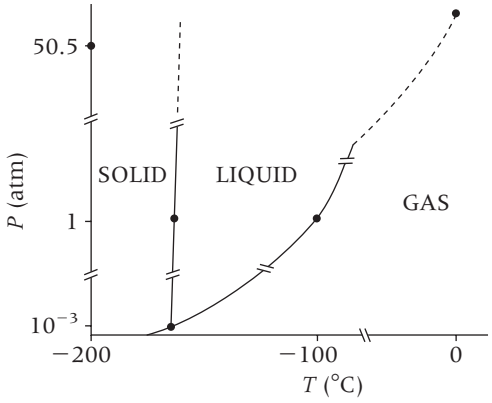
Chapter 12

Answer to Boxed Reading Problem: B12.1 1.76×10^{-10} m

• **12.1** In a solid, the energy of attraction of the particles is greater than their energy of motion; in a gas, it is less. Gases have high compressibility and the ability to flow, while solids have neither. **12.4**(a) Because the intermolecular forces are only partially overcome when fusion occurs but need to be totally overcome in vaporization. (b) Because solids have greater intermolecular forces than liquids do. (c) $\Delta H_{vap} = -\Delta H_{cond}$ **12.5**(a) intermolecular (b) intermolecular (c) intramolecular (d) intramolecular **12.7**(a) condensation (b) fusion (c) vaporization **12.9** The gas molecules slow down as the gas is compressed. Therefore, much of the kinetic energy lost by the propane

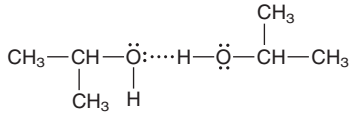
molecules is released to the surroundings. **12.13** At first, the vaporization of liquid molecules from the surface predominates, which increases the number of gas molecules and hence the vapor pressure. As more molecules enter the gas phase, more gas molecules hit the surface of the liquid and "stick" more frequently, so the condensation rate increases. When the vaporization and condensation rates become equal, the vapor pressure becomes constant. **12.14** As intermolecular forces increase, (a) critical temperature increases, (b) boiling point increases, (c) vapor pressure decreases, and (d) heat of vaporization increases. **12.18** because the condensation of the vapor supplies an additional 40.7 kJ/mol **12.19** 7.67×10^{3} J **12.21** 0.777 atm **12.23** 2×10^{4} J/mol

12.25

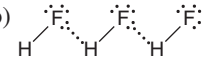


Solid ethylene is more dense than liquid ethylene. **12.27**(a) Rhombic sulfur will sublime when it is heated at a pressure less than 1×10^{-4} atm. (b) At 90°C and 1 atm, sulfur is in the solid (rhombic) form. As it is heated at constant pressure, it passes through the solid (monoclinic) phase, starting at 114°C. At about 120°C, the solid melts to form the liquid. At about 445°C, the liquid evaporates and changes to the gas. **12.30** 32 atm **12.34** O is smaller and more electronegative than Se; thus, the electron density of O is greater, which attracts H more strongly. **12.36** All particles (atoms and molecules) exhibit dispersion forces, but the total force is weak for small molecules. Dipole-dipole forces between small polar molecules dominate the dispersion forces. **12.39**(a) hydrogen bonding (b) dispersion forces (c) dispersion forces **12.41**(a) dipole-dipole forces (b) dispersion forces (c) hydrogen bonding

12.43(a)



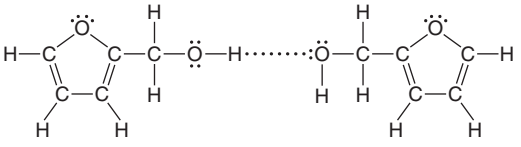
(b)



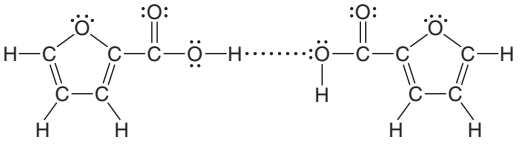
12.45(a) dispersion forces (b) hydrogen bonding (c) dispersion forces **12.47**(a) I^- (b) $CH_2{=}CH_2$ (c) H_2Se. In (a) and (c) the larger particle has the higher polarizability. In (b), the less tightly held π electron clouds are more easily distorted. **12.49**(a) C_2H_6; it is a smaller molecule exhibiting weaker dispersion forces than C_4H_{10}. (b) CH_3CH_2F; it has no H—F bonds, so it exhibits only dipole-dipole forces, which are weaker than the hydrogen bonds of CH_3CH_2OH. (c) PH_3; it has weaker intermolecular forces (dipole-dipole) than NH_3 (hydrogen bonding).

12.51(a) HCl; it has dipole-dipole forces, and there is stronger ionic bonding in LiCl. (b) PH_3; it has dipole-dipole forces, and there is stronger hydrogen bonding in NH_3. (c) Xe; it exhibits weaker dispersion forces since its smaller size results in lower polarizability than the larger I_2 molecules. **12.53**(a) C_4H_8 (cyclobutane), because it is more compact than C_4H_{10}. (b) PBr_3; the dipole-dipole forces in PBr_3 are weaker than the ionic bonds in NaBr. (c) HBr; the dipole-dipole forces in HBr are weaker than the hydrogen bonds in water. **12.55** As atomic size decreases and electronegativity increases, the electron density of an atom increases. Thus, the attraction to an H atom on another molecule increases while its bonded H atom becomes more positive. Fluorine is the smallest of the three and the most electronegative, so the H bonds in hydrogen fluoride are the strongest. Oxygen is smaller and more electronegative than nitrogen, so H bonds in water are stronger than H bonds in ammonia. **12.59** The cohesive forces in water and mercury are stronger than the adhesive forces to the nonpolar wax on the floor. Weak adhesive forces result in spherical drops. The adhesive forces overcome the even weaker cohesive forces in the oil, and so the oil drop spreads out. **12.61** Surface tension is defined as the energy needed to increase the surface area by a given amount, so units of energy per area are appropriate. **12.63** $CH_3CH_2CH_2OH < HOCH_2CH_2OH < HOCH_2CH(OH)CH_2OH$. More hydrogen bonding means more attraction between molecules, so more energy is needed to increase surface area. **12.65** $HOCH_2CH(OH)CH_2OH > HOCH_2CH_2OH > CH_3CH_2CH_2OH$. More hydrogen bonding means more attraction between molecules, so they flow less easily. **12.70** Water is a good solvent for polar and ionic substances and a poor solvent for nonpolar substances. Water is a polar molecule and dissolves polar substances because their intermolecular forces are of similar strength. **12.71** A single water molecule can form four H bonds. The two hydrogen atoms each form one H bond to oxygen atoms on neighboring water molecules. The two lone pairs on the oxygen atom form H bonds with hydrogen atoms on two neighboring molecules. **12.74** Water exhibits strong capillary action, which allows it to be easily absorbed by the plant's roots and transported upward to the leaves. **12.80** simple cubic **12.83** The energy gap is the energy difference between the highest filled energy level (valence band) and the lowest unfilled energy level (conduction band). In conductors and superconductors, the energy gap is zero because the valence band overlaps the conduction band. In semiconductors, the energy gap is small. In insulators, the gap is large. **12.85** atomic mass and atomic radius **12.86**(a) face-centered cubic (b) body-centered cubic (c) face-centered cubic **12.88** 1.54 g/cm^3 **12.90**(a) The change in unit cell is from a sodium chloride structure in CdO to a zinc blende structure in CdSe. (b) Yes, the coordination number of Cd changes from 6 in CdO to 4 in CdSe. **12.92** 524 pm **12.94**(a) Nickel forms a metallic solid since it is a metal whose atoms are held together by metallic bonds. (b) Fluorine forms a molecular solid since the F_2 molecules are held together by dispersion forces. (c) Methanol forms a molecular solid since the CH_3OH molecules are held together by hydrogen bonds.

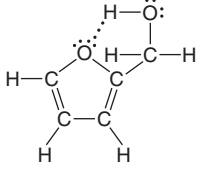
(d) Tin forms a metallic solid since it is a metal whose atoms are held together by metallic bonds. (e) Silicon is under carbon in Group 4A(14); it exhibits similar bonding properties. Since diamond and graphite are both network covalent solids, it makes sense that Si forms a network covalent solid as well. (f) Xe is an atomic solid since its individual atoms are held together by dispersion forces. **12.96** four **12.98**(a) four Se^{2-} ions, four Zn^{2+} ions (b) 577.48 amu (c) 1.77×10^{-22} cm^3 (d) 5.61×10^{-8} cm **12.100**(a) insulator (b) conductor (c) semiconductor **12.102**(a) Conductivity increases. (b) Conductivity increases. (c) Conductivity decreases. **12.104** 1.68×10^{-8} cm **12.111** A substance whose properties are the same in all directions is isotropic; otherwise, the substance is anisotropic. Liquid crystals have a degree of order only in certain directions, so they are anisotropic. **12.117**(a) n-type semiconductor (b) p-type semiconductor **12.119** $n = 3.4\times10^3$ **12.121** 8.4 pm **12.124**(a) 19.8 torr (b) 0.0485 g **12.130** 259 K **12.132**(a) 2.23×10^{-2} atm (b) 6.23 L **12.135**(a) furfuryl alcohol



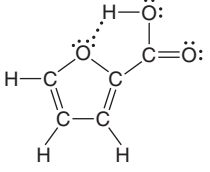
2-furoic acid



(b) furfuryl alcohol

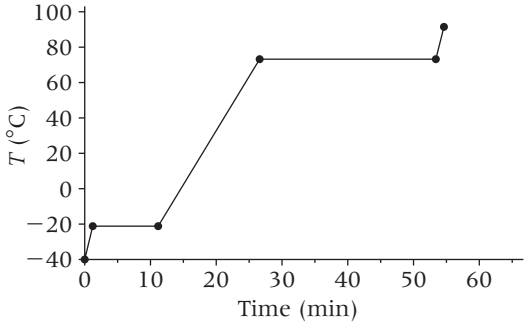


2-furoic acid



12.136(a) 49.3 metric tons H_2O (b) -1.11×10^8 kJ **12.137** 2.9 g/m^3 **12.142**(a) 1.1 min (b) 10. min

(c)

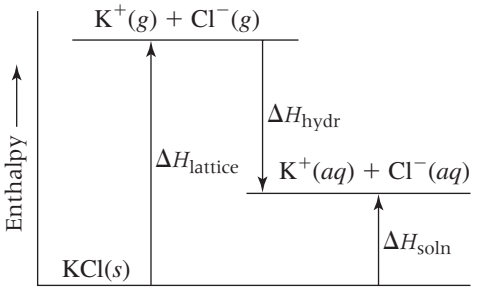


12.143 2.98×10^5 g BN **12.146** 45.98 amu

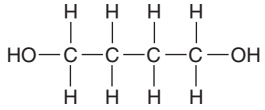
Chapter 13

Answers to Boxed Reading Problem: B13.1 (a) The colloidal particles in water generally have negatively charged surfaces and so repel each other, slowing the settling process. Cake alum, $Al_2(SO_4)_3$, is added to coagulate the colloids. The Al^{3+} ions neutralize the negative surface charges and allow the particles to aggregate and settle. (b) Water that contains large amounts of divalent cations (such as Ca^{2+} and Mg^{2+}) is called hard water. During cleaning, these ions combine with the fatty-acid anions in soaps to produce insoluble deposits. (c) In reverse osmosis, a pressure greater than the osmotic pressure is applied to the solution, forcing the water back through the membrane, leaving the ions behind. (d) Chlorine may give the water an unpleasant odor, and can form carcinogenic chlorinated compounds. (e) The high concentration of NaCl displaces the divalent and polyvalent ions from the ion-exchange resin.

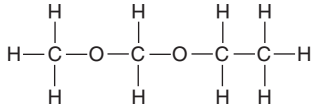
• **13.2** When a salt such as NaCl dissolves, ion-dipole forces cause the ions to separate, and many water molecules cluster around each ion in hydration shells. Ion-dipole forces bind the first shell to an ion. The water molecules in that shell form H bonds to others to create the next shell, and so on. **13.4** Sodium stearate is a more effective soap because the hydrocarbon chain in the stearate ion is longer than that in the acetate ion. The longer chain allows for more dispersion forces with grease molecules. **13.7** KNO_3 is an ionic compound and is therefore more soluble in water. **13.9**(a) ion-dipole forces (b) hydrogen bonding (c) dipole–induced dipole forces **13.11**(a) hydrogen bonding (b) dipole–induced dipole forces (c) dispersion forces **13.13**(a) HCl(g), because the molecular interactions (dipole-dipole forces) in ether are more like those in HCl than the ionic bonding in NaCl. (b) $CH_3CHO(l)$, because the molecular interactions with ether (dipole-dipole) can replace those between CH_3CHO, but not the H bonds in water. (c) $CH_3CH_2MgBr(s)$, because the molecular interactions (dipole-dipole and dispersion forces) with ether are greater than between ether and the ions in $MgBr_2$. **13.16** Gluconic acid is soluble in water due to extensive hydrogen bonding by the —OH groups attached to five of its carbons. The dispersion forces in the nonpolar tail of caproic acid are more similar to the dispersion forces in hexane; thus, caproic acid is soluble in hexane. **13.18** The nitrogen-containing bases form H bonds to their complementary bases. The flat, N-containing bases stack above each other, which allows extensive dispersion forces. The exterior negatively charged sugar-phosphate chains form ion-dipole and H bonds with water molecules in the aqueous surroundings, which also stabilizes the structure. **13.21** Dispersion forces are present between the nonpolar tails of the lipid molecules within the bilayer. The polar heads interact with the aqueous surroundings through H bonds and ion-dipole forces. **13.25** The enthalpy changes needed to separate the solvent ($\Delta H_{solvent}$) and to mix the solvent and solute (ΔH_{mix}) combine to give $\Delta H_{solvation}$. **13.29** very soluble, because a decrease in enthalpy and an increase in entropy both favor the formation of a solution **13.30**



13.32(a) The volume of Na^+ is smaller. (b) Sr^{2+} has a larger ionic charge and a smaller volume. (c) Na^+ is smaller than Cl^-. (d) O^{2-} has a larger ionic charge. (e) OH^- has a smaller volume than SH^-. (f) Mg^{2+} has a smaller volume. (g) Mg^{2+} has both a smaller volume and a larger ionic charge. (h) CO_3^{2-} has a larger ionic charge. **13.34**(a) Na^+ (b) Sr^{2+} (c) Na^+ (d) O^{2-} (e) OH^- (f) Mg^{2+} (g) Mg^{2+} (h) CO_3^{2-} **13.36**(a) -704 kJ/mol (b) The K^+ ion contributes more because it is smaller and, therefore, has a greater charge density. **13.38**(a) increases (b) decreases (c) increases **13.41** Add a pinch of X to each solution. Addition of a "seed" crystal of solute to a supersaturated solution causes the excess solute to crystallize immediately, leaving behind a saturated solution. The solution in which the added X dissolves is the unsaturated solution. The solution in which the added X remains undissolved is the saturated solution. **13.44**(a) increase (b) decrease **13.46**(a) 0.102 g O_2 (b) 0.0214 g O_2 **13.49** 0.20 mol/L **13.52**(a) molarity and % w/v or % v/v (b) parts-by-mass (% w/w) (c) molality **13.54** With just this information, you can convert between molality and molarity, but you need to know the molar mass of the solvent to convert to mole fraction. **13.56**(a) 0.944 *M* $C_{12}H_{22}O_{11}$ (b) 0.167 *M* $LiNO_3$ **13.58**(a) 0.0749 *M* NaOH (b) 0.36 *M* HNO_3 **13.60**(a) Add 4.25 g KH_2PO_4 to enough water to make 365 mL of aqueous solution. (b) Add 125 mL of 1.25 *M* NaOH to enough water to make 465 mL of solution. **13.62**(a) Weigh out 48.0 g KBr, dissolve it in about 1 L distilled water, and then dilute to 1.40 L with distilled water. (b) Measure 82.7 mL of the 0.264 *M* $LiNO_3$ solution and add distilled water to make a total of 255 mL. **13.64**(a) 0.896 *m* glycine (b) 1.21 *m* glycerol **13.66** 4.48 *m* C_6H_6 **13.68**(a) Add 2.39 g $C_2H_6O_2$ to 308 g H_2O. (b) Add 0.0508 kg of 52.0% HNO_3 by mass to 1.15 kg H_2O to make 1.20 kg of 2.20% HNO_3 by mass. **13.70**(a) 0.29 (b) 58 mass % (c) 23 *m* C_3H_7OH **13.72** 42.6 g CsBr; mole fraction $= 7.16\times10^{-3}$; 7.84% by mass **13.74** 5.11 *m* NH_3; 4.53 *M* NH_3; mole fraction $= 0.0843$ **13.76** 2.5 ppm Ca^{2+}; 0.56 ppm Mg^{2+} **13.80** It conducts a "strong" current. A strong electrolyte dissociates completely into ions in solution. **13.82** The boiling point is higher and the freezing point is lower for the solution than for the solvent. **13.85** A dilute solution of an electrolyte behaves more ideally than a concentrated one. With increasing concentration, the effective concentration deviates from the molar concentration because of ionic attractions. Thus, 0.050 *m* NaF has a boiling point closer to its predicted value. **13.88**(a) strong electrolyte (b) strong electrolyte (c) nonelectrolyte (d) weak electrolyte **13.90**(a) 0.6 mol of solute particles (b) 0.13 mol (c) 2×10^{-4} mol (d) 0.06 mol **13.92**(a) CH_3OH in H_2O (b) H_2O in CH_3OH solution **13.94**(a) $\Pi_{II} < \Pi_I < \Pi_{III}$ (b) $bp_{II} < bp_I < bp_{III}$ (c) $fp_{III} < fp_I < fp_{II}$ (d) $vp_{III} < vp_I < vp_{II}$ **13.96** 23.4 torr **13.98** -0.467°C **13.100** 79.5°C **13.102** 1.18×10^4 g $C_2H_6O_2$ **13.104** 2.44×10^{-3} atm **13.106** -14.6°C **13.108**(a) NaCl: 0.173 *m* and $i = 1.84$ (b) CH_3COOH: 0.0837 *m* and $i = 1.02$ **13.111** 209 torr for CH_2Cl_2; 48.1 torr for CCl_4 **13.112** The fluid inside a bacterial cell is both a solution and a colloid. It is a solution of ions and small molecules and a colloid of large molecules (proteins and nucleic acids). **13.116** Soap micelles have nonpolar tails pointed inward and anionic heads pointed outward. The like charges on the heads of one micelle repel those on the heads of a neighboring micelle. This repulsion between micelles keeps them from coagulating. Soap is more effective in freshwater than in seawater because the divalent cations in seawater combine with the anionic heads to form a precipitate. **13.120** 3.4×10^9 L **13.124** 0.0°C: 4.53×10^{-4} *M* O_2; 20.0°C: 2.83×10^{-4} *M* O_2; 40.0°C: 2.00×10^{-4} *M* O_2 **13.126**(a) 89.9 g/mol (b) C_2H_5O; $C_4H_{10}O_2$ (c) Forms H bonds:



Does not form H bonds:

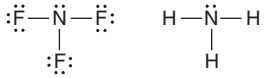


13.130(a) 9.45 g NaF (b) 0.0017 g F^- **13.133**(a) 68 g/mol (b) 2.1×10^2 g/mol (c) The molar mass of CaN_2O_6 is 164.10 g/mol. This value is less than the 2.1×10^2 g/mol calculated when the compound is assumed to be a strong electrolyte and is greater than the 68 g/mol calculated when the compound is assumed to be a nonelectrolyte. Thus, the compound forms a nonideal solution because the ions interact but do not dissociate completely in solution. (d) $i = 2.4$ **13.137**(a) 1.82×10^4 g/mol (b) 3.41×10^{-5}°C **13.138** 8.2×10^5 ng/L **13.142**(a) 0.02 (b) 5×10^{-3} atm·L/mol (c) yes **13.144** Weigh 3.11 g of $NaHCO_3$ and dissolve in 247 g of water. **13.148** $M = m$ (kg solvent/L solution) $= m \times d_{solution}$. Thus, for very dilute solutions, molality $\times$ density $=$ molarity. For an aqueous solution, the number of liters of solution is approximately the same as the kg of solvent because the density of water is close to 1 kg/L, so $m = M$. **13.150**(a) 2.5×10^{-3} *M* SO_2 (b) The base reacts with the sulfur dioxide to produce calcium sulfite. This removal of sulfur dioxide allows more sulfur dioxide to dissolve. **13.155**(a) 7.83×10^{-3} mol L·atm (b) 4×10^{-5} *M* (c) 3×10^{-6} (d) 1 ppm **13.159**(a) 0.0212 mol/L·atm (b) 8.86 ppm (c) k_H: $C_6F_{14} > C_6H_{14} >$ ethanol $>$ water. To dissolve oxygen in a solvent, the solvent molecules must be moved apart to make room for the gas. The stronger the intermolecular forces in the solvent, the more difficult it is to separate solvent particles and the lower the solubility of the gas. Both C_6F_{14} and C_6H_{14} have weak dispersion forces, with C_6F_{14} having the weaker forces due to the electronegative fluorine atoms repelling each other. In both ethanol and water, the molecules are held together by strong hydrogen bonds with those bonds being stronger in water, as the boiling point indicates. **13.161**(a) Yes, the phases of water can still coexist at some temperature and can therefore establish equilibrium. (b) The triple point would occur at a lower pressure and lower temperature because the dissolved air would lower the vapor pressure of the solvent. (c) Yes, this is possible because the gas-solid phase boundary exists below the new triple point. (d) No; at both temperatures, the presence of the solute lowers the vapor pressure of the liquid. **13.163**(a) 2.8×10^{-4} g/mL (b) 81 mL

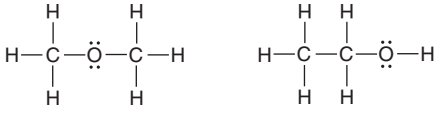
Chapter 14

14.1 The outermost electron is attracted by a smaller effective nuclear charge in Li because of shielding by the inner electrons, and it is farther from the nucleus in Li. Both of these factors lead to a lower ionization energy for Li.

14.3(a) NH_3 will hydrogen bond.



(b) CH_3CH_2OH will hydrogen bond.



14.5(a) $2Al(s) + 6HCl(aq) \longrightarrow 2AlCl_3(aq) + 3H_2(g)$

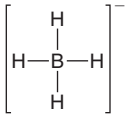
(b) $LiH(s) + H_2O(l) \longrightarrow LiOH(aq) + H_2(g)$

14.7(a) $NaBH_4$: +1 for Na, +3 for B, −1 for H

$Al(BH_4)_3$: +3 for Al, +3 for B, −1 for H

$LiAlH_4$: +1 for Li, +3 for Al, −1 for H

(b) tetrahedral



14.10 For Groups 1A(1) to 4A(14), the number of covalent bonds equals the A-group number. For Groups 5A(15) to 7A(17), it equals 8 minus the A-group number. There are exceptions in Period 3 to Period 6 because it is possible for the 3A(13) to 7A(17) elements to use *d* orbitals and form more bonds. **14.13**(a) Group 3A(13) or 3B(3) (b) If E is in Group 3B(3), the oxide will be more basic and the fluoride will be more ionic; if E is in Group 3A(13), the oxide will be more acidic and the fluoride will be more covalent.

14.16(a) reducing agent (b) Alkali metals have relatively low ionization energies, which means they easily lose the outermost electron.

(c) $2Na(s) + 2H_2O(l) \longrightarrow 2Na^+(aq) + 2OH^-(aq) + H_2(g)$

$2Na(s) + Cl_2(g) \longrightarrow 2NaCl(s)$

14.18 Density and ionic size increase down a group; the other three properties decrease down a group.

14.20 $2Na(s) + O_2(g) \longrightarrow Na_2O_2(s)$

14.22 $K_2CO_3(s) + 2HI(aq) \longrightarrow 2KI(aq) + H_2O(l) + CO_2(g)$

14.26 Group 2A(2) metals have an additional valence electron to increase the strength of metallic bonding, which leads to higher melting points, higher boiling points, greater hardness, and greater density.

14.27(a) $CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s)$

(b) $2Ca(s) + O_2(g) \longrightarrow 2CaO(s)$

14.30(a) $BeO(s) + H_2O(l) \longrightarrow$ no reaction

(b) $BeCl_2(l) + 2Cl^-(\text{solvated}) \longrightarrow BeCl_4^{2-}(\text{solvated})$

Be behaves like other Group 2A(2) elements in reaction (b).

14.33 The electron removed from Group 2A(2) atoms occupies the outer *s* orbital, whereas in Group 3A(13) atoms, the electron occupies the outer *p* orbital. For example, the electron configuration for Be is $1s^22s^2$ and for B it is $1s^22s^22p^1$. It is easier to remove the *p* electron of B than an *s* electron of Be, because the energy of a *p* orbital is higher than that of the *s* orbital of the same level. Even though atomic size decreases because of increasing Z_{eff}, IE decreases from 2A(2) to 3A(13). **14.34**(a) Most atoms form stable compounds when they complete their outer shell (octet). Some compounds of Group 3A(13) elements, like boron, have only six electrons around the central atom. Having fewer than eight electrons is called *electron deficiency*.

(b) $BF_3(g) + NH_3(g) \longrightarrow F_3B{-}NH_3(g)$

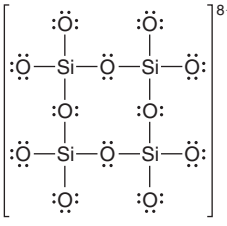
$B(OH)_3(aq) + OH^-(aq) \longrightarrow B(OH)_4^-(aq)$

14.36 $In_2O_3 < Ga_2O_3 < Al_2O_3$ **14.38** Apparent O.N., +3; actual O.N., +1. $\left[:\ddot{I}{-}\ddot{I}{-}\ddot{I}:\right]^-$ The anion I_3^- has the general formula AX_2E_3 and bond angles of 180°. $(Tl^{3+})(I^-)_3$ does not exist because of the low strength of the Tl—I bond.

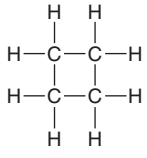
14.43(a) $B_2O_3(s) + 2NH_3(g) \longrightarrow 2BN(s) + 3H_2O(g)$

(b) 1.30×10^2 kJ (c) 5.3 kg borax **14.44** Basicity in water is greater for the oxide of a metal. Tin(IV) oxide is more basic in water than carbon dioxide because tin has more metallic character than carbon. **14.46**(a) Ionization energy generally decreases down a group. (b) The deviations (increases) from the expected trend are due to the presence of the first transition series between Si and Ge and of the lanthanides between Sn and Pb. (c) Group 3A(13) **14.49** Atomic size increases down a group. As atomic size increases, ionization energy decreases and so it is easier to form a positive ion. An atom that is easier to ionize exhibits greater metallic character.

14.51(a)



(b)



14.54(a) diamond, C (b) calcium carbonate, $CaCO_3$ (c) carbon dioxide, CO_2 (d) carbon monoxide, CO (e) silicon, Si

14.58(a) −3 to +5 (b) For a group of nonmetals, the oxidation states range from the lowest, A-group number − 8, or 5 − 8 = −3 for Group 5A, to the highest, equal to the A-group number, or +5 for Group 5A. **14.61** $H_3AsO_4 < H_3PO_4 < HNO_3$

14.63(a) $4As(s) + 5O_2(g) \longrightarrow 2As_2O_5(s)$

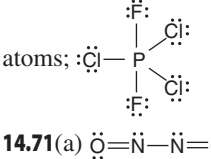
(b) $2Bi(s) + 3F_2(g) \longrightarrow 2BiF_3(s)$

(c) $Ca_3As_2(s) + 6H_2O(l) \longrightarrow 3Ca(OH)_2(s) + 2AsH_3(g)$

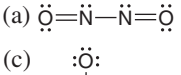
14.65(a) $N_2(g) + 2Al(s) \xrightarrow{\Delta} 2AlN(s)$

(b) $PF_5(g) + 4H_2O(l) \longrightarrow H_3PO_4(aq) + 5HF(g)$

14.67 trigonal bipyramidal, with axial F atoms and equatorial Cl atoms;

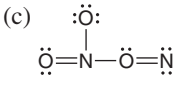


14.71(a)

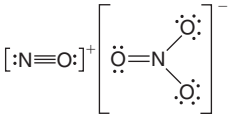


(b)

(c)



(d)



14.73(a) $2KNO_3(s) \xrightarrow{\Delta} 2KNO_2(s) + O_2(g)$ (b) $4KNO_3(s) \xrightarrow{\Delta} 2K_2O(s) + 2N_2(g) + 5O_2(g)$ **14.75**(a) Boiling point and conductivity vary in similar ways down both groups. (b) Degree

of metallic character and types of bonding vary in similar ways down both groups. (c) Both P and S have allotropes, and both bond covalently with almost every other nonmetal. (d) Both N and O are diatomic gases at normal temperatures and pressures. (e) O_2 is a reactive gas, whereas N_2 is not. Nitrogen can have any of six oxidation states, whereas oxygen has two.

14.77(a) $NaHSO_4(aq) + NaOH(aq) \longrightarrow Na_2SO_4(aq) + H_2O(l)$

(b) $S_8(s) + 24F_2(g) \longrightarrow 8SF_6(g)$

(c) $FeS(s) + 2HCl(aq) \longrightarrow H_2S(g) + FeCl_2(aq)$

(d) $Te(s) + 2I_2(s) \longrightarrow TeI_4(s)$

14.79(a) acidic (b) acidic (c) basic (d) amphoteric (e) basic **14.81** $H_2O < H_2S < H_2Te$ **14.84**(a) O_3, ozone (b) SO_3, sulfur trioxide (c) SO_2, sulfur dioxide (d) H_2SO_4, sulfuric acid (e) $Na_2S_2O_3 \cdot 5H_2O$, sodium thiosulfate pentahydrate

14.86 $S_2F_{10}(g) \longrightarrow SF_4(g) + SF_6(g)$; O.N. of S in S_2F_{10} is +5; O.N. of S in SF_4 is +4; O.N. of S in SF_6 is +6. **14.88**(a) −1, +1, +3, +5, +7 (b) The electron configuration for Cl is [Ne] $3s^23p^5$. By gaining one electron, Cl achieves an octet. By forming covalent bonds, Cl completes or expands its valence level by maintaining electron pairs in bonds or as lone pairs. (c) Fluorine has only the −1 oxidation state because its small size and absence of *d* orbitals prevent it from forming more than one covalent bond. **14.90**(a) Cl—Cl bond is stronger than Br—Br bond. (b) Br—Br bond is stronger than I—I bond. (c) Cl—Cl bond is stronger than F—F bond. The fluorine atoms are so small that electron-electron repulsion of the lone pairs decreases the strength of the bond.

14.92(a) $3Br_2(l) + 6OH^-(aq) \longrightarrow 5Br^-(aq) + BrO_3^-(aq) + 3H_2O(l)$

(b) $ClF_5(l) + 6OH^-(aq) \longrightarrow 5F^-(aq) + ClO_3^-(aq) + 3H_2O(l)$

14.93(a) $2Rb(s) + Br_2(l) \longrightarrow 2RbBr(s)$

(b) $I_2(s) + H_2O(l) \longrightarrow HI(aq) + HIO(aq)$

(c) $Br_2(l) + 2I^-(aq) \longrightarrow I_2(s) + 2Br^-(aq)$

(d) $CaF_2(s) + H_2SO_4(l) \longrightarrow CaSO_4(s) + 2HF(g)$

14.95 HIO < HBrO < HClO < $HClO_2$ **14.99** $I_2 < Br_2 < Cl_2$, because Cl_2 is able to oxidize Re to the +6 oxidation state, Br_2 only to +5, and I_2 only to +4 **14.100** helium; argon **14.102** Only dispersion forces hold atoms of noble gases together.

14.106 $\Delta H_{soln} = -411$ kJ **14.110**(a) Second ionization energies for alkali metals are so high because the electron being removed is from the next lower energy level and these are very tightly held by the nucleus. Also, the alkali metal would lose its noble gas electron configuration.

(b) $2CsF_2(s) \longrightarrow 2CsF(s) + F_2(g)$; $\Delta H_{rxn} = -405$ kJ/mol

14.112(a) hyponitrous acid, $H_2N_2O_2$; nitroxyl, HNO

(b) H—Ö—N=N—Ö—H H—N=Ö:

(c) In both species the shape is bent about the N atoms.

(d)  
cis *trans*

14.116 13 t **14.118** In a disproportionation reaction, a substance acts as both a reducing agent and an oxidizing agent because atoms of an element within the substance attain both higher and lower oxidation states in the products. The disproportionation reactions are b, c, d, e, and f. **14.120**(a) Group 5A(15) (b) Group 7A(17) (c) Group 6A(16) (d) Group 1A(1) (e) Group 3A(13) (f) Group 8A(18)

14.122 117.2 kJ

14.127 
The nitronium ion (NO_2^+) has a linear shape because the central N atom has two surrounding electron groups, which achieve maximum repulsion at 180°. The nitrite ion (NO_2^-) bond angle is more compressed than the nitrogen dioxide (NO_2) bond angle because the lone pair of electrons takes up more space than the lone electron. **14.129** 2.29×10^4 g UF_6 **14.133** O^+, O^-, and O^{2+} **14.134**(a) 39.96 mass % in $CuHAsO_3$; As, 62.42 mass % in $(CH_3)_3As$ (b) 0.35 g $CuHAsO_3$

Chapter 15

Answers to Boxed Reading Problems: B15.1 butane, 2 peaks; 2-methylpropane, 2 peaks; pentane, 3 peaks; 2-methylbutane, 4 peaks; 2,2-dimethylpropane, 1 peak **B15.2** 0.08 J/mol **B15.4** ddATP: four complementary chain pieces; ddCTP: three complementary chain pieces

• **15.2**(a) Carbon's electronegativity is midway between the most metallic and most nonmetallic elements of Period 2. To attain a filled outer shell, carbon forms covalent bonds to other atoms in molecules, network covalent solids, and polyatomic ions. (b) Since carbon has four valence shell electrons, it forms four covalent bonds to attain an octet. (c) To reach the He electron configuration, a carbon atom must lose four electrons, requiring too much energy to form the C^{4+} cation. To reach the Ne electron configuration, the carbon atom must gain four electrons, also requiring too much energy to form the C^{4-} anion. (d) Carbon is able to bond to itself extensively because its small size allows for close approach and great orbital overlap. The extensive orbital overlap results in a strong, stable bond. (e) The C—C σ bond is short enough to allow sideways overlap of unhybridized *p* orbitals of neighboring C atoms. The sideways overlap of *p* orbitals results in the π bonds that are part of double and triple bonds. **15.3**(a) H, O, N, P, S, and halogens (b) Heteroatoms are atoms of any element other than carbon and hydrogen. (c) More electronegative than C: N, O, F, Cl, and Br; less electronegative than C: H and P. Sulfur and iodine have the same electronegativity as carbon. (d) Since carbon can bond to a wide variety of heteroatoms and to carbon atoms, it can form many different compounds. **15.6** The C—H and C—C bonds are unreactive because electronegativities are close and the bonds are short. The C—I bond is somewhat reactive because it is long and weak. The C=O bond is reactive because oxygen is more electronegative than carbon and the partially positive C atom attracts electron-rich atoms. The C—Li bond is also reactive because the bond polarity results in an electron-rich region around carbon and an electron-poor region around lithium. **15.7**(a) An alkane and a cycloalkane are organic compounds that consist of carbon and hydrogen and have only single bonds. A cycloalkane has a ring of

carbon atoms. An alkene is a hydrocarbon with at least one double bond. An alkyne is a hydrocarbon with at least one triple bond. (b) alkane = C_nH_{2n+2}, cycloalkane = C_nH_{2n}, alkene = C_nH_{2n}, alkyne = C_nH_{2n-2} (c) Alkanes and cycloalkanes are saturated hydrocarbons. **15.10** a, c, and f

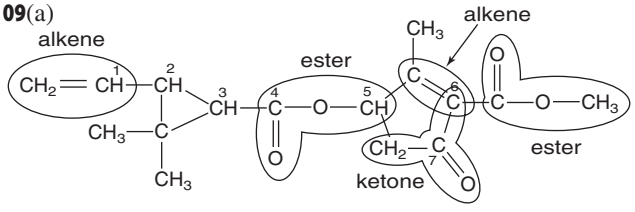
15.109(a)



(b) Carbon 1 is sp^2 hybridized. Carbon 2 is sp^3 hybridized. Carbon 3 is sp^3 hybridized. Carbon 4 is sp^2 hybridized. Carbon 5 is sp^3 hybridized. Carbons 6 and 7 are sp^2 hybridized.

(c) Carbons 2, 3, and 5 are chiral centers, as they are each bonded to four different groups.

15.113 The resonance structures show that the bond between carbon and nitrogen will have some double bond character that restricts rotation around the bond.

15.116(a) Hydrolysis requires the addition of water to break the peptide bonds. (b) glycine, 4; alanine, 1; valine, 3; proline, 6; serine, 7; arginine, 49 (c) 10,700 g/mol **15.117** When 2-butanone is reduced, equal amounts of both isomers are produced because the reaction does not favor the production of one over the other. The mixture is not optically active since the rotation of light to the right by one isomer cancels the rotation of light to the left by the other isomer.

Chapter 16

Answers to Boxed Reading Problems:

B16.2 (a) Step 1 $\cancel{NO(g)} + O_3(g) \longrightarrow \cancel{NO_2(g)} + O_2(g)$

Step 2 $\cancel{NO_2(g)} + O(g) \longrightarrow \cancel{NO(g)} + O_2(g)$

Overall $O_3(g) + O(g) \longrightarrow 2O_2(g)$

(b) rate $= 3\times10^7$ molecule/s

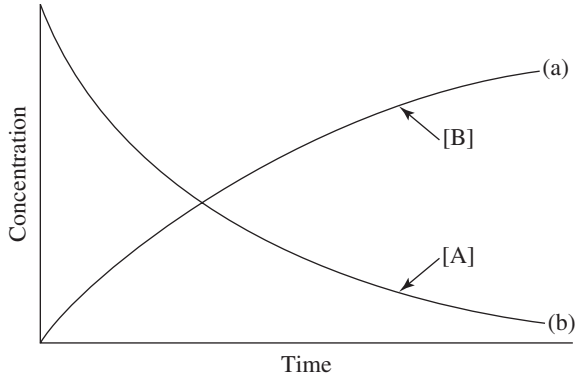
B16.3 (a) Step 1 with Cl will have the higher value for the *p* factor. Since Cl is a single atom, no matter how it collides with the ozone molecule, the two particles should react, if the collision has enough energy. NO is a molecule. If the O_3 molecule collides with the N atom in the NO molecule, reaction can occur as a bond can form between N and O; if the O_3 molecule collides with the O atom in the NO molecule, reaction will not occur as the bond between N and O cannot form. The probability of a successful collision is smaller with NO.

(b)

• **16.2** Reaction rate is proportional to concentration. An increase in pressure will increase the concentration, resulting in an increased rate. **16.3** The addition of water will lower the concentrations of all dissolved solutes, and the rate will decrease.

16.5 An increase in temperature increases the rate by increasing the number of collisions between particles, but more importantly, it increases the energy of collisions. **16.8**(a) The instantaneous rate is the rate at one point in time during the reaction. The average rate is the average over a period of time. On a graph of reactant concentration vs. time, the instantaneous rate is the slope of the tangent to the curve at any point. The average rate is the slope of the line connecting two points on the curve. The closer together the two points (the shorter the time interval), the closer the average rate is to the instantaneous rate. (b) The initial rate is the instantaneous rate at the point on the graph where $t = 0$, that is, when reactants are mixed.

16.10

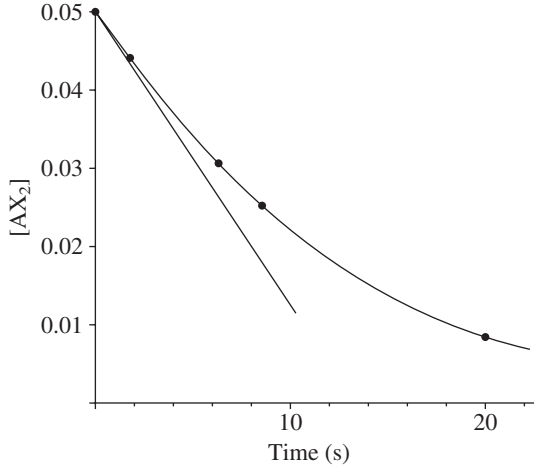


16.12(a) $$\text{rate} = -\left(\frac{1}{2}\right)\frac{\Delta AX_2}{\Delta t}$$

$$= -\left(\frac{1}{2}\right)\frac{(0.0088\ M - 0.0500\ M)}{(20.0\ \text{s} - 0\ \text{s})}$$

$$= 0.0010\ M/\text{s}$$

(b)



Estimated initial rate = 0.004 *M*/s. The initial rate is higher than the average rate because the rate decreases as reactant concentration decreases.

16.14 $\text{rate} = -\frac{1}{2}\frac{\Delta[A]}{\Delta t} = \frac{\Delta[B]}{\Delta t} = \frac{\Delta[C]}{\Delta t}$; 4 mol/L·s

16.16 $\text{rate} = -\frac{\Delta[A]}{\Delta t} = -\frac{1}{2}\frac{\Delta[B]}{\Delta t} = \frac{\Delta[C]}{\Delta t}$; 0.2 mol/L·s

16.18 $2N_2O_5(g) \longrightarrow 4NO_2(g) + O_2(g)$

16.21 $\text{rate} = -\frac{\Delta[N_2]}{\Delta t} = -\frac{1}{3}\frac{\Delta[H_2]}{\Delta t} = \frac{1}{2}\frac{\Delta[NH_3]}{\Delta t}$

16.22(a) $\text{rate} = -\frac{1}{3}\frac{\Delta[O_2]}{\Delta t} = \frac{1}{2}\frac{[\Delta O_3]}{\Delta t}$

(b) 1.45×10^{-5} mol/L·s

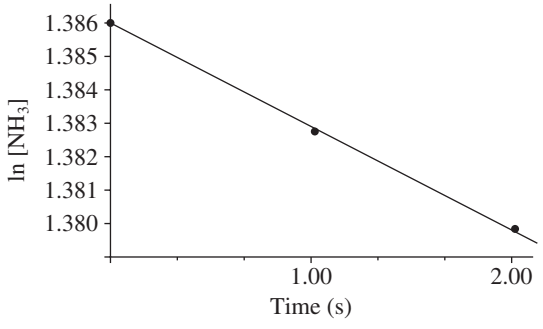
16.23(a) k is the rate constant, the proportionality constant in the rate law; it is reaction and temperature specific. (b) m represents the order of the reaction with respect to [A], and n represents the order of the reaction with respect to [B]. The order of a reactant does not necessarily equal its stoichiometric coefficient in the balanced equation. (c) $L^2/mol^2\cdot min$ **16.25**(a) Rate doubles. (b) Rate decreases by a factor of 4. (c) Rate increases by a factor of 9. **16.26** first order in BrO_3^-; first order in Br^-; second order in H^+; fourth order overall **16.28**(a) Rate doubles. (b) Rate is halved. (c) The rate increases by a factor of 16. **16.30** second order in NO_2; first order in Cl; third order overall **16.32**(a) Rate increases by a factor of 9. (b) Rate increases by a factor of 8. (c) Rate is halved. **16.34**(a) second order in A; first order in B (b) rate $= k[A]^2[B]$ (c) 5.00×10^3 $L^2/mol^2\cdot min$ **16.36**(a) $time^{-1}$ (b) $L/mol\cdot time$ (c) $L^2/mol^2\cdot time$ (d) $L^{3/2}/mol^{3/2}\cdot time$

16.39(a) first order (b) second order (c) zero order **16.41** 7 s

16.43(a) $k = 0.0660\ min^{-1}$ (b) 21.0 min

16.45(a)

***x*-axis (time, s)**	**$[NH_3]$**	***y*-axis (ln $[NH_3]$)**
0	4.000 *M*	1.38629
1.000	3.986 *M*	1.38279
2.000	3.974 *M*	1.37977

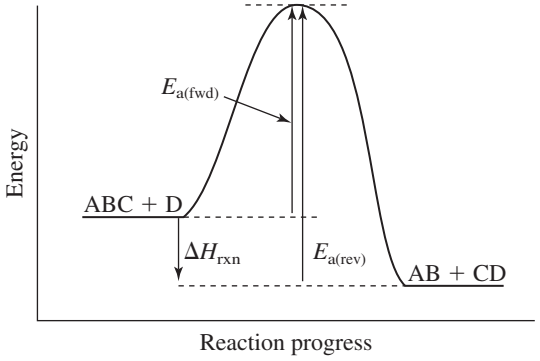


$k = 3\times10^{-3}\ s^{-1}$

(b) $t_{1/2} = 2\times10^2$ s

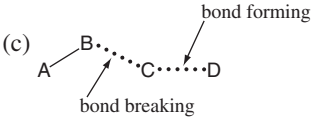
16.47 No, other factors that affect the rate are the energy and orientation of the collisions. **16.50** Measure the rate constant at a series of temperatures and plot ln k versus $1/T$. The slope of the line equals $-E_a/R$. **16.53** No, reaction is reversible and will eventually reach a state where the forward and reverse rates are equal. When this occurs, there are no concentrations equal to zero. Since some reactants are reformed from EF, the amount of EF will be less than 4×10^{-5} mol. **16.54** At the same temperature, both reaction mixtures have the same average kinetic energy, but the reactant molecules do not have the same average velocity. The trimethylamine molecule has greater mass than the ammonia molecule, so trimethylamine molecules will collide less often with HCl. Moreover, the bulky groups bonded to nitrogen in trimethylamine mean that collisions with HCl having the correct orientation occur less frequently. Therefore, the rate of the reaction between NH_3 and HCl is higher. **16.55** 12 unique collisions **16.57** 2.96×10^{-18} **16.59** 0.033 s^{-1}

16.61(a)

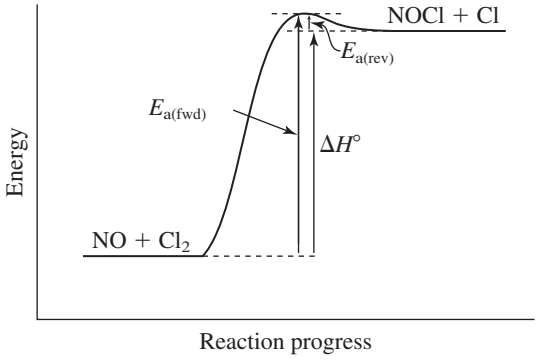


(b) 2.70×10^2 kJ/mol

(c)



16.64(a) Because the enthalpy change is positive, the reaction is endothermic.



(b) 3 kJ (c) 
16.65 The rate of an overall reaction depends on the rate of the slowest step. The rate of the overall reaction will be lower than the average of the individual rates because the average includes higher rates as well. **16.69** The probability of three particles colliding with one another with the proper energy and orientation is much less than the probability for two particles. **16.70** No, the overall rate law must contain only reactants (no intermediates), and the overall rate is determined by the slow step.

16.72(a) $A(g) + B(g) + C(g) \longrightarrow D(g)$

(b) X and Y are intermediates.

(c)

Step	**Molecularity**	**Rate Law**
$A(g) + B(g) \rightleftharpoons X(g)$	bimolecular	$rate_1 = k_1[A][B]$
$X(g) + C(g) \longrightarrow Y(g)$	bimolecular	$rate_2 = k_2[X][C]$
$Y(g) \longrightarrow D(g)$	unimolecular	$rate_3 = k_3[Y]$

(d) yes (e) yes **16.74** The proposed mechanism is valid because the individual steps are chemically reasonable, they add to

give the overall equation, and the rate law for the mechanism matches the observed rate law. **16.77** No. A catalyst changes the mechanism of a reaction to one with lower activation energy. Lower activation energy means a faster reaction. An increase in temperature does not influence the activation energy, but increases the fraction of collisions with sufficient energy to equal or exceed the activation energy. **16.78**(a) No. The spark provides energy that is absorbed by the H_2 and O_2 molecules to achieve the activation energy. (b) Yes. The powdered metal acts as a heterogeneous catalyst, providing a surface on which the oxygen-hydrogen reaction can proceed with a lower activation energy.

16.83(a) Water does not appear as a reactant in the rate-determining step.

(b) Step 1: $\text{rate}_1 = k_1[(CH_3)_3CBr]$
Step 2: $\text{rate}_2 = k_2[(CH_3)_3C^+]$
Step 3: $\text{rate}_3 = k_3[(CH_3)_3COH_2^+]$

(c) $(CH_3)_3C^+$ and $(CH_3)_3COH_2^+$

(d) The rate-determining step is step 1. The rate law for this step agrees with the rate law observed with $k = k_1$.

16.85 4.61×10^4 J/mol **16.89**(a) Rate increases 2.5 times. (b) Rate is halved. (c) Rate decreases by a factor of 0.01. (d) Rate does not change. **16.90** second order **16.93** 57 yr **16.96**(a) 0.21 h^{-1}; 3.3 h (b) 6.6 h (c) If the concentration of sucrose is relatively low, the concentration of water remains nearly constant even with small changes in the amount of water. This gives an apparent zero-order reaction with respect to water. Thus, the reaction is first order overall because the rate does not change with changes in the amount of water. **16.99**(a) 0.68 *M* (b) 0.57 **16.102** 71 kPa **16.106** 7.3×10^3 J/mol **16.108**(a) 2.4×10^{-15} *M* (b) 2.4×10^{-11} mol/L·s **16.111**(a) 2.8 days (b) 7.4 days (c) 4.5 mol/m^3 **16.114**(a) $\text{rate}_1 = 1.7\times10^{-5}$ *M* s^{-1}; $\text{rate}_2 = 3.4\times10^{-5}$ *M* s^{-1}; $\text{rate}_3 = 3.4\times10^{-5}$ *M* s^{-1} (b) zero order with respect to $S_2O_8^{2-}$; first order with respect to I^- (c) 4.3×10^{-4} s^{-1} (d) rate = $(4.3\times10^{-4}\ s^{-1})$[KI] **16.117**(a) 7×10^4 cells/L (b) 2.0×10^1 min **16.120**(a) Use the Monod equation.

Equilibrium position changes as a result of a change in reactant and product concentrations. **17.59**(a) B, because the amount of product increases with temperature (b) A, because the lowest temperature will give the least product **17.63**(a) shifts toward products (b) shifts toward products (c) does not shift (d) shifts toward reactants **17.65**(a) more F and less F_2 (b) more C_2H_2 and H_2 and less CH_4 **17.67**(a) no effect (b) less H_2 and O_2 and more H_2O **17.69**(a) no change (b) increase volume **17.71**(a) amount decreases (b) amounts increase (c) amounts increase (d) amount decreases **17.73** 2.0 **17.76**(a) lower temperature, higher pressure (b) Q decreases; no change in K (c) Reaction rates are lower at lower temperatures, so a catalyst is used to speed up the reaction. **17.78**(a) $P_{N_2} = 31$ atm; $P_{H_2} = 93$ atm; $P_{total} = 174$ atm (b) $P_{N_2} = 18$ atm; $P_{H_2} = 111$ atm; $P_{total} = 179$ atm; not a valid argument **17.81** 0.204 atm **17.84**(a) 3×10^{-3} atm (b) high pressure; low temperature (c) 2×10^5 (d) No, because water condenses at a higher temperature. **17.87**(a) 0.016 atm (b) $K_c = 5.6\times10^2$; $P_{O_2} = 0.16$ atm **17.89** 12.5 g $CaCO_3$ **17.93** Both concentrations increased by a factor of 2.2. **17.95**(a) 3.0×10^{-14} atm (b) 0.013 pg CO/L **17.97**(a) 98.0% (b) 99.0% (c) 2.60×10^5 J/mol **17.99**(a) $2CH_4(g) + O_2(g) + 2H_2O(g) \rightleftharpoons 2CO_2(g) + 6H_2(g)$ (b) 1.76×10^{29} (c) 3.19×10^{23} (d) 48 atm **17.100**(a) 4.0×10^{-21} atm (b) 5.5×10^{-8} atm (c) 29 N atoms/L; 4.0×10^{14} H atoms/L (d) The more reasonable step is $N_2(g) + H(g) \longrightarrow NH(g) + N(g)$. With only 29 N atoms in 1.0 L, the first reaction would produce virtually no $NH(g)$ molecules. There are orders of magnitude more N_2 molecules than N atoms, so the second reaction is the more reasonable step. **17.103**(a) $P_{N_2} = 0.780$ atm; $P_{O_2} = 0.210$ atm; $P_{NO} = 2.67\times10^{-16}$ atm (b) 0.990 atm (c) $K_c = K_p = 4.35\times10^{-31}$ **17.105**(a) 1.26×10^{-3} (b) 794 (c) −51.8 kJ (d) 1.2×10^4 J/mol **17.109**(a) 1.52 (b) 0.9626 atm (c) 0.2000 mol CO (d) 0.01097 M

Chapter 18

18.2 All Arrhenius acids have H in their formula and produce hydronium ion (H_3O^+) in aqueous solution. All Arrhenius bases have OH in their formula and produce hydroxide ion (OH^-) in aqueous solution. Neutralization occurs when each H_3O^+ ion combines with an OH^- ion to form two molecules of H_2O. Chemists found the reaction of any strong base with any strong acid always had a ΔH of −56 kJ/mol H_2O produced.
18.4 Strong acids and bases dissociate completely into ions when dissolved in water. Weak acids and bases dissociate only partially. The characteristic property of all weak acids is that a great majority of the acid molecules are undissociated.
18.5 a, c, and d
18.7 b and d

18.9(a) $K_a = \dfrac{[CN^-][H_3O^+]}{[HCN]}$
(b) $K_a = \dfrac{[CO_3^{2-}][H_3O^+]}{[HCO_3^-]}$
(c) $K_a = \dfrac{[HCOO^-][H_3O^+]}{[HCOOH]}$

18.11(a) $K_a = \dfrac{[NO_2^-][H_3O^+]}{[HNO_2]}$
(b) $K_a = \dfrac{[CH_3COO^-][H_3O^+]}{[CH_3COOH]}$
(c) $K_a = \dfrac{[BrO_2^-][H_3O^+]}{[HBrO_2]}$

18.13 $CH_3COOH < HF < HIO_3 < HI$ **18.15**(a) weak acid (b) strong base (c) weak acid (d) strong acid **18.17**(a) strong base (b) strong acid (c) weak acid (d) weak acid
18.22(a) The acid with the smaller K_a (4×10^{-5}) has the higher pH, because less dissociation yields fewer hydronium ions.

(b) The acid with the larger pK_a (3.5) has the higher pH, because it has a smaller K_a and, thus, lower $[H_3O^+]$.
(c) Lower concentration (0.01 *M*) contains fewer hydronium ions. (d) A 0.1 *M* weak acid solution contains fewer hydronium ions. (e) The 0.01 *M* base solution contains more hydroxide ions, so fewer hydronium ions. (f) The solution that has pOH = 6.0 has the higher pH: pH = 14.0 − 6.0 = 8.0.

18.23(a) 12.05; basic (b) 11.13; acidic **18.25**(a) 2.212; acidic (b) −0.708; basic

18.36(a) Rising temperature increases the value of K_w. (b) $K_w = 2.5\times10^{-14}$; pOH = 6.80; $[OH^-] = 1.6\times10^{-7}$ *M* **18.37** The Brønsted-Lowry theory defines acids as proton donors and bases as proton acceptors, while the Arrhenius definition looks at acids as containing ionizable hydrogen atoms and at bases as containing hydroxide ions. In both definitions, an acid produces H_3O^+ ions and a base produces OH^- ions when added to water. Ammonia and carbonate ion are two Brønsted-Lowry bases that are not Arrhenius bases because they do not contain OH^- ions. Brønsted-Lowry acids must contain an ionizable hydrogen atom in order to be proton donors, so a Brønsted-Lowry acid is also an Arrhenius acid. **18.40** An amphiprotic species is one that can lose a proton to act as an acid or gain a proton to act as a base. The dihydrogen phosphate ion, $H_2PO_4^-$, is an example.

Chapter 19

Answers to Boxed Reading Problem: B19.2 (a) 65 mol (b) 6.28 (c) 4.0×10^3 g HCO_3^-

• **19.2** The acid component neutralizes added base, and the base component neutralizes added acid, so the pH of the buffer solution remains relatively constant. The components of a buffer do not neutralize one another because they are a conjugate acid-base pair. **19.7** The buffer range, the pH over which the buffer acts effectively, is consistent with a buffer-component concentration ratio from 10 to 0.1. This gives a pH range of p$K_a \pm 1$. **19.9**(a) Ratio and pH increase; added OH^- reacts with HA. (b) Ratio and pH decrease; added H^+ reacts with A^-. (c) Ratio and pH increase; added A^- increases $[A^-]$. (d) Ratio and pH decrease; added HA increases [HA]. **19.11** $[H_3O^+] = 5.6\times10^{-6}\ M$; pH = 5.25 **19.13** $[H_3O^+] = 5.2\times10^{-4}\ M$; pH = 3.28 **19.15** 3.89 **19.17** 10.03 **19.19** 9.47 **19.21**(a) K_{a2} (b) 10.55 **19.23** 3.6

19.25 0.20 **19.27** 3.37 **19.29** 8.82 **19.31**(a) 4.81 (b) 0.66 g KOH **19.33**(a) $HOOC(CH_2)_4COOH/HOOC(CH_2)_4COO^-$ or $C_6H_5NH_3^+/C_6H_5NH_2$ (b) $H_2PO_4^-/HPO_4^{2-}$ or $H_2AsO_4^-/HAsO_4^{2-}$ **19.35**(a) $HOCH_2CH(OH)COOH/HOCH_2CH(OH)COO^-$ or $CH_3COOC_6H_4COOH/CH_3COOC_6H_4COO^-$ (b) $C_5H_5NH^+/C_5H_5N$ **19.38** 1.6 **19.40** To see a distinct color in a mixture of two colors, you need one to have about 10 times the intensity of the other. For this to be the case, the concentration ratio $[HIn]/[In^-]$ has to be greater than 10/1 or less than 1/10. This occurs when $pH = pK_a - 1$ or $pH = pK_a + 1$, respectively, giving a pH range of about 2 units. **19.42** The equivalence point in a titration is the point at which the number of moles of base is stoichiometrically equivalent to the number of moles of acid. The endpoint is the point at which the added indicator changes color. If an appropriate indicator is selected, the endpoint is close to the equivalence point, but they are not usually the same. The pH at the endpoint, or color change, may precede or follow the pH at the equivalence point, depending on the indicator chosen. **19.44**(a) initial pH: *strong acid*–strong base < *weak acid*–strong base < *weak base*–strong acid (b) pH at equivalence point: *weak base*–strong acid < *strong acid*–strong base < *weak acid*–strong base **19.46** At the center of the buffer region, the concentrations of weak acid and conjugate base are equal, so the $pH = pK_a$ of the acid. **19.48** pH range from 7.5 to 9.5 **19.50**(a) bromthymol blue (b) thymol blue or phenolphthalein **19.52**(a) methyl red (b) bromthymol blue **19.54**(a) 1.0000 (b) 1.6368 (c) 2.898 (d) 3.903 (e) 7.00 (f) 10.10 (g) 12.05 **19.56**(a) 2.91 (b) 4.81 (c) 5.29 (d) 6.09 (e) 7.41 (f) 8.76 (g) 10.10 (h) 12.05 **19.58**(a) 8.54 and 59.0 mL (b) 4.39 and 66.0 mL, 9.68 and total 132.1 mL **19.60**(a) 5.17 and 123 mL (b) 5.80 and 194 mL **19.63** Fluoride ion is the conjugate base of a weak acid and reacts with H_2O: $F^-(aq) + H_2O(l) \rightleftharpoons HF(aq) + OH^-(aq)$. As the pH increases, the equilibrium shifts to the left and $[F^-]$ increases. As the pH decreases, the equilibrium shifts to the right and $[F^-]$ decreases. The changes in $[F^-]$ influence the solubility of BaF_2. Chloride ion is the conjugate base of a strong acid, so it does not react with water and its concentration is not influenced by pH. **19.65** The compound precipitates. **19.66**(a) $K_{sp} = [Ag^+]^2[CO_3^{2-}]$ (b) $K_{sp} = [Ba^{2+}][F^-]^2$ (c) $K_{sp} = [Cu^{2+}][HS^-][OH^-]$ **19.68**(a) $K_{sp} = [Ca^{2+}][CrO_4^{2-}]$ (b) $K_{sp} = [Ag^+][CN^-]$ (c) $K_{sp} = [Ni^{2+}][HS^-][OH^-]$ **19.70** 1.3×10^{-4} **19.72** 2.8×10^{-11} **19.74**(a) 2.3×10^{-5} *M* (b) 4.2×10^{-9} *M* **19.76**(a) 1.7×10^{-3} *M* (b) 2.0×10^{-4} *M* **19.78**(a) $Mg(OH)_2$ (b) PbS (c) Ag_2SO_4 **19.80**(a) $CaSO_4$ (b) $Mg_3(PO_4)_2$ (c) $PbSO_4$ **19.82**(a) $AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$. The chloride ion is the anion of a strong acid, so it does not react with H_3O^+. No change with pH. (b) $SrCO_3(s) \rightleftharpoons Sr^{2+}(aq) + CO_3^{2-}(aq)$. The strontium ion is the cation of a strong base, so pH will not affect its solubility. The carbonate ion acts as a base: $CO_3^{2-}(aq) + H_2O(l) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$; also $CO_2(g)$ forms and escapes: $CO_3^{2-}(aq) + 2H_3O^+(aq) \longrightarrow CO_2(g) + 3H_2O(l)$. Therefore, the solubility of $SrCO_3$ will increase with addition of H_3O^+ (decreasing pH).

19.84(a) $Fe(OH)_2(s) \rightleftharpoons Fe^{2+}(aq) + 2OH^-(aq)$. The OH^- ion reacts with added H_3O^+: $OH^-(aq) + H_3O^+(aq) \longrightarrow 2H_2O(l)$. The added H_3O^+ consumes the OH^-, driving the equilibrium toward the right to dissolve more $Fe(OH)_2$. Solubility increases with addition of H_3O^+ (decreasing pH). (b) $CuS(s) + H_2O(l) \rightleftharpoons Cu^{2+}(aq) + HS^-(aq) + OH^-(aq)$. Both HS^- and OH^- are anions of weak acids, so both ions react with added H_3O^+. Solubility increases with addition of H_3O^+ (decreasing pH). **19.86** yes **19.88** yes **19.91**(a) $Fe(OH)_3$ (b) The two metal ions are separated by adding just enough NaOH to precipitate iron(III) hydroxide. (c) 2.0×10^{-7} *M* **19.94** No, because it indicates that a complex ion forms between the lead ion and hydroxide ions, such as $Pb^{2+}(aq) + 3OH^-(aq) \rightleftharpoons Pb(OH)_3^-(aq)$ **19.95** $Hg(H_2O)_4^{2+}(aq) + 4CN^-(aq) \rightleftharpoons Hg(CN)_4^{2-}(aq) + 4H_2O(l)$ **19.97** $Ag(H_2O)_2^+(aq) + 2S_2O_3^{2-}(aq) \rightleftharpoons Ag(S_2O_3)_2^{3-}(aq) + 2H_2O(l)$ **19.99** 8.1×10^{-15} *M* **19.101** 0.05 *M* **19.103** 1.0×10^{-16} *M* Zn^{2+}; 0.025 *M* $Zn(CN)_4^{2-}$; 0.049 *M* CN^- **19.105** 0.035 L of 2.00 *M* NaOH and 0.465 L of 0.200 *M* HCOOH **19.107**(a) 0.99 (b) assuming the volumes are additive: 0.468 L of 1.0 *M* HCOOH and 0.232 L of 1.0 *M* NaOH (c) 0.34 *M* **19.110** 1.3×10^{-4} *M* **19.113**(a) 14 (b) 1 g from the second beaker **19.116**(a) 0.088 (b) 0.14 **19.117** 0.260 *M* TRIS; pH = 8.53 **19.119** Lower the pH below 6.6 **19.123** 8×10^{-5} **19.125**(a)

Chapter 20

Answer to Boxed Reading Problem: B20.2 −12.6 kJ/mol

• **20.2** A spontaneous process occurs by itself, whereas a nonspontaneous process requires a continuous input of energy to make it happen. It is possible to cause a nonspontaneous process to occur, but the process stops once the energy source is removed. A reaction that is nonspontaneous under one set of conditions may be spontaneous under a different set of conditions. **20.5** The transition from liquid to gas involves a greater increase in dispersal of energy and freedom of motion than does the transition from solid to liquid. **20.6** In an exothermic reaction, $\Delta S_{surr} > 0$. In an endothermic reaction, $\Delta S_{surr} < 0$. A chemical cold pack for injuries is an example of an application using a spontaneous endothermic process. **20.8** a, b, and c **20.10** a and b **20.12**(a) positive (b) negative (c) negative **20.14**(a) positive (b) positive (c) positive **20.16**(a) negative (b) negative (c) positive **20.18**(a) positive (b) negative (c) positive **20.20**(a) positive (b) negative (c) positive **20.22**(a) Butane. The double bond in 2-butene restricts freedom of rotation. (b) Xe(*g*). It has the greater molar mass. (c) $CH_4(g)$. Gases have greater entropy than liquids. **20.24**(a) $C_2H_5OH(l)$. It is a more complex molecule. (b) $KClO_3(aq)$. Ions in solution have their energy more dispersed than those in a solid. (c) K(*s*). It has a greater molar mass. **20.26**(a) Diamond < graphite < charcoal. Freedom of motion is least in the network solid; more freedom between graphite sheets; most freedom in amorphous solid. (b) Ice < liquid water < water vapor. Entropy increases as a substance changes from solid to liquid to gas. (c) O atoms < O_2 < O_3. Entropy increases with molecular complexity. **20.28**(a) $ClO_4^-(aq) > ClO_3^-(aq) > ClO_2^-(aq)$; decreasing molecular complexity (b) $NO_2(g) > NO(g) > N_2(g)$. N_2 has lower standard molar entropy because it consists of two of the same atoms; the other species have two different types of atoms. NO_2 is more complex than NO. (c) $Fe_3O_4(s) > Fe_2O_3(s) > Al_2O_3(s)$. Fe_3O_4 is more complex and more massive. Fe_2O_3 is more massive than Al_2O_3. **20.31** For a system at equilibrium, $\Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr} = 0$. For a system moving to equilibrium, $\Delta S_{univ} > 0$. **20.32** $S^\circ_{Cl_2O(g)} = 2S^\circ_{HClO(g)} - S^\circ_{H_2O(g)} - \Delta S^\circ_{rxn}$ **20.33**(a) negative; $\Delta S^\circ = -172.4$ J/K (b) positive; $\Delta S^\circ =$ 141.6 J/K (c) negative; $\Delta S^\circ = -837$ J/K **20.35** $\Delta S^\circ =$ 93.1 J/K; yes, the positive sign of ΔS is expected because there is a net increase in the number of gas molecules. **20.37** $\Delta S^\circ = -311$ J/K; yes, the negative entropy change matches the decrease in moles of gas. **20.39**(a) −75.6 J/K; (b) 490. J/K; because ΔS_{univ} is positive, the reaction is spontaneous at 298 K. **20.41** (a) −242 J/K (b) 559 J/K; because ΔS_{univ} is positive, the reaction is spontaneous at 298 K. **20.44** −97.2 J/K **20.46** A spontaneous process has $\Delta S_{univ} > 0$. Since the absolute temperature is always positive, ΔG_{sys} must be negative ($\Delta G_{sys} < 0$) for a spontaneous process. **20.48**(a) ΔH_{sys} is negative. Bonds are being formed, an exothermic process. (b) ΔS_{sys} is negative. As molecules form from atoms, the total number of particles decreases and, with it, the entropy of the system. (c) Since ΔH_{sys} is negative, heat is released, so ΔS_{surr} will be positive. (d) Because both ΔH_{sys} and ΔS_{sys} are negative, this reaction will become more spontaneous (ΔG_{sys} will become more negative) as temperature decreases. **20.49** ΔH° is positive and ΔS° is positive. Melting is an example. **20.50** The entropy changes little within a phase. As long as the substance does not change phase, the value of ΔS° is relatively unaffected by temperature. **20.51**(a) −1138.0 kJ (b) −1379.4 kJ (c) −224 kJ **20.53**(a) −1138 kJ (b) −1379 kJ (c) −226 kJ **20.55**(a) Entropy decreases (ΔS° is negative) because the number of moles of gas decreases. The combustion of CO releases energy (ΔH° is negative). (b) −257.2 kJ or −257.3 kJ, depending on the method **20.57**(a) −0.409 kJ/mol·K (b) −197 kJ/mol **20.59**(a) $\Delta H^\circ_{rxn} = 90.7$ kJ; $\Delta S^\circ_{rxn} = 221$ J/K (b) At 28°C, $\Delta G^\circ =$ 24.3 kJ; at 128°C, $\Delta G^\circ = 2.2$ kJ; at 228°C, $\Delta G^\circ = -19.9$ kJ (c) For the substances in their standard states, the reaction is nonspontaneous at 28°C, near equilibrium at 128°C, and spontaneous at 228°C. (d) 410. K **20.61**(a) $\Delta H^\circ_{rxn} = -241.826$ kJ, $\Delta S^\circ_{rxn} = -44.4$ J/K, $\Delta G^\circ_{rxn} = -228.60$ kJ (b) Yes. The reaction will become nonspontaneous at higher temperatures. (c) The reaction is spontaneous below 5.45×10^3 K. **20.63**(a) ΔG° is a relatively large positive value. (b) $K >> 1$. Q depends on initial conditions, not equilibrium conditions. **20.66** The standard free energy change, ΔG°, applies when all components of the system are in their standard states; $\Delta G^\circ = \Delta G$ when all concentrations equal 1 *M* and all partial pressures equal 1 atm. **20.67**(a) 2.0×10^{-8} (b) 1.27×10^{21} **20.69**(a) 3.46×10^4 (b) 8.2×10^{-7} **20.71** $\Delta H^\circ = 30910$ J, $\Delta S^\circ = 93.15$ J/K, $T = 331.8$ K **20.73** 4.89×10^{-51} **20.75** 3.36×10^5 **20.77** 2.7×10^4 J/mol; no **20.79**(a) 2.9×10^4 J/mol (b) The reverse direction, formation of reactants, is spontaneous, so the reaction proceeds to the left. (c) 7.0×10^3 J/mol; the reaction proceeds to the left to reach equilibrium. **20.81**(a) Scene 1 (b) Scene 3 > scene 1 > scene 2 **20.83**(a) no T (b) 163 kJ (c) 1×10^2 kJ/mol **20.86**(a) spontaneous (b) + (c) + (d) − (e) −, not spontaneous (f) − **20.90**(a) 2.3×10^2 (b) The treatment is to administer oxygen-rich air; increasing the concentration of oxygen shifts the equilibrium to the left, in the direction of Hb·O_2. **20.92** −370. kJ **20.94**(a) $2N_2O_5(g) + 6F_2(g) \longrightarrow 4NF_3(g) + 5O_2(g)$

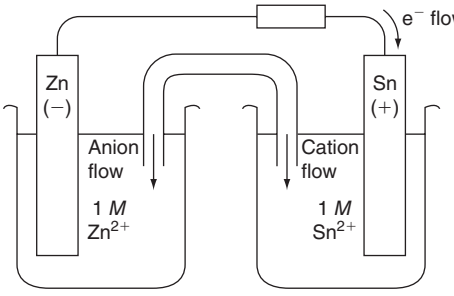
(b) $\Delta G^\circ_{rxn} = -569$ kJ (c) $\Delta G_{rxn} = -5.60\times10^2$ kJ/mol
20.96 $\Delta H^\circ_{rxn} = -137.14$ kJ; $\Delta S^\circ_{rxn} = -120.3$ J/K; $\Delta G^\circ_{rxn} = -101.25$ kJ **20.104**(a) 1.67×10^3 J/mol (b) 7.37×10^3 J/mol (c) -4.04×10^3 J/mol (d) 0.19 **20.108**(a) 465 K (b) 6.59×10^{-4} (c) The reaction rate is higher at the higher temperature. The shorter time required (kinetics) overshadows the lower yield (thermodynamics).

Chapter 21

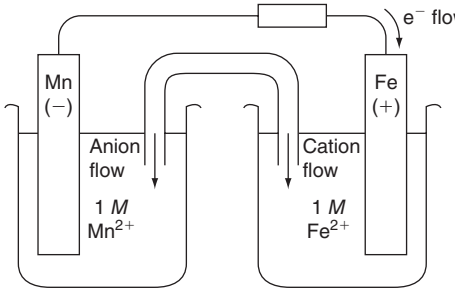
Answers to Boxed Reading Problem: B21.1 (a) reduction: $Fe^{3+} + e^- \longrightarrow Fe^{2+}$; oxidation: $Cu^+ \longrightarrow Cu^{2+} + e^-$
(b) Overall: $Fe^{3+} + Cu^+ \longrightarrow Fe^{2+} + Cu^{2+}$

• **21.1** Oxidation is the loss of electrons and results in a higher oxidation number; reduction is the gain of electrons and results in a lower oxidation number. **21.3** No, one half-reaction cannot take place independently because there is a transfer of electrons from one substance to another. If one substance loses electrons, another substance must gain them. **21.6** To remove H^+ ions from an equation, add an equal number of OH^- ions to both sides to neutralize the H^+ ions and produce water.
21.8 Spontaneous reactions, for which $\Delta G_{sys} < 0$, take place in voltaic cells (also called galvanic cells). Nonspontaneous reactions, for which $\Delta G_{sys} > 0$, take place in electrolytic cells.
21.10(a) Cl^- (b) MnO_4^- (c) MnO_4^- (d) Cl^- (e) from Cl^- to MnO_4^- (f) $8H_2SO_4(aq) + 2KMnO_4(aq) + 10KCl(aq) \longrightarrow 2MnSO_4(aq) + 5Cl_2(g) + 8H_2O(l) + 6K_2SO_4(aq)$
21.12(a) $ClO_3^-(aq) + 6H^+(aq) + 6I^-(aq) \longrightarrow Cl^-(aq) + 3H_2O(l) + 3I_2(s)$
Oxidizing agent is ClO_3^- and reducing agent is I^-.
(b) $2MnO_4^-(aq) + H_2O(l) + 3SO_3^{2-}(aq) \longrightarrow 2MnO_2(s) + 3SO_4^{2-}(aq) + 2OH^-(aq)$
Oxidizing agent is MnO_4^- and reducing agent is SO_3^{2-}.
(c) $2MnO_4^-(aq) + 6H^+(aq) + 5H_2O_2(aq) \longrightarrow 2Mn^{2+}(aq) + 8H_2O(l) + 5O_2(g)$
Oxidizing agent is MnO_4^- and reducing agent is H_2O_2.
21.14(a) $Cr_2O_7^{2-}(aq) + 14H^+(aq) + 3Zn(s) \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l) + 3Zn^{2+}(aq)$
Oxidizing agent is $Cr_2O_7^{2-}$ and reducing agent is Zn.
(b) $MnO_4^-(aq) + 3Fe(OH)_2(s) + 2H_2O(l) \longrightarrow MnO_2(s) + 3Fe(OH)_3(s) + OH^-(aq)$
Oxidizing agent is MnO_4^- and reducing agent is $Fe(OH)_2$.
(c) $2NO_3^-(aq) + 12H^+(aq) + 5Zn(s) \longrightarrow N_2(g) + 6H_2O(l) + 5Zn^{2+}(aq)$
Oxidizing agent is NO_3^- and reducing agent is Zn.
21.16(a) $4NO_3^-(aq) + 4H^+(aq) + 4Sb(s) \longrightarrow 4NO(g) + 2H_2O(l) + Sb_4O_6(s)$
Oxidizing agent is NO_3^- and reducing agent is Sb.
(b) $5BiO_3^-(aq) + 14H^+(aq) + 2Mn^{2+}(aq) \longrightarrow 5Bi^{3+}(aq) + 7H_2O(l) + 2MnO_4^-(aq)$
Oxidizing agent is BiO_3^- and reducing agent is Mn^{2+}.
(c) $Pb(OH)_3^-(aq) + 2Fe(OH)_2(s) \longrightarrow Pb(s) + 2Fe(OH)_3(s) + OH^-(aq)$
Oxidizing agent is $Pb(OH)_3^-$ and reducing agent is $Fe(OH)_2$.

21.18(a) $5As_4O_6(s) + 8MnO_4^-(aq) + 18H_2O(l) \longrightarrow 20AsO_4^{3-}(aq) + 8Mn^{2+}(aq) + 36H^+(aq)$
Oxidizing agent is MnO_4^- and reducing agent is As_4O_6.
(b) $P_4(s) + 6H_2O(l) \longrightarrow 2HPO_3^{2-}(aq) + 2PH_3(g) + 4H^+(aq)$
P_4 is both the oxidizing agent and the reducing agent.
(c) $2MnO_4^-(aq) + 3CN^-(aq) + H_2O(l) \longrightarrow 2MnO_2(s) + 3CNO^-(aq) + 2OH^-(aq)$
Oxidizing agent is MnO_4^- and reducing agent is CN^-.
21.21(a) $Au(s) + 3NO_3^-(aq) + 4Cl^-(aq) + 6H^+(aq) \longrightarrow AuCl_4^-(aq) + 3NO_2(g) + 3H_2O(l)$ (b) Oxidizing agent is NO_3^- and reducing agent is Au. (c) HCl provides chloride ions that combine with the gold(III) ion to form the stable $AuCl_4^-$ complex ion. **21.22**(a) A (b) E (c) C (d) A (e) E (f) E
21.25 An active electrode is a reactant or product in the cell reaction. An inactive electrode does not take part in the reaction and is present only to conduct a current. Platinum and graphite are commonly used as inactive electrodes. **21.26**(a) A (b) B (c) A (d) Hydrogen bubbles will form when metal A is placed in acid. Metal A is a better reducing agent than metal B, so if metal B reduces H^+ in acid, then metal A will reduce it also.
21.27(a) left to right (b) left (c) right (d) Ni (e) Fe (f) Fe (g) 1 *M* $NiSO_4$ (h) K^+ and NO_3^- (i) neither (j) from right to left
(k) Oxidation: $Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$
Reduction: $Ni^{2+}(aq) + 2e^- \longrightarrow Ni(s)$
Overall: $Fe(s) + Ni^{2+}(aq) \longrightarrow Fe^{2+}(aq) + Ni(s)$
21.29(a) Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$
Reduction: $Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s)$
Overall: $Zn(s) + Sn^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Sn(s)$
(b)



21.31(a) Reduction: $Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s)$
Oxidation: $Mn(s) \longrightarrow Mn^{2+}(aq) + 2e^-$
Overall: $Fe^{2+}(aq) + Mn(s) \longrightarrow Fe(s) + Mn^{2+}(aq)$
(b)



21.33(a) $Al(s) \mid Al^{3+}(aq) \parallel Cr^{3+}(aq) \mid Cr(s)$
(b) $Pt(s) \mid SO_2(g) \mid SO_4^{2-}(aq), H^+(aq) \parallel Cu^{2+}(aq) \mid Cu(s)$
21.36 A negative E°_{cell} indicates that the redox reaction is not spontaneous at the standard state, that is, $\Delta G^\circ > 0$. The reverse

reaction is spontaneous with $E^\circ_{cell} > 0$. **21.37** Similar to other state functions, E° changes sign when a reaction is reversed. Unlike ΔG°, ΔH°, and S°, E° (the ratio of energy to charge) is an intensive property. When the coefficients in a reaction are multiplied by a factor, the values of ΔG°, ΔH°, and S° are multiplied by that factor. However, E° does not change because both the energy and charge are multiplied by the factor and thus their ratio remains unchanged.

21.38(a) Oxidation: $Se^{2-}(aq) \longrightarrow Se(s) + 2e^-$

Reduction: $2SO_3^{2-}(aq) + 3H_2O(l) + 4e^- \longrightarrow S_2O_3^{2-}(aq) + 6OH^-(aq)$

(b) $E^\circ_{anode} = E^\circ_{cathode} - E^\circ_{cell} = -0.57\ V - 0.35\ V = -0.92\ V$

21.40(a) $Br_2 > Fe^{3+} > Cu^{2+}$ (b) $Ca^{2+} < Ag^+ < Cr_2O_7^{2-}$

21.42(a) $Co(s) + 2H^+(aq) \longrightarrow Co^{2+}(aq) + H_2(g)$

$E^\circ_{cell} = 0.28$ V; spontaneous

(b) $Hg_2^{2+}(aq) \longrightarrow Hg^{2+}(aq) + Hg(l)$

$E^\circ_{cell} = -0.07$ V; not spontaneous

21.44(a) $Cr_2O_7^{2-}(aq) + 3Cd(s) + 14H^+(aq) \longrightarrow 2Cr^{3+}(aq) + 3Cd^{2+}(aq) + 7H_2O(l)$

$E^\circ_{cell} = 1.73$ V; spontaneous

(b) $Pb(s) + Ni^{2+}(aq) \longrightarrow Pb^{2+}(aq) + Ni(s)$

$E^\circ_{cell} = -0.12$ V; not spontaneous

21.46 $3N_2O_4(g) + 2Al(s) \longrightarrow 6NO_2^-(aq) + 2Al^{3+}(aq)$

$E^\circ_{cell} = 0.867\ V - (-1.66\ V) = 2.53\ V$

$2Al(s) + 3SO_4^{2-}(aq) + 3H_2O(l) \longrightarrow 2Al^{3+}(aq) + 3SO_3^{2-}(aq) + 6OH^-(aq)$

$E^\circ_{cell} = 2.59$ V

$SO_4^{2-}(aq) + 2NO_2^-(aq) + H_2O(l) \longrightarrow SO_3^{2-}(aq) + N_2O_4(g) + 2OH^-(aq)$

$E^\circ_{cell} = 0.06$ V

Oxidizing agents: $Al^{3+} < N_2O_4 < SO_4^{2-}$

Reducing agents: $SO_3^{2-} < NO_2^- < Al$

21.48 $2HClO(aq) + Pt(s) + 2H^+(aq) \longrightarrow Cl_2(g) + Pt^{2+}(aq) + 2H_2O(l)$

$E^\circ_{cell} = 0.43$ V

$2HClO(aq) + Pb(s) + SO_4^{2-}(aq) + 2H^+(aq) \longrightarrow Cl_2(g) + PbSO_4(s) + 2H_2O(l)$

$E^\circ_{cell} = 1.94$ V

$Pt^{2+}(aq) + Pb(s) + SO_4^{2-}(aq) \longrightarrow Pt(s) + PbSO_4(s)$

$E^\circ_{cell} = 1.51$ V

Oxidizing agents: $PbSO_4 < Pt^{2+} < HClO$

Reducing agents: $Cl_2 < Pt < Pb$

21.50(a) yes; (b) C > A > B **21.53** $A(s) + B^+(aq) \longrightarrow A^+(aq) + B(s)$ with $Q = [A^+]/[B^+]$. (a) $[A^+]$ increases and $[B^+]$ decreases. (b) E_{cell} decreases. (c) $E_{cell} = E^\circ_{cell} - (RT/nF) \ln([A^+]/[B^+])$; $E_{cell} = E^\circ_{cell}$ when $(RT/nF) \ln([A^+]/[B^+]) = 0$. This occurs when $\ln([A^+]/[B^+]) = 0$, that is, $[A^+]$ equals $[B^+]$. (d) Yes, when $[A^+] > [B^+]$. **21.55** In a concentration cell, the overall reaction decreases the concentration of the more concentrated electrolyte because it is reduced in the cathode compartment. **21.56**(a) 3×10^{35} (b) 4×10^{-31} **21.58**(a) 1×10^{-67} (b) 6×10^{9} **21.60**(a) -2.03×10^5 J (b) 1.74×10^5 J **21.62**(a) 3.82×10^5 J (b) -5.6×10^4 J **21.64** $E^\circ = 0.28$ V; $\Delta G^\circ = -2.7\times10^4$ J **21.66** $E^\circ_{cell} = 0.054$ V; $\Delta G^\circ = -1.0\times10^4$ J **21.68** $8.8\times10^{-5}\ M$ **21.70**(a) 0.05 V (b) 0.50 M (c) $[Co^{2+}] = 0.91\ M$; $[Ni^{2+}] = 0.09\ M$ **21.72** A; 0.083 V **21.74** Electrons flow from the anode, where oxidation occurs, to the cathode, where reduction occurs. The electrons always flow from the anode to the cathode no matter what type of battery.

21.76 A D-sized alkaline battery is larger than an AAA-sized one, so it contains greater amounts of the cell components. The cell potential is an intensive property and does not depend on the amounts of the cell components. The total charge, however, does depend on the amount of cell components, so the D-sized battery produces more charge. **21.78** The Teflon spacers keep the two metals separated so that the copper cannot conduct electrons that would promote the corrosion (rusting) of the iron skeleton. **21.81** Sacrificial anodes are made of metals with E° less than that of iron, -0.44 V, so they are more easily oxidized than iron. Only (b), (f), and (g) will work for iron: (a) will form an oxide coating that prevents further oxidation; (c) will react with groundwater quickly; (d) and (e) are less easily oxidized than iron. **21.83** To reverse the reaction requires 0.34 V with the cell in its standard state. A 1.5 V cell supplies more than enough potential, so the Cd metal is oxidized to Cd^{2+} and Cr metal plates out. **21.85** The oxidation number of N in NO_3^- is +5, the maximum O.N. for N. In the nitrite ion, NO_2^-, the O.N. of N is +3, so nitrogen can be further oxidized. **21.87**(a) Br_2 (b) Na **21.89** I_2 gas forms at the anode; magnesium (liquid) forms at the cathode. **21.91** Bromine gas forms at the anode; calcium metal forms at the cathode. **21.93** copper and bromine **21.95** iodine, zinc, and silver

21.97(a) Anode: $2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$

Cathode: $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$

(b) Anode: $2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$

Cathode: $Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s)$

21.99(a) Anode: $2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$

Cathode: $NO_3^-(aq) + 4H^+(aq) + 3e^- \longrightarrow NO(g) + 2H_2O(l)$

(b) Anode: $2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^-$

Cathode: $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$

21.101(a) 3.75 mol e^- (b) 3.62×10^5 C (c) 28.7 A **21.103** 0.275 g Ra **21.105** 9.20×10^3 s **21.107**(a) The sodium and sulfate ions conduct a current, facilitating electrolysis. Pure water, which contains very low ($10^{-7}\ M$) concentrations of H^+ and OH^-, conducts electricity very poorly. (b) The reduction of H_2O has a more positive half-potential than does the reduction of Na^+; the oxidation of H_2O is the only reaction possible because SO_4^{2-} cannot be oxidized. Thus, it is easier to reduce H_2O than Na^+ and easier to oxidize H_2O than SO_4^{2-}. **21.109** 62.6 g Zn **21.111**(a) 3.3×10^{11} C (b) 4.8×10^{11} J (c) 1.2×10^4 kg **21.114** 64.3 mass % Cu **21.115**(a) 8 days (b) 32 days (c) \$940 **21.118**(a) 2.4×10^4 days (b) 2.1 g (c) 6.1×10^{-5} dollars **21.121**(a) Pb/Pb^{2+}: $E^\circ_{cell} = 0.13$ V; Cu/Cu^{2+}: $E^\circ_{cell} = 0.34$ V (b) The anode (negative electrode) is Pb. The anode in the other cell is platinum in the standard hydrogen electrode. (c) The precipitation of PbS decreases $[Pb^{2+}]$, which increases the potential. (d) -0.13 V

21.124 The three steps equivalent to the overall reaction $M^+(aq) + e^- \longrightarrow M(s)$ are

(1) $M^+(aq) \longrightarrow M^+(g)$ $\quad \Delta H$ is $-\Delta H_{hydration}$

(2) $M^+(g) + e^- \longrightarrow M(g)$ $\quad \Delta H$ is $-IE$

(3) $M(g) \longrightarrow M(s)$ $\quad \Delta H$ is $-\Delta H_{atomization}$

The energy for step 3 is similar for all three elements, so the difference in energy for the overall reaction depends on the values for $\Delta H_{hydration}$ and IE. The Li^+ ion has a greater hydration energy than Na^+ and K^+ because it is smaller, with a larger charge density that holds the water molecules more tightly. The energy required to remove the waters surrounding Li^+ offsets the lower ionization energy, making the overall energy for the reduction of Li^+ ion larger than expected. **21.125** The very high and very low standard electrode potentials involve extremely reactive substances, such as F_2 (a powerful oxidizer) and Li (a powerful reducer). These substances react directly with water because any aqueous cell with a voltage of more than 1.23 V has the ability to electrolyze water into hydrogen and oxygen.

21.127(a) 1.073×10^5 s (b) 1.5×10^4 kW·h (c) 0.92¢

21.129 If metal E and a salt of metal F are mixed, the salt is reduced, producing metal F because E has the greatest reducing strength of the three metals; F < D < E.

21.131(a) Cell I: 4 mol electrons; $\Delta G = -4.75\times10^5$ J
Cell II: 2 mol electrons; $\Delta G = -3.94\times10^5$ J
Cell III: 2 mol electrons; $\Delta G = -4.53\times10^5$ J
(b) Cell I: −13.2 kJ/g
Cell II: −0.613 kJ/g
Cell III: −2.63 kJ/g
Cell I has the highest ratio (most energy released per gram) because the reactants have very low mass, while Cell II has the lowest ratio because the reactants have large masses.

Chapter 22

22.2 Fe from Fe_2O_3; Ca from $CaCO_3$; Na from NaCl; Zn from ZnS **22.3**(a) Differentiation refers to the processes involved in the formation of Earth into regions (core, mantle, and crust) of differing composition. Substances separated according to their densities, with the more dense material in the core and the less dense in the crust. (b) O, Si, Al, and Fe (c) O **22.7** Plants produced O_2, slowly increasing the oxygen concentration in the atmosphere and creating an environment for oxidizing metals. The oxygen-free decay of plant and animal material created large fossil fuel deposits. **22.9** Fixation refers to the process of converting a substance in the atmosphere into a form more readily usable by organisms. Carbon and nitrogen; fixation of carbon dioxide gas by plants and fixation of nitrogen gas by nitrogen-fixing bacteria. **22.12** Atmospheric nitrogen is fixed by three pathways: atmospheric, industrial, and biological. Atmospheric fixation requires high-temperature reactions (e.g., initiated by lightning) to convert N_2 into NO and other oxidized species. Industrial fixation involves mainly the formation of ammonia, NH_3, from N_2 and H_2. Biological fixation occurs in nitrogen-fixing bacteria that live on the roots of legumes. Human activity is an example of industrial fixation. It contributes about 17% of the fixed nitrogen. **22.14**(a) the atmosphere (b) Plants excrete acid from their roots to convert PO_4^{3-} ions into more soluble $H_2PO_4^-$ ions, which the plant can absorb. Through excretion and decay, organisms return soluble phosphate compounds to the cycle. **22.17**(a) 1.1×10^3 L (b) 4.2×10^2 m^3 **22.18**(a) The iron(II) ions form an insoluble salt, $Fe_3(PO_4)_2$, that decreases the yield of phosphorus. (b) 8.8 t **22.20**(a) Roasting consists of heating a mineral sulfide in air at high temperatures to convert it to the oxide. (b) Smelting is the reduction of the metal oxide to the free metal using heat and a reducing agent such as coke. (c) Flotation is a separation process in which the ore is removed from the gangue by exploiting the difference in density in the presence of detergent. The gangue sinks to the bottom and the lighter ore-detergent mix is skimmed off the top. (d) Refining, using electricity or heat, is the final step in the process to yield the pure element. **22.25**(a) Slag is a byproduct of steel-making and contains the impurity SiO_2. (b) Pig iron is the impure product of iron metallurgy (containing 3–4% C and other impurities). (c) Steel refers to iron alloyed with other elements to attain desirable properties. (d) The basic-oxygen process is used to purify pig iron and obtain carbon steel. **22.27** Iron and nickel are more easily oxidized and less easily reduced than copper. They are separated from copper in the roasting step and converted to slag. In the electrorefining process, all three metals are in solution, but only Cu^{2+} ions are reduced at the cathode to form Cu(*s*). **22.30** Le Châtelier's principle says that the system shifts toward formation of K as the gaseous metal leaves the cell.

22.31(a) $E^\circ_{half\text{-}cell} = -3.05$ V, −2.93 V, and −2.71 V for Li^+, K^+, and Na^+, respectively. In all of these cases, it is energetically

more favorable to reduce H_2O to H_2 than to reduce M^+ to M. (b) $2RbX + Ca \longrightarrow CaX_2 + 2Rb$, where $\Delta H = IE_1(Ca) + IE_2(Ca) - 2IE_1(Rb) = 929$ kJ/mol. Based on the IEs and positive ΔH for the forward reaction, it seems more reasonable that Rb metal will reduce Ca^{2+} than the reverse. (c) If the reaction is carried out at a temperature greater than the boiling point of Rb, the product mixture will contain gaseous Rb, which can be removed from the reaction vessel; this would cause a shift in equilibrium to form more Rb as product. (d) $2CsX + Ca \longrightarrow CaX_2 + 2Cs$, where $\Delta H = IE_1(Ca) + IE_2(Ca) - 2IE_1(Cs) = 983$ kJ/mol. This reaction is less favorable than for Rb, but Cs has a lower boiling point. **22.32**(a) 4.5×10^4 L (b) 1.30×10^8 C (c) 1.69×10^6 s **22.35**(a) Mg^{2+} is more difficult to reduce than H_2O, so $H_2(g)$ would be produced instead of Mg metal. $Cl_2(g)$ forms at the anode due to overvoltage. (b) The ΔH_f° of $MgCl_2(s)$ is -641.6 kJ/mol. High temperature favors the reverse (endothermic) reaction, the formation of magnesium metal and chlorine gas. **22.37**(a) Sulfur dioxide is the reducing agent and is oxidized to the +6 state (SO_4^{2-}). (b) $HSO_4^-(aq)$ (c) $H_2SeO_3(aq) + 2SO_2(g) + H_2O(l) \longrightarrow Se(s) + 2HSO_4^-(aq) + 2H^+(aq)$ **22.42**(a) O.N. for Cu: in Cu_2S, +1; in Cu_2O, +1; in Cu, 0 (b) Cu_2S is the reducing agent, and Cu_2O is the oxidizing agent. **22.47** $2ZnS(s) + C(\text{graphite}) \longrightarrow 2Zn(s) + CS_2(g)$; $\Delta G^\circ_{rxn} = 463$ kJ. Since ΔG°_{rxn} is positive, this reaction is not spontaneous at standard-state conditions. $2ZnO(s) + C(s) \longrightarrow 2Zn(s) + CO_2(g)$; $\Delta G^\circ_{rxn} = 242.0$ kJ. This reaction is also not spontaneous, but is less unfavorable. **22.48** The formation of sulfur trioxide is very slow at ordinary temperatures. Increasing the temperature can speed up the reaction, but because the reaction is exothermic, increasing the temperature decreases the yield. Adding a catalyst increases the rate of the reaction, allowing a lower temperature to be used to enhance the yield. **22.51**(a) Cl_2, H_2, and NaOH (b) The mercury-cell method yields higher purity NaOH, but releases some Hg, which is harmful in the environment. **22.52**(a) $\Delta G^\circ = -142$ kJ; yes (b) The rate of the reaction is very low at 25°C. (c) $\Delta G^\circ_{500} = -53$ kJ, so the reaction is spontaneous. (d) $K_{25} = 7.8\times10^{24} > K_{500} = 3.8\times10^3$ (e) 1.05×10^3 K **22.53** 7×10^2 lb Cl_2 **22.56**(a) $P_4O_{10}(s) + 6H_2O(l) \longrightarrow 4H_3PO_4(l)$ (b) 1.52 **22.58**(a) 9.006×10^9 g CO_2 (b) The 4.3×10^{10} g CO_2 produced by automobiles is much greater than that from the blast furnace. **22.60**(a) If $[OH^-] > 1.1\times10^{-4}$ *M* (i.e., if pH > 10.04), $Mg(OH)_2$ will precipitate. Chapter 23

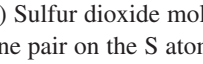
Answer to Boxed Reading Problem: B23.2 Zinc ions prefer a tetrahedral environment. The other ions listed prefer other environments (Ni^{2+} forms square planar complex ions while Fe^{2+} and Mn^{2+} form octahedral complex ions). If these ions are placed in a tetrahedral environment in place of the zinc, they cannot function as well as zinc since the enzyme catalyst would have a different shape.

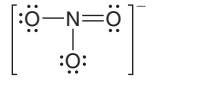
• **23.2**(a) $1s^22s^22p^63s^23p^64s^23d^{10}4p^65s^24d^x$ (b) $1s^22s^22p^63s^23p^64s^23d^{10}4p^65s^24d^{10}5p^66s^24f^{14}5d^x$ **23.4** Five; examples are Mn: [Ar] $4s^23d^5$, and Fe^{3+}: [Ar] $3d^5$. **23.6**(a) The elements should increase in size as they increase in mass from Period 5 to Period 6. Because there are 14 inner transition elements in Period 6, the effective nuclear charge increases significantly; so the atomic size decreases, or "contracts." This effect is significant enough that Zr^{4+} and Hf^{4+} are almost the same size but differ greatly in atomic mass. (b) The atomic size increases from Period 4 to Period 5, but stays fairly constant from Period 5 to Period 6. (c) Atomic mass increases significantly from Period 5 to Period 6, but atomic radius (and thus volume) increases slightly, so Period 6 elements are very dense. **23.9**(a) A paramagnetic substance is attracted to a magnetic field, while a diamagnetic substance is slightly repelled by one. (b) Ions of transition elements often have half-filled *d* orbitals whose unpaired electrons make the ions paramagnetic. Ions of main-group elements usually have a noble-gas configuration with no partially filled levels. (c) Some *d* orbitals in the transition element ions are empty, which allows an electron from one *d* orbital to move to a slightly higher energy one. The energy required is small and falls in the visible range, so the ion is colored. All orbitals are filled in ions of main-group elements, so enough energy would have to be added to move an electron to the next principal energy level, not just another orbital within

the same energy level. This amount of energy is very large and much greater than the visible range of wavelengths.
23.10(a) $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^3$
(b) $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^1$ (c) [Xe] $6s^2 4f^{14} 5d^{10}$
23.12(a) [Xe] $6s^2 4f^{14} 5d^6$ (b) [Ar] $4s^2 3d^7$ (c) [Kr] $5s^1 4d^{10}$
23.14(a) [Ar], no unpaired electrons (b) [Ar] $3d^9$, one unpaired electron (c) [Ar] $3d^5$, five unpaired electrons (d) [Kr] $4d^2$, two unpaired electrons **23.16**(a) +5 (b) +4 (c) +7 **23.18** Cr, Mo, and W **23.20** in CrF_2, because the chromium is in a lower oxidation state **23.22** Atomic size increases slightly down a group of transition elements, but nuclear charge increases much more, so the first ionization energy generally increases. The reduction potential for Mo is lower, so it is more difficult to oxidize Mo than Cr. In addition, the ionization energy of Mo is higher than that of Cr, so it is more difficult to remove electrons from Mo. **23.24** CrO_3, with Cr in a higher oxidation state, yields a more acidic aqueous solution. **23.28**(a) seven (b) This corresponds to a half-filled *f* subshell. **23.30**(a) [Xe] $6s^2 5d^1$
(b) [Xe] $4f^1$ (c) [Rn] $7s^2 5f^{11}$ (d) [Rn] $5f^2$
23.32(a) Eu^{2+}: [Xe] $4f^7$; Eu^{3+}: [Xe] $4f^6$; Eu^{4+}: [Xe] $4f^5$. The stability of the half-filled *f* subshell makes Eu^{2+} most stable.
(b) Tb^{2+}: [Xe] $4f^9$; Tb^{3+}: [Xe] $4f^8$; Tb^{4+}: [Xe] $4f^7$. Tb should show a +4 oxidation state because that gives a half-filled subshell. **23.34** Gd has the electron configuration [Xe] $6s^2 4f^7 5d^1$ with eight unpaired electrons. Gd^{3+} has seven unpaired electrons: [Xe] $4f^7$. **23.37** The coordination number indicates the number of ligand atoms bonded to the metal ion. The oxidation number represents the number of electrons lost to form the ion. The coordination number is unrelated to the oxidation number. **23.39** 2, linear; 4, tetrahedral or square planar; 6, octahedral **23.42** The complex ion has a negative charge.
23.45(a) hexaaquanickel(II) chloride
(b) tris(ethylenediamine)chromium(III) perchlorate (c) potassium hexacyanomanganate(II) **23.47**(a) 2+, 6 (b) 3+, 6
(c) 2+, 6 **23.49**(a) potassium dicyanoargentate(I) (b) sodium tetrachlorocadmate(II) (c) tetraammineaquabromocobalt(III) bromide **23.51**(a) 1+, 2 (b) 2+, 4 (c) 3+, 6
23.53(a) $[Zn(NH_3)_4]SO_4$ (b) $[Cr(NH_3)_5Cl]Cl_2$
(c) $Na_3[Ag(S_2O_3)_2]$ **23.55**(a) 4, two ions (b) 6, three ions
(c) 2, four ions **23.57**(a) $[Cr(H_2O)_6]_2(SO_4)_3$ (b) $Ba[FeBr_4]_2$
(c) $[Pt(en)_2]CO_3$ **23.59**(a) 6, five ions (b) 4, three ions (c) 4, two ions **23.61**(a) The nitrite ion forms linkage isomers because it can bind to the metal ion through the lone pair on the N atom or any lone pair on either O atom.

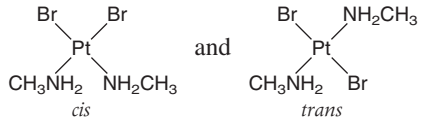


(b) Sulfur dioxide molecules form linkage isomers because the lone pair on the S atom or any lone pair on either O atom can bind the central metal ion.

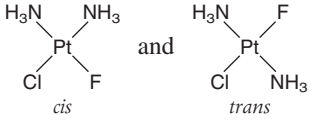
(c) Nitrate ions have an N atom with no lone pair and three O atoms, all with lone pairs that can bind to the metal ion. But all of the O atoms are equivalent, so these ions do not form linkage isomers.



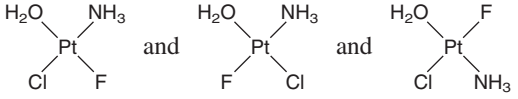
23.63(a) geometric isomerism



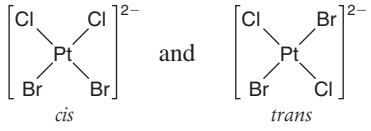
(b) geometric isomerism



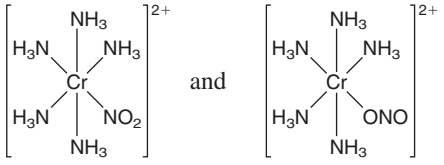
(c) geometric isomerism



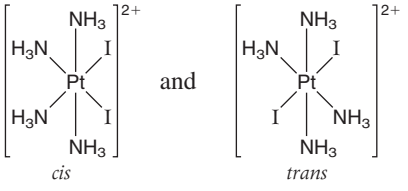
23.65(a) geometric isomerism



(b) linkage isomerism



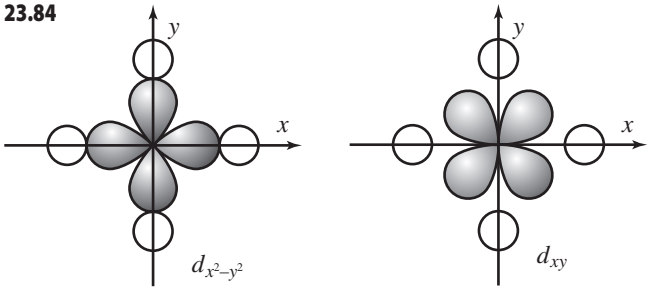
(c) geometric isomerism



23.67 The compound with the traditional formula is $CrCl_3 \cdot 4NH_3$; the actual formula is $[Cr(NH_3)_4Cl_2]Cl$.
23.69(a) $K[Pd(NH_3)Cl_3]$ (b) $[PdCl_2(NH_3)_2]$ (c) $K_2[PdCl_6]$
(d) $[Pd(NH_3)_4Cl_2]Cl_2$ **23.71**(a) dsp^2 (b) sp^3 **23.74** absorption of orange light or absorption of all colors except blue **23.75**(a) The crystal field splitting energy (Δ) is the energy difference between the two sets of *d* orbitals that result from electrostatic effects of ligands on a central transition metal atom. (b) In an octahedral field of ligands, the ligands approach along the *x*, *y*, and *z* axes. The $d_{x^2-y^2}$ and d_{z^2} orbitals are located *along* the *x*, *y*, and *z* axes, so ligand interaction is higher in energy. The other orbital-ligand interactions are lower in energy because the d_{xy}, d_{yz}, and d_{xz} orbitals are located *between* the *x*, *y*, and *z* axes.
(c) In a tetrahedral field of ligands, the ligands do not approach along the *x*, *y*, and *z* axes. The ligand interaction is greater for the d_{xy}, d_{yz}, and d_{xz} orbitals and lesser for the $d_{x^2-y^2}$ and d_{z^2} orbitals. Therefore, the crystal field splitting is reversed, and the d_{xy}, d_{yz}, and d_{xz} orbitals are higher in energy than the $d_{x^2-y^2}$ and d_{z^2} orbitals. **23.78** If Δ is greater than $E_{pairing}$, electrons will pair

their spins in the lower energy set of *d* orbitals before entering the higher energy set of *d* orbitals as unpaired electrons. If Δ is less than $E_{pairing}$, electrons will occupy the higher energy set of *d* orbitals as unpaired electrons before pairing in the lower energy set of *d* orbitals. **23.80**(a) no *d* electrons (b) eight *d* electrons (c) six *d* electrons **23.82**(a) five (b) ten (c) seven

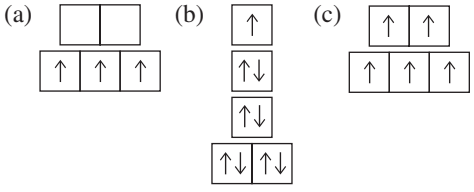
23.84



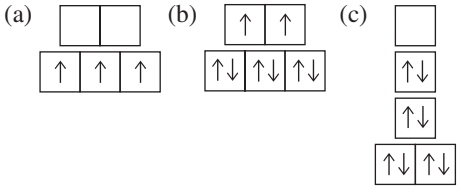
In an octahedral field of ligands, the ligands approach along the *x*, *y*, and *z* axes. The lobes of the $d_{x^2-y^2}$ orbital lie *along* the *x* and *y* axes, so ligand interaction is greater. The lobes of the d_{xy} orbital lie *between* the *x* and *y* axes, so ligand interaction is less. The greater interaction of the $d_{x^2-y^2}$ orbital results in its higher energy.

23.86 a and d

23.88



23.90



23.92 $[Cr(H_2O)_6]^{3+} < [Cr(NH_3)_6]^{3+} < [Cr(NO_2)_6]^{3-}$

23.94 A violet complex absorbs yellow-green light. The light absorbed by a complex with a weaker field ligand would be at a lower energy and higher wavelength. Light of lower energy than yellow-green light is yellow, orange, or red. The color observed would be blue or green. **23.97** The H_2O ligand is weaker than the NH_3 ligand. The weaker field ligand results in a lower splitting energy and absorbs visible light of lower energy. The hexaaqua complex appears green because it absorbs red light. The hexaammine complex appears violet because it absorbs yellow light, which has higher energy (shorter λ) than red light. **23.101** Hg^+ is [Xe] $6s^14f^{14}5d^{10}$ and Cu^+ is [Ar] $3d^{10}$. The mercury(I) ion has one electron in the 6*s* orbital that can form a covalent bond with the electron in the 6*s* orbital of another mercury(I) ion. In the copper(I) ion there are no electrons in the *s* orbital, so these ions cannot bond with one another. **23.102**(a) 6 (b) +3 (c) two (d) 1 mol

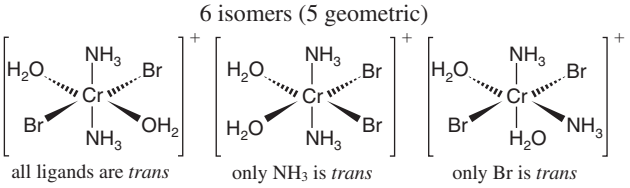
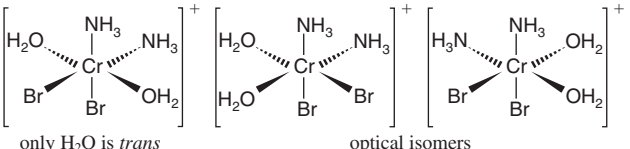
6 isomers (5 geometric)

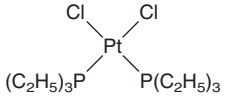


all ligands are *trans* only NH_3 is *trans* only Br is *trans*

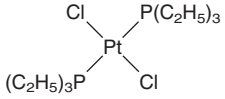


only H_2O is *trans* optical isomers
all three ligands are *cis*

23.115(a) no optical isomers (b) no optical isomers (c) no optical isomers (d) no optical isomers (e) optical isomers
23.116 $Pt[P(C_2H_5)_3]_2Cl_2$



cis-dichlorobis(triethylphosphine)platinum(II)



trans-dichlorobis(triethylphosphine)platinum(II)

23.118(a) The first reaction shows no change in the number of particles. In the second reaction, the number of reactant particles is greater than the number of product particles. A decrease in the number of particles means a decrease in entropy. Based on entropy change only, the first reaction is favored. (b) The ethylenediamine complex will be more stable with respect to ligand exchange in water because the entropy change for that exchange is unfavorable (negative).

Chapter 24

Answers to Boxed Reading Problems: B24.1 In the *s*-process, a nucleus captures a neutron sometime over a long period of time. Then the nucleus emits a beta particle to form another element. The stable isotopes of most heavy elements up to ^{209}Bi form by the *s*-process. The *r*-process very quickly forms less stable isotopes and those with *A* greater than 230 by multiple neutron captures, followed by multiple beta decays.
B24.3 The simultaneous fusion of three nuclei is a termolecular process. Termolecular processes have a very low probability of occurring. The bimolecular fusion of ^{8}Be with ^{4}He is more likely. **B24.4** $^{210}_{83}Bi \longrightarrow {}^{0}_{-1}\beta + {}^{210}_{84}Po$ (nuclide A); $^{210}_{84}Po \longrightarrow {}^{4}_{2}\alpha + {}^{206}_{82}Pb$ (nuclide B); $^{206}_{82}Pb + 3{}^{1}_{0}n \longrightarrow {}^{209}_{82}Pb$ (nuclide C); $^{209}_{82}Pb \longrightarrow {}^{0}_{-1}\beta + {}^{210}_{83}Bi$ (nuclide D)

• **24.1**(a) Chemical reactions are accompanied by relatively small changes in energy; nuclear reactions are accompanied by relatively large changes in energy. (b) Increasing temperature increases the rate of a chemical reaction but has no effect on a nuclear reaction. (c) Both chemical and nuclear reaction rates increase with higher reactant concentrations. (d) If the reactant is limiting in a chemical reaction, then more reactant produces more product and the yield increases. The presence of more radioactive reactant results in more decay product, so a higher reactant concentration increases the yield. **24.2**(a) 95.02% (b) The atomic mass is larger than the isotopic mass of ^{32}S. Sulfur-32 is the lightest isotope. **24.4**(a) *Z* down by 2, *N* down by 2 (b) *Z* up by 1, *N* down by 1 (c) no change in *Z* or *N* (d) *Z* down by 1, *N* up by 1 (e) *Z* down by 1, *N* up by 1 A different element is produced in all cases except (c). **24.6** A neutron-rich nuclide decays by beta (minus) decay. A neutron-poor nuclide undergoes positron decay or electron capture.
24.8(a) $^{234}_{92}U \longrightarrow {}^{4}_{2}\alpha + {}^{230}_{90}Th$ (b) $^{232}_{93}Np + {}^{0}_{-1}e \longrightarrow {}^{232}_{92}U$ (c) $^{12}_{7}N \longrightarrow {}^{0}_{1}\beta + {}^{12}_{6}C$ **24.10**(a) $^{27}_{12}Mg \longrightarrow {}^{0}_{-1}\beta + {}^{27}_{13}Al$ (b) $^{23}_{12}Mg \longrightarrow {}^{0}_{1}\beta + {}^{23}_{11}Na$ (c) $^{103}_{46}Pd + {}^{0}_{-1}e \longrightarrow {}^{103}_{45}Rh$
24.12(a) $^{48}_{23}V \longrightarrow {}^{48}_{22}Ti + {}^{0}_{1}\beta$ (b) $^{107}_{48}Cd + {}^{0}_{-1}e \longrightarrow {}^{107}_{47}Ag$ (c) $^{210}_{86}Rn \longrightarrow {}^{206}_{84}Po + {}^{4}_{2}\alpha$ **24.14**(a) $^{186}_{78}Pt + {}^{0}_{-1}e \longrightarrow {}^{186}_{77}Ir$ (b) $^{225}_{89}Ac \longrightarrow {}^{221}_{87}Fr + {}^{4}_{2}\alpha$ (c) $^{129}_{52}Te \longrightarrow {}^{129}_{53}I + {}^{0}_{-1}\beta$
24.16(a) Appears stable because its *N* and *Z* values are both magic numbers, but its *N*/*Z* ratio (1.50) is too high; it is unstable. (b) Appears unstable because its *Z* value is an odd number, but its *N*/*Z* ratio (1.19) is in the band of stability, so it is stable. (c) Unstable because its *N*/*Z* ratio is too high.
24.18(a) The *N*/*Z* ratio for ^{127}I is 1.4; it is stable. (b) The *N*/*Z* ratio for ^{106}Sn is 1.1; it is unstable because this ratio is too low. (c) The *N*/*Z* ratio is 1.1 for ^{68}As. The ratio is within the range of stability, but the nuclide is most likely unstable because there are odd numbers of both protons and neutrons.
24.20(a) alpha decay (b) positron decay or electron capture (c) positron decay or electron capture **24.22**(a) beta (minus) decay (b) positron decay or electron capture (c) alpha decay
24.24 Stability results from a favorable *N*/*Z* ratio, even numbered *N* and/or *Z*, and the occurrence of magic numbers. The *N*/*Z* ratio of ^{52}Cr is 1.17, which is within the band of stability. The fact that *Z* is even does not account for the variation in stability because all isotopes of chromium have the same *Z*. However, ^{52}Cr has 28 neutrons, so *N* is both an even number and a magic number for this isotope only. **24.28** seven α emissions and four β^- emissions **24.31** No, it is not valid to conclude that $t_{1/2}$ equals 1 min because the number of nuclei is so small. Decay rate is an average rate and is only meaningful when the sample is macroscopic and contains a large number of nuclei. For the sample containing 6×10^{12} nuclei, the conclusion is valid. **24.33** 2.56×10^{-2} Ci/g **24.35** 1.4×10^{8} Bq/g
24.37 1×10^{-12} day^{-1} **24.39** 2.31×10^{-7} yr^{-1} **24.41** 1.49 mg
24.43 2.2×10^{9} yr **24.45** 30 dpm **24.47** 1.0×10^{6} yr
24.50 Neither γ radiation nor neutron beams have charge, so neither is deflected by a magnetic or electric field. Neutron beams differ from γ radiation in that a neutron has a mass approximately equal to that of a proton. It was observed that a neutron beam induces the emission of protons from a substance; γ radiation does not cause such emission. **24.52** Protons are repelled from the target nuclei due to interaction with like (positive) charges. Higher energy is required to overcome the repulsion.
24.53(a) $^{10}_{5}B + {}^{4}_{2}\alpha \longrightarrow {}^{1}_{0}n + {}^{13}_{7}N$ (b) $^{28}_{14}Si + {}^{2}_{1}H \longrightarrow {}^{1}_{0}n + {}^{29}_{15}P$ (c) $^{242}_{96}Cm + {}^{4}_{2}\alpha \longrightarrow 2{}^{1}_{0}n + {}^{244}_{98}Cf$ **24.58** Ionizing radiation is more dangerous to children because they have rapidly dividing cells, so there is more chance for radiation to cause cell damage or mutation. **24.60**(a) 5.4×10^{-7} rad (b) 5.4×10^{-9} Gy
24.62(a) 7.5×10^{-10} Gy (b) 7.5×10^{-5} mrem (c) 7.5×10^{-10} Sv
24.65 1.86×10^{-3} rad **24.67** NAA does not destroy the sample, while chemical analyses do. Neutrons bombard a nonradioactive sample, inducing some atoms within the sample to be radioactive. The radioisotopes decay by emitting radiation characteristic of each isotope. **24.73** Energy is released when a nucleus forms from nucleons. The nuclear binding energy is the quantity of energy holding 1 mol of nuclei together. This energy must be absorbed to break up the nucleus into nucleons and is released when nucleons come together. **24.75**(a) 1.861×10^{4} eV (b) 2.981×10^{-15} J **24.77** 7.6×10^{11} J
24.79(a) 7.976 MeV/nucleon (b) 127.6 MeV/atom

(c) 1.231×10^{10} kJ/mol **24.81**(a) 8.768 MeV/nucleon (b) 517.3 MeV/atom (c) 4.99×10^{10} kJ/mol **24.85** Radioactive decay is a spontaneous process in which unstable nuclei emit radioactive particles and energy. Fission occurs as the result of high-energy bombardment of nuclei that cause them to break into smaller nuclei, radioactive particles, and energy. All fission events are not the same. The nuclei split in a number of ways to produce several different products. **24.88** The water serves to slow the neutrons so that they are better able to cause a fission reaction. Heavy water is a better moderator because it does not absorb neutrons as well as light water does; thus, more neutrons are available to initiate the fission process. However, D_2O does not occur naturally in great abundance, so its production adds to the cost of a heavy-water reactor. **24.93**(a) 1.1×10^{-29} kg (b) 9.9×10^{-13} J (c) 5.9×10^{8} kJ/mol; this is approximately 1 million times larger than a typical enthalpy of reaction. **24.95** 8.0×10^{3} yr **24.98** 1.35×10^{-5} *M* **24.100** 6.2×10^{-2} **24.102**(a) 5.99 h (b) 21% **24.104**(a) 0.999 (b) 0.298 (c) 5.58×10^{-6} (d) Radiocarbon dating is more reliable for the fraction in part (b) because a significant amount of ^{14}C has decayed and a significant amount remains. Therefore, a change in the amount of ^{14}C will be noticeable. For the fraction in part (a), very little ^{14}C has decayed, and for (c) very little ^{14}C remains. In either case, it will be more difficult to measure the change, so the error will be relatively large. **24.106** 6.58 h **24.110** 4.904×10^{-9} L/h **24.113** 81 yr **24.115**(a) 0.15 Bq/L (b) 0.27 Bq/L (c) 3.3 days; a total of 12.8 days **24.118** 7.4 s **24.121** 1926 **24.124** 6.27×10^{5} eV/reaction, 6.05×10^{7} kJ/mol reaction **24.127**(a) 2.07×10^{-17} J (b) 1.45×10^{7} H atoms (c) 1.4960×10^{-5} J (d) 1.4959×10^{-5} J (e) No, the captain should continue using the current technology. **24.130**(a) 0.043 MeV, 2.9×10^{-11} m (b) 4.713 MeV **24.134**(a) 3.26×10^{3} days (b) 3.2×10^{-3} s (c) 2.78×10^{11} yr **24.136**(a) 1.80×10^{17} J (b) 6.15×10^{16} kJ (c) The procedure in part (b) produces more energy per kilogram of antihydrogen. **24.137** 9.316×10^{2} MeV **24.141** 7.81 days

Numbers in parentheses refer to the page(s) on which a term is introduced and/or discussed.

A

absolute scale (also *Kelvin scale*) The preferred temperature scale in scientific work, which has absolute zero (0 K, or −273.15°C) as the lowest temperature. (25) [See also *kelvin* (*K*).]

absorption spectrum The spectrum produced when atoms absorb specific wavelengths of incoming light and become excited from lower to higher energy levels. (300)

abundance The amount of an element in a particular region of the natural world. (977)

accuracy The closeness of a measurement to the actual value. (31)

acid In common laboratory terms, any species that produces H^+ ions when dissolved in water. (159) [See also *Arrhenius, Brønsted-Lowry,* and *Lewis acid-base definitions.*]

acid anhydride A compound, usually formed by a dehydration-condensation reaction of an oxoacid, that yields two molecules of the acid when it reacts with water. (647)

acid-base buffer (also *buffer*) A solution that resists changes in pH when a small amount of either strong acid or strong base is added. (827)

acid-base indicator An organic molecule whose color is different in acid and in base and is used to monitor the equivalence point of a titration or the pH of a solution. (687)

acid-base reaction Any reaction between an acid and a base. (158) (See also *neutralization reaction.*)

acid-base titration curve A plot of the pH of a solution of acid (or base) versus the volume of base (or acid) added to the solution. (837)

acid-dissociation (acid-ionization) constant (K_a) An equilibrium constant for the dissociation of an acid (HA) in H_2O to yield the conjugate base (A^-) and H_3O^+:

$$K_a = \frac{[H_3O^+][A^-]}{[HA]} \qquad (780)$$

actinides The Period 7 elements that constitute the second inner transition series (5*f* block), which includes thorium (Th; $Z = 90$) through lawrencium (Lr; $Z = 103$). (335, 1024)

activated complex (See *transition state.*)

activation energy (E_a) The minimum energy with which molecules must collide to react. (700)

active site The region of an enzyme formed by specific amino acid side chains at which catalysis occurs. (715)

activity ($\mathcal{A}$) (also *decay rate*) The change in number of nuclei ($\mathcal{N}$) of a radioactive sample divided by the change in time (t). (1064)

activity series of the metals A listing of metals arranged in order of decreasing strength of the metal as a reducing agent in aqueous reactions. (179)

actual yield The amount of product actually obtained in a chemical reaction. (123)

addition polymer (also *chain-reaction,* or *chain-growth, polymer*) A polymer formed when monomers (usually containing C═C) combine through an addition reaction. (652)

addition reaction A type of organic reaction in which atoms linked by a multiple bond become bonded to more atoms. (635)

adduct The product of a Lewis acid-base reaction characterized by the formation of a new covalent bond. (811)

adenosine triphosphate (ATP) A high-energy molecule that serves most commonly as a store and source of energy in organisms. (902)

alcohol An organic compound (ending, *-ol*) that contains a  functional group. (638)

aldehyde An organic compound (ending, *-al*) that contains the carbonyl functional group ( ) in which the carbonyl C is also bonded to H. (644)

alkane A hydrocarbon that contains only single bonds and no rings (general formula, C_nH_{2n+2}). (622)

alkene A hydrocarbon that contains at least one C═C bond (general formula, C_nH_{2n}). (630)

alkyl group A saturated hydrocarbon chain with one bond available. (635)

alkyl halide (See *haloalkane.*)

alkyne A hydrocarbon that contains at least one C≡C bond (general formula, C_nH_{2n-2}). (630)

allotrope One of two or more crystalline or molecular forms of an element. In general, one allotrope is more stable than another at a particular pressure and temperature. (584)

alloy A mixture with metallic properties that consists of solid phases of two or more pure elements, a solid-solid solution, or distinct intermediate phases. (386, 522, 992)

alpha (α) decay A radioactive process in which an alpha particle is emitted from a nucleus. (1057)

alpha particle (α or $^4_2He^{2+}$) A positively charged particle, identical to a helium-4 nucleus, that is one of the common types of radioactive emissions. (1055)

amide An organic compound that contains the  functional group. (646)

amine An organic compound (general formula, ) derived structurally by replacing one or more H atoms of ammonia with organic groups; a weak organic base. (641)

amino acid An organic compound [general formula, $H_2N—CH(R)—COOH$] with at least one carboxyl and one amine group on the same molecule; the monomer unit of a protein. (523, 656)

amorphous solid A solid that has a poorly defined shape because it lacks extensive molecular-level ordering of its particles. (479)

ampere (A) The SI unit of electric current; 1 ampere of current results when 1 coulomb flows through a conductor in 1 second. (959)

amphoteric Able to act as either an acid or a base. (346)

amplitude The height of the crest (or depth of the trough) of a wave; related to the intensity of the energy (brightness of the light). (288)

angular momentum quantum number (l) An integer from 0 to $n - 1$ that is related to the shape of an atomic orbital. (308)

anion A negatively charged ion. (61)

anode The electrode at which oxidation occurs in an electrochemical cell. Electrons are given up by the reducing agent and leave the cell at the anode. (924)

antibonding MO A molecular orbital formed when wave functions are subtracted from each other, which decreases electron density between the nuclei and leaves a node. Electrons occupying such an orbital destabilize the molecule. (440)

apatite A compound of general formula $Ca_5(PO_4)_3X$, where X is generally F, Cl, or OH; a source of phosphorus. (986)

aqueous solution A solution in which water is the solvent. (77)

aromatic hydrocarbon A compound of C and H with one or more rings of C atoms (often drawn with alternating C—C and C═C bonds), in which there is extensive delocalization of π electrons. (631)

Arrhenius acid-base definition A model of acid-base behavior in which an acid is a substance that has H in its formula and dissociates in water to yield H_3O^+, and a base is a substance that has OH in its formula and produces OH^- in water. (778)

Arrhenius equation An equation that expresses the exponential relationship between temperature and the rate constant: $k = Ae^{-E_a/RT}$. (699)

atmosphere The mixture of gases that extends from a planet's surface and eventually merges with outer space; the gaseous portion of Earth's crust. (233, 980) (For the unit, see *standard atmosphere.*)

atom The smallest unit of an element that retains the chemical nature of the element. A neutral, spherical entity composed of a positively charged central nucleus surrounded by one or more negatively charged electrons. (47)

atomic mass (also *atomic weight*) The average of the masses of the naturally occurring isotopes of an element weighted according to their abundances. (55)

atomic mass unit (amu) (also *dalton, Da*) A mass exactly equal to $\frac{1}{12}$ the mass of a carbon-12 atom. (55)

atomic number (*Z*) The unique number of protons in the nucleus of each atom of an element (equal to the number of electrons in the neutral atom). An integer that expresses the positive charge of a nucleus or subatomic particle in multiples of the electronic charge. (53)

atomic orbital (also *wave function*) A mathematical expression that describes the motion of the electron's matter-wave in terms of time and position in the region of the nucleus. The term is used qualitatively to mean the region of space in which there is a high probability of finding the electron. (306)

atomic size A measure of how closely one atom lies next to another, atomic size is determined from the distances between nuclei of adjacent atoms. (336) (See also *metallic radius* and *covalent radius*.)

atomic solid A solid consisting of individual atoms held together by dispersion forces; the frozen noble gases are the only examples. (488)

atomic symbol (also *element symbol*) A one- or two-letter abbreviation for the English, Latin, or Greek name of an element. (54)

atomic weight (See *atomic mass.*)

aufbau principle The conceptual approach for building up atoms by adding one proton at a time to the nucleus and one electron around it to obtain the ground-state electron configurations of the elements. (327)

autoionization (also *self-ionization*) A reaction in which two molecules of a substance react to give ions. The most important example is for water:

$$2H_2O(l) \rightleftharpoons H_3O^+(aq) + OH^-(aq) \qquad (782)$$

average rate The change in concentration of reactants (or products) divided by a finite time period. (679)

Avogadro's law The gas law stating that, at fixed temperature and pressure, equal volumes of any ideal gas contain equal numbers of particles, and, therefore, the volume of a gas is directly proportional to its amount (mol): $V \propto n$. (208)

Avogadro's number A number (6.022×10^{23} to four significant figures) equal to the number of atoms in exactly 12 g of carbon-12; the number of atoms, molecules, or formula units in one mole of an element or compound. (92)

axial group An atom (or group) that lies above or below the trigonal plane of a trigonal bipyramidal molecule, or a similar structural feature in a molecule. (410)

B

background radiation Natural ionizing radiation, the most important form of which is cosmic radiation. (1075)

balancing coefficient (also *stoichiometric coefficient*) A numerical multiplier of all the atoms in the formula immediately following it in a balanced chemical equation. (108)

band of stability The band of stable nuclides that appears on a plot of number of neutrons versus number of protons for all nuclides. (1059)

band theory An extension of molecular orbital (MO) theory that explains many properties of metals and other solids, in particular, the differences in electrical conductivity of conductors, semiconductors, and insulators. (490)

barometer A device used to measure atmospheric pressure. Most commonly, a tube open at one end, which is filled with mercury and inverted into a dish of mercury. (202)

base In common laboratory terms, any species that produces OH^- ions when dissolved in water. (159) [See also *Arrhenius, Brønsted-Lowry,* and *Lewis acid-base definitions.*]

base-dissociation (base-ionization) constant (K_b) An equilibrium constant for the reaction of a base (B) with H_2O to yield the conjugate acid (BH^+) and OH^-:

$$K_b = \frac{[BH^+][OH^-]}{[B]} \qquad (802)$$

base pair Two complementary mononucleotide bases that are H bonded to each other; guanine (G) always pairs with cytosine (C), and adenine (A) always pairs with thymine (T) (or uracil, U). (660)

base unit (also *fundamental unit*) A unit that defines the standard for one of the seven physical quantities in the International System of Units (SI). (13)

basic-oxygen process The method used to convert pig iron to steel, in which O_2 is blown over and through molten pig iron to oxidize impurities and decrease the content of carbon. (997)

battery A group of voltaic cells arranged in series; primary and secondary types are self-contained, but flow batteries are not. (947)

becquerel (Bq) The SI unit of radioactivity; 1 Bq = 1 d/s (disintegration per second). (1064)

bent shape (also *V shape*) A molecular shape that arises when a central atom is bonded to two other atoms and has one or two lone pairs; occurs as the AX_2E shape class (bond angle $< 120°$) in the trigonal planar arrangement and as the AX_2E_2 shape class (bond angle $< 109.5°$) in the tetrahedral arrangement. (408)

beta (β) decay A radioactive change that encompasses any of three specific processes—β^- decay, β^+ emission, and e^- capture. (1057)

beta (β^-) decay A radioactive process in which a beta particle is emitted from a nucleus. (1057)
beta particle (β, β^-, or $_{-1}^{0}\beta$) A negatively charged particle, identified as a high-speed electron, that is one of the common types of radioactive emissions. (1055)
bimolecular reaction An elementary reaction involving the collision of two reactant species. (707)
binary covalent compound A compound that consists of atoms of two elements in which bonding occurs primarily through electron sharing. (71)
binary ionic compound A compound that consists of the oppositely charged ions of two elements. (61)
biomass conversion The process of applying chemical and biological methods to convert plant or animal matter into fuels. (273)
biosphere The living systems that inhabit Earth. (980)
blast furnace A tower-shaped furnace made of brick material in which intense heat and blasts of air are used to convert iron ore and coke to iron metal and carbon dioxide. (996)
body-centered cubic unit cell A unit cell in which a particle lies at each corner and in the center of a cube. (480)
boiling point (bp or T_b) The temperature at which the vapor pressure of a gas equals the external (atmospheric) pressure. (465)
boiling point elevation (ΔT_b) The increase in the boiling point of a solvent caused by the presence of dissolved solute. (543)
bond angle The angle formed by the nuclei of two surrounding atoms with the nucleus of the central atom at the vertex. (407)
bond energy (BE) (also *bond enthalpy* or *bond strength*) The enthalpy change (always >0) accompanying the breakage of a given bond in 1 mol of gaseous molecules. (370)
bond length The distance between the nuclei of two bonded atoms. (371)
bond order The number of electron pairs shared by two bonded atoms. (370)
bonding MO A molecular orbital formed when wave functions are added to each other, which increases electron density between the nuclei. Electrons occupying such an orbital stabilize the molecule. (440)
bonding pair (also *shared pair*) An electron pair shared by two nuclei; the mutual attraction between the nuclei and the electron pair forms a covalent bond. (370)
Born-Haber cycle A series of hypothetical steps and their enthalpy changes that convert elements to an ionic compound; it is used to calculate the lattice energy. (364)
Boyle's law The gas law stating that, at constant temperature and amount of gas, the volume occupied by a gas is inversely proportional to the applied (external) pressure: $V \propto 1/P$. (205)
branch A side chain appended to a polymer backbone or longest sequence of atoms in an organic compound. (503)
bridge bond (also *three-center, two-electron bond*) A covalent bond in which three atoms are held together by two electrons. (581)
Brønsted-Lowry acid-base definition A model of acid-base behavior based on proton transfer, in which an acid and a base are defined, respectively, as species that donate and accept a proton. (787)
buffer (See *acid-base buffer.*)
buffer capacity A measure of the ability of a buffer to resist a change in pH; related to the total concentrations and relative proportions of buffer components. (833)
buffer range The pH range over which a buffer acts effectively. (833)

C

calibration The process of correcting for systematic error of a measuring device by comparing it to a known standard. (32)
calorie (cal) A unit of energy defined as exactly 4.184 joules; originally defined as the heat needed to raise the temperature of 1 g of water 1°C (from 14.5°C to 15.5°C). (255)
calorimeter A device used to measure the heat released or absorbed by a physical or chemical process taking place within it. (262)
capillarity (or *capillary action*) A property that results in a liquid rising through a narrow space against the pull of gravity. (475)
carbon steel The steel that is produced by the basic-oxygen process, contains about 1% to 1.5% C and other impurities, and is alloyed with metals that prevent corrosion and increase strength. (997)
carbonyl group The C═O grouping of atoms. (644)
carboxylic acid An organic compound (ending, *-oic acid*) that contains the  group. (646)
catalyst A substance or mixture that increases the rate of a reaction without being used up in the process. (712)
catenation The process by which atoms of an element bond to each other in chains; most common with carbon in organic compounds but also occurs with boron, silicon, sulfur, and several other elements. (618)
cathode The electrode at which reduction occurs in an electrochemical cell. Electrons enter the cell and are acquired by the oxidizing agent at the cathode. (924)
cathode ray The ray of light emitted by the cathode (negative electrode) in a gas discharge tube; travels in straight lines, unless deflected by magnetic or electric fields. (50)
cation A positively charged ion. (61)
cell potential (E_{cell}) (also *electromotive force,* or *emf; cell voltage*) The potential difference between the electrodes of an electrochemical cell when no current flows. (930)
Celsius scale (formerly *centigrade scale*) A temperature scale in which the freezing and boiling points of water are defined as 0°C and 100°C, respectively. (25)
ceramic A nonmetallic, nonpolymeric solid that is hardened by heating it to high temperatures and, in most cases, consists of silicate microcrystals suspended in a glassy cementing medium. (498)
chain reaction In nuclear fission, a self-sustaining process in which neutrons released by splitting of one nucleus cause other nuclei to split, which releases more neutrons, and so on. (1085)
change in enthalpy (ΔH) The change in internal energy plus the product of the constant pressure and the change in volume: $\Delta H = \Delta E + P\Delta V$; the heat lost or gained at constant pressure: $\Delta H = q_P$. (258)
charge density The ratio of the charge of an ion to its volume. (529)
Charles's law The gas law stating that at constant pressure, the volume occupied by a fixed amount of gas is directly proportional to its absolute temperature: $V \propto T$. (207)
chelate A complex ion in which the metal ion is bonded to a bidentate or polydentate ligand. (1027)
chemical bond The force that holds two atoms together in a molecule (or formula unit). (61)
chemical change (also *chemical reaction*) A change in which one or more substances are converted into one or more substances with different composition and properties. (5)

chemical equation A statement that uses chemical formulas to express the identities and quantities of the substances involved in a chemical or physical change. (107)
chemical formula A notation of atomic symbols and numerical subscripts that shows the type and number of each atom in a molecule or formula unit of a substance. (65)
chemical kinetics The study of the rates and mechanisms of reactions. (675)
chemical property A characteristic of a substance that appears as it interacts with, or transforms into, other substances. (5)
chemical reaction (See *chemical change.*)
chemistry The scientific study of matter and its properties, the changes it undergoes, and the energy associated with those changes. (4)
chiral molecule One that is not superimposable on its mirror image; an optically active molecule. In organic compounds, a chiral molecule typically contains a C atom bonded to four different groups (asymmetric C). (626)
chlor-alkali process An industrial method that electrolyzes concentrated aqueous NaCl and produces Cl_2, H_2, and NaOH. (1008)
chromatography A separation technique in which a mixture is dissolved in a fluid (gas or liquid), and the components are separated through differences in adsorption to (or solubility in) a solid surface (or viscous liquid). (79)
***cis-trans* isomers** (See *geometric isomers.*)
Clausius-Clapeyron equation An equation that expresses the linear relationship between vapor pressure P of a liquid and temperature T; in two-point form, it is

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{vap}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right) \qquad (464)$$

coal gasification An industrial process for altering the large molecules in coal to sulfur-free gaseous fuels. (273)
colligative property A property of a solution that depends on the number, not the identity, of solute particles. (533) (See also *boiling point elevation, freezing point depression, osmotic pressure,* and *vapor pressure lowering.*)
collision frequency The average number of collisions per second that a particle undergoes. (232)
collision theory A model that explains reaction rate as based on the number, energy, and orientation of colliding particles. (699)
colloid A heterogeneous mixture in which a solute-like phase is dispersed throughout a solvent-like phase. (552)
combustion The process of burning in air, often with release of heat and light. (11)
combustion analysis A method for determining the formula of a compound from the amounts of its combustion products; used commonly for organic compounds. (104)
common-ion effect The shift in the position of an ionic equilibrium away from an ion involved in the process that is caused by the addition or presence of that ion. (828)
complex (See *coordination compound.*)
complex ion An ion consisting of a central metal ion bonded covalently to molecules and/or anions called ligands (859, 1026)
composition The types and amounts of simpler substances that make up a sample of matter. (4)
compound A substance composed of two or more elements that are chemically combined in fixed proportions. (42)
concentration A measure of the quantity of solute dissolved in a given quantity of solution (or solvent). (144)
concentration cell A voltaic cell in which both compartments contain the same components but at different concentrations. (944)
condensation The process of a gas changing into a liquid. (457)
condensation polymer A polymer formed by monomers with two functional groups that are linked together in a dehydration-condensation reaction. (653)
conduction band In band theory, the empty, higher energy portion of the band of molecular orbitals into which electrons move when conducting heat and electricity. (491)
conductor A substance (usually a metal) that conducts an electric current well. (492)
conjugate acid-base pair Two species related to each other through the gain or loss of a proton; the acid has one more proton than its conjugate base. (788)
constitutional isomers (also *structural isomers*) Compounds with the same molecular formula but different arrangements of atoms. (625, 1031)
contact process An industrial process for the manufacture of sulfuric acid based on the catalyzed oxidation of SO_2. (1006)
controlled experiment An experiment that measures the effect of one variable at a time by keeping other variables constant. (12)
conversion factor A ratio of equivalent quantities that is equal to 1 and used to convert the units of a quantity. (18)
coordinate covalent bond A covalent bond formed when one atom donates both electrons to provide the shared pair and, once formed, is identical to any covalent single bond. (1034)
coordination compound (also *complex*) A substance containing at least one complex ion and counter ion(s). (1026)
coordination isomers Two or more coordination compounds with the same composition in which the complex ions have different ligand arrangements. (1031)
coordination number In a crystal, the number of nearest neighbors surrounding a particle. (480) In a complex, the number of ligand atoms bonded to the central metal ion. (1026)
copolymer A polymer that consists of two or more types of monomer. (504)
core The dense, innermost region of Earth. (978)
core electrons (See *inner electrons.*)
corrosion The natural redox process that results in unwanted oxidation of a metal. (951)
coulomb (C) The SI unit of electric charge. One coulomb is the charge of 6.242×10^{18} electrons; one electron possesses a charge of 1.602×10^{-19} C. (930)
Coulomb's law A law stating that the electrostatic energy between particles A and B is directly proportional to the product of their charges and inversely proportional to the distance between them:

$$\text{electrostatic energy} \propto \frac{\text{charge A} \times \text{charge B}}{\text{distance}} \qquad (365)$$

counter ion A simple ion associated with a complex ion in a coordination compound. (1026)
coupling of reactions The pairing of reactions of which one releases enough free energy for the other to occur. (901)
covalent bond A type of bond in which atoms are bonded through the sharing of electrons; the mutual attraction of the nuclei and an electron pair that holds atoms together in a molecule. (63, 369)
covalent bonding The idealized bonding type that is based on localized electron-pair sharing between two atoms with little

difference in their tendencies to lose or gain electrons (most commonly nonmetals). (360)
covalent compound A compound that consists of atoms bonded together by shared electron pairs. (61)
covalent radius One-half the shortest distance between nuclei of identical covalently bonded atoms. (336)
critical mass The minimum mass needed to achieve a chain reaction. (1086)
critical point The point on a phase diagram above which the vapor cannot be condensed to a liquid; the end of the liquid-gas curve. (466)
crosslink A branch that covalently joins one polymer chain to another. (504)
crust The thin, light, heterogeneous outer layer of Earth, which consists of gasous, liquid, and solid regions. (978)
crystal defect Any of a variety of disruptions in the regularity of a crystal structure. (493)
crystal field splitting energy (Δ) The difference in energy between two sets of metal-ion *d* orbitals that results from electrostatic interactions with the surrounding ligands. (1038)
crystal field theory A model that explains the color and magnetism of coordination compounds based on the effects of ligands on metal-ion *d*-orbital energies. (1036)
crystalline solid Solid with a well-defined shape because of the orderly arrangement of the atoms, molecules, or ions. (479)
crystallization A technique used to separate and purify the components of a mixture through differences in solubility in which a component comes out of solution as crystals. (79)
cubic closest packing A crystal structure based on the face-centered cubic unit cell in which the layers have an *abcabc* . . . pattern. (482)
cubic meter (m^3) The SI-derived unit of volume. (15)
curie (Ci) The most common unit of radioactivity, defined as the number of nuclei disintegrating each second in 1 g of radium-226; 1 Ci = 3.70×10^{10} d/s (disintegrations per second). (1064)
cyclic hydrocarbon A hydrocarbon with one or more rings in its structure. (623)

D

***d* orbital** An atomic orbital with $l = 2$. (312)
dalton (Da) A unit of mass identical to *atomic mass unit.* (55)
Dalton's law of partial pressures A gas law stating that, in a mixture of unreacting gases, the total pressure is the sum of the partial pressures of the individual gases: $P_{total} = P_1 + P_2 + \cdots$. (219)
data Pieces of quantitative information obtained by observation. (12)
de Broglie wavelength The wavelength of a moving particle obtained from the de Broglie equation: $\lambda = h/mu$. (303)
decay constant The rate constant *k* for radioactive decay. (1064)
decay series (also *disintegration series*) The succession of steps a parent nucleus undergoes as it decays into a stable daughter nucleus. (1062)
degree of polymerization (*n*) The number of monomer repeat units in a polymer chain. (500)
dehydration-condensation reaction A reaction in which an H_2O molecule is lost for every pair of OH groups that join. (595)
delocalization (See *electron-pair delocalization.*)
density (*d*) An intensive physical property of a substance at a given temperature and pressure, defined as the ratio of the mass to the volume: $d = m/V$. (23)
deposition The process of changing directly from gas to solid. (457)
derived unit Any of various combinations of the seven SI base units. (13)
desalination A process used to remove large amounts of ions from seawater, usually by reverse osmosis. (555)
deuterons Nuclei of the stable hydrogen isotope deuterium, ^2H. (1070)
diagonal relationship Physical and chemical similarities between a Period 2 element and one located diagonally down and to the right in Period 3. (577)
diamagnetism The tendency of a species not to be attracted (or to be slightly repelled) by a magnetic field as a result of its electrons being paired. (349)
diastereomers (See *geometric isomers.*)
differentiation The geochemical process of forming regions in Earth based on differences in composition and density. (978)
diffraction The phenomenon in which a wave striking the edge of an object bends around it. A wave passing through a slit as wide as its wavelength forms a circular wave. (290)
diffusion The movement of one fluid through another. (231)
dimensional analysis (also *factor-label method*) A calculation method in which arithmetic steps are accompanied by canceling units that represent physical dimensions. (19)
dipole-dipole force The intermolecular attraction between oppositely charged poles of nearby polar molecules. (469)
dipole–induced dipole force The intermolecular attraction between a polar molecule and the oppositely charged pole it induces in a nearby molecule. (518)
dipole moment (μ) A measure of molecular polarity; the magnitude of the partial charges on the ends of a molecule (in coulombs) times the distance between them (in meters). (417)
disaccharide An organic compound formed by a dehydration-condensation reaction between two simple sugars (monosaccharides). (655)
disintegration series (See *decay series.*)
dispersion force (also *London force*) The intermolecular attraction between all particles as a result of instantaneous polarizations of their electron clouds; the intermolecular force primarily responsible for the condensed states of nonpolar substances. (472)
disproportionation reaction A reaction in which a given substance is both oxidized and reduced. (593)
distillation A separation technique in which a more volatile component of a mixture vaporizes and condenses separately from the less volatile components. (79)
donor atom An atom that donates a lone pair of electrons to form a covalent bond, usually from ligand to metal ion in a complex. (1027)
doping Adding small amounts of other elements into the crystal structure of a semiconductor to enhance a specific property, usually conductivity. (494)
double bond A covalent bond that consists of two bonding pairs; two atoms sharing four electrons in the form of one σ and one π bond. (370)
double helix The two intertwined polynucleotide strands held together by H bonds that form the structure of DNA (deoxyribonucleic acid). (527, 660)
Downs cell An industrial apparatus that electrolyzes molten NaCl to produce sodium and chlorine. (994)
dynamic equilibrium The condition at which the forward and reverse reactions are taking place at the same rate, so there is no net change in the amounts of reactants or products. (181)

E

e_g orbitals The set of orbitals (composed of $d_{x^2-y^2}$ and d_{z^2}) that results when the energies of the metal-ion *d* orbitals are split by a ligand field. This set is higher in energy than the other (t_{2g}) set in an octahedral field of ligands and lower in energy in a tetrahedral field. (1038)

effective collision A collision in which the particles meet with sufficient energy and an orientation that allows them to react. (702)

effective nuclear charge (Z_{eff}) The nuclear charge an electron actually experiences as a result of shielding effects due to the presence of other electrons. (325)

effusion The process by which a gas escapes from its container through a tiny hole into an evacuated space. (229)

elastomer A polymeric material that can be stretched and springs back to its original shape when released. (508)

electrochemical cell A system that incorporates a redox reaction to produce or use electrical energy. (919)

electrochemistry The study of the relationship between chemical change and electrical work. (919)

electrode The part of an electrochemical cell that conducts the electricity between the cell and the surroundings. (924)

electrolysis The nonspontaneous lysing (splitting) of a substance, often to its component elements, by supplying electrical energy. (955)

electrolyte A substance that conducts a current when it dissolves in water. (141, 541) A mixture of ions, in which the electrodes of an electrochemical cell are immersed, that conducts a current. (924)

electrolytic cell An electrochemical system that uses electrical energy to drive a nonspontaneous chemical reaction ($\Delta G > 0$). (924)

electromagnetic radiation (also *electromagnetic energy* or *radiant energy*) Oscillating, perpendicular electric and magnetic fields moving simultaneously through space as waves and manifested as visible light, x-rays, microwaves, radio waves, and so on. (287)

electromagnetic spectrum The continuum of wavelengths of radiant energy. (288)

electromotive force (emf) (See *cell potential.*)

electron (e^-) A subatomic particle that possesses a unit negative charge (-1.60218×10^{-19} C) and occupies the space around the atomic nucleus. (53)

electron affinity (EA) The energy change (in kJ) accompanying the addition of one mole of electrons to one mole of gaseous atoms or ions. (343)

electron capture (EC) A type of radioactive decay in which a nucleus draws in an orbital electron, usually one from the lowest energy level, and releases energy. (1057)

electron cloud depiction An imaginary representation of an electron's rapidly changing position around the nucleus over time. (307)

electron configuration The distribution of electrons within the orbitals of the atoms of an element; also the notation for such a distribution. (323)

electron deficient Referring to a bonded atom, such as Be or B, that has fewer than eight valence electrons. (403)

electron density diagram (also *electron probability density diagram*) The pictorial representation for a given energy sublevel of the quantity ψ^2 (the probability density of the electron lying within a particular tiny volume) as a function of *r* (distance from the nucleus). (307)

electron-pair delocalization (also *delocalization*) The process by which electron density is spread over several atoms rather than remaining between two. (400)

electron-sea model A qualitative description of metallic bonding proposing that metal atoms pool their valence electrons into a delocalized "sea" of electrons in which the metal cores (metal ions) are submerged in an orderly array. (385)

electron volt (eV) The energy (in joules, J) that an electron acquires when it moves through a potential difference of 1 volt; $1\text{ eV} = 1.602\times10^{-19}$ J. (1082)

electronegativity (EN) The relative ability of a bonded atom to attract shared electrons. (380)

electronegativity difference (ΔEN) The difference in electronegativities between the atoms in a bond. (382)

electrorefining An industrial, electrolytic purification process in which a sample of impure metal acts as the anode and a sample of the pure metal acts as the cathode. (992)

element The simplest type of substance with unique physical and chemical properties. An element consists of only one kind of atom, so it cannot be broken down into simpler substances. (42)

element symbol (See *atomic symbol.*)

elementary reaction (also *elementary step*) A simple reaction that describes a single molecular event in a proposed reaction mechanism. (706)

elimination reaction A type of organic reaction in which C atoms are bonded to fewer atoms in the product than in the reactant, which leads to multiple bonding. (635)

emission spectrum The line spectrum produced when excited atoms return to lower energy levels and emit photons characteristic of the element. (300)

empirical formula A chemical formula that shows the lowest relative number of atoms of each element in a compound. (100)

enantiomers (See *optical isomers.*)

end point The point in a titration at which the indicator changes color. (166, 839)

endothermic process A process that occurs with an absorption of heat from the surroundings and therefore an increase in the enthalpy of the system ($\Delta H > 0$). (260)

energy The capacity to do work, that is, to move matter. (8) [See also *kinetic energy* (E_k) and *potential energy* (E_p).]

enthalpy (H) A thermodynamic quantity that is the sum of the internal energy plus the product of the pressure and volume. (258)

enthalpy diagram A graphic depiction of the enthalpy change of a system. (260)

enthalpy of formation (ΔH_f) (also *heat of formation*) The enthalpy change occurring when 1 mol of a compound forms from its elements. When all components are in their standard states, this is called the *standard enthalpy of formation* (ΔH_f°). (270)

enthalpy of fusion (See *heat of fusion.*)

enthalpy of hydration (See *heat of hydration.*)

enthalpy of reaction (ΔH_{rxn}) (also *heat of reaction*) The enthalpy change that occurs during a reaction. When all components are in their standard states, this is called the *standard enthalpy of reaction* (ΔH_{rxn}°). (270)

enthalpy of solution (See *heat of solution.*)

enthalpy of sublimation (See *heat of sublimation.*)

enthalpy of vaporization (See *heat of vaporization.*)

entropy (S) A thermodynamic quantity related to the number of ways the energy of a system can be dispersed through the motions of its particles. (531, 880)

environmental cycle The physical, chemical, and biological paths through which the atoms of an element move within Earth's crust. (982)
enzyme A biological macromolecule (usually a protein) that acts as a catalyst. (715)
enzyme-substrate complex (ES) The intermediate in an enzyme-catalyzed reaction, which consists of enzyme and substrate(s) and whose concentration determines the rate of product formation. (716)
equatorial group An atom (or group) that lies in the trigonal plane of a trigonal bipyramidal molecule, or a similar structural feature in a molecule. (410)
equilibrium constant (*K*) The value obtained when equilibrium concentrations are substituted into the reaction quotient. (733)
equilibrium vapor pressure (See *vapor pressure.*)
equivalence point The point in a titration when the number of moles of the added species is stoichiometrically equivalent to the original number of moles of the other species. (166, 839)
ester An organic compound that contains the  group. (646)
exact number A quantity, usually obtained by counting or based on a unit definition, that has no uncertainty associated with it and, therefore, contains as many significant figures as a calculation requires. (30)
exchange reaction (See *metathesis reaction.*)
excited state Any electron configuration of an atom or molecule other than the lowest energy (ground) state. (296)
exclusion principle A principle developed by Wolfgang Pauli stating that no two electrons in an atom can have the same set of four quantum numbers. The principle arises from the fact that an orbital has a maximum occupancy of two electrons and their spins are paired. (325)
exothermic process A process that occurs with a release of heat to the surroundings and therefore a decrease in the enthalpy of the system ($\Delta H < 0$). (259)
expanded valence shell A valence level that can accommodate more than eight electrons by using available *d* orbitals; occurs only with central nonmetal atoms from Period 3 or higher. (404)
experiment A set of procedural steps that tests a hypothesis. (12)
extensive property A property, such as mass, that depends on the quantity of substance present. (26)

F

face-centered cubic unit cell A unit cell in which a particle occurs at each corner and in the center of each face of a cube. (480)
Faraday constant (*F*) The physical constant representing the charge of 1 mol of electrons: $F = 96{,}485$ C/mol e^-. (939)
fatty acid A carboxylic acid that has a long hydrocarbon chain and is derived from a natural source. (647)
filtration A method of separating the components of a mixture on the basis of differences in particle size. (79)
first law of thermodynamics (See *law of conservation of energy.*)
fission The process by which a heavier nucleus splits into lighter nuclei with the release of energy. (1081)
fixation A chemical/biochemical process that converts a gaseous substance in the environment into a condensed form that can be used by organisms. (984)
flame test A procedure for identifying the presence of metal ions in which a granule of a compound or a drop of its solution is placed in a flame to observe a characteristic color. (300)
flotation A metallurgical process in which oil and detergent are mixed with pulverized ore in water to create a slurry that separates the mineral from the gangue. (989)
formal charge The hypothetical charge on an atom in a molecule or ion, equal to the number of valence electrons minus the sum of all the unshared and half the shared valence electrons. (401)
formation constant (K_f) An equilibrium constant for the formation of a complex ion from the hydrated metal ion and ligands. (859)
formation equation An equation in which 1 mole of a compound forms from its elements. (270)
formula mass The sum (in amu) of the atomic masses of a formula unit of a (usually ionic) compound. (73)
formula unit The chemical unit of a compound that contains the relative numbers of the types of atoms or ions expressed in the chemical formula. (66)
fossil fuel Any fuel, including coal, petroleum, and natural gas, derived from the products of the decay of dead organisms. (273)
fraction by mass (also *mass fraction*) The portion of a compound's mass contributed by an element; the mass of an element in a compound divided by the mass of the compound. (45)
fractional distillation A physical process involving numerous vaporization-condensation steps used to separate two or more volatile components. (548)
free energy (*G*) A thermodynamic quantity that is the difference between the enthalpy and the product of the absolute temperature and the entropy: $G = H - TS$. (893)
free energy change (ΔG) The change in free energy that occurs during a reaction. (894)
free radical A molecular or atomic species with one or more unpaired electrons, which typically make it very reactive. (403, 1074)
freezing The process of cooling a liquid until it solidifies. (457)
freezing point depression (ΔT_f) The lowering of the freezing point of a solvent caused by the presence of dissolved solute particles. (545)
frequency (ν) The number of complete waves, or cycles, that pass a given point per second, expressed in units of 1/second, or s^{-1} [also called *hertz* (Hz)]; related inversely to wavelength. (288)
frequency factor (*A*) The product of the collision frequency Z and an orientation probability factor p that is specific for a reaction. (702)
fuel cell (also *flow battery*) A battery that is not self-contained and in which electricity is generated by the controlled oxidation of a fuel. (950)
functional group A specific combination of atoms, typically containing a carbon-carbon multiple bond and/or carbon-heteroatom bond, that reacts in a characteristic way no matter what molecule it occurs in. (619)
fundamental unit (See *base unit.*)
fusion (See *melting.*)
fusion (nuclear) The process by which light nuclei combine to form a heavier nucleus with the release of energy. (1081)

G

galvanic cell (See *voltaic cell.*)
gamma emission The type of radioactive decay in which gamma rays are emitted from an excited nucleus. (1058)
gamma (γ) ray A very high-energy photon. (1055)
gangue In an ore, the debris, such as sand, rock, and clay, attached to the mineral. (988)
gas One of the three states of matter. A gas fills its container regardless of the shape because its particles are far apart. (4)

Geiger-Müller counter An ionization counter that detects radioactive emissions through their ionization of gas atoms within the instrument. (1063)

genetic code The set of three-base sequences that is translated into specific amino acids during the process of protein synthesis. (660)

geometric isomers (also *cis-trans isomers* or *diastereomers*) Stereoisomers in which the molecules have the same connections between atoms but differ in the spatial arrangements of the atoms. The *cis* isomer has similar groups on the same side of a double bond; the *trans* isomer has them on opposite sides. (628, 1032)

Graham's law of effusion A gas law stating that the rate of effusion of a gas is inversely proportional to the square root of its density (or molar mass):

$$\text{rate} \propto \frac{1}{\sqrt{\mathcal{M}}} \tag{229}$$

gray (Gy) The SI unit of absorbed radiation dose; 1 Gy = 1 J/kg tissue. (1073)

green chemistry Field that is focused on developing methods to synthesize compounds efficiently and reduce or prevent the release of harmful products into the environment. (124)

ground state The electron configuration of an atom or ion that is lowest in energy. (296)

group A vertical column in the periodic table; elements in a group usually have the same outer electron configuration and, thus, similar chemical behavior. (59)

H

H bond (See *hydrogen bond.*)

Haber process An industrial process used to form ammonia from its elements. (763)

half-cell A portion of an electrochemical cell in which a half-reaction takes place. (926)

half-life ($t_{1/2}$) In chemical processes, the time required for half the initial reactant concentration to be consumed. (695) In nuclear processes, the time required for half the initial number of nuclei in a sample to decay. (1065)

half-reaction method A method of balancing redox reactions by treating the oxidation and reduction half-reactions separately. (920)

haloalkane (also *alkyl halide*) A hydrocarbon with one or more halogen atoms (X) in place of H; contains a  group. (640)

hard water Water that contains large amounts of divalent cations, especially Ca^{2+} and Mg^{2+}. (554)

heat (q) (also *thermal energy*) The energy transferred between objects because of a difference in their temperatures only. (24, 252)

heat capacity The quantity of heat required to change the temperature of an object by 1 K. (261)

heat of formation (See *enthalpy of formation.*)

heat of fusion (ΔH_{fus}) (also *enthalpy of fusion*) The enthalpy change occurring when 1 mol of a solid substance melts; designated ΔH°_{fus} at the standard state. (457)

heat of hydration (ΔH_{hydr}) (also *enthalpy of hydration*) The enthalpy change occurring when 1 mol of a gaseous species (often an ion) is hydrated. The sum of the enthalpies from separating water molecules and mixing the gaseous species with them; designated ΔH°_{hydr} at the standard state. (529)

heat of reaction (ΔH_{rxn}) (See *enthalpy of reaction.*)

heat of solution (ΔH_{soln}) (also *enthalpy of solution*) The enthalpy change occurring when a solution forms from solute and solvent. The sum of the enthalpies from separating solute and solvent substances and mixing them; designated ΔH°_{soln} at the standard state. (528)

heat of sublimation (ΔH_{subl}) (also *enthalpy of sublimation*) The enthalpy change occurring when 1 mol of a solid substance changes directly to a gas. The sum of the heats of fusion and vaporization; designated ΔH°_{subl} at the standard state. (458)

heat of vaporization (ΔH_{vap}) (also *enthalpy of vaporization*) The enthalpy change occurring when 1 mol of a liquid substance vaporizes; designated ΔH°_{vap} at the standard state. (457)

heating-cooling curve A plot of temperature vs. time for a substance when heat is absorbed or released by the system at a constant rate. (459)

Henderson-Hasselbalch equation An equation for calculating the pH of a buffer system:

$$\text{pH} = \text{p}K_a + \log\left(\frac{[\text{base}]}{[\text{acid}]}\right) \tag{832}$$

Henry's law A law stating that the solubility of a gas in a liquid is directly proportional to the partial pressure of the gas above the liquid: $S_{gas} = k_H \times P_{gas}$. (535)

Hess's law A law stating that the enthalpy change of an overall process is the sum of the enthalpy changes of the individual steps. (268)

heteroatom Any atom in an organic compound other than C or H. (619)

heterogeneous catalyst A catalyst that occurs in a different phase from the reactants, usually a solid interacting with gaseous or liquid reactants. (714)

heterogeneous mixture A mixture that has one or more visible boundaries among its components. (77)

hexagonal closest packing A crystal structure based on the hexagonal unit cell in which the layers have an *abab . . .* pattern. (482)

high-spin complex Complex ion that has the same number of unpaired electrons as in the isolated metal ion; contains weak-field ligands. (1040)

homogeneous catalyst A catalyst (gas, liquid, or soluble solid) that exists in the same phase as the reactants. (713)

homogeneous mixture (also *solution*) A mixture that has no visible boundaries among its components. (77)

homologous series A series of organic compounds in which each member differs from the next by a $-CH_2-$ (methylene) group. (622)

homonuclear diatomic molecule A molecule composed of two identical atoms. (442)

Hund's rule A principle stating that when orbitals of equal energy are available, the electron configuration of lowest energy has the maximum number of unpaired electrons with parallel spins. (328)

hybrid orbital An atomic orbital postulated to form during bonding by the mathematical mixing of specific combinations of non-equivalent orbitals in a given atom. (430)

hybridization A postulated process of orbital mixing to form hybrid orbitals. (430)

hydrate A compound in which a specific number of water molecules are associated with each formula unit. (69)

hydration Solvation in water. (529)

hydration shell The oriented cluster of water molecules that surrounds an ion in aqueous solution. (518)

hydrocarbon An organic compound that contains only H and C atoms. (620)
hydrogen bond (H bond) A type of dipole-dipole force that arises between molecules that have an H atom bonded to a small, highly electronegative atom with lone pairs, usually N, O, or F. (470)
hydrogenation The addition of hydrogen to a carbon-carbon multiple bond to form a carbon-carbon single bond. (714)
hydrolysis Cleaving a molecule by reaction with water, in which one part of the molecule bonds to the water —OH and the other to the water H. (648)
hydronium ion (H_3O^+) A proton covalently bonded to a water molecule. (778)
hydrosphere The liquid portion of Earth's crust. (980)
hypothesis A testable proposal made to explain an observation. If inconsistent with experimental results, a hypothesis is revised or discarded. (12)

I

ideal gas A hypothetical gas that exhibits linear relationships among volume, pressure, temperature, and amount (mol) at all conditions; approximated by simple gases at ordinary conditions. (204)
ideal gas law (also *ideal gas equation*) An equation that expresses the relationships among volume, pressure, temperature, and amount (mol) of an ideal gas: $PV = nRT$. (209)
ideal solution A solution whose vapor pressure equals the mole fraction of the solvent times the vapor pressure of the pure solvent; approximated only by very dilute solutions. (542) (See also *Raoult's law.*)
indicator (See *acid-base indicator.*)
induced-fit model A model of enzyme action that pictures the binding of the substrate as inducing the active site to change its shape and become catalytically active. (715)
infrared (IR) The region of the electromagnetic spectrum between the microwave and visible regions. (289)
infrared (IR) spectroscopy An instrumental technique for determining the types of bonds in a covalent molecule by measuring the absorption of IR radiation. (374)
initial rate The instantaneous rate occurring as soon as the reactants are mixed, that is, at $t = 0$. (680)
inner electrons (also *core electrons*) Electrons that fill all the energy levels of an atom except the valence level; electrons also present in atoms of the previous noble gas and any completed transition series. (334)
inner transition elements The elements of the periodic table in which *f* orbitals are being filled; the lanthanides and actinides. (335, 1024)
instantaneous rate The reaction rate at a particular time, given by the slope of a tangent to a plot of reactant concentration vs. time. (679)
insulator A substance (usually a nonmetal) that does not conduct an electric current. (492)
integrated rate law A mathematical expression for reactant concentration as a function of time. (691)
intensive property A property, such as density, that does not depend on the quantity of substance present. (26)
interhalogen compound A compound consisting entirely of halogens. (604)
intermolecular forces (also *interparticle forces*) The attractive and repulsive forces among the particles—molecules, atoms, or ions—in a sample of matter. (455)
internal energy (*E*) The sum of the kinetic and potential energies of all the particles in a system. (252)
ion A charged particle that forms from an atom (or covalently bonded group of atoms) when it gains or loses one or more electrons. (61)
ion-dipole force The intermolecular attractive force between an ion and a polar molecule (dipole). (469)
ion exchange A process of softening water by exchanging one type of ion (usually Ca^{2+}) for another (usually Na^+) by binding the ions on a specially designed resin. (554)
ion–induced dipole force The attractive force between an ion and the dipole it induces in the electron cloud of a nearby nonpolar molecule. (518)
ion pair A pair of ions that form a gaseous ionic molecule; sometimes formed when a salt boils. (368)
ion-product constant for water (K_w) The equilibrium constant for the autoionization of water; equal to 1.0×10^{-14} at 298 K.

$$K_w = [H_3O^+]\,[OH^-] \qquad (783)$$

ionic atmosphere A cluster of ions of net opposite charge surrounding a given ion in solution. (549)
ionic bonding The idealized type of bonding based on the attraction of oppositely charged ions that arise through electron transfer between atoms with large differences in their tendencies to lose or gain electrons (typically metals and nonmetals). (360)
ionic compound A compound that consists of oppositely charged ions. (61)
ionic radius The size of an ion as measured by the distance between the nuclei of adjacent ions in a crystalline ionic compound. (350)
ionic solid A solid whose unit cell contains cations and anions. (488)
ionization In nuclear chemistry, the process by which a substance absorbs energy from high-energy radioactive particles and loses an electron to become ionized. (1072)
ionization energy (IE) The energy (in kJ) required to remove completely one mole of electrons from one mole of gaseous atoms or ions. (339)
ionizing radiation The high-energy radiation from natural and artificial sources that forms ions in a substance by causing electron loss. (1073)
isoelectronic Having the same number and configuration of electrons as another species. (347)
isomer One of two or more compounds with the same molecular formula but different properties, often as a result of different arrangements of atoms. (106, 625, 1031)
isotopes Atoms of a given atomic number (that is, of a specific element) that have different numbers of neutrons and therefore different mass numbers. (54, 1054)
isotopic mass The mass (in amu) of an isotope relative to the mass of carbon-12. (55)

J

joule (J) The SI unit of energy; 1 J = 1 kg·m^2/s^2. (255)

K

kelvin (K) The SI base unit of temperature. The kelvin is the same size as the Celsius degree. (24)
Kelvin scale (See *absolute scale.*)
ketone An organic compound (ending, *-one*) that contains a carbonyl group bonded to two other C atoms,  . (644)

kilogram (kg) The SI base unit of mass. (16)
kinetic energy (E_k) The energy an object has because of its motion. (8)
kinetic-molecular theory The model that explains gas behavior in terms of particles in random motion whose volumes and interactions are negligible. (224)

L

lanthanide contraction The additional decrease in atomic and ionic size, beyond the expected trend, caused by the poor shielding of the increasing nuclear charge by *f* electrons in the elements following the lanthanides. (1021)
lanthanides (also *rare earths*) The Period 6 ($4f$) series of inner transition elements, which includes cerium (Ce; $Z = 58$) through lutetium (Lu; $Z = 71$). (335, 1024)
lattice The three-dimensional arrangement of points created by choosing each point to be at the same location within each particle of a crystal; thus, the lattice consists of all points with identical surroundings. (479)
lattice energy ($\Delta H^\circ_{\text{lattice}}$) The enthalpy change (always positive) that accompanies the separation of 1 mol of a solid ionic compound into gaseous ions. (364)
law (See *natural law.*)
law of chemical equilibrium (also *law of mass action*) The law stating that when a system reaches equilibrium at a given temperature, the ratio of quantities that make up the reaction quotient has a constant numerical value. (734)
law of conservation of energy (also *first law of thermodynamics*) A basic observation that the total energy of the universe is constant; thus, $\Delta E_{\text{universe}} = \Delta E_{\text{system}} + \Delta E_{\text{surroundings}} = 0$. (255)
law of definite (or constant) composition A mass law stating that, no matter what its source, a particular compound is composed of the same elements in the same parts (fractions) by mass. (45)
law of mass action (See *law of chemical equilibrium.*)
law of mass conservation A mass law stating that the total mass of substances does not change during a chemical reaction. (44)
law of multiple proportions A mass law stating that if elements A and B react to form two or more compounds, the different masses of B that combine with a fixed mass of A can be expressed as a ratio of small whole numbers. (45)
Le Châtelier's principle A principle stating that if a system in a state of equilibrium is disturbed, it will undergo a change that shifts its equilibrium position in a direction that reduces the effect of the disturbance. (754)
leaching A hydrometallurgical process that extracts a metal selectively, usually through formation of a complex ion. (989)
level (also *shell*) A specific energy state of an atom given by the principal quantum number *n*. (309)
leveling effect The inability of a solvent to distinguish the strength of an acid (or base) that is stronger than the conjugate acid (or conjugate base) of the solvent. (811)
Lewis acid-base definition A model of acid-base behavior in which acids and bases are defined, respectively, as species that accept and donate an electron pair. (811)
Lewis electron-dot symbol A notation in which the element symbol represents the nucleus and inner electrons, and surrounding dots represent the valence electrons. (361)
Lewis structure (also *Lewis formula*) A structural formula consisting of electron-dot symbols, with lines as bonding pairs and dots as lone pairs. (395)
ligand A molecule or anion bonded to a central metal ion in a complex ion. (859, 1026)
like-dissolves-like rule An empirical observation stating that substances having similar kinds of intermolecular forces dissolve in each other. (518)
limiting reactant (also *limiting reagent*) The reactant that is consumed when a reaction occurs and, therefore, the one that determines the maximum amount of product that can form. (117)
line spectrum A series of separated lines of different colors representing photons whose wavelengths are characteristic of an element. (294) (See also *emission spectrum.*)
linear arrangement The geometric arrangement obtained when two electron groups maximize their separation around a central atom. (407)
linear shape A molecular shape formed by three atoms lying in a straight line, with a bond angle of 180° (shape class AX_2 or AX_2E_3). (407)
linkage isomers Coordination compounds with the same composition but with different ligand donor atoms linked to the central metal ion. (1031)
lipid Any of a class of biomolecules, including fats, that are soluble in nonpolar solvents and not soluble in water. (647)
lipid bilayer An extended sheetlike double layer of phospholipid molecules that forms in water and has the charged heads of the molecules on the surfaces of the bilayer and the nonpolar tails within the interior. (526)
liquid One of the three states of matter. A liquid fills a container to the extent of its own volume and thus forms a surface. (4)
liquid crystal A substance that flows like a liquid but packs like a crystalline solid at the molecular level. (495)
liter (L) A non-SI unit of volume equivalent to 1 cubic decimeter (0.001 m^3). (15)
lithosphere The solid portion of Earth's crust. (980)
lock-and-key model A model of enzyme function that pictures the enzyme active site and the substrate as rigid shapes that fit together as a lock and key, respectively. (715)
London force (See *dispersion force.*)
lone pair (also *unshared pair*) An electron pair that is part of an atom's valence level but not involved in covalent bonding. (370)
low-spin complex Complex ion that has fewer unpaired electrons than in the free metal ion because of the presence of strong-field ligands. (1040)

M

macromolecule (See *polymer.*)
magnetic quantum number (m_l) An integer from $-l$ through 0 to $+l$ that specifies the orientation of an atomic orbital in the three-dimensional space about the nucleus. (308)
manometer A device used to measure the pressure of a gas in a laboratory experiment. (202)
mantle A thick homogeneous layer of Earth's internal structure that lies between the core and the crust. (978)
mass The quantity of matter an object contains. Balances are designed to measure mass. (16)
mass-action expression (See *reaction quotient.*)
mass fraction (See *fraction by mass.*)
mass number (A) The total number of protons and neutrons in the nucleus of an atom. (53)
mass percent (also *mass %* or *percent by mass*) The fraction by mass expressed as a percentage. (45) A concentration term [% (w/w)] expressed as the mass of solute dissolved in 100. parts by mass of solution. (538)

mass spectrometry An instrumental method for measuring the relative masses of particles in a sample by creating charged particles and separating them according to their mass-charge ratio. (55)
matter Anything that possesses mass and occupies volume. (4)
mean free path The average distance a molecule travels between collisions at a given temperature and pressure. (232)
melting (also *fusion*) The change of a substance from a solid to a liquid. (457)
melting point (mp or T_f) The temperature at which the solid and liquid forms of a substance are at equilibrium. (465)
metabolic pathway A biochemical reaction sequence that flows in one direction and has each reaction enzyme catalyzed. (765)
metal A substance or mixture that is relatively shiny and malleable and is a good conductor of heat and electricity. In reactions, metals tend to transfer electrons to nonmetals and form ionic compounds. (59)
metallic bonding An idealized type of bonding based on the attraction between metal ions and their delocalized valence electrons. (361) (See also *electron-sea model.*)
metallic radius One-half the shortest distance between the nuclei of adjacent individual atoms in a crystal of an element. (336)
metallic solid A solid whose individual atoms are held together by metallic bonding. (489)
metalloid (also *semimetal*) An element with properties between those of metals and nonmetals. (59)
metallurgy The branch of materials science concerned with the extraction and utilization of metals. (988)
metathesis reaction (also *double-displacement reaction*) A reaction in which atoms or ions of two compounds exchange bonding partners. Precipitation and acid-base reactions are examples. (153)
meter (m) The SI base unit of length. The distance light travels in a vacuum in 1/299,792,458 second. (14)
methanogenesis The process of producing methane by anaerobic biodegradation of plant and animal waste. (273)
microstate An instantaneous, quantized state of a system of particles throughout which the total energy of the system is dispersed. (880)
milliliter (mL) A volume (0.001 L) equivalent to 1 cm^3. (15)
millimeter of mercury (mmHg) A unit of pressure based on the difference in the heights of mercury in a barometer or manometer. Renamed the *torr* in honor of Torricelli. (203)
mineral The portion of an ore that contains the element of interest, a mineral is a naturally occurring, homogeneous, crystalline inorganic solid, with a well-defined composition. (988)
miscible Soluble in any proportion. (518)
mixture A group of two or more elements and/or compounds that are physically intermingled. (43)
MO bond order One-half the difference between the number of electrons in bonding and antibonding MOs. (441)
model (also *theory*) A simplified conceptual picture based on experiment that explains how a natural phenomenon occurs. (12)
molality (m) A concentration term expressed as number of moles of solute dissolved in 1000 g (1 kg) of solvent. (537)
molar heat capacity (C) The quantity of heat required to change the temperature of 1 mol of a substance by 1 K. (261)
molar mass ($\mathcal{M}$) The mass of 1 mol of entities (atoms, molecules, or formula units) of a substance, in units of g/mol. (92)
molarity (M) A concentration term expressed as the moles of solute dissolved in 1 L of solution. (144)
mole (mol) The SI base unit for amount of a substance. The amount that contains a number of objects equal to the number of atoms in exactly 12 g of carbon-12 (which is 6.022×10^{23}). (92)
mole fraction (X) A concentration term expressed as the ratio of moles of one component of a mixture to the total moles present. (219, 538)
molecular equation A chemical equation showing a reaction in solution in which reactants and products appear as intact, undissociated compounds. (150)
molecular formula A formula that shows the actual number of atoms of each element in a molecule of a compound. (101)
molecular mass (also *molecular weight*) The sum (in amu) of the atomic masses of the elements in a molecule (or formula unit) of a compound. (72)
molecular orbital (MO) An orbital of given energy and shape that extends over a molecule and can be occupied by no more than two paired electrons. (440)
molecular orbital (MO) diagram A depiction of the relative energy and number of electrons in each MO, as well as the atomic orbitals from which the MOs form. (441)
molecular orbital (MO) theory A model that describes a molecule as a collection of nuclei and electrons in which the electrons occupy orbitals that extend over the entire molecule. (440)
molecular polarity The overall distribution of electronic charge in a molecule, determined by its shape and bond polarities. (416)
molecular shape The three-dimensional structure defined by the relative positions of the atomic nuclei in a molecule. (406)
molecular solid A solid held together by intermolecular forces between individual molecules. (488)
molecular weight (See *molecular mass.*)
molecularity The number of reactant particles involved in an elementary step. (706)
molecule A structure consisting of two or more atoms that are bound chemically and behave as an independent unit. (42)
monatomic ion An ion derived from a single atom. (61)
monomer A small molecule, linked covalently to others of the same or similar type to form a polymer; the repeat unit of the polymer. (500)
mononucleotide A monomer unit of a nucleic acid, consisting of an N-containing base, a sugar, and a phosphate group. (527, 658)
monosaccharide A simple sugar; a polyhydroxy ketone or aldehyde with three to nine C atoms. (654)

N

nanotechnology The science and engineering of nanoscale (1–100 nm) systems. (505)
natural law (also *law*) A summary, often in mathematical form, of a universal observation. (12)
Nernst equation An equation stating that the voltage of an electrochemical cell under any conditions depends on the standard cell voltage and the concentrations of the cell components:

$$E_{\text{cell}} = E^\circ_{\text{cell}} - \frac{RT}{nF}\ln Q \qquad (941)$$

net ionic equation A chemical equation of a reaction in solution in which spectator ions have been eliminated to show the actual chemical change. (151)
network covalent solid A solid in which all the atoms are bonded covalently so that individual molecules are not present. (489)
neutralization Process that occurs when an H^+ ion from an acid combines with an OH^- ion from a base to form H_2O. (778)
neutralization reaction An acid-base reaction that yields water and a solution of a salt; when the H^+ ions of a strong acid react with an equivalent amount of the OH^- ions of a strong base, the solution is neutral. (158)

neutron (n^0) An uncharged subatomic particle found in the nucleus, with a mass slightly greater than that of a proton. (53)
nitrile An organic compound containing the —C≡N: group. (650)
node A region of an orbital where the probability of finding the electron is zero. (311)
nonbonding MO A molecular orbital that is not involved in bonding. (447)
nonelectrolyte A substance whose aqueous solution does not conduct an electric current. (144, 541)
nonmetal An element that lacks metallic properties. In reactions, nonmetals tend to share electrons with each other to form covalent compounds or accept electrons from metals to form ionic compounds. (59)
nonpolar covalent bond A covalent bond between identical atoms such that the bonding pair is shared equally. (382)
nuclear binding energy The energy required to break 1 mole of nuclei of an element into individual nucleons. (1082)
nuclear magnetic resonance (NMR) spectroscopy An instrumental technique used to determine the molecular environment of a given type of nucleus, most often ^1H, from its absorption of radio waves in a magnetic field. (633)
nuclear transmutation The induced conversion of one nucleus into another by bombardment with a particle. (1069)
nucleic acid An unbranched polymer consisting of mononucleotides that occurs as two types, DNA and RNA (deoxyribonucleic and ribonucleic acids), which differ chemically in the nature of the sugar portion of the mononucleotides. (527, 658)
nucleon A subatomic particle found in the nucleus; a proton or neutron. (1054)
nucleus The tiny central region of the atom that contains all the positive charge and essentially all the mass. (52)
nuclide A nuclear species with specified numbers of protons and neutrons. (1054)

O

observation A fact obtained with the senses, often with the aid of instruments. Quantitative observations provide data that can be compared. (12)
occurrence (also *source*) The form(s) in which an element exists in nature. (981)
octahedral arrangement The geometric arrangement obtained when six electron groups maximize their space around a central atom; when all six groups are bonding groups, the molecular shape is octahedral (AX_6; ideal bond angle = 90°). (411)
octet rule The observation that when atoms bond, they often lose, gain, or share electrons to attain a filled outer level of eight electrons (or two for H and Li). (362)
optical isomers (also *enantiomers*) A pair of stereoisomers consisting of a molecule and its mirror image that cannot be superimposed on each other. (626, 1032)
optically active Able to rotate the plane of polarized light. (627)
orbital diagram A depiction of orbital occupancy in terms of electron number and spin shown by means of arrows in a series of small boxes, lines, or circles. (327)
ore A naturally occurring compound or mixture of compounds from which an element can be profitably extracted. (981)
organic compound A compound in which carbon is nearly always bonded to itself and to hydrogen, and often to other elements. (617)
organometallic compound An organic compound in which carbon has a polar covalent bond to a metal atom. (645)
osmosis The process by which solvent flows through a semipermeable membrane from a dilute to a concentrated solution. (546)
osmotic pressure (Π) The pressure that results from the ability of solvent, but not solute, particles to cross a semipermeable membrane. The pressure required to prevent the net movement of solvent across the membrane. (546)
outer electrons Electrons that occupy the highest energy level (highest n value) and are, on average, farthest from the nucleus. (334)
overall (net) equation A chemical equation that is the sum of two or more balanced sequential equations in which a product of one becomes a reactant for the next. (116)
overvoltage The additional voltage, usually associated with gaseous products forming at an electrode, that is required above the standard cell voltage to accomplish electrolysis. (858)
oxidation The loss of electrons by a species, accompanied by an increase in oxidation number. (169)
oxidation number (O.N.) (also *oxidation state*) A number equal to the magnitude of the charge an atom would have if its shared electrons were held completely by the atom that attracts them more strongly. (170)
oxidation-reduction reaction (also *redox reaction*) A process in which there is a net movement of electrons from one reactant (reducing agent) to another (oxidizing agent). (168)
oxidation state (See *oxidation number.*)
oxidizing agent The substance that accepts electrons in a reaction and undergoes a decrease in oxidation number. (169)
oxoanion An anion in which an element is bonded to one or more oxygen atoms. (68)

P

***p* orbital** An atomic orbital with $l = 1$. (312)
packing efficiency The percentage of the available volume occupied by atoms, ions, or molecules in a unit cell. (482)
paramagnetism The tendency of a species with unpaired electrons to be attracted by an external magnetic field. (349)
partial ionic character An estimate of the actual charge separation in a bond (caused by the electronegativity difference of the bonded atoms) relative to complete separation. (382)
partial pressure The portion of the total pressure contributed by a gas in a mixture of gases. (219)
particle accelerator A device used to impart high kinetic energies to nuclear particles. (1070)
pascal (Pa) The SI unit of pressure; 1 Pa = 1 N/m^2. (202)
penetration The process by which an outer electron moves through the region occupied by the core electrons to spend part of its time closer to the nucleus; penetration increases the average effective nuclear charge for that electron. (326)
percent by mass (mass %) (See *mass percent.*)
percent yield (% yield) The actual yield of a reaction expressed as a percentage of the theoretical yield. (123)
period A horizontal row of the periodic table. (59)
periodic law A law stating that when the elements are arranged by atomic number, they exhibit a periodic recurrence of properties. (323)
periodic table of the elements A table in which the elements are arranged by atomic number into columns (groups) and rows (periods). (58)
pH The negative common logarithm of $[H_3O^+]$. (784)
phase A physically distinct and homogeneous part of a system. (455)

phase change A physical change from one phase to another, usually referring to a change in physical state. (456)
phase diagram A diagram used to describe the stable phases and phase changes of a substance as a function of temperature and pressure. (466)
photoelectric effect The observation that when monochromatic light of sufficient frequency shines on a metal, an electric current is produced. (292)
photon A quantum of electromagnetic radiation. (293)
photovoltaic cell A device capable of converting light directly into electricity. (276)
physical change A change in which the physical form (or state) of a substance, but not its composition, is altered. (5)
physical property A characteristic shown by a substance itself, without interacting with or changing into other substances. (5)
pi (π) bond A covalent bond formed by sideways overlap of two atomic orbitals that has two regions of electron density, one above and one below the internuclear axis. (437)
pi (π) MO A molecular orbital formed by combination of two atomic (usually *p*) orbitals whose orientations are perpendicular to the internuclear axis. (443)
Planck's constant (*h*) A proportionality constant relating the energy and frequency of a photon, equal to 6.626×10^{-34} J·s. (292)
plastic A material that, when deformed, retains its new shape. (503)
polar covalent bond A covalent bond in which the electron pair is shared unequally, so the bond has partially negative and partially positive poles. (382)
polar molecule A molecule with an unequal distribution of charge as a result of its polar bonds and shape. (140)
polarimeter A device used to measure the rotation of plane-polarized light by an optically active compound. (627)
polarizability The ease with which a particle's electron cloud can be distorted. (472)
polyatomic ion An ion in which two or more atoms are bonded covalently. (64)
polymer (also *macromolecule*) An extremely large molecule that results from the covalent linking of many simpler molecular units (monomers). (500)
polyprotic acid An acid with more than one ionizable proton. (797)
polysaccharide A macromolecule composed of many simple sugars linked covalently. (655)
positron (β^+) The antiparticle of an electron. (1057)
positron emission A type of radioactive decay in which a positron is emitted from a nucleus. (1057)
potential energy (E_p) The energy an object has as a result of its position relative to other objects or because of its composition. (8)
precipitate The insoluble product of a precipitation reaction. (151)
precipitation reaction A reaction in which two soluble ionic compounds form an insoluble product, a precipitate. (151)
precision (also *reproducibility*) The closeness of a measurement to other measurements of the same phenomenon in a series of experiments. (31)
pressure (*P*) The force exerted per unit of surface area. (201)
pressure-volume work (*PV* work) A type of work in which a volume change occurs against an external pressure. (258)
principal quantum number (*n*) A positive integer that specifies the energy and relative size of an atomic orbital; a number that specifies an energy level in an atom. (308)
probability contour A shape that defines the volume around an atomic nucleus within which an electron spends a given percentage of its time. (308)
product A substance formed in a chemical reaction. (108)
property A characteristic that gives a substance its unique identity. (5)
protein A natural, linear polymer composed of any of about 20 types of amino acid monomers linked together by peptide bonds. (522, 656)
proton (p^+) A subatomic particle found in the nucleus that has a unit positive charge (1.60218×10^{-19} C). (53)
proton acceptor A substance that accepts an H^+ ion; a Brønsted-Lowry base. (787)
proton donor A substance that donates an H^+ ion; a Brønsted-Lowry acid. (787)
pseudo–noble gas configuration The $(n-1)d^{10}$ configuration of a *p*-block metal ion that has an empty outer energy level. (347)

Q

quantum A packet of energy equal to $h\nu$. The smallest quantity of energy that can be emitted or absorbed. (292)
quantum mechanics The branch of physics that examines the wave motion of objects on the atomic scale. (306)
quantum number A number that specifies a property of an orbital or an electron. (292)

R

rad (*r*adiation-*a*bsorbed *d*ose) The quantity of radiation that results in 0.01 J of energy being absorbed per kilogram of tissue; 1 rad = 0.01 J/kg tissue = 10^{-2} Gy. (1073)
radial probability distribution plot The graphic depiction of the total probability distribution (sum of ψ^2) of an electron in the region near the nucleus. (307)
radioactivity The emissions resulting from the spontaneous disintegration of an unstable nucleus. (1053)
radioisotope An isotope with an unstable nucleus that decays through radioactive emissions. (1067)
radioisotopic dating A method for determining the age of an object based on the rate of decay of a particular radioactive nuclide relative to a stable nuclide. (1067)
radius of gyration (R_g) A measure of the size of a coiled polymer chain, expressed as the average distance from the center of mass of the chain to its outside edge. (501)
random coil The shape adopted by most polymer chains and caused by random rotation about the bonds joining the repeat units. (501)
random error Error that occurs in all measurements (with its size depending on the measurer's skill and the instrument's precision) and results in values *both* higher and lower than the actual value. (31)
Raoult's law A law stating that the vapor pressure of solvent above a solution equals the mole fraction of solvent times the vapor pressure of pure solvent: $P_{solvent} = X_{solvent} \times P^\circ_{solvent}$. (542)
rare earths (See *lanthanides*.)
rate constant (*k*) The proportionality constant that relates reaction rate to reactant (and product) concentrations. (682)
rate-determining step (also *rate-limiting step*) The slowest step in a reaction mechanism and therefore the step that limits the overall rate. (708)
rate law (also *rate equation*) An equation that expresses the rate of a reaction as a function of reactant (and product) concentrations. (682)

reactant A starting substance in a chemical reaction. (108)
reaction energy diagram A graph that shows the potential energy of a reacting system as it progresses from reactants to products. (704)
reaction intermediate A substance that is formed and used up during the overall reaction and therefore does not appear in the overall equation. (708)
reaction mechanism A series of elementary steps that sum to the overall reaction and is consistent with the rate law. (706)
reaction order The exponent of a reactant concentration in a rate law that shows how the rate is affected by changes in that concentration. (682)
reaction quotient (*Q*) (also *mass-action expression*) A ratio of terms for a given reaction consisting of product concentrations multiplied together and divided by reactant concentrations multiplied together, each raised to the power of their balancing coefficient. The value of Q changes until the system reaches equilibrium, at which point it equals K. (734)
reaction rate The change in the concentrations of reactants (or products) with time. (675)
reactor core The part of a nuclear reactor that contains the fuel rods and generates heat from fission. (1086)
redox reaction (See *oxidation-reduction reaction.*)
reducing agent The substance that donates electrons in a redox reaction and undergoes an increase in oxidation number. (169)
reduction The gain of electrons by a species, accompanied by a decrease in oxidation number. (169)
refraction A phenomenon in which a wave changes its speed and therefore its direction as it passes through a phase boundary into a different medium. (290)
rem (*roentgen equivalent for man*) The unit of radiation dosage for a human based on the product of the number of rads and a factor related to the biological tissue; 1 rem = 10^{-2} Sv. (1073)
reproducibility (See *precision.*)
resonance hybrid The weighted average of the resonance structures of a molecule. (399)
resonance structure (also *resonance form*) One of two or more Lewis structures for a molecule that cannot be adequately depicted by a single structure. Resonance structures differ only in the position of bonding and lone electron pairs. (399)
reverse osmosis A process for preparing drinkable water that uses an applied pressure greater than the osmotic pressure to remove ions from an aqueous solution, typically seawater. (555)
rms (root-mean-square) speed (u_{rms}) The speed of a molecule having the average kinetic energy; very close to the most probable speed. (229)
roasting A pyrometallurgical process in which metal sulfides are converted to oxides. (990)
round off The process of removing digits based on a series of rules to obtain an answer with the proper number of significant figures (or decimal places). (29)

S

***s* orbital** An atomic orbital with $l = 0$. (311)
salt An ionic compound that results from an Arrhenius acid-base reaction after solvent is removed. (161)
salt bridge An inverted U tube containing a solution of a nonreacting electrolyte that connects the compartments of a voltaic cell and maintains neutrality by allowing ions to flow between compartments. (927)
saturated hydrocarbon A hydrocarbon in which each C is bonded to four other atoms. (623)
saturated solution A solution that contains the maximum amount of dissolved solute at a given temperature (prepared with undissolved solute present). (533)
scanning tunneling microscopy An instrumental technique that uses electrons moving across a minute gap to observe the topography of a surface on the atomic scale. (486)
Schrödinger equation An equation that describes how the electron matter-wave changes in space around the nucleus. Solutions of the equation provide allowable energy levels of the atom. (306)
scientific method A process of creative thinking and testing aimed at objective, verifiable discoveries of the causes of natural events. (12)
scintillation counter A device used to measure radioactivity through its excitation of atoms and their subsequent emission of light. (1063)
screening (See *shielding.*)
second (s) The SI base unit of time. (16)
second law of thermodynamics A law stating that a process occurs spontaneously in the direction that increases the entropy of the universe. (883)
seesaw shape A molecular shape caused by the presence of one equatorial lone pair in a trigonal bipyramidal arrangement (AX_4E). (411)
selective precipitation The process of separating ions through differences in the solubility of their compounds with a given precipitating ion. (856)
self-ionization (See *autoionization.*)
semiconductor A substance whose electrical conductivity is poor at room temperature but increases significantly with rising temperature. (492)
semimetal (See *metalloid.*)
semipermeable membrane A membrane that allows solvent, but not solute, to pass through. (546)
shared pair (See *bonding pair.*)
shell (See *level.*)
shielding (also *screening*) The ability of other electrons, especially those occupying inner orbitals, to lessen the nuclear attraction for an outer electron. (325)
SI unit A unit composed of one or more of the base units of the Système International d'Unités, a revised metric system. (13)
side reaction An undesired chemical reaction that consumes some of the reactant and reduces the overall yield of the desired product. (123)
sievert (Sv) The SI unit of human radiation dosage; 1 Sv = 100 rem. (1073)
sigma (σ) bond A type of covalent bond that arises through end-to-end orbital overlap and has most of its electron density along an imaginary line joining the nuclei. (437)
sigma (σ) MO A molecular orbital that is cylindrically symmetrical about an imaginary line that runs through the nuclei of the component atoms. (441)
significant figures The digits obtained in a measurement. The greater the number of significant figures, the greater the certainty of the measurement. (27)
silicate A type of compound found throughout rocks and soil and consisting of repeating —Si—O groupings and, in most cases, metal cations. (587)
silicone A type of synthetic polymer containing —Si—O repeat units, with organic groups and crosslinks. (587)
simple cubic unit cell A unit cell in which a particle occupies each corner of a cube. (480)

single bond A bond that consists of one electron pair. (370)
slag A molten waste product formed in a blast furnace by the reaction of acidic silica with a basic metal oxide. (997)
smelting Heating a mineral with a reducing agent, such as coke, to obtain a metal. (990)
soap The salt formed in a reaction between a fatty acid and a strong base, usually a Group 1A(1) or 2A(2) hydroxide. (523)
solid One of the three states of matter. A solid has a fixed shape that does not conform to the container shape. (4)
solubility (*S*) The maximum amount of solute that dissolves in a fixed quantity of a particular solvent at a specified temperature. (518)
solubility-product constant (K_{sp}) An equilibrium constant for a slightly soluble ionic compound dissolving in water. (846)
solute The substance that dissolves in the solvent. (139, 518)
solution (See *homogeneous mixture.*)
solvated Surrounded closely by solvent molecules. (141)
solvation The process of surrounding a solute particle with solvent particles. (529)
solvent The substance in which the solute(s) dissolve. (139, 518)
source (See *occurrence.*)
***sp* hybrid orbital** An orbital formed by the mixing of one *s* and one *p* orbital of a central atom. (430)
***sp*^{2} hybrid orbital** An orbital formed by the mixing of one *s* and two *p* orbitals of a central atom. (432)
***sp*^{3} hybrid orbital** An orbital formed by the mixing of one *s* and three *p* orbitals of a central atom. (432)
***sp*^{3}*d* hybrid orbital** An orbital formed by the mixing of one *s*, three *p*, and one *d* orbital of a central atom. (433)
***sp*^{3}*d*^{2} hybrid orbital** An orbital formed by the mixing of one *s*, three *p*, and two *d* orbitals of a central atom. (434)
specific heat capacity (*c*) The quantity of heat required to change the temperature of 1 gram of a material by 1 K. (261)
spectator ion An ion that is present as part of a reactant but is not involved in the chemical change. (150)
spectrochemical series A ranking of ligands in terms of their ability to split *d*-orbital energies. (1039)
spectrometry Any instrumental technique that uses a portion of the electromagnetic spectrum to measure the atomic and molecular energy levels of a substance. (300)
speed of light (*c*) A fundamental constant giving the speed at which electromagnetic radiation travels in a vacuum: $c = 2.99792458 \times 10^8$ m/s. (288)
spin quantum number (m_s) A number, either $+\frac{1}{2}$ or $-\frac{1}{2}$, that indicates the direction of electron spin. (324)
spontaneous change A change that occurs by itself, that is, without an ongoing input of external energy. (877)
square planar shape A molecular shape (AX_4E_2) caused by the presence of two lone pairs at opposite vertices in an octahedral arrangement. (412)
square pyramidal shape A molecular shape (AX_5E) caused by the presence of one lone pair in an octahedral arrangement. (412)
standard atmosphere (atm) The average atmospheric pressure measured at sea level and 0°C, defined as 1.01325×10^5 Pa. (203)
standard cell potential (E°_{cell}) The potential of a cell measured with all components in their standard states and no current flowing. (930)
standard electrode potential ($E^\circ_{half\text{-}cell}$) (also *standard half-cell potential*) The standard potential of a half-cell, with the half-reaction written as a reduction. (930)
standard enthalpy of formation (ΔH°_f) (also *standard heat of formation*) The enthalpy change occurring when 1 mol of a compound forms from its elements with all components in their standard states. (270)
standard enthalpy of reaction (ΔH°_{rxn}) (also *standard heat of reaction*) The enthalpy change that occurs during a reaction when all components are in their standard states. (270)
standard entropy of reaction (ΔS°_{rxn}) The entropy change that occurs when all components are in their standard states. (888)
standard free energy change (ΔG°) The free energy change that occurs when all components are in their standard states. (894)
standard free energy of formation (ΔG°_f) The standard free energy change that occurs when 1 mol of a compound is made from its elements with all components in their standard states. (895)
standard half-cell potential (See *standard electrode potential.*)
standard heat of formation (See *standard enthalpy of formation.*)
standard heat of reaction (See *standard enthalpy of reaction.*)
standard hydrogen electrode (See *standard reference half-cell.*)
standard molar entropy (S°) The entropy of 1 mol of a substance in its standard state. (883)
standard molar volume The volume of 1 mol of an ideal gas at standard temperature and pressure: 22.4141 L. (209)
standard reference half-cell (also *standard hydrogen electrode*) A specially prepared platinum electrode immersed in 1 *M* $H^+(aq)$ through which H_2 gas at 1 atm is bubbled. $E^\circ_{half\text{-}cell}$ is defined as 0 V. (931)
standard state A set of specifications used to compare thermodynamic data: 1 atm for gases behaving ideally, 1 *M* for dissolved species, or the pure substance for liquids and solids. (270)
standard temperature and pressure (STP) The reference conditions for a gas:

0°C (273.15 K) and 1 atm (760 torr) (209)

state function A property of the system determined by its current state, regardless of how it arrived at that state. (256)
state of matter One of the three physical forms of matter: solid, liquid, or gas. (4)
stationary state In the Bohr model, one of the allowable energy levels of the atom in which it does not release or absorb energy. (295)
steel An alloy of iron with small amounts of carbon and usually other metals. (996)
stellar nucleosynthesis The process by which elements are formed in the stars through nuclear fusion. (1090)
stereoisomers Molecules with the same connections of atoms but different orientations of groups in space. (626, 1032) (See also *geometric isomers* and *optical isomers.*)
stoichiometric coefficient (See *balancing coefficient.*)
stoichiometry The study of the mass-mole-number relationships of chemical formulas and reactions. (91)
strong-field ligand A ligand that causes larger crystal field splitting energy and therefore is part of a low-spin complex. (1038)
strong force An attractive force that exists between all nucleons and is many times stronger than the electrostatic repulsive force. (1060)
structural formula A formula that shows the actual number of atoms, their relative placement, and the bonds between them. (101)
structural isomers (See *constitutional isomers.*)
sublevel (also *subshell*) An energy substate of an atom within a level. Given by the *n* and *l* values, the sublevel designates the size and shape of the atomic orbitals. (309)

sublimation The process by which a solid changes directly into a gas. (457)
substance A type of matter, either an element or a compound, that has a fixed composition. (42)
substitution reaction An organic reaction that occurs when an atom (or group) from one reactant substitutes for one in another reactant. (636)
substrate A reactant that binds to the active site in an enzyme-catalyzed reaction. (715)
superconductivity The ability to conduct a current with no loss of energy to resistive heating. (492)
supersaturated solution An unstable solution in which more solute is dissolved than in a saturated solution. (533)
surface tension The energy required to increase the surface area of a liquid by a given amount. (475)
surroundings All parts of the universe other than the system being considered. (252)
suspension A heterogeneous mixture containing particles that are distinct from the surrounding medium. (552)
synthetic natural gas (SNG) A gaseous fuel mixture, mostly methane, formed from coal. (273)
system The defined part of the universe under study. (252)
systematic error A type of error producing values that are all either higher or lower than the actual value, often caused by faulty equipment or a consistent flaw in technique. (31)

T

t_{2g} orbitals The set of orbitals (composed of d_{xy}, d_{yz}, and d_{xz}) that results when the energies of the metal-ion *d* orbitals are split by a ligand field. This set is lower in energy than the other (e_g) set in an octahedral field and higher in energy in a tetrahedral field. (1038)
T shape A molecular shape caused by the presence of two equatorial lone pairs in a trigonal bipyramidal arrangement (AX_3E_2). (411)
temperature (*T*) A measure of how hot or cold a substance is relative to another substance. (24) A measure of the average kinetic energy of the particles in a sample. (228)
tetrahedral arrangement The geometric arrangement formed when four electron groups maximize their separation around a central atom; when all four groups are bonding groups, the molecular shape is tetrahedral (AX_4; ideal bond angle 109.5°). (409)
theoretical yield The amount of product predicted by the stoichiometrically equivalent molar ratio in the balanced equation. (123)
theory (See *model.*)
thermochemical equation A chemical equation that shows the heat involved for the amounts of substances specified. (266)
thermochemistry The branch of thermodynamics that focuses on the heat involved in chemical and physical change. (251)
thermodynamics The study of heat (thermal energy) and its interconversions. (251)
thermometer A device for measuring temperature that contains a fluid that expands or contracts within a graduated tube. (24)
third law of thermodynamics A law stating that the entropy of a perfect crystal is zero at 0 K. (883)
titration A method of determining the concentration of a solution by monitoring relative amounts during its reaction with a solution of known concentration. (166)
torr A unit of pressure identical to 1 mmHg. (203)
total ionic equation An equation for an aqueous reaction that shows all the soluble ionic substances dissociated into ions. (150)
tracer A radioisotope that signals the presence of the species of interest by radioactive emissions. (1077)
transcription The process of producing messenger RNA from DNA. (661)
transition element An element that occupies the *d* block of the periodic table; one whose *d* orbitals are being filled. (332, 1017)
transition state (also *activated complex*) An unstable species formed in an effective collision of reactants that exists momentarily when the system is highest in energy and that can either form products or re-form reactants. (703)
transition state theory A model that explains how the energy of reactant collisions is used to form a high-energy transitional species that can change to reactant or product. (703)
translation The process by which messenger RNA specifies the sequence of amino acids and synthesizes proteins. (661)
transuranium element An element with atomic number higher than that of uranium ($Z = 92$). (1072)
trigonal bipyramidal arrangement The geometric arrangement formed when five electron groups maximize their separation around a central atom. When all five groups are bonding groups, the molecular shape is trigonal bipyramidal (AX_5; ideal bond angles, axial-center-equatorial 90° and equatorial-center-equatorial 120°). (410)
trigonal planar arrangement The geometric arrangement formed when three electron groups maximize their separation around a central atom. When all three groups are bonding groups, the molecular shape is trigonal planar (AX_3; ideal bond angle 120°). (408)
trigonal pyramidal shape A molecular shape (AX_3E) caused by the presence of one lone pair in a tetrahedral arrangement. (410)
triple bond A covalent bond that consists of three bonding pairs, two atoms sharing six electrons; one σ and two π bonds. (370)
triple point The pressure and temperature at which three phases of a substance are in equilibrium. In a phase diagram, the point at which three phase-transition curves meet. (466)
Tyndall effect The scattering of light by a colloid. (553)

U

ultraviolet (UV) Radiation in the region of the electromagnetic spectrum between the visible and the x-ray regions. (289)
uncertainty A characteristic of every measurement that results from the inexactness of the measuring device and the need to estimate when taking a reading. (27)
uncertainty principle The principle stated by Werner Heisenberg that it is impossible to know simultaneously the exact position and velocity of a particle; the principle becomes important only for particles of very small mass. (305)
unimolecular reaction An elementary reaction that involves the decomposition or rearrangement of a single particle. (707)
unit cell The smallest portion of a crystal that, if repeated in all three directions, gives the crystal. (479)
universal gas constant (*R*) A proportionality constant that relates the energy, amount of substance, and temperature of a system; $R = 0.0820578\ \text{atm·L/mol·K} = 8.31447\ \text{J/mol·K}$. (209)
unsaturated hydrocarbon A hydrocarbon with at least one carbon-carbon multiple bond; one in which at least two C atoms are bonded to fewer than four atoms. (628)
unsaturated solution A solution in which more solute can be dissolved at a given temperature. (533)
unshared pair (See *lone pair.*)

V

V shape (See *bent shape.*)
valence band In band theory, the lower energy portion of the band of molecular orbitals, which is filled with valence electrons. (491)
valence bond (VB) theory A model that attempts to reconcile the shapes of molecules with those of atomic orbitals through the concepts of orbital overlap and hybridization. (429)
valence electrons The electrons involved in compound formation; in main-group elements, the electrons in the valence (outer) level. (334)
valence-shell electron-pair repulsion (VSEPR) theory A model explaining that the shapes of molecules and ions result from minimizing electron-pair repulsions around a central atom. (406)
van der Waals constants Experimentally determined positive numbers used in the van der Waals equation to account for the intermolecular attractions and molecular volume of real gases. (237)
van der Waals equation An equation that accounts for the behavior of real gases. (237)
van der Waals radius One-half of the shortest distance between the nuclei of identical nonbonded atoms. (468)
vapor pressure (also *equilibrium vapor pressure*) The pressure exerted by a vapor at equilibrium with its liquid in a closed system. (463)
vapor pressure lowering (ΔP) The lowering of the vapor pressure of a solvent caused by the presence of dissolved solute particles. (463, 542)
vaporization The process of changing from a liquid to a gas. (457)
variable A quantity that can have more than a single value. (12) (See also *controlled experiment.*)
viscosity A measure of the resistance of a liquid to flow. (476)
volatility The tendency of a substance to become a gas. (79)
volt (V) The SI unit of electric potential: 1 V = 1 J/C. (930)
voltage (See *cell potential.*)
voltaic cell (also *galvanic cell*) An electrochemical cell that uses a spontaneous redox reaction to generate electric energy. (924)
volume (V) The space occupied by a sample of matter. (15)
volume percent [% (v/v)] A concentration term defined as the volume of solute in 100. volumes of solution. (538)

W

wastewater Used water, usually containing industrial and/or residential waste, that is treated before being returned to the environment. (555)
water softening The process of replacing the hard-water ions Ca^{2+} and Mg^{2+} with Na^{+} ions. (554)
wave function (See *atomic orbital.*)
wave-particle duality The principle stating that both matter and energy have wavelike and particle-like properties. (304)
wavelength (λ) The distance between any point on a wave and the corresponding point on the next wave, that is, the distance a wave travels during one cycle. (288)
weak-field ligand A ligand that causes smaller crystal field splitting energy and therefore is part of a high-spin complex. (1038)
weight The force exerted by a gravitational field on an object that is directly proportional to its mass. (16)
work (w) The energy transferred when an object is moved by a force. (253)

X

x-ray diffraction analysis An instrumental technique used to determine dimensions of a crystal structure by measuring the diffraction patterns caused by x-rays impinging on the crystal. (486)

Z

zone refining A process used to purify metals and metalloids in which impurities are removed from a bar of the element by concentrating them in a thin molten zone. (992)

INDEX

Page numbers followed by *f* indicate figures; *mn*, marginal notes; *n*, footnotes; and *t*, tables. Page numbers preceded by "A-" indicate pages in the *Appendix*. Page numbers preceded by "G-" indicate pages in the *Glossary*.

A

AB block copolymer, 504
Absolute temperature scale, 207, G-1
Absolute zero, 25, 207
Absorption spectrum, 300–301, 300*f*, 301*f*, G-1
Abundance, of elements, 977–982, 978*f*, 981*t*, G-1
Accuracy, 31, 31*f*, G-1
Acetaldehyde
  boiling point, 469, 470*f*
  dipole moment, 469, 470*f*
  molecular structure, 639*t*, 644*f*
Acetamide, molecular structure, 639*t*
Acetaminophen, molecular structure, 648*f*
Acetate ion, 68*t*, 828–831, 828*t*
Acetic acid
  acid-dissociation constant (K_a), 781*t*, A-8
  as a base, 811
  boiling point elevation constant, 544*t*
  buffer action and, 828–831, 828*t*
  dissociation constant, 780, 781*t*
  formula, 106*t*
  freezing point depression constant, 544*t*
  molecular structure, 639*t*, 646
  reaction with bases, 164, 164*f*, 164*t*
  relation between K_a and pK_a, 785*t*
  reversible dissociation of, 183
  uses, 106*t*, 777*t*
Acetone
  bonds and orbitals, 438–439
  molecular shape, 416
  molecular structure, 639*t*, 644*f*
  nuclear magnetic resonance spectroscopy, 633, 633*f*
Acetonitrile
  boiling point, 470*f*
  dipole moment, 470*f*
  molecular structure, 639*t*
Acetylene
  bonds, 437, 437*f*, 438
  electron density and bond order, 438*f*
  molecular shape, 437, 437*f*
  molecular structure, 639*t*
  production of, 221–222
Acetylsalicylic acid, acid-dissociation constant (K_a), A-8
Acid(s)
  acidic solutions, balancing redox reactions in, 921–922
  Arrhenius acids, 778, 814
  Brønsted-Lowry acids, 162, 787–792, 810–811, 814
  buffers, 827–837
  concentration, finding from titration, 167–168
  conjugate acid-base pairs, 788–791, 788*t*, 790*f*, 828, 828*f*, 835–836
  defined, 159, 162, 777, 778, 787, 809, 811–812, 814, G-1
  dissociation, 159–160, 731, 779*f*, 781*t*, 795–796, 808, 810–811, 828–831, 828*t*, A-8–A-10
  as electrolytes, 159–160, 159*f*
  household uses, 777t
  indicators, 166–167, 167*f*, 786, 787*f*, 837–838, 837*f*
  leveling effect, 811
  Lewis acids, 811–814, 859
  monoprotic, 781, 781*t*
  names, 70–71
  polyprotic, 797–799, 797*t*, 844–846, 845*f*
  proton transfer, 162–165, 163*f*
  sourness of, 777
  strong, 159–161, 159*t*, 163–165, 164*f*, 778–781, 779*f*, 780*f*, 786, 789, 838–840, 843–844
  structural features, 160, 800–801
  titrations, 167–168, 837–845
  in water, 731, 778–782
  weak, 159*t*, 160–161, 164, 164*f*, 164*t*, 183, 779–781, 779*f*, 780*f*, 790, 791–799, 840–843
    weak bases and, 802–806
    weak-acid equilibrium, 792–799
Acid anhydride, 647, 650, 650*f*, G-1
Acid rain, 273, 857–858, 858*f*
  carbonates as protection from effects of, 587, 858
  Hess's law applied to, 268
  sulfuric acid and, 600, 600*mn*, 858
Acid strength, 779–782
  acid-dissociation constant and, 779–781, 781*t*
  direction of reaction and, 789–791
  hydrated metal ions, 801, 801*f*
  molecular properties and, 799–801
  of nonmetal hydrides, 799–800, 799*f*
  of oxoacids, 800, 800*f*
  strong acids, 778–781, 779*f*, 780*f*, 786, 789, 810–811, 838–840, 843–844
  weak acids, 779–781, 779*f*, 780*f*, 790, 791–799, 840–843
Acid-base behavior, of element oxides, 345–346, 346*f*
Acid-base buffers, 827–837
  buffer capacity, 833, 833*f*
  buffer range, 833–834
  common-ion effect, 828
  defined, 827, G-1
  Henderson-Hasselbalch equation, 832–833
  how a buffer works, 827–832, 829*f*
  molecular scene representation, 834
  preparing, 835–836
Acid-base equilibria, 776–814
  acid-base indicators, 786, 787*f*, 837–838, 837*f*
  acid-dissociation constant (K_a), 779–782, 781*t*, A-8–A-10
    weak bases and weak acids, 802–806
    weak-acid equilibrium problem solving, 792–799
  autoionization of water, 782–786, 783*f*, 811
  base-dissociation constant (K_b), 802–806, 803*t*, A-11–A-12
  Brønsted-Lowry acid-base definition, 787–792, 810–811, 814
  conjugate acid-base pairs, 788–791, 788*t*, 790*f*, 828, 828*f*, 835–838
  hydrated metal ions, 801, A-12
  hydronium ion, 778, 783–787
  ion-product constant for water (K_w), 782–786, 783*f*
  Lewis acid-base definition, 811–814, 859–860
  pH, 784–787, 784*f*, 785*f*, 787*f*
  polyprotic acids, 797–799, 797*t*
  salt solutions, 807–810
    amphiprotic anions, 809
    of weakly acidic cations and weakly basic anions, 808
    yielding acidic solutions, 807, 809*t*
    yielding basic solutions, 807, 809*t*
    yielding neutral solutions, 807, 809*t*
  variation in acid strength, 779–782, 779*f*, 781*t*
  weak-acid equilibrium problem solving, 792–799
    acid-dissociation constant (K_a), 792–799, 797*t*
    concentrations, 793–796
    notation system, 792
    polyprotic acids, 797–799, 797*t*
Acid-base indicator
  acid-base titration, 166–167, 167*f*, 837–838, 837*f*
  color and pH range of common, 837–838, 837*f*
  defined, 786, 837, G-1
  pH paper, 786, 787*f*
Acid-base (neutralization) reactions, 158–168
  acid-base indicator, 166–167, 167*f*, 837–838, 837*f*
  defined, 158, G-1
  of element oxides, 345–346, 346*f*
  end point, 166, 167*f*
  equivalence point, 166
  gas-forming reactions, 163–164, 164*f*, 183
  heat change during, 263–264
  key event, 161
  proton transfer, 162–165, 163*f*
  relative acid-base strength and the net direction of reaction, 789–791
  salt formation, 161
  stoichiometry of, 165–168
  titrations, 165–168, 167*f*, 837–845
  water formation, 161
  writing ionic equations for, 161–162
Acid-base titration, 165–168, 167*f*, 837–845
Acid-base titration curves
  acid-base indicators, 837–838, 837*f*
  defined, 837, G-1
  end point, 839
  equivalence point, 838*f*, 839–845, 840*f*, 844*f*, 845*f*
  polyprotic acids, 844–845, 845*f*
  strong acid–strong base, 838–840, 838*f*
  weak acid–strong base, 840–843, 840*f*
  weak base–strong acid, 843–844, 844*f*
Acid-dissociation constant (K_a)
  defined, 780, G-1
  of hydrated metal ions, A-12
  meaning of, 780
  range of values, 780
  relation with K_b in conjugate pair, 805
  relation with pK_a, 785*t*
  tables of, A-8–A-10
  values for monoprotic acids, 781, 781*t*
  weak acid equilibrium problem solving, 792–799
Acidic solutions, balancing redox reactions in, 921–922
Acid-ionization constant. *See* Acid-dissociation constant (K_a)
Acrylonitrile
  infrared (IR) spectrum of, 375*f*
  molecular structure, 586*f*
Actin, arrangement of filaments, 497*f*
Actinides
  defined, 335, 1024, G-1
  electron configuration, 333*f*, 335
  properties, 1025
Actinium, 335
Activated complex, 703
Activated state, 700, 700*f*
Activation energy (E_a), 700–702, 700*f*–701*f*, 701*t*, 703–705, 705*f*, 711*f*, 712, 713*f*, 714, 717, G-1
Active metal
  activity series of the metals, 178–179, 179*f*, 937–938, G-1
  displacing hydrogen from water, 178, 178*f*
  reactivity, 938
  reduction with, 991, 991*f*
Active site, enzyme, 715–716, 715*f*, 765, 765*f*, G-1
Activity (*A*), and radioactive decay, 1064, G-1
Activity series of the halogens, 180
Activity series of the metals, 178–179, 179*f*, 937–938, G-1
Actual yield, 123, G-1
Addition, significant figures and, 29
Addition polymers, 652, 652*f*, 653*t*, G-1
Addition reaction
  with benzene, 644
  defined, 635, G-1
  organic, 635, 644, 652
  polymers, 652
Adduct, 811–813, 814, G-1
Adenine, 641*f*, 659
Adenosine triphosphate. *See* ATP
Adhesive forces, 475, 476*f*
Adhesives, 504
Adipic acid, acid-dissociation constant (K_a), A-8
Advanced materials, intermolecular forces and, 493–506
Aerosol, 552*t*
Air
  composition of, 199, 233, 233*t*
  as solution, 200
Air pollution
  acid rain, 268, 273, 586, 600, 857–858, 858*f*
  from auto exhaust, 269
  chlorofluorocarbons (CFCs), 586, 586*f*, 716–717
  smog, 217, 593, 593*mn*
  thermal pollution, 534–535, 535*f*, 1088
Airbags, 199
Airplane, de-icers, 550
-al (suffix), 639*t*, 644
Alanine
  optical isomers, 626, 627, 627*f*
  structure of, 656*f*
Alchemy, 10, 10*f*, 47
Alcohols
  defined, 638, G-1
  functional group, 638, 638*f*, 639*t*, 640
  grain alcohol, density of, 23*t*
  solubility, 519–521, 519*f*
Aldehydes, 639*t*, 644–645, 644*f*, G-1
Alizarin, 837*f*
Alizarin yellow R, 837*f*

Alkali metals, 574–576
  alkaline earth metals compared, 577
  anomalous behavior of lithium, 571
  electron configuration, 575, 576
  halides, 981, 982*f*
    lattice energy, 366
  important reactions, 575
  industrial production and uses, 994–995, 995*f*
  ionization energy, 340*f*
  melting point, 386, 386*f*
  periodic table, 60
  properties, 574–576
  reactions with halogens, 223–224
  reactivity, 331*f*, 576
Alkaline battery, 948, 948*f*, 959
Alkaline earth metals, 576–579
  alkali metals compared, 577
  anomalous behavior of beryllium, 574, 574*f*
  diagonal relationships, 577, 579, 579*f*
  electron configuration, 577, 578
  important reactions, 578
  melting point, 386, 386*f*
  periodic table, 60
  properties, 576–579
Alkanes
  chiral molecules, 626–628, 627*f*, 628*f*
  cycloalkanes, 624–625, 624*f*
  defined, 72, G-1
  depicting with formulas and models, 624, 624*f*
  general formula, 622
  homologous series, 622–623
  isomers
    constitutional, 625, 626*t*
    optical, 626–628, 626*f*, 627*f*, 628*f*
  naming, 72, 72*t*, 623, 623*t*, 630
  properties, 625, 625*f*
  saturated hydrocarbons, 623
  straight-chain, 72
Alkenes
  defined, 628, G-1
  functional group, 639*t*, 643
  general formula, 628
  isomerism, 628–630, 628*t*
  naming, 628, 630
  reactivity, 643–644
Alkyl group, 635, G-1
Alkyl halides, 640–641, 643, G-8
Alkynes, 630, 639*t*, 650, G-1
Allotropes
  carbon, 584–585, 584*f*
  defined, 584, G-1
  entropy and, 886
  oxygen, 596
  phosphorus, 590, 590*f*
  selenium, 598
  sulfur, 596, 632
  tin, 585
Alloying, 493
Alloys
  binary, 993, 993*f*
  composition and uses of common, 993*t*
  crystal defects in, 493
  defined, 386, 992, G-1
  interstitial, 522, 522*f*
  magnesium, 1003
  metallurgy, 992–994
  samarium-cobalt, 1025
  as solid-solid solutions, 522, 522*f*
  substitutional, 522, 522*f*
Alpha (α) decay, 1056*t*, 1057, G-1
Alpha helix, 657, 657*f*
Alpha (α) particles
  behavior in electric field, 1055, 1055*f*
  de Broglie wavelength, 303*t*
  defined, 1055, G-1
  nuclear reactions, 1070
  penetrating power, 1073*f*, 1074
  radioactive decay, 1056*t*, 1057
  Rutherford's α-scattering experiment, 51–52, 52*f*
  transmutation by, 1070
Aluminate, 582
Aluminosilicates, 858
Aluminum
  acid strength of hydrated ion, 801, 801*f*
  from bauxite, 267, 999
  bond type, 582*t*
  density, 23*t*
  diagonal relationship with beryllium, 582
  diffraction pattern, 303, 303*f*
  electron configuration, 330*t*, 331, 331*f*
  hydrogen displacement by, 178
  isolation, 999–1001, 1000*f*
  melting point, 582*t*
  metallic radius, 336*f*
  metallurgy, 999–1001
  mineral sources of, 988*t*
  properties, 345, 347, 579–581
  recycling, 1001, 1001*mn*
  specific heat capacity, 261*t*
  uses, 1001, 1001*f*
Aluminum chloride, 579, 579*f*, 807, 812, 885
  electron density distribution, 384*f*
  ionic properties, 383–384
Aluminum hydroxide, 848*t*, 863, 864*f*
Aluminum ion, 66*t*
Aluminum oxide, 175, 346, 999–1001
Aluminum salts, uses of, 777*t*
Aluminum sulfate, 554
Amides, 639*t*, 646, 648–650, 648*f*, 650*f*, G-1
-amine (suffix), 639*t*, 641
Amines
  defined, 641, 802, G-1
  functional group, 639*t*, 641–642, 641*f*
  as weak bases, 781
Amino acids. *See also* Proteins
  defined, 523, 656, G-1
  optical isomers, 626, 627, 627*f*
  physiological form, 523*f*
  polarity of side chains, 523–524
  as polyprotic acids, 845–846
  structures of, 523–524, 656–657, 656*f*
Ammonia
  base-dissociation constant (K_b), A-11
  in complex ion formation, 859–861
  as covalent hydride, 570
  dissociation, 160, 183
  fixed mass ratio of, 42
  formation, 175, 591, 735, 739, 888, 889, 890–891
  Haber process for synthesis of, 763–764, 764*f*, 985
  hybrid orbitals, 433, 433*f*
  industrial uses, 763
  Lewis structure, 803*t*
  molecular shape, 418
  nitric acid from, 272
  polarity, 418
  properties, 591
  synthesis of, 985, 1004
  titration of, 843–844, 844*f*
  uses, 777*t*
  as weak base, 781, 787, 802, 803*t*
Ammonium carbonate, 97
Ammonium cyanide, 808
Ammonium ion, 68*t*, 410, 787–788
Ammonium nitrate, 98–99, 100, 530, 530*f*, 533, 534, 879, 879*f*, 893
Ammonium perchlorate, 606
Amontons's law, 207
Amorphous solids, 479, 490, 490*f*, G-1
Amount (mol) of gases
  Avogadro's law and, 208, 208*f*, 216, 225, 227, 227*f*
  pressure and, 212–213
  volume and, 208, 208*f*, 212–213, 216
Amount of substance, 13*t*
Amount-mass-number conversions, 93–98, 123
  in solutions, 144–146, 156*f*
Amount-mass-number relationships, 93–98, 94*f*, 96*f*, 113*f*, 122*f*
  in chemical equation, 113*f*
  compounds, 96*f*
  elements, 94*f*
Ampere (A) (unit), 13*t*, 958, G-1
Amphoteric
  amphoteric hydroxides, complex ions of, 863–864, 864*f*
  defined, 346, G-1
  nature of water, 787
Ampicillin, 107, 107*f*
Amplitude, wave, 288, 288*f*, G-1
Analysis. *See* Chemical analysis
-ane (suffix), 72, 623, 623*t*
Angstrom (Å) (unit), 288
Angular momentum quantum number *(l)*, 308–310, 308*t*, 324*t*, G-1
Anhydrides, acid, 647, 650, 650*f*
Aniline
  base-dissociation constant (K_b), 803*t*, A-11
  Lewis structure, 803*t*
Anionic ligands, 1030, 1030*t*
Anions
  amphiprotic, 809
  complex, 1028, 1030, 1030*t*
  defined, 61, G-2
  electron configuration, 347
  ionic radius, 350, 350*f*
  monatomic, 66*t*
  names, 70–71
  polyatomic, 68*t*
  salts of weakly acidic cations and weakly basic anions, 808
  of weak acids as weak bases, 804–805
Anisotropic, liquid crystal phase, 495
Anode
  defined, 924, G-2
  half-reaction at, 924, 924*mn*
  sacrificial, 953, 953*f*
Antacid, 165–166
Antarctic ozone hole, 716, 716*f*
Antibiotics, dual polarity of, 526, 527*f*
Antibonding MO, 441, 441*f*, G-2
Anticancer drugs, 1032
Antifluorite crystal structure, 489
Antifreeze, 545, 550
Antilogarithms, A-2
Antimony
  bond type, 582*t*
  melting point, 582*t*
  properties, 344, 346, 588–591
Antineutrino, 1057, 1074
Antioxidants, 403
Apatites, 986, G-2
Aqueous equilibria, 826–864
  acid-base buffer systems, 827–837
  acid-base titration curves, 837–845
  complex ions, 859–864
  slightly soluble ionic compounds, 846–857
Aqueous heats of solution, 530–531
Aqueous ionic equations
  molecular equations, 150, 150*f*
  net ionic equation, 150*f*, 151
  spectator ions, 150
  total ionic equation, 150, 150*f*
Aqueous reaction, enthalpy change during, 263–264
Aqueous solutions
  defined, 77, G-2
  determining moles of ions in aqueous ionic solution, 142–143
  electrolysis of, 957–959
  salts, 807–810
  standard state, 270
Arginine, structure of, 656*f*
Argon
  cubic closest packing, 488, 488*f*
  electron configuration, 330*t*, 331, 331*f*
  heats of vaporization and fusion, 457*f*
  in ionization counters, 1063, 1063*f*
  mole fraction of air at sea level, 233*t*
  properties, 606, 607
Aristotle, 41
Arithmetic operations

  standard state, 270
Carbon capture and storage (CCS), 275
Carbon compounds, naming, 623*t*
Carbon cycle, 982–984, 983*f*
Carbon dioxide
  atmospheric, 983–984
  as blowing agent, 216
  in carbon cycle, 983–984, 983*f*
  carbon monoxide formation, 745–746
  CO-shift reaction, 273
  dipole moment, 417
  dissolved in water, 477
  dry ice, 457, 465, 880
  formation from limestone decomposition, 735–736
  formation from methane and oxygen, 8*mn*
  from gas-forming reactions, 163
  greenhouse effect and global warming, 274–275, 274*f*, 275*f*
  IR radiation absorption, 374
  law of multiple proportions, 47, 48
  linear shape, 408, 417
  mole fraction of air at sea level, 233*t*
  phase changes, 457
  phase diagram, 466, 466*f*
  release from limestone, 203–204
  sequestration, 275
  in soda pop, 535
  solubility of, 521
  suffocation from, 218
  supercritical, 466
  uses, 587
Carbon disulfide
  boiling point elevation constant, 544*t*
  freezing point depression constant, 544*t*
Carbon family
  allotropes, 584–585, 584*f*
  important reactions, 583
  properties, 582–588
Carbon fixation, 984
Carbon monoxide, 269, 273
  atmospheric concentration in volume percent, 538
  boiling point, 521*t*
  depiction of molecule, 76*t*
  formation, 587, 745–746
  law of multiple proportions, 47, 48
  mole fraction of air at sea level, 233*t*
  reaction with nitrogen dioxide, 689, 708
  as reducing agent, 991
  solubility in water, 521*t*
  toxicity, 1043–1044
  uses, 587
Carbon steel, 522, 522*f*, 997, G-3
Carbon tetrachloride
  boiling point elevation constant, 544*t*
  freezing point depression constant, 544*t*
  polarity, 417
  specific heat capacity, 261*t*
Carbonate buffer, 835–836
Carbonate ion, 64, 64*f*, 400
Carbonates
  conversion to oxides, 990
  in coral reefs, 477
  as protection from effects of acid rain, 587, 858
  reaction with acids, 163
  solubility-product constant (K_{sp}), A-13
  sources of elements, 981–982, 982*f*
  test for presence of, 852, 852*f*
  uses, 577, 586–587
Carbonic acid, 797*t*
  acid-dissociation constant (K_a), A-8
  formation, 852
Carbonic anhydrase, 1044, 1044*f*
Carbon-skeleton formula, 624, 624*f*
Carbonyl functional group, 644–645, 644*f*, 645*f*, G-3
Carboxylate ion, 647
Carboxylic acids
  defined, 646, G-3
  functional group, 639*t*, 646–647, 646*f*
  molecular structures, 646*f*
  odor, 648, 648*mn*
  reactions, 646–647
  strength, 781
Carnauba wax, 522
Cars. *See* Automobiles
Cast iron, 997
Catalysis, 712–717
  basis of, 712, 713*f*
  in biological systems, 714–717, 715*f*
  heterogeneous, 714, 714*f*, 716–717
  homogeneous, 713, 713*f*, 716–717
  ozone depletion and, 716–717
Catalyst
  biological (enzymes), 714–717, 715*f*
  defined, 712, G-3
  heterogeneous, 714, 716–717
  homogeneous, 713, 716–717
  lack of effect on equilibrium, 761, 761*t*
Catalytic converter, automobile, 714, 858
Catalytic hydrogenation, 714
Catenation, 586, 618, 632, G-3
Cathode, 924, 924*mn*, G-3
Cathode ray, 49–50, 50*f*, G-3
Cathode ray tube, 50, 50*f*
Cathodic protection, 953, 953*f*
Cation-electron pairs, 1073
Cations
  complex, 1028
  defined, 61, G-3
  electron configuration, 347
  ionic radius, 349–350, 350*f*
  metal cations as Lewis acids, 813
  monatomic, 66*t*
  polyatomic, 68*t*
  salts of weakly acidic cations and weakly basic anions, 808
Caves, limestone, 853, 853*f*
Cell membrane, structure of, 526, 526*f*
Cell potential (E_{cell}), 930–947
  concentration and, 941–947
  defined, 930, G-3
  standard cell potential (E°_{cell}), 930–933, 930*f*
  voltaic cells, 930–938
Cell shape, osmotic pressure and, 551, 551*f*
Cellular electrochemistry, 962–963, 962*f*, 963*f*
Cellular metabolism, metabolic pathways, 765, 765*f*
Cellulose, 655
Celsius temperature scale, 24–26, 25*f*, 26*t*, G-3
Cement, specific heat capacity, 261*t*
Centi- (prefix), 14*t*
Ceramic materials, 498–499
  defined, 498, G-3
  preparation, 498–499
  structures, 499, 499*f*
  uses, 498*t*, 499
Cerium, 1024
Cerium sulfate, 534, 534*f*
Cesium
  atomic clock, 16
  electronegativity, 382, 382*n*
  properties, 574–576
Cesium ion, 66*t*
Cetyl palmitate, molecular structure, 647*f*
CFCs (chlorofluorocarbons), 586, 586*f*, 716–717
CFLs (compact fluorescent lamps), 277
Chadwick, James, 52, 1070
Chain reaction, nuclear reactions, 1085–1086, 1085*f*, G-3
Chain-reaction (chain-growth) polymers, 652, 652*f*, 653*t*
Chair conformation, of cyclohexane, 624
Chalcocite, 114, 115, 116
Chalcopyrite, 998, 998*mn*
Change in enthalpy (ΔH), 258, G-3. *See also* Enthalpy change (ΔH)
Charcoal, as amorphous solid, 490
Charge, electron, 50–51, 51*f*, 53, 53*t*
Charge density, 529–530, G-3

Charge distribution, unequal, 140, 140*f*
Charge-induced dipole forces
  polarizability and, 472
  in solutions, 518
  types, 472
Charles, J. A. C., 206, 218
Charles's law
  breathing and, 208–209, 208*f*
  combined gas law, 207
  defined, 207, G-3
  Earth's atmosphere and, 234
  ideal gas law, relationship to, 210*f*
  kinetic-molecular theory, 225, 227, 227*f*
  molecular view of, 227, 227*f*
  volume-temperature relationship, 206–207, 206*f*, 216
Chelate, 1027, G-3
Chemical analysis
  nuclear magnetic resonance (NMR) spectroscopy, 633–634, 633*f*
  scanning tunneling microscopy, 486–487, 487*f*
  spectrophotometry, 300–301, 300*f*, 301*f*
  X-ray diffraction analysis, 486, 486*f*
Chemical bonds, 61, G-4. *See also* Bonding
Chemical change. *See also* Chemical reactions
  bond energy, 376–379
  chemical equation, 108
  defined, 5, G-4
  physical change compared, 5*f*, 6, 7–8

Mass laws
definite composition, 45–46, 46*f*, 48
explained by atomic theory, 48–49
mass conservation, 44–45, 44*f*, 48
multiple proportions, 46–47, 48
visualization of, 48–49
Mass number *(A)*, 53–54, 54*f*, G-11
nuclide, 1054, 1061
Mass percent (mass %), 45, 46*f*, 98, 538, G-11
Mass ratio, fixed, 42
Mass spectrometry, 55, 57, 57*f*, G-11
Mass-action expression. *See* Reaction quotient *(Q)*
Mass/charge ratio *(m/e)*, 50, 57, 57*f*
Mass-energy equivalence, 878*n*
Matches, 595, 605
Material flow, tracers and, 1078
Materials, advanced, 493–506. *See also* Electronic Materials, Liquid Crystals, Ceramic Materials, Polymers, Nanotechnology
Mathematical operations, A-1–A-4
Matter
ancient Greek view of, 41
classification, 78*f*
composition of, 4
conservation, 44
de Broglie wavelength, 303, 303*t*
defined, 4, G-11
effects of nuclear radiation on, 1073–1077
energy distinct from, 290–291
importance of energy in study of, 8–10
properties of, 5, 7*t*
states of, 4, 4*f*, 108, 199–201, 200*f*
entropy and, 531–532
types, 42–44
wave-particle duality, 302–306
Maxwell, James Clerk, 224
Mean free path, 232, G-11
Measurement
accuracy, 31, 31*f*
density, 23–24
length, 14–15
mass, 16
precision, 31, 31*f*
SI units, 13–26
significant figures, 27–31, 28*f*
standards, 13
temperature, 24–26
time, 16–17
uncertainty, 27–32
volume, 15–16, 15*f*, 16*f*
Mechanical balance, 16
Medical diagnosis, radioactive tracer use, 1077–1079, 1079*f*, 1080*f*
Medical tradition, in chemistry, 10
Mega- (prefix), 14*t*
Meitner, Lise, 1084
Meitnerium, 1072, 1084
Melting, 457, 458*f*, 465, G-11
as endothermic, spontaneous process, 879
Melting point
alkali metals, 575
alkaline earth metals, 578
boron family elements, 580
carbon family elements, 583
defined, 465, G-11
halogen family elements, 602
ionic compounds, 368*t*
metals, 386, 386*f*, 386*t*
nitrogen family elements, 589
noble gases, 607
oxygen family elements, 597
Period 3 chlorides, 385*f*
Membrane-cell process, of chlorine production, 1009
Membranes, free radical attack on, 1074
Mendeleev, Dmitri, 58, 323
Meniscus, 16*f*, 475–476, 476*f*
Mercury
barometer, 202, 202*f*
in batteries, 948
Boyle's experiments with, 205, 205*f*
calx, 11
heats of vaporization and of fusion, 457*f*
Lavoisier's experiments with, 11
line spectra, 294*f*
manometer, 202, 203*f*
meniscus shape in glass, 475–476, 476*f*
mercury(I) and mercury(II), 67*t*
mineral sources of, 988*t*
as neurotoxin, 273
surface tension, 475*t*
Mercury-cell process, 1009
Mercury(I) iodide, solubility-product constant, 848*t*
Mercury(II) nitrate, 157–158
Mercury(II) oxide, 176, 177*f*
Mercury(II) sulfide, 157–158
Mesosphere, 233*f*, 234
Messenger RNA (mRNA), 661, 661*f*
Metabolic pathways, 117, 765, 765*f*, G-11
Metal(s)
acid strength of hydrated metal ions, 801, 801*f*
activity series, 178–179, 179*f*, 937–938
alloys, 386, 992–994
boiling point, 386, 386*t*
calx, 11

combination reaction, 175, 175*f*
conductivity, 387, 492
crystal structure, 489, 489*f*
defined, G-11
displacement reactions, 177–179, 178*f*, 179*f*
electron affinity, 343
electron configuration, 348, 349–350
electronegativity, 380, 384
examples, 59*f*
forming more than one ion, 67–68, 67*t*
ionic bonding, 175, 360
ionization energy, 343
Lewis electron-dot symbols, 361
mechanical properties, 386–387, 387*f*
melting point, 386, 386*f*, 386*t*
metal cations as Lewis acids, 813
metallic bonding, 361
names of ionic compounds, 67–68, 67*t*
nonmetals compared to, 360*f*
periodic table and, 58*f*, 59
properties, 344–346
acid-base behavior of element oxides, 345–346, 346*f*
magnetic, 349–350
tendency to lose electrons, 344–345
properties of, and electron-sea model, 386–387, 386*f*–387*f*, 386*t*
relative reactivities, 937–938
Metal oxide (calx), Lavoisier and, 11
Metal sulfides, 600
ion-product expression, 847
roasting of, 990
Metallic bonding, 385–387
alkali metals, 575
alkaline earth metals, 578
band theory, 492
characteristics of, 360*f*, 361
defined, 361, G-11
electron-sea model, 385–386
intermolecular forces, 469*t*
in mercury, 475
Metallic (interstitial) hydrides, 276, 570–571, 570*f*
Metallic radius, 336, 336*f*, G-11
Metallic solids, 487*t*, 489, 489*f*, G-11
Metalloid(s)
defined, G-11
examples, 59*f*
oxides, 346
periodic table and, 58*f*, 59
properties, 344
as semiconductors, 492
zone refining of, 992
Metallurgy, 988–994
alloying, 992–994, 993*t*
aluminum, 999–1001
converting mineral to element, 990–991, 992*f*
copper, 998–999, 998*f*
defined, 988, G-11
iron, 996–997, 996*f*, 997*f*
magnesium, 1002–1003
ore pretreatment, 989–990
potassium, 994–995
refining (purifying) the element, 992, 992*f*
sodium, 994, 995
steps in, 989*f*
Metathesis reaction, 153, 161, 177, G-11
Meteorites, 986, 1068
Meter (m) (unit)
defined, 14–15, G-11
English equivalents, 14*t*
as SI base unit, 13*t*
wavelength expressed in, 288
Meth- (numerical root), 623*t*
Methanal, molecular structure, 644*f*
Methane
boiling point, 625*f*
chlorination of, 378–379
combustion of, 378, 378*f*
conversion to hydrogen fuel, 747
cubic closest packing, 488, 488*f*
effusion rate, 230
entropy, 887
formula and model, 72*t*
heats of vaporization and of fusion, 457*f*
hybrid orbitals, 430, 432, 432*f*
for hydrogen production, 1003, 1004
mole fraction in air at sea level, 233*t*
molecular shape, 409
in residential heating systems, 276
syngas, 273
Methanogenesis, 273, G-11
Methanoic acid, molecular structure, 646, 646*f*
Methanol
hybrid orbitals, 435
intermolecular forces, 518*f*
Lewis structure, 398
molecular structure, 638*f*, 639*t*
production, 1004
solubility, 519*f*, 520, 520*t*, 521
Methionine, structure of, 656*f*
Methyl acetate, molecular structure, 639*t*
Methyl bromide, 703, 703*f*
Methyl chloride, 684
boiling point, 469, 470*f*
dipole moment, 469, 470*f*
molecular structure, 639*t*
Methyl cyanide, molecular structure, 639*t*
Methyl ethanoate, molecular structure, 639*t*
Methyl ethyl ketone, 644*f*
Methyl red, 837*f*, 838*f*, 839, 840*f*, 841, 844, 844*f*
Methylamine, 183, 802, 802*f*, 803*t*, A-11
Methylbenzene, 631–632
Methylhexane, 626, 627*f*
Methylisocyanate, 218
Methylpropane, 106*t*
Methylpropene, 640
Metric system, 13
Mica, 588
Micelles, 553
Micro- (prefix), 14*t*
Microscope, electron, 303–304, 304*f*
Microstate, 880–883, 890, G-11
Milk of magnesia, 850
Milli- (prefix), 14*t*
Millikan, Robert, 50
Millikan's oil-drop experiment, 50, 51*f*
Milliliter (mL), 15, G-11
Millimeter of mercury (mmHg), 202, 203, 203*t*, G-11
Minerals
converting to elements, 990–991, 992*f*
defined, 988, G-11
as element source, 988, 988*t*
iron, 996*t*
Minimicroanalysis, 947*f*
Misch metal, 1025
Miscibility, G-11
Miscible substances, 518
Mitochondrion, 962–963, 962*f*, 963*f*
Mixing, convective, 234
Mixtures, 516–555. *See also* Colloids; Solution
atomic-scale view of, 42*f*, 43–44
classification, 77
compounds distinguished from, 43, 77, 77*f*
defined, 43, 517, G-11
heterogeneous, 77, 517, 552
homogeneous, 77, 517, 552
partial pressure of gas in gas mixture, 219–220
particle size and, 552
racemic, 627
reaction direction and, 752–753
separation, 79
substances distinguished from, 43
MO. *See* Molecular orbital
MO bond order, 441, G-11
Mobile phase, chromatography, 79
Model (theory), in the scientific method, 12–13, 13*f*, G-11
Molal boiling point elevation constant, 544, 544*t*
Molal freezing point depression constant, 544*t*, 545
Molality *(m)*
calculating, 537
defined, 536*t*, 537, G-11
Molar heat capacity *(C)*, 261, G-11
Molar mass ($\mathcal{M}$)
boiling point and, 472, 472*f*
of compounds, 93
defined, 92, G-11
determining for unknown volatile liquid, 218–219
dispersion (London) forces and, 472, 472*f*
of elements, 92–93
entropy and, 886
gas, 216, 218–219
Graham's law of effusion, 229–230
in molecular formula determination, 103–104
molecular speed relationship, 228, 228*f*
polymer, 500, 500*t*
of solutes, from colligative properties, 547
Molar ratio, stoichiometrically equivalent, 112–115
Molar solubility, 848–850, 850*t*
Molar volume, of common gases, 235*t*
Molarity *(M)*, 144, 536*t*, 537, G-11
Mole (mol)
amount-mass-number relationships, 93–98, 94*f*, 96*f*, 113*f*
Avogadro's number and, 92, 93–97, 94*f*, 96*f*
of common substances, 92*f*
definition, 91–92, 92*f*, G-11
ions in aqueous ionic solutions, 142–143
molar mass, 92–93
as SI base unit, 13*t*
standard molar volume, 209, 209*f*
Mole fraction *(X)*, 219, 536*t*, 538, 539, G-11
Molecular complexity, entropy and, 886–887, 887*f*
Molecular compounds, G-11
Molecular depictions
to determine formula, name, and mass, 74
in limiting-reactant problem, 119–120
precipitation reactions, 154–155
Molecular equation
for acid-base reactions, 161–164, 164*f*, 164*t*
for aqueous ionic reactions, 150, 150*f*
defined, 150, G-11
Molecular formula, 360
converting to Lewis structure, 396–399, 396*f*
converting to molecular shape, 412, 413*f*, 414–415
defined, 75, 101, G-11
determining from combustion analysis, 104–105, 104*f*
determining from elemental analysis and molar mass, 103–104
different compounds with same formula, 106–107, 106*t*
hybrid orbitals and, 434, 435*f*
Molecular hydrides, 570
Molecular (formula) mass
calculating, 72–73
defined, G-11
Molecular orbital (MO)
antibonding, 440, 441
band theory, 490–492, 491*f*
bond order, 441
bonding, 440
defined, 440, G-11
electrons in, 440–441
energy and shape of, 440–441, 441*f*
formation, 440
of hydrogen, 440–441, 441*f*
of lithium, 491, 491*f*
nonbonding, 447
Molecular orbital (MO) band theory, 490–492, 491*f*, 492*f*
Molecular orbital (MO) diagram, 441, 441*f*–447*f*, G-11
Molecular orbital (MO) theory, 440–448
antibonding MO, 440, 441
atomic 2*p*-orbital combinations, 442*f*, 443–444, 443*f*
bonding MO, 440
central themes, 440–442
defined, 440, G-11
formation of molecular orbitals, 440
heteronuclear diatomic molecules, 446–447, 447*f*
homonuclear diatomic molecules, 442–446
atomic *p*-orbital combinations, 443–444, 443*f*, 444*f*
bonding in *p*-block, 444–445
bonding in *s*-block, 442–443, 443*f*
MO bond order, 441, G-11
nonbonding, 447
pi (π) MOs, 443–444, 443*f*
polyatomic molecules, 447–448, 448*f*
sigma (σ) MOs, 441
Molecular polarity
bond angle, 417
bond polarity, 417
defined, 416, G-11
dipole moment, 417
effect on behavior, 419
liquid solutions and, 519–521
molecular shape and, 416–419
pi (π) bonds and, 439
Molecular scene problems
balancing an equation from, 110–111
buffers, 834
determining reaction orders from, 690–691
determining signs of ΔH, ΔS, and ΔG, 898–899
equilibrium parameter determination, 762–763
to find ΔG for reaction at nonstandard conditions, 905–906
heat of phase change, 461–462
ionic compound in aqueous solution, 142
predicting net direction of an acid-base reaction, 791
predicting precipitate formation, 854–855
reaction direction determination, 743–744
using to find quantities at various times, 696–697

Molecular shape, 394–421
  bent shape, 140, 140*f*
  biological significance, 420–421, 420*f*–421*f*
  converting molecular formula, 412, 413*f*, 414–415
  defined, 406, G-12
  dispersion forces and, 473, 473*f*
  Lewis structure (formula), 395–406
    defined, 395, 395*n*
    electron-deficient molecules, 400
    expanded valence shells, 404–405
    formal charge, 401–402, 403–404
    molecules with multiple bonds, 397, 398–399
    molecules with single bonds, 396–398
    odd-electron molecules, 403–404
    resonance, 399–401
  molecular polarity and, 416–419
  organic molecules, 618
  valence-shell electron-pair repulsion (VSEPR) theory, 406–416
    defined, 406
    electron-group arrangements, 407, 407*f*
    linear arrangement, 407–408, 407*f*, 413*f*
    molecules with multiple central atoms, 415–416, 415*f*
    octahedral arrangement, 407*f*, 411–412, 412*f*, 413*f*
    seesaw shape, 411, 411*f*, 413*f*, G-15
    square planar shape, 412, 412*f*, 413*f*
    square pyramidal shape, 412, 412*f*, 413*f*
    T shape, 411, 411*f*, 413*f*, G-16
    tetrahedral arrangement, 407*f*, 409–410, 409*f*, 413*f*
    trigonal bipyramidal arrangement, 407*f*, 410–411, 411*f*, 413*f*
    trigonal planar arrangement, 407*f*, 408–409, 408*f*, 413*f*
    trigonal pyramidal, 409*f*, 410, 413*f*
    using VSEPR to determine molecular shape, 414–415
    V shape, 408, 408*f*, 409*f*, 413*f*
  viscosity, effect on, 476
Molecular solids, 487*t*, 488, 488*f*, G-12

Nickel(II) hydroxide, 855
Nickel–metal hydride (Ni-MH) battery, 949, 950*f*
Nickel(II) nitrate hexahydrate, 146, 1023*f*
Nile River, 553, 553*f*
Niobium, 1024
Nitrate ion, 68*t*, 593, 593*f*
  molecular shape, 408
  resonance structure, 400–401
Nitrates, 593–594
Nitric acid, 160, 593–594, 593*f*, 789, 857, 985
  production from ammonia, 272
Nitric oxide, 592–593, 592*t*
  boiling point, 521*t*
  molecular orbitals, 447, 447*f*
  solubility in water, 521*t*
Nitride ion, 66*t*
Nitrides, 595–596
Nitrification, 555
-nitrile (suffix), 639*t*
Nitriles, 639*t*, 650, G-12
Nitrite ion, 68*t*, 593*f*, 594
Nitrogen
  abundance, 980, 981*t*
  bond type, 582*t*
  chemistry, 591–594
  critical temperature, 466
  diatomic molecule, orbitals of, 445, 445*f*
  electron configuration, 328, 330*f*, 331*f*
  fixation, 589, 763, 985, 985*f*
  ionization energy, 342*t*
  irradiation of, 1089
  Lewis structure, 399
  liquid, 492
  mean free path of, 232
  melting point, 582*t*
  mole fraction in air at sea level, 233*t*
  pollutants, 858
  properties, 344, 573*t*, 588–591
  triple bond, 370
Nitrogen cycle, 984–985, 985*f*
Nitrogen dioxide
  atmospheric concentration, 593
  depiction of molecule, 76*t*
  equilibrium with dinitrogen tetroxide, 732–734, 732*f*, 734*f*, 734*t*
  formation, 593
  formation of, 111
  Lewis structure, 403–404
  mass of oxygen in, 99
  mass-number conversion, 96–97
  mole fraction in air at sea level, 233*t*
  reaction with carbon monoxide, 689, 708
  reaction with fluorine, 709, 711, 711*f*
  structures and properties, 592*t*
Nitrogen family, 588–596
  important reactions, 589
  oxygen family compared, 596, 598–599
  properties, 588–590
Nitrogen fixation, 589, 763
Nitrogen gas
  the bends and, 535
  boiling point, 521*t*
  solubility in water, 521*t*
Nitrogen monoxide, 176, 233*t*, 592–593, 592*t*. *See also* Nitric oxide
  reaction with hydrogen, 684
  reaction with oxygen, 687–688, 687*t*, 709–710, 711, 711*f*
  reaction with ozone, 676, 677, 677*f*, 683, 684
Nitrogen oxides, 592–593, 592*t*, 857, 858, 887, 887*f*
Nitrogen trifluoride, 396–397
Nitrous acid, 593*f*, 594, 781*t*, 785*t*, 807, A-10
Nitrous oxide, 269, 592, 592*t*
NMR (nuclear magnetic resonance) spectroscopy, 633–634, 633*f*, 634*f*, G-12
Noble gas configuration, 346–347, 347*f*
Noble gases
  as atomic solids, 488
  electron affinity, 343
  electron configuration, 331, 346–347, 347*f*
  ionization energy, 339*f*, 343
  ions formed and nearest noble gas, 62–63, 62*f*
  periodic table, 60
  properties, 606–608
  reactivity, 606, 608
Node, 311, G-12
Nomenclature
  acids, 70–71
  alkanes, 623, 623*t*, 630
  alkenes, 628, 630
  aromatic hydrocarbons, 631–632
  binary covalent compounds, 71–72
  binary ionic compounds, 65–67
  coordination compounds, 1029–1031, 1030*t*
  hydrates, 69, 69*t*
  ionic compounds, 65–71
  ions, 66*t*–68*t*
  metals that form more than one ion, 67–68, 67*t*
  numerical roots, 623, 623*t*
  organic compounds, 72, 72*t*
  oxoanions, 68, 68*f*
  Roman numerals, for metal ions, 67–68, 67*t*
  transuranium elements, naming of, 1072
Non- (numerical root), 623*t*
Nona- (prefix), 69*t*
Nonane
  boiling point, 625*f*
  formula and model, 72*t*
Nonbonding MO, 447, G-12

Nonelectrolytes
colligative properties
nonvolatile nonelectrolyte solutions, 541–547
volatile nonelectrolyte solutions, 548
defined, 144, G-12
non-conductivity of, 541, 541*f*
Nonmetal(s)
covalent bonding, 175, 360
covalent radius, 336
defined, G-12
electron affinity, 343
electronegativity, 380, 384
examples, 59*f*
as insulators, 492
ionic bonding, 175, 360
ionization energy, 343
Lewis electron-dot symbols, 361
metals compared to, 360*f*
oxide, 346
oxoacids, esters, and amides of, 650, 650*f*
periodic table and, 58*f*, 59
properties, 344
Nonmetal hydrides, trends in acid strength, 799–800, 799*f*
Nonpolar covalent bond, 382, G-12
Nonrechargeable batteries, 947–949
Nonstandard half-cell potentials, 957
Nonvolatile nonelectrolyte solutions, colligative properties of, 541–547
Northern lights, 50
n-type semiconductor, 494–495, 494*f*
Nuclear atom model, 49–52
Nuclear binding energy, 1082–1084, 1083*f*, G-12
Nuclear charge *(Z)*, effect on orbital energy, 325, 325*f*
Nuclear energy reactors, 1086–1088, 1087*f*
Nuclear equations, 1058
Nuclear fission
atomic bomb, 1086, 1086*f*, 1086*n*
binding energy per nucleon and, 1083–1084, 1083*f*
chain reaction, 1085–1086, 1085*f*
defined, 1081, G-7
energy from, 276
nuclear energy reactors, 1086–1088, 1087*f*
Nuclear fuel, 230–231
Nuclear fusion
binding energy per nucleon and, 1083–1084, 1083*f*
defined, 1081, G-8
as energy source, 276
promise of, 1088–1089
Nuclear magnetic resonance (NMR) spectroscopy, 633–634, 633*f*, 634*f*, G-12
Nuclear reactions, 1052–1091
atomic bomb, 1086, 1086*f*, 1086*n*
balancing, 1058
chain reaction, 1085–1086, 1085*f*
chemical reactions compared, 1054, 1054*t*
fission, 1081, 1084–1088
fusion, 1081, 1084, 1088–1089
mass difference and, 1081–1082
nuclear binding energy, 1082–1084
nuclear energy reactors, 1086–1088, 1087*f*
nuclear radiation, effect on matter, 1073–1077
nuclear stability, 1058–1060, 1059*f*, 1060*t*
radioactive decay
decay series, 1062, 1062*f*
half-life, 1065–1066, 1065*f*, 1066*t*
kinetics, 1062–1069
nuclear equations, 1058
nuclear stability and, 1058–1060, 1059*f*, 1060*t*
predicting mode of, 1061–1062
radioisotopic dating, 1067–1069, 1068*f*
rate of, 1064–1067, 1065*f*
types of, 1055–1058, 1056*t*
transuranium elements, 1072, 1072*t*, 1084
Nuclear stability, and the mode of decay, 1058–1061, 1059*f*, 1060*t*
Nuclear transmutation, 1069–1072
cyclotron accelerator, 1071, 1071*f*
defined, 1069, G-12
early transmutation experiments, 1070
linear accelerators, 1070, 1071*f*
particle accelerators, 1070–1071, 1070*f*, 1071*f*
shorthand notation, 1070
synchrotron accelerators, 1071
tevatron accelerator, 1071
transuranium elements, 1072, 1072*t*, 1084
Nuclear waste disposal, 1088
Nucleic acids, 527, 658–664, G-12
Nucleons
binding energy per, 1082–1084, 1083*f*
defined, 1054, G-12
energy levels, 1060
Nucleoside triphosphates, 659, 659*f*, 663–664, 663*f*
Nucleotides, 658–659
Nucleus
components of, 53, 53*f*, 53*t*, 1054
defined, 49, 52, G-12
discovery, 51–52, 52*f*
notation, 1054
size, 53, 53*mn*, 1054*mn*
strong force and, 1060
Nuclide
defined, 1054, G-12
notation, 1054
parent and daughter, 1055
predicting mode of decay, 1061–1062
stability, 1058–1062, 1059*f*, 1060*t*
Number, of chemical species
amount-mass-number conversions and solutions, 144–146, 156*f*
Nutrient turnover in lakes, 478
Nylon-66, molecular model, 76*t*
Nylons, 653–654, 654*f*
N/Z (neutron-to-proton) ratio, 1059–1062, 1059*f*

O

o- (ortho), 632
-oate (suffix), 639*t*, 647
Observations, in the scientific method, 12, 13*f*, G-12
Occurrence, element, 981, G-12
Oceans
abundance of elements, 980
carbon cycle and, 983, 983*f*
Oct- (numerical root), 623*t*
Octa- (prefix), 69*t*
Octadecanoic acid, molecular structure, 646*f*
Octahedral arrangement
defined, 411, G-12
hybrid orbitals, 434, 434*f*, 434*t*
VSEPR, 407*f*, 411–412, 412*f*, 413*f*
Octahedral complexes
coordination compounds, 1032, 1032*f*
crystal field theory and, 1037–1038, 1037*f*, 1038*f*
hemoglobin, 1043
valence bond theory, 1035, 1035*f*
Octahedral shape, 407*f*, 411–412, 412*f*, 413*f*
complex ion, 1027, 1027*t*
hybrid orbitals, 434*t*
Octane
boiling point, 625*f*
combustion, 256, 257*f*, 896
combustion of, 110
formula and model, 72*t*
in hexane solvent, 532*f*, 533
intermolecular forces, 518*f*
solubility of, 144
Octet rule, 362
defined, G-12
exceptions to, 402–406
Lewis structures, 395–399
Odd-electron molecules, 403–404
Odor
molecular shape and, 420, 420*f*
of organic compounds, 648, 648*mn*
-oic acid (suffix), 639*t*, 646
Oil, solubility of, 519
Olfaction, 420, 420*f*
-ol (suffix), 638, 639*t*
-one (suffix), 639*t*, 644
Open-end manometer, 202, 203*f*
Optical isomers, 626–628, 626*f*–628*f*, 1032–1033, 1033*f*, G-12
Optically active substance, 627, 627*f*, G-12
Orbital diagram, 327–330, 328*f*, 330*f*, G-12
Orbital overlap
description, 429–430, 429*f*
molecular rotation and, 439, 439*f*
in single and multiple bonds, 436–439, 437*f*–438*f*
Ores
defined, 981, G-12
elements in, 981–982, 981*mn*
gangue, 988–989, 989*f*
mineral, 988
pretreating, 989
Organic chemistry
defined, 60
history, 617
Organic compounds, 616–665
alcohols, 638, 638*f*, 639*t*, 640
aldehydes, 639*t*, 644–645, 644*f*
alkanes, 622–628, 623*t*, 624*f*–628*f*, 626*t*
alkenes, 628–630, 639*t*, 643–644
alkynes, 630, 639*t*, 650
amides, 639*t*, 646, 648–650, 648*f*, 650*f*
amines, 639*t*, 641–642, 641*f*
aromatic compounds, 631–632, 631*f*, 632*f*, 643–644, 644*f*
carbonyl group, 644–646, 644*f*, 645*f*
carboxylic acid, 639*t*, 646–647, 646*f*
chemical diversity, factors in, 618–619, 619*f*
combustion analysis of, 104–105, 104*f*
defined, 617, G-12
esters, 639*t*, 646, 647–648, 647*f*, 648*mn*
haloalkanes, 639*t*, 640–641
ketones, 639*t*, 644–645, 644*f*
naming, 623, 623*t*, 631–632
nitriles, 639*t*, 650
odor, 648, 648*mn*
organic synthesis, 645
organometallic compounds, 645
vitalism, 617
Organic molecules
bond properties, 618
chemical diversity, 618–619, 619*t*

Rad (radiation-absorbed dose) (unit), 1073, G-14
Radial probability distribution plot, 307, 307*f*, 307*mn*, 311–312, 311*f*–313*f*, 326, 326*f*, 332, G-14
Radiant energy, 287, 288, 289
Radiation
background, 1075
blackbody, 291–292, 291*f*, 292*n*
cosmic, 1067, 1075
counters for detection of, 1063, 1063*f*
electromagnetic, 287–289
infrared (IR), 288*f*, 289
intensity, 288
ionizing
applications, 1080
background radiation, 1075
defined, 1073
free radical formation, 1074
penetrating power of, 1073–1074, 1073*f*
risk from, 1076–1077, 1076*f*
sources, 1075–1076, 1075*f*
units of radiation dose, 1073
nuclear radiation, effect on matter, 1073–1077
ultraviolet (UV), 288*f*, 289, 399, 716
Radiation therapy, 1080
Radiation-absorbed dose (rad) (unit), 1073, G-14
Radioactive decay
decay series, 1062, 1062*f*
as first-order process, 695
half-life, 1065–1066, 1065*f*, 1066*t*
kinetics, 1062–1069
nuclear equations, 1058
nuclear stability and, 1058–1061, 1059*f*, 1060*t*
predicting mode of, 1061–1062
radioisotopic dating, 1067–1069, 1068*f*
rate of, 1064–1067, 1065*f*
types of, 1055–1058, 1056*t*
Radioactive emissions
alpha (α) particles, 51–52, 1055, 1056*t*, 1057, 1070, 1073*f*
behavior in electric field, 1055, 1055*f*
beta (β) particles, 1055, 1056*t*, 1057, 1073*f*, 1074
detection, 1063, 1063*f*
gamma rays, 1055, 1056*t*, 1058, 1073*f*, 1074
ionization, 1072
penetrating power of, 1073–1074, 1073*f*
positron emission, 1056*n*, 1056*t*, 1057, 1074
Radioactive tracers, 1077–1079, 1079*f*, 1079*t*, 1080*f*
Radioactivity. *See also* Nuclear reactions
of actinides, 1025
defined, 1053, G-14
detection and measurement of, 1063, 1063*f*
discovery, 1055
Radiocarbon dating, 1067–1069, 1067*n*, 1068*f*
Radioisotope heater unit (RHU), 1080
Radioisotopes
applications, 1077–1080
artificial, 1070
dating, 1067–1069, 1068*f*
defined, 1067, G-14
ionizing radiation, 1080
tracers, 1077–1079, 1079*f*, 1079*t*, 1080*f*
Radioisotopic dating, 1067–1069, 1068*f*, G-14
Radium
discovery of, 1055
Ernest Rutherford and, 51
paint, 1074
properties, 577–578
radioactive decay, 1057
Radius of gyration (R_g), 501–502, 501*f*, 501*n*, G-14
Radon
properties, 606, 607
risk from, 1075, 1075*f*
Rainbows, diffraction of light and, 290
Random coil, polymer, 501, 501*f*, G-14
Random error, 31, 31*f*, G-14
Raoult's law, 542–543, 548, G-14
Rare earth elements. *See also* Lanthanides
electron configuration, 333*f*, 335
Rate constant *(k)*
defined, 682, G-14
determining, 688–690
temperature and, 699–700, 699*f*
units, 688, 688*t*
Rate law (rate equation)
collision theory, 699–703, 699*f*–702*f*, 701*t*
defined, 682, G-14
elementary steps, 707*t*
integrated, 691–698, 694*f*
rate constant, 682, 688–690
reaction mechanism and, 708–711
reaction order terminology, 683
reaction orders, 682–691
Rate of reaction. *See* Reaction rate
Rate-determining step, 708, 708*mn*, G-14
Rate-limiting step, 708
Reactant-favored reaction, 908–909, 908*f*
Reactants
calculating amount of, 112–115
calculating amounts in limiting-reactant problem, 120–122
definition, 108, G-14
determining concentration after a given time, 692–693
expressing reaction rate in terms of concentration of, 680–682, 680*f*
limiting, 117–122, 118*f*
in precipitation reaction, 156–158
using gas variable to find amounts of, 222–224
Reaction direction
equilibrium, 742–744, 742*f*, 752–753
reaction quotient and, 742–744, 742*f*
using concentrations to determine, 744
Reaction energy diagram, 704–705, 704*f*, 705*f*, G-14
Reaction intermediate, 708, G-14
Reaction mechanism
defined, 706, G-14
elementary reaction, 706–708, 707*t*
molecularity, 706–708, 707*t*
rate law and, 708–711
rate-determining step, 708
Reaction order
defined, 682, G-14
determining
by changing reactant concentrations, 685–688
from the integrated rate law, 693–694, 694*f*
from molecular scenes, 690–691
from rate data, 689–690
from rate laws, 685
first order reactions, 683–684, 684*f*, 688*t*, 692, 693, 694*f*, 695–697, 698*t*
negative, 685
rate constant *(k)* and, 688, 688*t*
rate law and, 682–691
second order reactions, 683–684, 684*f*, 688*t*, 692, 694, 694*f*, 698, 698*t*
terminology, 683
third-order reactions, 688, 688*t*
zero-order reactions, 683–684, 684*f*, 688*t*, 692, 694, 694*f*, 698, 698*t*
Reaction quotient *(Q)*, 903–904
from balanced equation, 735, 736–737
based on concentrations, 735
changing value of, 734, 734*f*, 734*t*
defined, 734, G-14
for equation multiplied by a common factor, 738–739
law of mass action, 734
for overall reaction, 737–738
reaction direction, 738, 742–744, 742*f*
for reaction involving pure liquids or solids, 735–736
as unitless number, 735
variations in form, 735–739, 740*t*
writing, 735–739, 740*t*
Reaction rate
average, 679
catalysis, 712–717
collision energy and, 677, 677*f*, 698*f*, 700–702, 701*f*, 702*t*

concentration and, 676
defined, 675, 676*f*, G-14
expressing, 678–682
initial, 680, 683
instantaneous, 679
measurement of, 683
conductometric methods, 683
manometric methods, 683
spectrometric methods, 683
molecular structure and, 702–703, 702*f*
physical state and, 677
range of, 676, 676*f*
surface area and, 677, 677*f*
temperature and, 677, 699–701, 701*f*, 701*t*
terminology, 683
Reaction table, 118, 745–746
Reactions. *See* Chemical reactions; Nuclear reactions; Organic reactions
Reactivity
alkali metals, 576, 576*mn*
halogens, 601, 603
of organic molecules, 619
Reactor core, nuclear plant, 1086, G-14
Real gases
extreme conditions, 235–237, 235*f*
interparticle attractions, 236–237, 236*f*
particle volume, 236, 236*f*
van der Waals constants, 237, 237*t*
van der Waals equation, 237
Receptor, biological, 420
Receptor site, 420, 420*f*
Rechargeable batteries, 959–950
Rectifier, 494
Recycling, of aluminum, 1001, 1001*mn*
Red blood cells, 846, 846*f*
Red phosphorus, 590, 590*f*

Redox couple, 962
Redox reactions, 168–181
balancing, 920–923
in acidic solutions, 921–922
in basic solutions, 922–923
half-reaction method, 920–923
combination reaction, 174–176, 175*f*
combustion reactions, 180
decomposition reaction, 176–177, 177*f*
defined, 168, G-13
displacement reaction, 177–180, 178*f*, 179*f*
electrochemistry
acidic solutions, 921–922
basic solutions, 922–923
electrolytic cells, 924, 924*f*
elements in, 174–181
identifying, 171–172
identifying the type of, 180–181
key event in, 168–169, 169*f*
in metallurgy, 990–991, 992*f*
movement of electrons between reactants, 168–169, 169*f*
organic reactions, 637–638
oxidation, 169, 171
oxidizing agent, 169, 171–172, 920, 933–938
redox titrations, 172–174, 173*f*
reducing agent, 169, 171–172, 575, 576, 577, 578, 920, 933–938
reduction, 169, 171
terminology, 169, 172*f*, 919–920, 920*f*
voltaic cells, 924, 924*f*, 925–938
relative reactivities of metals, 937–938
spontaneous redox reactions in, 925–929, 925*f*
writing spontaneous, by combining half-reactions, 934–937
Redox titrations, 172–174, 173*f*
Reducing agent
alkali metals, 575, 576
alkaline earth agents, 577, 578
defined, 169, 920, G-14
identifying, 171–172, 173–174
metals as, 175, 178
relative strengths, 933–938
Reducing agents, 345
Reduction, 919–920, 920*f*, 924
in converting compound to element, 990–991
as decrease in oxidation number, 171
defined, 169, G-14
of organic molecules, 637–638, 649
Reduction half-cell, 924, 926
Reference electrodes, 946–947, 946*f*
Refining, 551, 551*f*, 992
Refraction, 290, 290*f*, G-14
Relative atomic mass, 93*n*
Relativity, theory of, 302

Rem (roentgen equivalent for man) (unit), 1073, G-14
Replication, of DNA (deoxyribonucleic acid), 662, 662*f*
Reproducibility, 31
Resonance arrow, 399
Resonance hybrid, 399–401, 399*mn*, G-14
benzene, 631, 631*f*
Resonance structures (resonance forms)
choosing the more important form, 402
defined, 399, G-14
formal charge and, 401–402
need for, 399
writing, 400–401
Respiration, 180, 891, 891*f*, 984
Restricted rotation, around π bond, 439, 439*f*
Retinal, 629–630, 629*f*
Reverse osmosis, 555, 555*f*, G-14
Reversible process, simulation of, 882–883, 882*f*
Rhenium, density of, 1021
Rhodopsin, 629
RHU (radioisotope heater unit), 1080
Ribonucleic acid (RNA), 658, 659, 661–662
Ribose
formula, 106*t*
in RNA, 658–659
uses, 106*t*
Ribosome, 661, 661*f*
rms (root-mean-square) speed (u_{rms}), 228–229, G-14
RNA (ribonucleic acid), 658, 659, 661–662
Roasting, in metallurgy
defined, 990, G-14
of sulfides, 990, 998
Rocket fuel, 121–122
Roentgen equivalent for man (rem) (unit), 1073
Roentgenium, 1072
Rohrer, Heinrich, 486
Roman numeral, in compound names, 67–68, 67*t*
Root-mean-square speed (u_{rms}), 228–229
Roots, in organic compound naming, 623, 623*t*
Rosenberg, Barnett, 1032
Rounding off, 29–31, G-14
Rowland, F. Sherwood, 716
r-process, 1091
Rubber, 490
Rubidium, 574–576, 991
Rusting of iron, 951–953, 952*f*, 953*f*
Rutherford, Ernest, 51–52, 295, 1055, 1070
Rutherfordium, 1072
Rutherford's α-scattering experiment, 51–52, 52*f*
Rydberg, Johannes, 295
Rydberg equation, 295

S

s block, 442–443, 443*f*
s orbital, 311–312, 311*f*, 430, G-14
Sacrificial anodes, for prevention of corrosion, 953, 953*f*
Salt(s)
corrosion and, 952, 952*f*
defined, 161, G-14
dissolution and entropy change, 879, 885, 885*f*
electrolysis
of mixed molten salts, 956–957
of pure molten salts, 956
formation, 161
solubility of, 519
of weakly acidic cations and weakly basic anions, 808
yielding acidic solutions, 807, 809*t*
yielding basic solutions, 807, 809*t*
yielding neutral solutions, 807, 809*t*
Salt bridge, 927, G-14
Salt link, 524*f*, 525
Saltlike hydrides, 570
Saltwater, 43
Samarium, 1025
Sanger chain-termination method, of DNA sequencing, 663–664, 663*f*
Saponification, 648
Saturated calomel electrode, 946, 946*f*
Saturated hydrocarbons, 623, G-14
Saturated solution, 533, G-14
Scale, in plumbing, 554
Scandium
appearance of, 1018*f*
electron configuration, 332*t*, 333, 348, 1019, 1019*t*
oxidation states, 1022*t*
Scandium oxide, 1023*f*
Scanning tunneling microscopy, 486–487, 487*f*, G-15
Schrödinger, Erwin, 306

Sodium acetate, 533*f*, 807
Sodium atoms, emission and absorption spectra, 300, 300*f*
Sodium borate, 581
Sodium bromide, 363*f*
Sodium carbonate, 777*t*
Sodium chloride
  crystal structure, 488, 488*f*
  diluting solution of, 147–148
  dissolving, 530, 530*f*
  electrolysis, 960
  electron density distribution, 384*f*
  formation, 61, 61*f*
  in hexane, 532, 532*f*
  ionic properties, 384
  isotonic, 551
  lattice energy, 576*f*
  to melt ice, 551
  properties, 42, 43*t*
  solubility, 141, 518
  uses, 551
Sodium chromate, 149–150, 150*f*, 850–851, 851*f*, 1023*f*
Sodium diphosphate, 595
Sodium fluoride, 554
Sodium formate, 835
Sodium hydrogen carbonate, 164, 164*f*, 777*t*
Sodium hydrogen phosphate, 145, 595
Sodium hydroxide
  dissolving, 530, 530*f*, 534, 807
  reaction with acetic acid, 164*t*
  in titrations, 167, 838*f*, 840–843
  uses, 777*t*
Sodium hypochlorite, 603
Sodium iodide, 151–153, 153*f*
Sodium ions, 66*t*, 519*f*, 551, 554–555, 555*f*, 947
Sodium nitrate, 149–150, 150*f*
Sodium perchlorate, 102, 606
Sodium phosphate, 777*t*
Sodium stearate, 525
Sodium sulfate, 276
Sodium sulfide, 157–158
Sodium thiosulfate, 862
Soil formation, 478
Solar cells, 495
Solar energy, 276
Solar system, age of, 1068
Solder, 993*t*
Solid
  advanced materials, 493–506
    ceramics, 498–499, 498*t*, 499*f*
    electronic materials, 493–495, 494*f*
    liquid crystals, 495–497, 495*f*–497*f*
    nanotechnology and, 505–506, 505*f*, 506*f*
    polymeric materials, 500–504, 500*t*, 501*f*–503*f*, 504*t*
    semiconductors, 493–495, 494*f*
  amorphous, 479, 490, 490*f*
  behavior of gases distinguished from, 199–201, 200*f*
  bonding in, molecular orbital band theory, 490–492, 491*f*
  crystalline, 479–490
  defined, 4, G-15
  density, 23, 23*t*
  entropy change with dissolution, 885–886, 885*f*
  entropy of, 531–532
  kinetic-molecular view, 456
  particle arrangement in, 4, 4*f*
  phase changes, 465, 465*f*
  properties, 456, 456*t*
  solubility and temperature, 534, 534*f*
  structural features, 479
Solid foam, 552–553, 552*t*
Solid-gas equilibria, 465
Solid-liquid equilibria, 465
Solid-solid solutions, 522, 533*f*
Sols, 552*t*, 553
Solubility
  boiling point and, 521*t*
  chromatography, 79
  common ion effect, 850–852, 851*f*
  comparing, with K_{sp} values, 850
  complex ion effect on, 861–863
  defined, 518, G-15
  dual polarity and, 519–520
  equilibria of slightly soluble ionic compounds, 846–857
  equilibrium, 533–536
  gas-gas solution, 521
  gas-liquid solution, 521
  gas-solid solution, 522
  of ionic compounds, 140–143, 140*f*, 153*t*
  and "like-dissolves-like" rule, 518
  liquid-liquid solution, 519–521
  pH effect on, 852
  of precipitates, 853–856
  pressure and, 535–536, 535*f*
  protein, 525
  solid-solid solutions, 522
  temperature and, 534–535, 534*f*
Solubility rules for ionic compounds in water, 153*t*
Solubility-product constant (K_{sp}), 846–852, 848*t*, 850*t*, A-13, G-15
Solute
  defined, 139, 518, G-15
  entropy and, 885–886, 885*f*
  molar mass determination from colligative properties, 547
  parts by parts of solution, 538
  vapor pressure and, 542–543, 542*f*
Solution. *See also* Solubility; Solute; Solution process; Solvent

sign conventions, 255*t*
units of, 255
Wulfanite, 479*f*

X

Xanthophylls, 1036–1037
Xenon
intermolecular forces, 518*f*
mole fraction of air at sea level, 233*t*
properties of, 606, 607
Xenon tetrafluoride, 412, 608, 608*f*
X-ray diffraction analysis, 486, 486*f*, G-18
X-ray photon, 1056*t*, 1057
X-rays
diffraction pattern, 303, 303*f*
opacity of barium sulfate suspension, 852
radiation dose, 1075, 1076*f*
wavelength, 288*f*, 289–290
Xylenes, 632

Y

Yield
actual, 123
green chemistry perspective on, 124–125
in multistep syntheses, 124
overall, 124
percent, 123–124
side reaction effect on, 123, 123*f*
theoretical, 123
-yl (suffix), 623, 623*t*
-yne (suffix), 630, 639*t*
Yttrium, 1024

Z

Zeolites, 1003
Zero, absolute, 25
Zero-order reactions
defined, 683
half-life, 698
integrated rate law, 692, 694, 694*f*, 698*t*
rate constant *(k)* for, 688*t*
rate law and, 683–684
rate versus reactant concentration, 684*f*
reactant concentration versus time, 684*f*
Zewail, Ahmed H., 703
Ziegler, Karl, 652
Ziegler-Natta catalysts, 652
Zinc
abundance, 980, 981*t*
alloys, 993, 993*f*, 993*t*
appearance, 1019*f*
in batteries, 948, 948*f*
as dietary trace element, 1044*t*
electron configuration, 332*t*, 333, 349, 1019, 1019*t*
enzyme function and, 1044
in galvanizing process, 953
mineral sources of, 988*t*
oxidation of, 920*f*
oxidation states, 1022, 1022*t*
reaction with a strong and a weak acid, 780, 780*f*
reaction with acetic acid, 683
in voltaic cells, 925–934, 925*f*, 926*f*, 930*f*, 942–944
Zinc blende, crystal structure, 489, 489*f*
Zinc chloride, 145–146
Zinc formate, 810
Zinc hydroxide, 863
Zinc iodate, solubility-product constant, 848*t*
Zinc ion, 66*t*
Zinc oxide, 498, 990
Zinc sulfate heptahydrate, 1023*f*
Zircon, 587, 587*f*
Zirconia, 499
Zirconium, 1024, 1058
Zone refining, 583, 992, 992*f*, G-18
Zwitterion, 846
